You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.
The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines.

8. The cluster name that you specified in your DNS records.

9. A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

**NOTE**

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \(2^{32 - 23} - 2\) pod IPs addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for your platform.

**WARNING**

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as **installing a cluster on any platform**, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

7.1.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

NOTE

For bare metal installations, if you do not assign node IP addresses from the range that is specified in the networking.machineNetwork[].cidr field in the install-config.yaml file, you must include them in the proxy.noProxy field.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure
1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
noProxy: example.com
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 7.1.9. Configuring a three-node cluster

You can optionally install and run three-node clusters in OpenShift Container Platform with no workers. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for development, production, and testing.
Procedure

- Edit the `install-config.yaml` file to set the number of compute replicas, which are also known as worker replicas, to 0, as shown in the following `compute` stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

7.1.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │       └── kubeconfig
   │           ├── bootstrap.ign
   │           └── master.ign
   │                   ├── metadata.json
   │                   └── worker.ign
   ```

7.1.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.
NOTE

The compute node deployment steps included in this installation document are RHCS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- Kernel arguments: You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the APPEND parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special coreos.inst.* arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- Ignition configs: OpenShift Container Platform Ignition config files (*.ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the coreos-installer to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- coreos-installer: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the coreos-installer command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

NOTE

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

7.1.11.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image

Before you install a cluster on infrastructure that you provision, you must create RHCOS machines for it to use. You can use an ISO image to create the machines.

Prerequisites

- Obtain the Ignition config files for your cluster.

- Have access to an HTTP server that can be accessed from your computer, and from the machines that you create.
Procedure

1. Upload the control plane, compute, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   IMPORTANT

   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page.

   IMPORTANT

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

   ISO file names resemble the following example:

   rhcos-<version>-live.<architecture>.iso

3. Use the ISO to start the RHCOS installation. Use one of the following installation options:
   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection via a LOM interface.

4. Boot the ISO image. You can interrupt the installation boot process to add kernel arguments. However, for this ISO procedure you should use the coreos-installer command instead of adding kernel arguments. If you run the live installer without options or interruption, the installer boots up to a shell prompt on the live system, ready for you to install RHCOS to disk.

5. Review the Advanced RHCOS installation reference section for different ways of configuring features, such as networking and disk partitions, before running the coreos-installer.

6. Run the coreos-installer command. At a minimum, you must identify the Ignition config file location for your node type, and the location of the disk you are installing to. Here is an example:

   $ sudo coreos-installer install \
   --ignition-url=https://host/worker.ign /dev/sda

7. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

8. Continue to create the other machines for your cluster.
You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

7.1.11.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting

Before you install a cluster that uses manually-provisioned RHCOS nodes, such as bare metal, you must create RHCOS machines for it to use. You can use PXE or iPXE booting to create the machines.

Prerequisites

- Obtain the Ignition config files for your cluster.
- Configure suitable PXE or iPXE infrastructure.
- Have access to an HTTP server that you can access from your computer.

Procedure

1. Upload the master, worker, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**
   
   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS kernel, initramfs and rootfs files from the RHCOS image mirror page.

   **IMPORTANT**
   
   The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described below for this procedure. RHCOS qcow2 images are not supported for this installation type.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - kernel: rhcos-<version>-live-kernel-<architecture>
   - initramfs: rhcos-<version>-live-initramfs.<architecture>.img
   - rootfs: rhcos-<version>-live-rootfs.<architecture>.img

3. Upload the additional files that are required for your booting method:

   - For traditional PXE, upload the kernel and initramfs files to your TFTP server and the rootfs file to your HTTP server.
For iPXE, upload the **kernel**, **initramfs**, and **rootfs** files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

4. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

5. Configure PXE or iPXE installation for the RHCOS images.

Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

  ```
  DEFAULT pxeboot
  TIMEOUT 20
  PROMPT 0
  LABEL pxeboot
  KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
  APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  ```

  **1** Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

  **2** If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.

  **3** Specify locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.roots_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition_url** parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console** arguments to the **APPEND** line. For example, add **console=ttv0 console=ttvS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?.

- For iPXE:

  ```
  kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
  ```
<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
<architecture>.img

1. Specify locations of the RHCOS files that you uploaded to your HTTP server. The `kernel` parameter value is the location of the `kernel` file, the `initrd=main` argument is needed for booting on UEFI systems, the `coreos.live.rootfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.

2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify the location of the `initramfs` file that you uploaded to your HTTP server.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `kernel` line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see *How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?*

6. If you use PXE UEFI, perform the following actions:

a. Provide the `shimx64.efi` and `grubx64.efi` EFI binaries and the `grub.cfg` file that are required for booting the system.

   - Extract the necessary EFI binaries by mounting the RHCOS ISO to your host and then mounting the `images/efiboot.img` file to your host:

     ```
     $ mkdir -p /mnt/iso
     $ mkdir -p /mnt/efiboot
     $ mount -o loop rhcos-installer.x86_64.iso /mnt/iso
     $ mount -o loop,ro /mnt/iso/images/efiboot.img /mnt/efiboot
     $$ umount /mnt/efiboot
     ```

   - From the `efiboot.img` mount point, copy the `EFI/redhat/shimx64.efi` and `EFI/redhat/grubx64.efi` files to your TFTP server:

     ```
     $ cp /mnt/efiboot/EFI/redhat/shimx64.efi .
     $ cp /mnt/efiboot/EFI/redhat/grubx64.efi .
     $ umount /mnt/efiboot
     ```
$ umount /mnt/iso

- Copy the EFI/redhat/grub.cfg file that is included in the RHCOS ISO to your TFTP server.

b. Edit the grub.cfg file to include arguments similar to the following:

```bash
menuentry 'Install Red Hat Enterprise Linux CoreOS' --class fedora --class gnu-linux --class gnu --class os {
  linuxefi rhcos-<version>-live-kernel-<architecture> coreos.inst.install_dev=/dev/sda
  <architecture>.img coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  initrdelfi rhcos-<version>-live-initramfs.<architecture>.img
}
```

where:

- `rhcos-<version>-live-kernel-<architecture>`
  - Specifies the `kernel` file that you uploaded to your TFTP server.

  - Specifies the location of the live rootfs image that you uploaded to your HTTP server.

- `http://<HTTP_server>/bootstrap.ign`
  - Specifies the location of the bootstrap Ignition config file that you uploaded to your HTTP server.

- `rhcos-<version>-live-initramfs.<architecture>.img`
  - Specifies the location of the `initramfs` file that you uploaded to your TFTP server.

**NOTE**
For more information on how to configure a PXE server for UEFI boot, see the Red Hat Knowledgebase article: [How to configure/setup a PXE server for UEFI boot for Red Hat Enterprise Linux?](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html-single/openshift_container_platform_guide/openshift_container_platform_guide-how-to-configure-setup-a-pxe-server-for-uefi-boot-for-red_hat_enterprise_linux).

7. Continue to create the machines for your cluster.

**IMPORTANT**
You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

### 7.1.11.3. Advanced Red Hat Enterprise Linux CoreOS (RHCOS) installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

7.1.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

**Procedure**

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

   ```bash
   ```

   **IMPORTANT**

   The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

7.1.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.
However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

  IMPORTANT

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

7.1.11.3.2.1. Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   $ mkdir $HOME/clusterconfig

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
3. Create a MachineConfig object and add it to a file in the openshift directory. For example, name the file 98-var-partition.yaml, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
        - device: /dev/<device_name> ¹
      partitions:
        - label: var
          startMiB: <partition_start_offset> ²
          sizeMiB: <partition_size> ³
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
    systemd:
      units:
        - name: var.mount ⁴
          enabled: true
          contents: |
            [Unit]
            Before=local-fs.target
            [Mount]
            What=/dev/disk/by-partlabel/var
            Where=/var
            Options=defaults,prjquota ⁵
            [Install]
            WantedBy=local-fs.target
```

¹ The storage device name of the disk that you want to partition.
² When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
³ The size of the data partition in mebibytes.
The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-`

The `prjquota` mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth  bootstrap.ign  master.ign  metadata.json  worker.ign
```

Now you can use the Ignition config files as input to the ISO or PXE manual installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

7.1.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command line that causes the installer to maintain one or more existing partitions. For a PXE installation, you can `APPEND coreos.inst.*` options to preserve partitions.

Saved partitions might be partitions from an existing OpenShift Container Platform system that has data partitions that you want to keep. Here are a few tips:

- If you save existing partitions, and those partitions do not leave enough space for RHCOS, installation will fail without damaging the saved partitions.

- Identify the disk partitions you want to keep either by partition label or by number.

For an ISO installation

This example preserves any partition in which the partition label begins with `data` (`data*`):

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign /dev/sda
```

The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign /dev/sda
```

This example preserves partitions 5 and higher:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign /dev/sda
```
In the previous examples where partition saving is used, coreos-installer recreates the partition immediately.

**For a PXE installation**

This `APPEND` option preserves any partition in which the partition label begins with 'data' ('data*'):

```
coreos.inst.save_partlabel=data*
```

This `APPEND` option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This `APPEND` option preserves partition 6:

```
coreos.inst.save_partindex=6
```

7.1.11.3.3. Identifying Ignition configs

When doing an RHCOs manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config:** Every manual RHCOs installation needs to pass one of the Ignition config files generated by openshift-installer, such as bootstrap.ign, master.ign and worker.ign, to carry out the installation.

  IMPORTANT

  It is not recommended to modify these files.

  For PXE installations, you pass the Ignition configs on the `APPEND` line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the coreos-installer command line with the `--ignition-url=` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config:** This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or after the RHCOs system installs to disk. This method should only be used for performing tasks that must be performed once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

  For PXE or ISO boots, you can create the Ignition config and `APPEND` the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` `ignition.platform.id=metal` or the `ignition.config.url` option will be ignored.

7.1.11.3.3.1. Embedding an Ignition config in the RHCOs ISO

You can embed a live install Ignition config directly in an RHCOs ISO image. When the ISO image is booted, the embedded config will be applied automatically.

**Procedure**

1. Download the coreos-installer binary from the following image mirror page: https://mirror.openshift.com/pub/openshift-v4/clients/coreos-installer/latest/.
2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as `/mnt`:

```
# cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
# chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
```

3. Run the following command to embed the Ignition config into the ISO:

```
# ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign /mnt/rhcos-<version>-live.x86_64.iso
```

You can now use that ISO to install RHCOS using the specified live install Ignition config.

**IMPORTANT**

Using `coreos-installer iso ignition embed` to embed a file generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

```
# ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
# diff -s bootstrap.ign mybootstrap.ign
```

**Example output**

Files `bootstrap.ign` and `mybootstrap.ign` are identical

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

```
# ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
```

You can now embed another Ignition config into the ISO or use the ISO in its pristine state.

**7.11.3.4. Advanced RHCOS installation reference**

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

**Routing and bonding options at RHCOS boot prompt**

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node’s networking. If no networking arguments are used, the installation defaults to using DHCP.

**IMPORTANT**

When adding networking arguments, you must also add the `rd.neednet=1` kernel argument.
The following table describes how to use `ip=`, `nameserver=`, and `bond=` kernel arguments for live ISO installs.

**NOTE**
Ordering is important when adding kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

### Routing and bonding options for ISO

The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>To configure an IP address, either use DHCP (<code>ip=dhcp</code>) or set an individual static IP address (<code>ip=&lt;host_ip&gt;</code>). Then identify the DNS server IP address (<code>nameserver=&lt;dns_ip&gt;</code>) on each node. This example sets:</td>
<td><code>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code> \ <code>nameserver=4.4.4.41</code></td>
</tr>
<tr>
<td>- The node's IP address to <strong>10.10.10.2</strong></td>
<td></td>
</tr>
<tr>
<td>- The gateway address to <strong>10.10.10.254</strong></td>
<td></td>
</tr>
<tr>
<td>- The netmask to <strong>255.255.255.0</strong></td>
<td></td>
</tr>
<tr>
<td>- The hostname to <strong>core0.example.com</strong></td>
<td></td>
</tr>
<tr>
<td>- The DNS server address to <strong>4.4.4.41</strong></td>
<td></td>
</tr>
<tr>
<td>Specify multiple network interfaces by specifying multiple <code>ip=</code> entries.</td>
<td><code>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code> \ <code>ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</code></td>
</tr>
<tr>
<td>Optional: You can configure routes to additional networks by setting an <code>rd.route=</code> value.</td>
<td>To configure the default gateway:</td>
</tr>
<tr>
<td>If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</td>
<td><code>ip=::10.10.10.254:::</code></td>
</tr>
<tr>
<td>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used.</td>
<td>To configure the route for the additional network:</td>
</tr>
<tr>
<td></td>
<td><code>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</code></td>
</tr>
<tr>
<td></td>
<td><code>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code> \ <code>ip=:::core0.example.com:enp2s0:none</code></td>
</tr>
<tr>
<td>Description</td>
<td>Examples</td>
</tr>
<tr>
<td>-------------</td>
<td>----------</td>
</tr>
</tbody>
</table>
| You can combine DHCP and static IP configurations on systems with multiple network interfaces. | ip=enp1s0:dhcp
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none |
| Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter. | To configure a VLAN on a network interface and use a static IP address:
`ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0`
To configure a VLAN on a network interface and to use DHCP:
`ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0` |
| You can provide multiple DNS servers by adding a `nameserver=` entry for each server. | `nameserver=1.1.1.1
nameserver=8.8.8.8` |
| Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples: | To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:
`bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp`
To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:
`bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none` |
| • The syntax for configuring a bonded interface is: `bond=name[:network_interfaces][:options]`
• `name` is the bonding device name (`bond0`), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.
• When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface. |
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface with a VLAN and to use DHCP:

```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:non
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

Optional: Network teaming can be used as an alternative to bonding by using the `team=` parameter. In this example:

- The syntax for configuring a team interface is: `team=name[:network_interfaces]`
  - `name` is the team device name (team0) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (em1, em2).

**NOTE**

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

To configure a network team:

```
team=team0:em1,em2
ip=team0:dhcp
```

coreos.inst boot options for ISO or PXE install

While you can pass most standard installation boot arguments to the live installer, there are several arguments that are specific to the RHCOS live installer.

- For ISO, these options can be added by interrupting the RHCOS installer.

- For PXE or iPXE, these options must be added to the `APPEND` line before starting the PXE kernel. You cannot interrupt a live PXE install.

The following table shows the RHCOS live installer boot options for ISO and PXE installs.

**Table 7.11. coreos.inst boot options**
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>coreos.inst.image_url</td>
<td>Optional: Download and install the specified RHCOS image.</td>
</tr>
<tr>
<td></td>
<td>- This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>- While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>- If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>- Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.skip_reboot</td>
<td>Optional: The system will not reboot after installing. Once the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
</tbody>
</table>
**coreos-installer** options for ISO install

You can also install RHCOS by invoking the **coreos-installer** command directly from the command line. The kernel arguments in the previous table provide a shortcut for automatically invoking **coreos-installer** at boot time, but you can pass similar arguments directly to **coreos-installer** when running it from a shell prompt.

The following table shows the options and subcommands you can pass to the **coreos-installer** command from a shell prompt during a live install.

**Table 7.12. coreos-installer command-line options, arguments, and subcommands**

<table>
<thead>
<tr>
<th>Command-line options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-u, --image-url &lt;url&gt;</td>
<td>Specify the image URL manually.</td>
</tr>
<tr>
<td>-f, --image-file &lt;path&gt;</td>
<td>Specify a local image file manually.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>Embed an Ignition config from a file.</td>
</tr>
<tr>
<td>-I, --ignition-url &lt;URL&gt;</td>
<td>Embed an Ignition config from a URL.</td>
</tr>
<tr>
<td>--ignition-hash &lt;digest&gt;</td>
<td>Digest <strong>type-value</strong> of the Ignition config.</td>
</tr>
<tr>
<td>-p, --platform &lt;name&gt;</td>
<td>Override the Ignition platform ID.</td>
</tr>
<tr>
<td>--append-karg &lt;arg&gt;…</td>
<td>Append the default kernel argument.</td>
</tr>
<tr>
<td>--delete-karg &lt;arg&gt;…</td>
<td>Delete the default kernel argument.</td>
</tr>
</tbody>
</table>
-n, --copy-network
Copy the network configuration from the install environment.

**IMPORTANT**
The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

--network-dir <path>
For use with -n. Default is `/etc/NetworkManager/system-connections`.

--save-partlabel <lx>..
Save partitions with this label glob.

--save-partindex <id>…
Save partitions with this number or range.

--offline
Force offline installation.

--insecure
Skip signature verification.

--insecure-ignition
Allow Ignition URL without HTTPS or hash.

--architecture <name>
Target CPU architecture. Default is `x86_64`.

--preserve-on-error
Do not clear partition table on error.

-h, --help
Print help information.

**Command-line argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;device&gt;</td>
<td>The destination device.</td>
</tr>
</tbody>
</table>

**coreos-installer embedded Ignition commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$ coreos-installer iso ignition embed &lt;options&gt; --ignition-file &lt;file_path&gt; &lt;ISO_image&gt;</code></td>
<td>Embed an Ignition config in an ISO image.</td>
</tr>
<tr>
<td><code>coreos-installer iso ignition show &lt;options&gt; &lt;ISO_image&gt;</code></td>
<td>Show the embedded Ignition config from an ISO image.</td>
</tr>
</tbody>
</table>
Remove the embedded Ignition config from an ISO image.

**coreos-installer ISO Ignition options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f, --force</td>
<td>Overwrite an existing Ignition config.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

**coreos-installer PXE Ignition commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos-installer pxe ignition wrap &lt;options&gt;</td>
<td>Wrap an Ignition config in an image.</td>
</tr>
<tr>
<td>coreos-installer pxe ignition unwrap &lt;options&gt; &lt;image_name&gt;</td>
<td>Show the wrapped Ignition config in an image.</td>
</tr>
<tr>
<td>coreos-installer pxe ignition unwrap &lt;options&gt; &lt;initrd_name&gt;</td>
<td>Show the wrapped Ignition config in an initrd image.</td>
</tr>
</tbody>
</table>

**coreos-installer PXE Ignition options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

7.1.11.4. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.
NOTE

It is recommended that you use bootstrap only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install bootstrap by using the bootctl command-line tool.

1. Inspect the system status:

   ```
   # bootupctl status
   ```

   **Example output**

   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64, shim-x64-15-8.x86_64
   Update: At latest version

2. RHCOS images created without bootstrap installed on them require an explicit adoption phase. If the system status is Adoptable, perform the adoption:

   ```
   # bootupctl adopt-and-update
   ```

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64, shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```
   # bootupctl update
   ```

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64, shim-x64-15-8.x86_64

Machine config method

Another way to enable bootstrap is by providing a machine config.

- Provide a machine config file with the enabled systemd unit, as shown in the following example:

  **Example output**

  ```
  variant: rhcos
  version: 1.1.0
  systemd:
  units:
    - name: custom-bootstrap-auto.service
      enabled: true
      contents: |
      [Unit]
      Description=Bootstrap automatic update
  ```
7.1.12. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 
   --log-level=info
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   Example output

   ```
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.20.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.
7.1.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:
   
   `$ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   `oc whoami`

   **Example output**

   `system:admin`

7.1.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   `$ oc get nodes`

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>
The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

   **NOTE**

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

   - To approve them individually, run the following command for each valid CSR:
To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME        AGE     REQUESTOR                                                                  CONDITION
----------  -----   ---------------------------------- ---------------------------------
csr-bfd72   5m26s   system:node:ip-10-0-50-126.us-east-2.compute.internal                  Pending
csr-c57lv   5m26s   system:node:ip-10-0-95-157.us-east-2.compute.internal                  Pending
... 
```

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

**NOTE**

Please replace `<csr_name>` with the actual name of the CSR.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION
----------  -----   ------   -----  -------
master-0   Ready     master  73m  v1.20.0
```
It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see **Certificate Signing Requests**.

### 7.1.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

Configure the Operators that are not available.

### 7.1.15.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.

**NOTE**

The Prometheus console provides an **ImageRegistryRemoved** alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

### 7.1.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

#### 7.1.15.2.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim:
   
   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```bash
   $ oc get clusteroperator image-registry
   
   Example output
5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:
  
  ```bash
  $ oc edit configs.imageregistry/cluster
  ```
  
Then, change the line

  ```json
  managementState: Removed
  ```

  to

  ```json
  managementState: Managed
  ```

### 7.1.15.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":{"storage":{"emptyDir":{}}}}'
  ```

  **WARNING**

  Configure this option for only non-production clusters.

  If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  ```bash
  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
  ```

  Wait a few minutes and run the command again.

### 7.1.15.2.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.
IMPORTANT

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

7.1.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>

<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>kube-controller-manager</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   
   a. To view a list of all pods, use the following command:

   ```
   $ kube-scheduler                             4.7.0   True        False         False      29h
   kube-storage-version-migrator              4.7.0   True        False         False      4h2m
   machine-api                                4.7.0   True        False         False      29h
   machine-approver                           4.7.0   True        False         False      3h3m
   machine-config                             4.7.0   True        False         False      3h56m
   marketplace                                4.7.0   True        False         False      4h2m
   monitoring                                 4.7.0   True        False         False      6h34m
   network                                    4.7.0   True        False         False      29h
   node-tuning                                4.7.0   True        False         False      4h30m
   openshift-apiserver                        4.7.0   True        False         False      3h56m
   openshift-controller-manager               4.7.0   True        False         False      4h36m
   openshift-samples                          4.7.0   True        False         False      4h30m
   operator-lifecycle-manager                 4.7.0   True        False         False      29h
   operator-lifecycle-manager-catalog         4.7.0   True        False         False      29h
   operator-lifecycle-manager-packageserver   4.7.0   True        False         False      3h59m
   service-ca                                 4.7.0   True        False         False      29h
   storage                                    4.7.0   True        False         False      4h30m
   ```
$ oc get pods --all-namespaces

Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>

</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

$ oc logs <pod_name> -n <namespace>

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

See “Enabling multipathing with kernel arguments on RHCOS” in the Post-installation configuration documentation for more information.

### 7.1.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See About remote health monitoring for more information about the Telemetry service

### 7.1.18. Next steps

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.
7.2. INSTALLING A CLUSTER ON BARE METAL WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.7, you can install a cluster on bare metal infrastructure that you provision with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

### 7.2.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to access Red Hat Insights.

### 7.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.2.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

#### 7.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
At least two compute machines, which are also known as worker machines. If you are running a three-node cluster, running zero compute machines is supported. Running one compute machine is not supported.

NOTE

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

7.2.3.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. During the initial boot, the machines require either a DHCP server or that static IP addresses be set in order to establish a network connection to download their Ignition config files. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server. If a DHCP server provides NTP servers information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

7.2.3.3. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Table 7.13. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS or RHEL 7.9</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One CPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core \times cores) \times sockets = CPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

7.2.3.4. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

7.2.4. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

Prerequisites

- Review the [OpenShift Container Platform 4.x Tested Integrations](#) page before you create the supporting infrastructure for your cluster.

Procedure

1. Configure DHCP or set static IP addresses on each node.
2. Provision the required load balancers.
3. Configure the ports for your machines.
4. Configure DNS.
5. Ensure network connectivity.

7.2.4.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require either a DHCP server or that static IP addresses be set on each host in the cluster to establish a network connection, which allows them to download their Ignition config files.

It is recommended to use the DHCP server to manage the machines for the cluster long-term. Ensure that the DHCP server is configured to provide persistent IP addresses and host names to the cluster machines.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.
You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

**Network topology requirements**

The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.
Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   Do not configure session persistence for an API load balancer.

   Configure the following ports on both the front and back of the load balancers:

   **Table 7.17. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

   **NOTE**
   The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.
A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**

- Configuring chrony time service

**7.2.4.2. User-provisioned DNS requirements**

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>..`
Table 7.19. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>IMPORTANT</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</td>
</tr>
<tr>
<td>Routes</td>
<td>*apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.
Example 7.3. Sample DNS zone database

```bash
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
;
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
;
; The api identifies the IP of your load balancer.
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5
;
; The wildcard also identifies the load balancer.
*.apps.ocp4 IN A 192.168.1.5
;
; Create an entry for the bootstrap host.
bootstrap.ocp4 IN A 192.168.1.96
;
; Create entries for the master hosts.
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
master2.ocp4 IN A 192.168.1.99
;
; Create entries for the worker hosts.
worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.17
;
;EOF
```

The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 7.4. Sample DNS zone database for reverse records

```bash
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
; The syntax is "last octet" and the host must have an FQDN
```
NOTE
For clusters using installer-provisioned infrastructure, only the DNS records must be added.

7.2.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE
In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

NOTE
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```sh
$ ssh-keygen -t ed25519 -N "" \
    -f <path>/<file_name> 1
```

   1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the **ssh-agent** process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the **ssh-agent**:

   ```
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**7.2.6. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 7.2.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (``oc``) to interact with OpenShift Container Platform from a command-line interface. You can install ``oc`` on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of ``oc``, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of ``oc``.

#### 7.2.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (``oc``) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:
$ tar xzvf <file>

5. Place the `oc` binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the `oc` command:

   $ oc <command>

### 7.2.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the `oc` command:

   C:\> oc <command>

### 7.2.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

   `echo $PATH`

   `oc <command>`
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 7.2.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

#### Prerequisites

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**
   
   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**
   
   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**
   
   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

#### 7.2.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for
the required parameters through the command line. If you customize your cluster, you can modify the
install-config.yaml file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the install-config.yaml file.

**IMPORTANT**

The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 7.2.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Table 7.20. Required parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
</tr>
<tr>
<td>apiVersion</td>
</tr>
<tr>
<td>baseDomain</td>
</tr>
<tr>
<td>metadata</td>
</tr>
<tr>
<td>metadata.name</td>
</tr>
</tbody>
</table>
### 7.2.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 7.21. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>machineNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
networking.machineNetwork.cidr

Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

An IP network block in CIDR notation.
For example, 10.0.0.0/16.

NOTE
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

7.2.8.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 7.22. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>controlPlane.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
### credentialsMode

The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.
fips

Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
7.2.8.2. Sample install-config.yaml file for bare metal

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com 1
compute: 2
  -_hyperthreading: Enabled 3
  name: worker
  replicas: 0 4
controlPlane: 5
  _hyperthreading: Enabled 6
  name: master
  replicas: 3 7
metadata:
  name: test 8
networking:
  clusterNetwork:
```

**Parameter** | **Description** | **Values**
---|---|---
**publish** | How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes. | Internal or External. The default value is External.

Setting this field to Internal is not supported on non-cloud platforms.

**IMPORTANT**

If the value of the field is set to Internal, the cluster will become non-functional. For more information, refer to BZ#1953035.

**sshKey** | The SSH key or keys to authenticate access your cluster machines. | One or more keys. For example:

```yaml
sshKey:
  - <key1>
  - <key2>
  - <key3>
```

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading (SMT), or `hyperthreading`. By default, SMT is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**
Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the `hyperthreading` parameter has no effect.

**IMPORTANT**
If you disable `hyperthreading`, whether in the BIOS or in the `install-config.yaml`, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set the value of the `replicas` parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
NOTE
Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to `23`, then each node is assigned a `/23` subnet out of the given `cidr`, which allows for 510 \(2^{(32 - 23)} - 2\) pod IPs addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to `none`. You cannot provide additional platform configuration variables for your platform.

WARNING
Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to `none`, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).
NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

7.2.9. Network configuration phases

When specifying a cluster configuration prior to installation, there are several phases in the installation procedures when you can modify the network configuration:

Phase 1
After entering the `openshift-install create install-config` command. In the `install-config.yaml` file, you can customize the following network-related fields:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`

For more information on these fields, refer to "Installation configuration parameters".

NOTE
Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

Phase 2
After entering the `openshift-install create manifests` command. If you must specify advanced network configuration, during this phase you can define a customized Cluster Network Operator manifest with only the fields you want to modify.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

7.2.10. Specifying advanced network configuration

You can use advanced configuration customization to integrate your cluster into your existing network environment by specifying additional configuration for your cluster network provider. You can specify advanced network configuration only before you install the cluster.

IMPORTANT
Modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites
- Create the `install-config.yaml` file and complete any modifications to it.
Create the Ignition config files for your cluster.

Procedure

1. Change to the directory that contains the installation program and create the manifests:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

where:

```
<installation_directory>
```

Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

```
$ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
EOF
```

where:

```
<installation_directory>
```

Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and specify the advanced network configuration for your cluster, such as in the following examples:

**Specify a different VXLAN port for the OpenShift SDN network provider**

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    openshiftSDNConfig:
      vxlanPort: 4800
```

**Enable IPsec for the OVN-Kubernetes network provider**

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    ovnKubernetesConfig:
      ipsecConfig: {}
```
4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

### 7.2.11. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**
  - IP address pools from which pod IP addresses are allocated.

- **serviceNetwork**
  - IP address pool for services.

- **defaultNetwork.type**
  - Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

#### 7.2.11.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
</tbody>
</table>

This value is ready-only and specified in the `install-config.yaml` file.
spec.serviceNetwork array

A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

```yaml
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

This value is ready-only and specified in the `install-config.yaml` file.

---

spec.defaultNetwork object

Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

spec.kubeProxyConfig object

The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

---

### defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

#### Table 7.24. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong> OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</td>
</tr>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

---

### Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.
Table 7.25. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <code>NetworkPolicy</code>. The values <code>Multitenant</code> and <code>Subnet</code> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to (50) less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of (9001), and some have an MTU of (1500), you must set this value to (1450). This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is (4789). This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port (9000) and port (9999).</td>
</tr>
</tbody>
</table>

Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

```yaml
The following configuration is used for OpenShift SDN in the cluster:
```

1149
The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 7.26. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| mtu     | integer | The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

This value cannot be changed after cluster installation.

| genevePort | integer | The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

| ipsecConfig | object | Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.

Example OVN-Kubernetes configuration

defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}

kubeProxyConfig object configuration

The values for the kubeProxyConfig object are defined in the following table:

Table 7.27. kubeProxyConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
### Field | Type | Description
---|---|---
iptablesSyncPeriod | string | The refresh period for `iptables` rules. The default value is **30s**. Valid suffixes include `s`, `m`, and `h` and are described in the [Go time package documentation](https://golang.org/pkg/time/).

**NOTE**
Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the `iptablesSyncPeriod` parameter is no longer necessary.

`proxyArguments.iptables-min-sync-period` | array | The minimum duration before refreshing `iptables` rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include `s`, `m`, and `h` and are described in the [Go time package](https://golang.org/pkg/time/).
The default value is:

```
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period: -0s
```

### 7.2.12. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.

**IMPORTANT**
- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for [Recovering from expired control plane certificates](https://docs.openshift.com/container-platform/4.3/cluster_administration/cluster_security/ssl-certs.html) for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
Procedure

- Obtain the Ignition config files:

  ```
  $ ./openshift-install create ignition-configs --dir <installation_directory>
  ```

  For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

  **IMPORTANT**

  If you created an `install-config.yaml` file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

  The following files are generated in the directory:

  - `auth`
    - `kubeadmin-password`
    - `kubeconfig`
  - `bootstrap.ign`
  - `master.ign`
  - `metadata.json`
  - `worker.ign`

  7.2.13. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

  To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

  To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

  **NOTE**

  The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

  You can configure RHCOS during ISO and PXE installations by using the following methods:
Kernel arguments: You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the APPEND parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special coreos.inst.* arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

Ignition configs: OpenShift Container Platform Ignition config files (*.ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the coreos-installer to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

coreos-installer: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the coreos-installer command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

NOTE

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

7.2.13.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image

Before you install a cluster on infrastructure that you provision, you must create RHCOS machines for it to use. You can use an ISO image to create the machines.

Prerequisites

- Obtain the Ignition config files for your cluster.
- Have access to an HTTP server that can be accessed from your computer, and from the machines that you create.

Procedure

1. Upload the control plane, compute, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.
2. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

```
rhcos-<version>-live.<architecture>.iso
```

3. Use the ISO to start the RHCOS installation. Use one of the following installation options:
   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection via a LOM interface.

4. Boot the ISO image. You can interrupt the installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command instead of adding kernel arguments. If you run the live installer without options or interruption, the installer boots up to a shell prompt on the live system, ready for you to install RHCOS to disk.

5. Review the Advanced RHCOS installation reference section for different ways of configuring features, such as networking and disk partitions, before running the `coreos-installer`.

6. Run the `coreos-installer` command. At a minimum, you must identify the Ignition config file location for your node type, and the location of the disk you are installing to. Here is an example:

```
$ sudo coreos-installer install \
   --ignition-url=https://host/worker.ign /dev/sda
```

7. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

8. Continue to create the other machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

### 7.2.13.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting

Before you install a cluster that uses manually-provisioned RHCOS nodes, such as bare metal, you must create RHCOS machines for it to use. You can use PXE or iPXE booting to create the machines.

**Prerequisites**
- Obtain the Ignition config files for your cluster.
- Configure suitable PXE or iPXE infrastructure.
- Have access to an HTTP server that you can access from your computer.

**Procedure**

1. Upload the master, worker, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**
   
   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the RHCOS image mirror page.

   **IMPORTANT**
   
   The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS qcow2 images are not supported for this installation type.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - **kernel**: `rhcos-<version>-live-kernel-<architecture>`
   - **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
   - **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

3. Upload the additional files that are required for your booting method:

   - For traditional PXE, upload the **kernel** and **initramfs** files to your TFTP server and the **rootfs** file to your HTTP server.
   - For iPXE, upload the **kernel**, **initramfs**, and **rootfs** files to your HTTP server.

   **IMPORTANT**
   
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

4. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

5. Configure PXE or iPXE installation for the RHCOS images.
Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

```plaintext
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
    KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
        <architecture>.img coreos.live.rootsfs_url=http://<HTTP_server>/rhcos-<version>-live-
        rootsfs.<architecture>.img coreos.inst.install_dev=/dev/sda
        coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
```

1. Specify the location of the live kernel file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the initramfs file, the `coreos.live.rootsfs_url` parameter value is the location of the rootsfs file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the `APPEND` line to configure networking or other boot options.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=tty0` `console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?.

- For iPXE:

```plaintext
kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
        <architecture>.img coreos.inst.install_dev=/dev/sda
        coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
    1 2
        <architecture>.img
```

1. Specify locations of the RHCOS files that you uploaded to your HTTP server. The `kernel` parameter value is the location of the kernel file, the `initrd=main` argument is needed for booting on UEFI systems, the `coreos.live.rootsfs_url` parameter value is the location of the rootsfs file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.
2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify the location of the `initramfs` file that you uploaded to your HTTP server.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `kernel` line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?

6. If you use PXE UEFI, perform the following actions:

   a. Provide the `shimx64.efi` and `grubx64.efi` EFI binaries and the `grub.cfg` file that are required for booting the system.

      i. Extract the necessary EFI binaries by mounting the RHCOS ISO to your host and then mounting the `images/efiboot.img` file to your host:

         ```
         $ mkdir -p /mnt/iso
         $ mkdir -p /mnt/efiboot
         $ mount -o loop rhcos-installer.x86_64.iso /mnt/iso
         $ mount -o loop,ro /mnt/iso/images/efiboot.img /mnt/efiboot
         $$ mkdir -p /mnt/iso
         $$ mkdir -p /mnt/efiboot
         $$ mount -o loop rhcos-installer.x86_64.iso /mnt/iso
         $$ mount -o loop,ro /mnt/iso/images/efiboot.img /mnt/efiboot
         $ cp /mnt/efiboot/EFI/redhat/shimx64.efi .
         $ cp /mnt/efiboot/EFI/redhat/grubx64.efi .
         $ umount /mnt/efiboot
         $ umount /mnt/iso
         ```

      ii. From the `efiboot.img` mount point, copy the `EFI/redhat/shimx64.efi` and `EFI/redhat/grubx64.efi` files to your TFTP server:

         ```
         $ cp /mnt/efiboot/EFI/redhat/shimx64.efi .
         $ cp /mnt/efiboot/EFI/redhat/grubx64.efi .
         $ umount /mnt/efiboot
         ```

   b. Edit the `grub.cfg` file to include arguments similar to the following:

      ```
      menuentry 'Install Red Hat Enterprise Linux CoreOS' --class fedora --class gnu-linux --class gnu --class os {
      linuxefi rhcos--<version>--live-kernel--<architecture> coreos.installdev=/dev/sda
      ```
<architecture>.img coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
initrddefi rhcos-<version>-live-initramfs.<architecture>.img
}

where:

rhcos-<version>-live-kernel.<architecture>
    Specifies the **kernel** file that you uploaded to your TFTP server.

http://<HTTP_server>/rhcos-<version>-live-rootfs.<architecture>.img
    Specifies the location of the live rootfs image that you uploaded to your HTTP server.

http://<HTTP_server>/bootstrap.ign
    Specifies the location of the bootstrap Ignition config file that you uploaded to your HTTP server.

rhcos-<version>-live-initramfs.<architecture>.img
    Specifies the location of the **initramfs** file that you uploaded to your TFTP server.

**NOTE**

For more information on how to configure a PXE server for UEFI boot, see the Red Hat Knowledgebase article: How to configure/setup a PXE server for UEFI boot for Red Hat Enterprise Linux?.

7. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

### 7.2.13.3. Advanced Red Hat Enterprise Linux CoreOS (RHCOS) installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running **coreos-installer** manually from the live system
- Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

#### 7.2.13.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:
- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

### Procedure

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

   ```bash
   $ coreos-installer install --copy-network \
   --ignition-url=http://host/worker.ign /dev/sda
   ```

   **IMPORTANT**

   The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

### 7.2.13.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, a separate partition, but not both.

  **IMPORTANT**

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.
Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

7.2.13.3.2.1. Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   $ mkdir $HOME/clusterconfig

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...

3. Create a MachineConfig object and add it to a file in the openshift directory. For example, name the file 98-var-partition.yaml, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

   apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
  storage:
    disks:
      - device: /dev/<device_name>
        partitions:
          - label: var
            startMiB: $partition_start_offset$
            sizeMiB: $partition_size$
    filesystems:
      - device: /dev/disk/by-partlabel/var
        path: /var
        format: xfs
  systemd:
    units:
      - name: var.mount
        enabled: true
        contents: |
        [Unit]
        Before=local-fs.target
        [Mount]
        What=/dev/disk/by-partlabel/var
        Where=/var
        Options=defaults,prjquota
        [Install]
        WantedBy=local-fs.target

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
4. The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-lib-containers.mount`.
5. The `prjquota` mount option must be enabled for filesystems used for container storage.
NOTE

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
  auth  bootstrap.ign  master.ign  metadata.json  worker.ign
```

Now you can use the Ignition config files as input to the ISO or PXE manual installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

7.2.13.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command line that causes the installer to maintain one or more existing partitions. For a PXE installation, you can `APPEND coreos.inst.*` options to preserve partitions.

Saved partitions might be partitions from an existing OpenShift Container Platform system that has data partitions that you want to keep. Here are a few tips:

- If you save existing partitions, and those partitions do not leave enough space for RHCOS, installation will fail without damaging the saved partitions.
- Identify the disk partitions you want to keep either by partition label or by number.

For an ISO installation

This example preserves any partition in which the partition label begins with `data` (`data*`):

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partlabel 'data*' /dev/sda
```

The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

For a PXE installation

This `APPEND` option preserves any partition in which the partition label begins with `data` (`'data*`):
This **APPEND** option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This **APPEND** option preserves partition 6:

```
coreos.inst.save_partindex=6
```

### 7.2.13.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config** Every manual RHCOS installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.

  **IMPORTANT**

  It is not recommended to modify these files.

  For PXE installations, you pass the Ignition configs on the **APPEND** line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the `coreos-installer` command line with the `--ignition-url=` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config** This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be performed once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

  For PXE or ISO boots, you can create the Ignition config and **APPEND** the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` `ignition.platform.id=metal` or the `ignition.config.url` option will be ignored.

### 7.2.13.3.3.1. Embedding an Ignition config in the RHCOS ISO

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

**Procedure**

1. Download the `coreos-installer` binary from the following image mirror page:
   

2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as `/mnt`:

   ```
   # cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
   # chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
   ```
3. Run the following command to embed the Ignition config into the ISO:

```bash
# ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign \
/mnt/rhcos-<version>-live.x86_64.iso
```

You can now use that ISO to install RHCOS using the specified live install Ignition config.

**IMPORTANT**

Using `coreos-installer iso ignition embed` to embed a file generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

```bash
# ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
```

```
# diff -s bootstrap.ign mybootstrap.ign
```

**Example output**

Files `bootstrap.ign` and `mybootstrap.ign` are identical

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

```bash
# ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
```

You can now embed another Ignition config into the ISO or use the ISO in its pristine state.

### 7.2.13.3.4.  Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

#### Routing and bonding options at RHCOS boot prompt

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node’s networking. If no networking arguments are used, the installation defaults to using DHCP.

**IMPORTANT**

When adding networking arguments, you must also add the `rd.neednet=1` kernel argument.

The following table describes how to use `ip=`, `nameserver=`, and `bond=` kernel arguments for live ISO installs.
### Routing and bonding options for ISO

The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>To configure an IP address, either use DHCP (<code>ip=dhcp</code>) or set an individual static IP address (<code>ip=&lt;host_ip&gt;</code>). Then identify the DNS server IP address (<code>nameserver=&lt;dns_ip&gt;</code>) on each node. This example sets:</td>
<td><code>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code> <code>nameserver=4.4.4.41</code></td>
</tr>
<tr>
<td>- The node’s IP address to <strong>10.10.10.2</strong></td>
<td></td>
</tr>
<tr>
<td>- The gateway address to <strong>10.10.10.254</strong></td>
<td></td>
</tr>
<tr>
<td>- The netmask to <strong>255.255.255.0</strong></td>
<td></td>
</tr>
<tr>
<td>- The hostname to <strong>core0.example.com</strong></td>
<td></td>
</tr>
<tr>
<td>- The DNS server address to <strong>4.4.4.41</strong></td>
<td></td>
</tr>
<tr>
<td>Specify multiple network interfaces by specifying multiple <code>ip=</code> entries.</td>
<td><code>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code> <code>ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</code></td>
</tr>
<tr>
<td>Optional: You can configure routes to additional networks by setting an <code>rd.route=</code> value. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</td>
<td>To configure the default gateway:</td>
</tr>
<tr>
<td></td>
<td>To configure the route for the additional network:</td>
</tr>
<tr>
<td>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used.</td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>Examples</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| You can combine DHCP and static IP configurations on systems with multiple network interfaces. | `ip=enp1s0:dhcp`  
`ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none` |
| Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter. | To configure a VLAN on a network interface and use a static IP address:  
`ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none  
`vlan=enp2s0.100:enp2s0`  
To configure a VLAN on a network interface and to use DHCP:  
`ip=enp2s0.100:dhcp  
`vlan=enp2s0.100:enp2s0` |
| You can provide multiple DNS servers by adding a `nameserver=` entry for each server. | `nameserver=1.1.1.1  
nameserver=8.8.8.8` |
| Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples: | To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:  
`bond=bond0:em1,em2:mode=active-backup  
`ip=bond0:dhcp`  
To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:  
`bond=bond0:em1,em2:mode=active-backup  
`ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none` |
| • The syntax for configuring a bonded interface is:  
`bond=name[:network_interfaces] [:options]`  
• `name` is the bonding device name (`bond0`), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.  
• When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface. |
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface with a VLAN and to use DHCP:

```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

Optional: Network teaming can be used as an alternative to bonding by using the `team=` parameter. In this example:

- The syntax for configuring a team interface is: `team=name[:network_interfaces]`
  - `name` is the team device name (`team0`) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1`, `em2`).

```
team=team0:em1,em2
ip=team0:dhcp
```

**NOTE**

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

---

**coreos.inst boot options for ISO or PXE install**

While you can pass most standard installation boot arguments to the live installer, there are several arguments that are specific to the RHCOS live installer.

- For ISO, these options can be added by interrupting the RHCOS installer.
- For PXE or iPXE, these options must be added to the `APPEND` line before starting the PXE kernel. You cannot interrupt a live PXE install.

The following table shows the RHCOS live installer boot options for ISO and PXE installs.

**Table 7.28. coreos.inst boot options**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>

---

1167
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>coreos.inst.image_url</td>
<td>Optional: Download and install the specified RHCOS image.</td>
</tr>
<tr>
<td></td>
<td>● This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>● While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>● If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>● Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.skip_reboot</td>
<td>Optional: The system will not reboot after installing. Once the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
</tbody>
</table>
coreos.inst.platform_id

Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: `coreos.inst.platform_id=vmware`.

ignition.config.url

Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how `coreos-installer` is invoked, or to run code before or after the installation. This is different from `coreos.inst.ignition_url`, which is the Ignition config for the installed system.

coreos-installer options for ISO install

You can also install RHCOS by invoking the `coreos-installer` command directly from the command line. The kernel arguments in the previous table provide a shortcut for automatically invoking `coreos-installer` at boot time, but you can pass similar arguments directly to `coreos-installer` when running it from a shell prompt.

The following table shows the options and subcommands you can pass to the `coreos-installer` command from a shell prompt during a live install.

Table 7.29. `coreos-installer` command-line options, arguments, and subcommands

<table>
<thead>
<tr>
<th>Command-line options</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-u, --image-url &lt;url&gt;</td>
<td>Specify the image URL manually.</td>
</tr>
<tr>
<td></td>
<td>-f, --image-file &lt;path&gt;</td>
<td>Specify a local image file manually.</td>
</tr>
<tr>
<td></td>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>Embed an Ignition config from a file.</td>
</tr>
<tr>
<td></td>
<td>-I, --ignition-url &lt;URL&gt;</td>
<td>Embed an Ignition config from a URL.</td>
</tr>
<tr>
<td></td>
<td>--ignition-hash &lt;digest&gt;</td>
<td>Digest type-value of the Ignition config.</td>
</tr>
<tr>
<td></td>
<td>-p, --platform &lt;name&gt;</td>
<td>Override the Ignition platform ID.</td>
</tr>
<tr>
<td></td>
<td>--append-karg &lt;arg&gt;...</td>
<td>Append the default kernel argument.</td>
</tr>
<tr>
<td></td>
<td>--delete-karg &lt;arg&gt;...</td>
<td>Delete the default kernel argument.</td>
</tr>
</tbody>
</table>
-n, --copy-network

Copy the network configuration from the install environment.

**IMPORTANT**

The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

--network-dir <path>

For use with `-n`. Default is `/etc/NetworkManager/system-connections/`.

--save-partlabel <lx>..

Save partitions with this label glob.

--save-partindex <id>...

Save partitions with this number or range.

--offline

Force offline installation.

--insecure

Skip signature verification.

--insecure-ignition

Allow Ignition URL without HTTPS or hash.

--architecture <name>

Target CPU architecture. Default is `x86_64`.

--preserve-on-error

Do not clear partition table on error.

-h, --help

Print help information.

**Command-line argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;device&gt;</td>
<td>The destination device.</td>
</tr>
</tbody>
</table>

**coreos-installer embedded Ignition commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$ coreos-installer iso ignition embed &lt;options&gt; --ignition-file &lt;file_path&gt; &lt;ISO_image&gt;</code></td>
<td>Embed an Ignition config in an ISO image.</td>

</table>

### 7.2.13.4. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.
NOTE

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

**Manual install method**

You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:

   ```
   # bootupctl status
   
   Example output
   
   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version
   ```

2. RH COS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

   ```
   # bootupctl adopt-and-update
   
   Example output
   
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```
   # bootupctl update
   
   Example output
   
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

**Machine config method**

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

  ```
  # Example config file
  
  variant: rhcos
  version: 1.1.0
  systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update
  ```
7.2.14. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete
   --log-level=info
   ```

   ① For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   ② To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.20.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.
7.2.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output
   
   `system:admin`

7.2.16. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```

   Example output
   
   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.20.0
   master-1  Ready     master  63m  v1.20.0
   master-2  Ready     master  64m  v1.20.0
   ```
The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> ①

① <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

$ oc get csr

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

$ oc adm certificate approve <csr_name> ①

① <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

$ oc get nodes

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>
NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

### 7.2.17. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>

2. Configure the Operators that are not available.

### 7.2.17.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

**NOTE**

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

### 7.2.17.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

### 7.2.17.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the Recreate rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.
1. To set the image registry storage as a block storage type, patch the registry so that it uses the *Recreate* rollout strategy and runs with only one (1) replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

### 7.2.18. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

#### Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

#### Procedure

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

#### Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>

<td>True</td>
<td>False</td>
<td>3h56m</td>
</tr>
<tr>
<td>marketplace</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>4h2m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

**Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>OpenShift Container Platform 4.7 Installing</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>monitoring</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>network</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>

<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>openshift-samples</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>operator-lifecycle-manager</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>operator-lifecycle-manager-catalog</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>operator-lifecycle-manager-packageserver</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>service-ca</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>storage</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
</tr>
</tbody>
</table>
b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See “Enabling multipathing with kernel arguments on RHCOS” in the Post-installation configuration documentation for more information.

### 7.2.19. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 7.2.20. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.

### 7.3. INSTALLING A CLUSTER ON BARE METAL IN A RESTRICTED NETWORK
In OpenShift Container Platform version 4.7, you can install a cluster on bare metal infrastructure that you provision in a restricted network.

**IMPORTANT**

While you might be able to follow this procedure to deploy a cluster on virtualized or cloud environments, you must be aware of additional considerations for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you attempt to install an OpenShift Container Platform cluster in such an environment.

### 7.3.1. Prerequisites

- Create a registry on your mirror host and obtain the `imageContentSources` data for your version of OpenShift Container Platform.

  **IMPORTANT**

  Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

- Review details about the OpenShift Container Platform installation and update processes.

- If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.

  **NOTE**

  Be sure to also review this site list if you are configuring a proxy.

### 7.3.2. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.
Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

7.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes a **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

7.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access **Quay.io** to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

7.3.4. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

7.3.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
At least two compute machines, which are also known as worker machines. If you are running a three-node cluster, running zero compute machines is supported. Running one compute machine is not supported.

NOTE

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

7.3.4.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. During the initial boot, the machines require either a DHCP server or that static IP addresses be set in order to establish a network connection to download their Ignition config files. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server. If a DHCP server provides NTP servers information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

7.3.4.3. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Table 7.30. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

1. One CPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = CPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster
7.3.4.4. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

7.3.5. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

Prerequisites

- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the supporting infrastructure for your cluster.

Procedure

1. Configure DHCP or set static IP addresses on each node.
2. Provision the required load balancers.
3. Configure the ports for your machines.
4. Configure DNS.
5. Ensure network connectivity.

7.3.5.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require either a DHCP server or that static IP addresses be set on each host in the cluster to establish a network connection, which allows them to download their Ignition config files.

It is recommended to use the DHCP server to manage the machines for the cluster long-term. Ensure that the DHCP server is configured to provide persistent IP addresses and host names to the cluster machines.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.
You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. API load balancer: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 7.34. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer** Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

**Table 7.35. Application Ingress load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for [Configuring chrony time service](#).

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**

- [Configuring chrony time service](#)

### 7.3.5.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>..<cluster_name>..<base_domain>..

**Table 7.36. Required DNS records**

---

1188
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;..&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;..&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td>The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</td>
</tr>
<tr>
<td>Routes</td>
<td><code>*.apps.&lt;cluster_name&gt;..&lt;base_domain&gt;.</code></td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td><code>bootstrap.&lt;cluster_name&gt;..&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td><code>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;..&lt;base_domain&gt;.</code></td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td><code>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;..&lt;base_domain&gt;.</code></td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.
The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

Example 7.5. Sample DNS zone database

```text
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
;
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
;
; The api identifies the IP of your load balancer.
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5
;
; The wildcard also identifies the load balancer.
*.apps.ocp4 IN A 192.168.1.5
;
; Create an entry for the bootstrap host.
bootstrap.ocp4 IN A 192.168.1.96
;
; Create entries for the master hosts.
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
master2.ocp4 IN A 192.168.1.99
;
; Create entries for the worker hosts.
worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.17
;
; EOF
```

The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 7.6. Sample DNS zone database for reverse records

```text
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
```
NOTE

For clusters using installer-provisioned infrastructure, only the DNS records must be added.

7.3.6. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ ssh-keygen -t ed25519 -N "\n-f <path>/<file_name>
```
Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the **ssh-agent** process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the **ssh-agent**:

   ```bash
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   ```bash
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

**7.3.7. Manually creating the installation configuration file**

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**
• Obtain the OpenShift Container Platform installation program and the access token for your cluster.

• Obtain the imageContentSources section from the output of the command to mirror the repository.

• Obtain the contents of the certificate for your mirror registry.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   • Unless you use a registry that RHCOS trusts by default, such as docker.io, you must provide the contents of the certificate for your mirror repository in the `additionalTrustBundle` section. In most cases, you must provide the certificate for your mirror.

   • You must include the imageContentSources section from the output of the command to mirror the repository.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

**7.3.7.1. Installation configuration parameters**

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.
NOTE

After installation, you cannot modify these parameters in the `install-config.yaml` file.

IMPORTANT

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

7.3.7.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 7.37. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws**, **baremetal**, **azure**, **openstack**, **ovirt**, **vsphere**.

For additional information about `platform.<platform>` parameters, consult the table for your specific platform that follows.

---

### 7.3.7.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 7.38. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods. The default value is <code>10.128.0.0/14</code> with a host prefix of <code>/23</code>. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^{(32 - 23)} - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <code>172.30.0.0/16</code>. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
7.3.7.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 7.39. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is <strong>10.0.0.0/16</strong> for all platforms other than libvirt. For libvirt, the default value is <strong>192.168.126.0/24</strong>.</td>
<td>An IP network block in CIDR notation. For example, <strong>10.0.0.0/16</strong>.</td>
</tr>
</tbody>
</table>

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

---

1197
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>

<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
## Parameter Description Values

**controlPlane.hypertreading**  
Whether to enable or disable simultaneous multithreading, or *hyperthreading*, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.  

**IMPORTANT**  
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

**controlPlane.name**  
Required if you use `controlPlane`. The name of the machine pool.  
master

**controlPlane.platform**  
Required if you use `controlPlane`. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the `compute.platform` parameter value.  
aws, azure, gcp, openstack, ovirt, vsphere, or `{}`

**controlPlane.replicas**  
The number of control plane machines to provision.  
The only supported value is 3, which is the default value.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.
<table>

<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to **BZ#1953035**.

### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 7.3.7.2. Sample install-config.yaml file for bare metal

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
networking:
  clusterNetwork:
```
- cidr: 10.128.0.0/14
  - hostPrefix: 23
  - networkType: OpenShiftSDN
  - serviceNetwork: 172.30.0.0/16
  - platform:
    - none: {}
    - fips: false
  - pullSecret: '{"auths":{"<local_registry>": {"auth": "<credentials>", "email": "you@example.com"}}}
  - sshKey: 'ssh-ed25519 AAAA...
  - additionalTrustBundle: |-----BEGIN CERTIFICATE-----
    ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
    |-----END CERTIFICATE-----
  - imageContentSources:
    - mirrors:
      - <local_registry>/<local_repository_name>/release
        source: quay.io/openShift-release-dev/ocp-release
      - mirrors:
        - <local_registry>/<local_repository_name>/release
          source: quay.io/openShift-release-dev/ocp-v4.0-art-dev

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, `-`, and the first line of the controlPlane section must not. Only one control plane pool is used.

3. Whether to enable or disable simultaneous multithreading (SMT), or `hyperthreading`. By default, SMT is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to `Disabled`. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the `hyperthreading` parameter has no effect.

**IMPORTANT**

If you disable `hyperthreading`, whether in the BIOS or in the `install-config.yaml`, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4. You must set the value of the `replicas` parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

5. The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{32-23}-2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to none. You cannot provide additional platform configuration variables for your platform.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to none, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.
For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or

The public portion of the default SSH key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

### 7.3.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**NOTE**
For bare metal installations, if you do not assign node IP addresses from the range that is specified in the `networking.machineNetwork[].cidr` field in the `install-config.yaml` file, you must include them in the `proxy.noProxy` field.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**
The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:
API version: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----

① A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

② A proxy URL to use for creating HTTPS connections outside the cluster.

③ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

④ If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**
Only the Proxy object named cluster is supported, and no additional proxies can be created.

### 7.3.8. Configuring a three-node cluster

You can optionally install and run three-node clusters in OpenShift Container Platform with no workers. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for development, production, and testing.

**Procedure**
- Edit the `install-config.yaml` file to set the number of compute replicas, which are also known as worker replicas, to 0, as shown in the following `compute` stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

### 7.3.9. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

   **WARNING**

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>  
   
   1 For `<installation_directory>`, specify the same installation directory.
   
   The following files are generated in the directory:
   
   ├── auth
   │   └── kubeadmin-password
   │
   │   └── kubeconfig
   │
   │   └── bootstrap.ign
   │
   │   └── master.ign
   │
   │   └── metadata.json
   │
   │   └── worker.ign
   
7.3.10. Configuring chrony time service

You must set the time server and related settings used by the chrony time service (`chronyd`) by modifying the contents of the `chrony.conf` file and passing those contents to your nodes as a machine config.

Procedure

1. Create the contents of the `chrony.conf` file and encode it as base64. For example:

   ```bash
   $ cat << EOF | base64
   pool 0.rhel.pool.ntp.org iburst
   driftfile /var/lib/chrony/drift
   makestep 1.0 3
   rtsync
   logdir /var/log/chrony
   EOF
   ```
Specify any valid, reachable time source, such as the one provided by your DHCP server.

**Example output**

```
ICAgIHNlcnZlcIjiG9j5ay5yZWRoYXQuY29tIGlidXJzdAogICAgZHJpZnRmaWxlIC92YXJlbGliL2Nocm9ueS9kcmImmdAogICAgbWFrZXN0ZXAgMS4wIDMKICAgIHJ0Y3N5bmMKICAgIyExZ2RpciAv
dmFyL2xvZy9jaHJvbnkJ
```

2. Create the **MachineConfig** object file, replacing the base64 string with the one you just created. This example adds the file to **master** nodes. You can change it to **worker** or make an additional MachineConfig for the **worker** role. Create MachineConfig files for each type of machine that your cluster uses:

```
$ cat << EOF > ./99-masters-chrony-configuration.yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: master
  name: 99-masters-chrony-configuration
spec:
  config:
    ignition:
      config: {}
    security:
      tls: {}
    timeouts: {}
    version: 3.2.0
    networkd: {}
    passwd: {}
    storage:
      files:
        - contents:
          source: data:text/plain;charset=utf-8;base64,ICAgIHNlcnZlcIjiG9j5ay5yZWRoYXQuY29tIGlidXJzdAogICAgZHJpZnRmaWxlIC92YXJlbGliL2Nocm9ueS9kcmImmdAogICAgbWFrZXN0ZXAgMS4wIDMKICAgIHJ0Y3N5bmMKICAgIyExZ2RpciAvdmFyL2xvZy9jaHJvbnkJ
          mode: 420
          overwrite: true
          path: /etc/chrony.conf
          osImageURL: ""
EOF
```

1. Specify an octal value mode for the **mode** field in the machine config file. After creating the file and applying the changes, the **mode** is converted to a decimal value. You can check the YAML file with the command `oc get mc <mc-name> -o yaml`.

3. Make a backup copy of the configuration files.

4. Apply the configurations in one of two ways:

   - If the cluster is not up yet, after you generate manifest files, add this file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.
If the cluster is already running, apply the file:

```
$ oc apply -f ./99-masters-chrony-configuration.yaml
```

### 7.3.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

NOTE
The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments:** You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the `APPEND` parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special `coreos.inst.*` arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- **Ignition configs:** OpenShift Container Platform Ignition config files (`*.ign`) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the `coreos-installer` to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- **coreos-installer:** You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the `coreos-installer` command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.
As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

7.3.11.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image

Before you install a cluster on infrastructure that you provision, you must create RHCOS machines for it to use. You can use an ISO image to create the machines.

Prerequisites

- Obtain the Ignition config files for your cluster.
- Have access to an HTTP server that can be accessed from your computer, and from the machines that you create.

Procedure

1. Upload the control plane, compute, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**
   
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page.

   **IMPORTANT**
   
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

   ISO file names resemble the following example:

   `rhcos-<version>-live.<architecture>.iso`

3. Use the ISO to start the RHCOS installation. Use one of the following installation options:

   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection via a LOM interface.

4. Boot the ISO image. You can interrupt the installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command instead of adding kernel arguments. If you run the live installer without options or interruption, the installer boots up to a shell prompt on the live system, ready for you to install RHCOS to disk.
5. Review the *Advanced RHCOS installation reference section* for different ways of configuring features, such as networking and disk partitions, before running the `coreos-installer`.

6. Run the `coreos-installer` command. At a minimum, you must identify the Ignition config file location for your node type, and the location of the disk you are installing to. Here is an example:

```bash
$ sudo coreos-installer install \
  --ignition-url=https://host/worker.ign /dev/sda
```

7. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

8. Continue to create the other machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

7.3.11.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting

Before you install a cluster that uses manually-provisioned RHCOS nodes, such as bare metal, you must create RHCOS machines for it to use. You can use PXE or iPXE booting to create the machines.

**Prerequisites**

- Obtain the Ignition config files for your cluster.
- Configure suitable PXE or iPXE infrastructure.
- Have access to an HTTP server that you can access from your computer.

**Procedure**

1. Upload the master, worker, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

**IMPORTANT**

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS *kernel*, *initramfs* and *rootfs* files from the RHCOS image mirror page.
The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

3. Upload the additional files that are required for your booting method:

- For traditional PXE, upload the **kernel** and **initramfs** files to your TFTP server and the **rootfs** file to your HTTP server.

- For iPXE, upload the **kernel**, **initramfs**, and **rootfs** files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

4. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

5. Configure PXE or iPXE installation for the RHCOS images.

Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

  ```
  DEFAULT pxeboot
  TIMEOUT 20
  PROMPT 0
  LABEL pxeboot
    KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
    APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
    coreos.inst.install_dev=/dev/sda
    coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  ```

**IMPORTANT**

1. Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2. If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
### Step 3

Specify locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the `initramfs` file, the `coreos.live.rootsfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=tty0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](https://docs.redhat.com/docs/en-us/red-hat-enterprise-linux/).

- For iPXE:

```text
kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main

<architecture>.img

coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign

1

<architecture>.img

boot
```

1. Specify locations of the RHCOS files that you uploaded to your HTTP server. The `kernel` parameter value is the location of the `kernel` file, the `initrd=main` argument is needed for booting on UEFI systems, the `coreos.live.rootsfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.

2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify the location of the `initramfs` file that you uploaded to your HTTP server.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `kernel` line. For example, add `console=tty0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](https://docs.redhat.com/docs/en-us/red-hat-enterprise-linux/).

6. If you use PXE UEFI, perform the following actions:

   a. Provide the `shimx64.efi` and `grubx64.efi` EFI binaries and the `grub.cfg` file that are required for booting the system.

      - Extract the necessary EFI binaries by mounting the RHCOS ISO to your host and then mounting the `images/efiboot.img` file to your host:

        ```bash
        $ mkdir -p /mnt/iso
        ```
From the `efiboot.img` mount point, copy the `EFI/redhat/shimx64.efi` and `EFI/redhat/grubx64.efi` files to your TFTP server:

```
$ cp /mnt/efiboot/EFI/redhat/shimx64.efi .
$ cp /mnt/efiboot/EFI/redhat/grubx64.efi .
```

Copy the `EFI/redhat/grub.cfg` file that is included in the RHCOS ISO to your TFTP server.

b. Edit the `grub.cfg` file to include arguments similar to the following:

```
menuentry 'Install Red Hat Enterprise Linux CoreOS' --class fedora --class gnu-linux --class gnu --class os {
  linuxefi rhcos-<version>-live-kernel-<architecture> coreos.inst.install_dev=/dev/sda
<architecture>.img coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
initrdefi rhcos-<version>-live-initramfs.<architecture>.img
}
```

where:

- **rhcos-<version>-live-kernel-<architecture>**
  - Specifies the kernel file that you uploaded to your TFTP server.

- **http://<HTTP_server>/rhcos-<version>-live-rootfs.<architecture>.img**
  - Specifies the location of the live rootfs image that you uploaded to your HTTP server.

- **http://<HTTP_server>/bootstrap.ign**
  - Specifies the location of the bootstrap Ignition config file that you uploaded to your HTTP server.

- **rhcos-<version>-live-initramfs.<architecture>.img**
  - Specifies the location of the initramfs file that you uploaded to your TFTP server.

**NOTE**

For more information on how to configure a PXE server for UEFI boot, see the Red Hat Knowledgebase article: How to configure/setup a PXE server for UEFI boot for Red Hat Enterprise Linux?.

```bash
$ mkdir -p /mnt/efiboot
$ mount -o loop rhcos-installer.x86_64.iso /mnt/iso
$ mount -o loop,ro /mnt/iso/images/efiboot.img /mnt/efiboot
```
7. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

7.3.11.3. Advanced Red Hat Enterprise Linux CoreOS (RHCOS) installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
- Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

7.3.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

**Procedure**

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:
$ coreos-installer install --copy-network \ 
   --ignition-url=http://host/worker.ign /dev/sda

IMPORTANT

The --copy-network option only copies networking configuration found under /etc/NetworkManager/system-connections. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

7.3.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

IMPORTANT

Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

7.3.11.3.2.1. Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.

- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as
needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

   ```bash
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a `MachineConfig` object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

   ```yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
   name: 98-var-partition
   spec:
     config:
       ignition:
         version: 3.2.0
       storage:
         disks:
           - device: /dev/<device_name> 1
             partitions:
               - label: var
                 startMiB: <partition_start_offset> 2
                 sizeMiB: <partition_size> 3
             filesystems:
               - device: /dev/disk/by-partlabel/var
                 path: /var
                 format: xfs
       systemd:
       units:
   ```
The storage device name of the disk that you want to partition.

When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

The size of the data partition in mebibytes.

The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-lib-containers.mount`.

The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the ISO or PXE manual installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

7.3.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command line that causes the installer to maintain one or more existing partitions. For a PXE installation, you can `APPEND coreos.inst.*` options to preserve partitions.

Saved partitions might be partitions from an existing OpenShift Container Platform system that has data partitions that you want to keep. Here are a few tips:
• If you save existing partitions, and those partitions do not leave enough space for RHCos, installation will fail without damaging the saved partitions.

• Identify the disk partitions you want to keep either by partition label or by number.

For an ISO installation

This example preserves any partition in which the partition label begins with `data` (`data*`):

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
 --save-partlabel 'data*' /dev/sda
```

The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \n --save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \n --save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

For a PXE installation

This `APPEND` option preserves any partition in which the partition label begins with 'data' ('data*'):

```
coreos.inst.save_partlabel=data*
```

This `APPEND` option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This `APPEND` option preserves partition 6:

```
coreos.inst.save_partindex=6
```

7.3.11.3.3. Identifying Ignition configs

When doing an RHcos manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

• **Permanent install Ignition config** Every manual RHcos installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.

  **IMPORTANT**

  It is not recommended to modify these files.

  For PXE installations, you pass the Ignition configs on the `APPEND` line using the
coreos.inst.ignition_url= option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the coreos-installer command line with the --ignition-url= option. In both cases, only HTTP and HTTPS protocols are supported.

- Live install Ignition config: This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or after the RH COS system installs to disk. This method should only be used for performing tasks that must be performed once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

For PXE or ISO boots, you can create the Ignition config and APPEND the ignition.config.url= option to identify the location of the Ignition config. You also need to append ignition.firstboot ignition.platform.id=metal or the ignition.config.url option will be ignored.

7.3.11.3.3.1. Embedding an Ignition config in the RH COS ISO

You can embed a live install Ignition config directly in an RH COS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

**Procedure**

1. Download the coreos-installer binary from the following image mirror page: https://mirror.openshift.com/pub/openshift-v4/clients/coreos-installer/latest/.

2. Retrieve the RH COS ISO image and the Ignition config file, and copy them into an accessible directory, such as /mnt:

   ```
   # cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
   # chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
   ```

3. Run the following command to embed the Ignition config into the ISO:

   ```
   # ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign \
   /mnt/rhcos-<version>-live.x86_64.iso
   ```

   You can now use that ISO to install RH COS using the specified live install Ignition config.

   **IMPORTANT**

   Using coreos-installer iso ignition embed to embed a file generated by openshift-installer, such as bootstrap.ign, master.ign and worker.ign, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

   ```
   # ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
   # diff -s bootstrap.ign mybootstrap.ign
   ```

   **Example output**

   Files bootstrap.ign and mybootstrap.ign are identical
5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

```
# ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
```

You can now embed another Ignition config into the ISO or use the ISO in its pristine state.

### 7.3.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

**Routing and bonding options at RHCOS boot prompt**

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node’s networking. If no networking arguments are used, the installation defaults to using DHCP.

**IMPORTANT**

When adding networking arguments, you must also add the `rd.neednet=1` kernel argument.

The following table describes how to use `ip=`, `nameserver=`, and `bond=` kernel arguments for live ISO installs.

**NOTE**

Ordering is important when adding kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

**Routing and bonding options for ISO**

The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

<tr>
<td>Specify multiple network interfaces by specifying multiple (\text{ip}=) entries.</td>
<td>(\text{ip}=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ) (\text{nameserver}=4.4.4.41)</td>
</tr>
<tr>
<td>Optional: You can configure routes to additional networks by setting an (\text{rd.route=}) value. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</td>
<td>(\text{ip}=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ) (\text{nameserver}=4.4.4.41)</td>
</tr>
<tr>
<td>To configure the default gateway:</td>
<td>(\text{ip}=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ) (\text{nameserver}=4.4.4.41)</td>
</tr>
<tr>
<td>To configure the route for the additional network:</td>
<td>(\text{ip}=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ) (\text{nameserver}=4.4.4.41)</td>
</tr>
<tr>
<td>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used.</td>
<td>(\text{ip}=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ) (\text{nameserver}=4.4.4.41)</td>
</tr>
<tr>
<td>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</td>
<td>(\text{ip}=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none ) (\text{nameserver}=4.4.4.41)</td>
</tr>
<tr>
<td>Description</td>
<td>Examples</td>
</tr>
<tr>
<td>-------------</td>
<td>----------</td>
</tr>
</tbody>
</table>
| Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter. | To configure a VLAN on a network interface and use a static IP address:  
```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0```
To configure a VLAN on a network interface and to use DHCP:  
```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0```
| You can provide multiple DNS servers by adding a `nameserver=` entry for each server. | `nameserver=1.1.1.1
nameserver=8.8.8.8` |
| Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples: | To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:  
```
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp```
To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:  
```
bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com: bond0:none``` |
  * The syntax for configuring a bonded interface is: `bond=name[:network_interfaces] [:options]`
  * `name` is the bonding device name (`bond0`), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.
  * When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface with a VLAN and to use DHCP:
```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:
```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

Optional: Network teaming can be used as an alternative to bonding by using the `team=` parameter. In this example:

- The syntax for configuring a team interface is: `team=name[:]network_interfaces` where `name` is the team device name (`team0`) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1`, `em2`).

**NOTE**
Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this [Red Hat Knowledgebase Article](https://access.redhat.com/).

To configure a network team:
```
team=team0:em1,em2
ip=team0:dhcp
```

coreos.inst boot options for ISO or PXE install
While you can pass most standard installation boot arguments to the live installer, there are several arguments that are specific to the RHCOS live installer.

- For ISO, these options can be added by interrupting the RHCOS installer.
- For PXE or iPXE, these options must be added to the `APPEND` line before starting the PXE kernel. You cannot interrupt a live PXE install.

The following table shows the RHCOS live installer boot options for ISO and PXE installs.

### Table 7.40. coreos.inst boot options

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst</td>
<td>boot options for ISO or PXE install</td>
</tr>
</tbody>
</table>

While you can pass most standard installation boot arguments to the live installer, there are several arguments that are specific to the RHCOS live installer.

- For ISO, these options can be added by interrupting the RHCOS installer.
- For PXE or iPXE, these options must be added to the `APPEND` line before starting the PXE kernel. You cannot interrupt a live PXE install.
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>coreos.inst.image_url</td>
<td>Optional: Download and install the specified RHCOS image.</td>
</tr>
<tr>
<td></td>
<td>• This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>• While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>• If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>• Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.skip_reboot</td>
<td>Optional: The system will not reboot after installing. Once the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
</tbody>
</table>
coreos.inst.platform_id

Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: `coreos.inst.platform_id=vmware`.

ignition.config.url

Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how coreos-installer is invoked, or to run code before or after the installation. This is different from coreos.inst.ignition_url, which is the Ignition config for the installed system.

**coreos-installer options for ISO install**

You can also install RHCOS by invoking the coreos-installer command directly from the command line. The kernel arguments in the previous table provide a shortcut for automatically invoking coreos-installer at boot time, but you can pass similar arguments directly to coreos-installer when running it from a shell prompt.

The following table shows the options and subcommands you can pass to the coreos-installer command from a shell prompt during a live install.

**Table 7.41. coreos-installer command-line options, arguments, and subcommands**

<table>
<thead>
<tr>
<th>Command-line options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-u, --image-url &lt;url&gt;</td>
<td>Specify the image URL manually.</td>
</tr>
<tr>
<td>-f, --image-file &lt;path&gt;</td>
<td>Specify a local image file manually.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>Embed an Ignition config from a file.</td>
</tr>
<tr>
<td>-I, --ignition-url &lt;URL&gt;</td>
<td>Embed an Ignition config from a URL.</td>
</tr>
<tr>
<td>--ignition-hash &lt;digest&gt;</td>
<td>Digest type-value of the Ignition config.</td>
</tr>
<tr>
<td>-p, --platform &lt;name&gt;</td>
<td>Override the Ignition platform ID.</td>
</tr>
<tr>
<td>--append-karg &lt;arg&gt;...</td>
<td>Append the default kernel argument.</td>
</tr>
<tr>
<td>--delete-karg &lt;arg&gt;...</td>
<td>Delete the default kernel argument.</td>
</tr>
</tbody>
</table>
**-n, --copy-network**  
Copy the network configuration from the install environment.

**IMPORTANT**  
The **--copy-network** option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

**--network-dir <path>**  
For use with **-n**. Default is `/etc/NetworkManager/system-connections/`.

**--save-partlabel <lx>..**  
Save partitions with this label glob.

**--save-partindex <id>...**  
Save partitions with this number or range.

**--offline**  
Force offline installation.

**--insecure**  
Skip signature verification.

**--insecure-ignition**  
Allow Ignition URL without HTTPS or hash.

**--architecture <name>**  
Target CPU architecture. Default is `x86_64`.

**--preserve-on-error**  
Do not clear partition table on error.

**-h, --help**  
Print help information.

**Command-line argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;device&gt;</td>
<td>The destination device.</td>

7.3.11.4. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.
NOTE

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install `bootupd` by using the `bootctl` command-line tool.

1. Inspect the system status:

   ```
   # bootupctl status
   ```

   **Example output**

   ```
   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version
   ```

2. RHCOS images created without `bootupd` installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

   ```
   # bootupctl adopt-and-update
   ```

   **Example output**

   ```
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```
   # bootupctl update
   ```

   **Example output**

   ```
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

Machine config method

Another way to enable `bootupd` is by providing a machine config.

- Provide a machine config file with the enabled `systemd` unit, as shown in the following example:

**Example output**

```
variant: rhcos
version: 1.1.0
systemd:
  units:
  - name: custom-bootupd-auto.service
    enabled: true
    contents: |
    [Unit]
    Description=Bootupd automatic update
```
7.3.12. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.

Procedure

1. Monitor the bootstrap process:

   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   Example output

   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.20.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point.
   You can also remove or reformat the machine itself.

7.3.13. Logging in to the cluster by using the CLI
You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
echo 'export KUBECONFIG=<installation_directory>/auth/kubeconfig' > kubeadmin.sh
   chmod 700 kubeadmin.sh
   . kubeadmin.sh
   $$ oc whoami
   system:admin
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $$ oc get nodes
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.20.0
   master-1  Ready     master  63m  v1.20.0
   master-2  Ready     master  64m  v1.20.0
   ```

**7.3.14. Approving the certificate signing requests for your machines**

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $$ oc get nodes
   NAME    STATUS    ROLES   AGE   VERSION
   master-0 Ready    master 63m  v1.20.0
   master-1 Ready    master 63m  v1.20.0
   master-2 Ready    master 64m  v1.20.0
   ```
The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> ①

① <csr_name> is the name of a CSR from the list of current CSRs.

• To approve all pending CSRs, run the following command:

$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

$ oc get csr

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

• To approve them individually, run the following command for each valid CSR:

$ oc adm certificate approve <csr_name> ①

① <csr_name> is the name of a CSR from the list of current CSRs.

• To approve all pending CSRs, run the following command:

$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

$ oc get nodes

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>
NOTE
It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information
- For more information on CSRs, see [Certificate Signing Requests](#).

### 7.3.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

#### Prerequisites
- Your control plane has initialized.

#### Procedure

1. Watch the cluster components come online:

   ```shell
   $ watch -n5 oc get clusteroperators
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>

</table>
7.3.15.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '(["op": "add", "path": "/spec/disableAllDefaultSources", "value": true})'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

7.3.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

7.3.15.2.1. Changing the image registry’s management state

To start the image registry, you must change the Image Registry Operator configuration’s `managementState` from Removed to Managed.

Procedure

- Change `managementState` Image Registry Operator configuration from Removed to Managed.
• Change `managementState` Image Registry Operator configuration from `Removed` to `Managed`. For example:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
{"managementState":"Managed"}}'
```

### 7.3.15.2.2. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- Cluster administrator permissions.
- A cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

#### IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

#### Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   ```
   NOTE
   When using shared storage, review your security settings to prevent outside access.
   ```

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**

   ```
   No resources found in openshift-image-registry namespace
   ```

   ```
   NOTE
   If you do have a registry pod in your output, you do not need to continue with this procedure.
   ```

3. Check the registry configuration:
Example output

```
$ oc edit configs.imageregistry.operator.openshift.io
```

4. Check the `clusteroperator` status:

```
$ oc get clusteroperator image-registry
```

Example output

```
NAME             VERSION                              AVAILABLE   PROGRESSING   DEGRADED      SINCE   MESSAGE
image-registry   4.7                                  True        False         False      6h50m
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:
  
  ```
  $ oc edit configs.imageregistry/operator.openshift.io
  
  Then, change the line
  ```
  ```
  managementState: Removed
  ```
  to
  ```
  managementState: Managed
  ```

7.3.15.2.3. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:
  
  ```
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  
  "storage":{"emptyDir":{}}}'}
  ```
If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 7.3.15.2.4. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

### 7.3.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:
$ watch -n5 oc get clusteroperators

Example output

<table>
<thead>
<tr>

</tbody>
</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

      ```
      $ oc get pods --all-namespaces
      ```

      Example output

      | NAMESPACE                                  | NAME                                                    | READY | STATUS |
      |--------------------------------------------|---------------------------------------------------------|-------|--------|
      | openshift-apiserver-operator               | openshift-apiserver-operator-85cb746d55-zqhs8           | 1/1   | Running |
      | Running 1 9m                                |                                                         |       |        |
      | openshift-apiserver                        | apiserver-67b9g                                         | 1/1   | Running |
      | 3m                                         |                                                         |       |        |
      | openshift-apiserver                        | apiserver-ljcmx                                         | 1/1   | Running |
      | 1m                                         |                                                         |       |        |
      | openshift-apiserver                        | apiserver-z25h4                                         | 1/1   | Running |
      | 2m                                         |                                                         |       |        |
      | openshift-authentication-operator           | authentication-operator-69d5d8bf84-vh2n8                 | 1/1   | Running |
      | Running 0 5m                                |                                                         |       |        |
      |

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

      ```
      $ oc logs <pod_name> -n <namespace>
      ```

      Specify the pod name and namespace, as shown in the output of the previous command.

      If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See “Enabling multipathing with kernel arguments on RHCOS” in the Post-installation configuration documentation for more information.
4. Register your cluster on the Cluster registration page.

### 7.3.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 7.3.18. Next steps

- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
CHAPTER 8. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL

8.1. OVERVIEW

Installer-provisioned installation provides support for installing OpenShift Container Platform on bare metal nodes. This guide provides a methodology to achieving a successful installation.

During installer-provisioned installation on bare metal, the installer on the bare metal node labeled as provisioner creates a bootstrap VM. The role of the bootstrap VM is to assist in the process of deploying an OpenShift Container Platform cluster. The bootstrap VM connects to the baremetal network and to the provisioning network, if present, via the network bridges.

When the installation of OpenShift Container Platform control plane nodes is complete and fully operational, the installer destroys the bootstrap VM automatically and moves the virtual IP addresses (VIPs) to the appropriate nodes accordingly. The API VIP moves to the control plane nodes and the Ingress VIP moves to the worker nodes.

8.2. PREREQUISITES

Installer-provisioned installation of OpenShift Container Platform requires:

1. One provisioner node with Red Hat Enterprise Linux (RHEL) 8.x installed.
2. Three control plane nodes.
3. Baseboard Management Controller (BMC) access to each node.
4. At least one network:
   a. One required routable network
b. One optional network for provisioning nodes; and,

c. One optional management network.

Before starting an installer-provisioned installation of OpenShift Container Platform, ensure the hardware environment meets the following requirements.

8.2.1. Node requirements

Installer-provisioned installation involves a number of hardware node requirements:

- **CPU architecture**: All nodes must use x86_64 CPU architecture.

- **Similar nodes**: Red Hat recommends nodes have an identical configuration per role. That is, Red Hat recommends nodes be the same brand and model with the same CPU, memory, and storage configuration.

- **Baseboard Management Controller**: The provisioner node must be able to access the baseboard management controller (BMC) of each OpenShift Container Platform cluster node. You may use IPMI, Redfish, or a proprietary protocol.

- **Latest generation**: Nodes must be of the most recent generation. Because the installer-provisioned installation relies on BMC protocols, the hardware must support IPMI cipher suite 17. Additionally, RHEL 8 ships with the most recent drivers for RAID controllers. Ensure that the nodes are recent enough to support RHEL 8 for the provisioner node and RHCOS 8 for the control plane and worker nodes.

- **Registry node**: (Optional) If setting up a disconnected mirrored registry, it is recommended the registry reside in its own node.

- **Provisioner node**: Installer-provisioned installation requires one provisioner node.

- **Control plane**: Installer-provisioned installation requires three control plane nodes for high availability.

- **Worker nodes**: While not required, a typical production cluster has one or more worker nodes. Smaller clusters are more resource efficient for administrators and developers during development, production, and testing.

- **Network interfaces**: Each node must have at least one network interface for the routable baremetal network. Each node must have one network interface for a provisioning network when using the provisioning network for deployment. Using the provisioning network is the default configuration. Network interface naming must be consistent across control plane nodes for the provisioning network. For example, if a control plane node uses the eth0 NIC for the provisioning network, the other control plane nodes must use it as well.

- **Unified Extensible Firmware Interface (UEFI)**: Installer-provisioned installation requires UEFI boot on all OpenShift Container Platform nodes when using IPv6 addressing on the provisioning network. In addition, UEFI Device PXE Settings must be set to use the IPv6 protocol on the provisioning network NIC, but omitting the provisioning network removes this requirement.
**IMPORTANT**

When starting the installation from virtual media such as an ISO image, delete all old UEFI boot table entries. If the boot table includes entries that are not generic entries provided by the firmware, the installation might fail.

- **Secure Boot:** Many production scenarios require nodes with Secure Boot enabled to verify the node only boots with trusted software, such as UEFI firmware drivers, EFI applications, and the operating system. To deploy an OpenShift Container Platform cluster with Secure Boot, you must enable UEFI boot mode and Secure Boot on each control plane node and each worker node. Red Hat supports Secure Boot only when installer-provisioned installations use Red Fish Virtual Media. Red Hat does not support Secure Boot with self-generated keys.

### 8.2.2. Firmware requirements for installing with virtual media

The installer for installer-provisioned OpenShift Container Platform clusters validates the hardware and firmware compatibility with Redfish virtual media. The following table lists supported firmware for installer-provisioned OpenShift Container Platform clusters deployed with Redfish virtual media.

**Table 8.1. Firmware compatibility for Redfish virtual media**

<table>
<thead>
<tr>
<th>Hardware</th>
<th>Model</th>
<th>Management</th>
<th>Firmware Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP</td>
<td>10th Generation</td>
<td>iLO5</td>
<td>N/A</td>
</tr>
<tr>
<td>Dell</td>
<td>14th Generation</td>
<td>iDRAC 9</td>
<td>v4.20.20.20 - 04.40.00.00</td>
</tr>
<tr>
<td></td>
<td>13th Generation</td>
<td>iDRAC 8</td>
<td>v2.75.75.75+</td>
</tr>
</tbody>
</table>

**NOTE**

Refer to the hardware documentation for the nodes or contact the hardware vendor for information on updating the firmware.

For HP servers, Redfish virtual media is not supported on 9th generation systems running iLO4, because Ironic does not support iLO4 with virtual media.

For Dell servers, ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: **Configuration → Virtual Media → Attach Mode → AutoAttach**. With iDRAC 9 firmware version **04.40.00.00**, the Virtual Console plug-in defaults to **eHTML5**, which causes problems with the **InsertVirtualMedia** workflow. Set the plug-in to **HTML5** to avoid this issue. The menu path is: **Configuration → Virtual console → Plug-in Type → HTML5**.

**IMPORTANT**

The installer will not initiate installation on a node if the node firmware is below the foregoing versions when installing with virtual media.

### 8.2.3. Network requirements

Installer-provisioned installation of OpenShift Container Platform involves several network
requirements. First, installer-provisioned installation involves an optional non-routable **provisioning** network for provisioning the operating system on each bare metal node. Second, installer-provisioned installation involves a routable **baremetal** network.

### 8.2.3.1. Configuring NICs

OpenShift Container Platform deploys with two networks:

- **provisioning**: The **provisioning** network is an optional non-routable network used for provisioning the underlying operating system on each node that is a part of the OpenShift Container Platform cluster. When deploying using the **provisioning** network, the first NIC on each node, such as `eth0` or `eno1`, must interface with the **provisioning** network.

- **baremetal**: The **baremetal** network is a routable network. When deploying using the **provisioning** network, the second NIC on each node, such as `eth1` or `eno2`, must interface with the **baremetal** network. When deploying without a **provisioning** network, you can use any NIC on each node to interface with the **baremetal** network.

**IMPORTANT**

Each NIC should be on a separate VLAN corresponding to the appropriate network.

### 8.2.3.2. Configuring the DNS server

Clients access the OpenShift Container Platform cluster nodes over the **baremetal** network. A network administrator must configure a subdomain or subzone where the canonical name extension is the cluster name.

```
<cluster_name>.<domain-name>
```

For example:

```
test-cluster.example.com
```

OpenShift Container Platform includes functionality that uses cluster membership information to generate A/AAAA records. This resolves the node names to their IP addresses. Once the nodes are registered with the API, the cluster can disperse node information without using CoreDNS-mDNS. This eliminates the network traffic associated with multicast DNS.

### 8.2.3.3. Dynamic Host Configuration Protocol (DHCP) requirements

By default, installer-provisioned installation deploys **ironic-dnsmasq** with DHCP enabled for the **provisioning** network. No other DHCP servers should be running on the **provisioning** network when the **provisioningNetwork** configuration setting is set to **managed**, which is the default value. If you have a DHCP server running on the **provisioning** network, you must set the **provisioningNetwork** configuration setting to **unmanaged** in the **install-config.yaml** file.

Network administrators must reserve IP addresses for each node in the OpenShift Container Platform cluster for the **baremetal** network on an external DHCP server.

### 8.2.3.4. Reserving IP addresses for nodes with the DHCP server

For the **baremetal** network, a network administrator must reserve a number of IP addresses to ensure that they do not change after deployment, including:
1. Two virtual IP addresses:
   - One IP address for the API endpoint.
   - One IP address for the wildcard ingress endpoint.
2. One IP address for the provisioner node.
3. One IP address for each control plane (master) node.
4. One IP address for each worker node.

**RESERVING IP ADDRESSES SO THEY BECOME STATIC IP ADDRESSES**

Some administrators prefer to use static IP addresses so that each node’s IP address remains constant in the absence of a DHCP server. To use static IP addresses in the OpenShift Container Platform cluster, reserve the IP addresses with an infinite lease. During deployment, the installer will reconfigure the NICs from DHCP assigned addresses to static IP addresses. NICs with DHCP leases that are not infinite will remain configured to use DHCP.

Setting IP addresses with an infinite lease is incompatible with network configuration deployed by using the Machine Config Operator.

**ENSURING THAT YOUR DHCP SERVER CAN PROVIDE INFINITE LEASES**

Your DHCP server must provide a DHCP expiration time of 4294967295 seconds to properly set an infinite lease as specified by rfc2131. If a lesser value is returned for the DHCP infinite lease time, the node reports an error and a permanent IP is not set for the node. In RHEL 8, dhcpd does not provide infinite leases. If you want to use the provisioner node to serve dynamic IP addresses with infinite lease times, use dnsmasq rather than dhcpd.

**DO NOT CHANGE IP ADDRESSES MANUALLY AFTER DEPLOYMENT**

Do not change a worker node’s IP address manually after deployment. To change the IP address of a worker node after deployment, you must mark the worker node unschedulable, evacuate the pods, delete the node, and recreate it with the new IP address. See “Working with nodes” for additional details. To change the IP address of a control plane node after deployment, contact support.

The storage interface requires a DHCP reservation.

The following table provides an exemplary embodiment of fully qualified domain names. The API and Nameserver addresses begin with canonical name extensions. The hostnames of the control plane and worker nodes are exemplary, so you can use any host naming convention you prefer.

<table>
<thead>
<tr>
<th>Usage</th>
<th>Host Name</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>API</td>
<td>api.&lt;cluster_name&gt;.&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Ingress LB (apps)</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
</tbody>
</table>

1247
<table>
<thead>
<tr>
<th>Usage</th>
<th>Host Name</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provisioner node</td>
<td>provisioner.&lt;cluster_name&gt;..&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Master-0</td>
<td>openshift-master-0.&lt;cluster_name&gt;..&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Master-1</td>
<td>openshift-master-1.&lt;cluster_name&gt;..&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Master-2</td>
<td>openshift-master-2.&lt;cluster_name&gt;..&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Worker-0</td>

<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Worker-1</td>
<td>openshift-worker-1.&lt;cluster_name&gt;..&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Worker-n</td>
<td>openshift-worker-n.&lt;cluster_name&gt;..&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
</tbody>
</table>

### 8.2.3.5. Network Time Protocol (NTP)

Each OpenShift Container Platform node in the cluster must have access to an NTP server. OpenShift Container Platform nodes use NTP to synchronize their clocks. For example, cluster nodes use SSL certificates that require validation, which might fail if the date and time between the nodes are not in sync.

**IMPORTANT**

Define a consistent clock date and time format in each cluster node’s BIOS settings, or installation might fail.

You may reconfigure the control plane nodes to act as NTP servers on disconnected clusters, and reconfigure worker nodes to retrieve time from the control plane nodes.

### 8.2.3.6. State-driven network configuration requirements (Technology Preview)

OpenShift Container Platform supports additional post-installation state-driven network configuration on the secondary network interfaces of cluster nodes using `kubernetes-nmstate`. For example, system administrators might configure a secondary network interface on cluster nodes after installation for a storage network.

**NOTE**

Configuration must occur before scheduling pods.

State-driven network configuration requires installing `kubernetes-nmstate`, and also requires Network Manager running on the cluster nodes. See [OpenShift Virtualization > Kubernetes NMState (Tech Preview)](https://docs.openshift.com/container-platform/4.7/virtualization/index.html#kubernetes-nmstate) for additional details.

### 8.2.3.7. Port access for the out-of-band management IP address
The out-of-band management IP address is on a separate network from the node. To ensure that the out-of-band management can communicate with the baremetal node during installation, the out-of-band management IP address address must be granted access to the TCP 6180 port.

8.2.4. Configuring nodes

Configuring nodes when using the provisioning network

Each node in the cluster requires the following configuration for proper installation.

**WARNING**

A mismatch between nodes will cause an installation failure.

While the cluster nodes can contain more than two NICs, the installation process only focuses on the first two NICs:

<table>
<thead>
<tr>
<th>NIC</th>
<th>Network</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC1</td>
<td>provisioning</td>
<td>&lt;provisioning-vlan&gt;</td>
</tr>
<tr>
<td>NIC2</td>
<td>baremetal</td>
<td>&lt;baremetal-vlan&gt;</td>
</tr>
</tbody>
</table>

NIC1 is a non-routable network (provisioning) that is only used for the installation of the OpenShift Container Platform cluster.

The Red Hat Enterprise Linux (RHEL) 8.x installation process on the provisioner node might vary. To install Red Hat Enterprise Linux (RHEL) 8.x using a local Satellite server or a PXE server, PXE-enable NIC2.

<table>
<thead>
<tr>
<th>PXE</th>
<th>Boot order</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC1 PXE-enabled provisioning network</td>
<td>1</td>
</tr>
<tr>
<td>NIC2 baremetal network. PXE-enabled is optional.</td>
<td>2</td>
</tr>
</tbody>
</table>

**NOTE**

Ensure PXE is disabled on all other NICs.

Configure the control plane and worker nodes as follows:
### Configuring nodes without the provisioning network

The installation process requires one NIC:

<table>
<thead>
<tr>
<th>NIC</th>
<th>Network</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NICx</td>
<td>baremetal</td>
<td>&lt;baremetal-vlan&gt;</td>
</tr>
</tbody>
</table>

NICx is a routable network (baremetal) that is used for the installation of the OpenShift Container Platform cluster, and routable to the internet.

### Configuring nodes for Secure Boot

Secure Boot prevents a node from booting unless it verifies the node is using only trusted software, such as UEFI firmware drivers, EFI applications and the operating system. Red Hat only supports Secure Boot when deploying with RedFish Virtual Media.

To enable Secure Boot, refer to the hardware guide for the node. To enable Secure Boot, execute the following:

1. Boot the node and enter the BIOS menu.
2. Set the node's boot mode to UEFI Enabled.
3. Enable Secure Boot.

**IMPORTANT**

Red Hat does not support Secure Boot with self-generated keys.

### 8.2.5. Out-of-band management

Nodes will typically have an additional NIC used by the Baseboard Management Controllers (BMCs). These BMCs must be accessible from the provisioner node.

Each node must be accessible via out-of-band management. When using an out-of-band management network, the provisioner node requires access to the out-of-band management network for a successful OpenShift Container Platform 4 installation.

The out-of-band management setup is out of scope for this document. We recommend setting up a separate management network for out-of-band management. However, using the provisioning network or the baremetal network are valid options.

### 8.2.6. Required data for installation

Prior to the installation of the OpenShift Container Platform cluster, gather the following information from all cluster nodes:

- Out-of-band management IP
  - Examples
When using the provision network

- NIC1 **provisioning** MAC address
- NIC2 **baremetal** MAC address

When omitting the provision network

- NICx **baremetal** MAC address

### 8.2.7. Validation checklist for nodes

#### When using the provision network

- NIC1 VLAN is configured for the **provisioning** network. (optional)
- NIC1 is PXE-enabled on the provisioner, control plane (master), and worker nodes when using a **provisioning** network. (optional)
- NIC2 VLAN is configured for the **baremetal** network.
- PXE has been disabled on all other NICs.
- Control plane and worker nodes are configured.
- All nodes accessible via out-of-band management.
- A separate management network has been created. (optional)
- Required data for installation.

#### When omitting the provision network

- NICx VLAN is configured for the **baremetal** network.
- Control plane and worker nodes are configured.
- All nodes accessible via out-of-band management.
- A separate management network has been created. (optional)
- Required data for installation.

### 8.3. SETTING UP THE ENVIRONMENT FOR AN OPENSSHIFT INSTALLATION

#### 8.3.1. Installing RHEL on the provisioner node
With the networking configuration complete, the next step is to install RHEL 8.x on the provisioner node. The installer uses the provisioner node as the orchestrator while installing the OpenShift Container Platform cluster. For the purposes of this document, installing RHEL on the provisioner node is out of scope. However, options include but are not limited to using a RHEL Satellite server, PXE, or installation media.

### 8.3.2. Preparing the provisioner node for OpenShift Container Platform installation

Perform the following steps to prepare the environment.

**Procedure**

1. Log in to the provisioner node via ssh.

2. Create a non-root user (**kni**) and provide that user with **sudo** privileges:

   ```
   # useradd kni
   # passwd kni
   # echo "kni ALL=(root) NOPASSWD:ALL" | tee -a /etc/sudoers.d/kni
   # chmod 0440 /etc/sudoers.d/kni
   # su - kni -c "ssh-keygen -t ed25519 -f /home/kni/.ssh/id_rsa -N ""
   # su - kni
   $ sudo subscription-manager register --username=<user> --password=<pass> --auto-attach
   $ sudo subscription-manager repos --enable=rhel-8-for-x86_64-appstream-rpms --enable=rhel-8-for-x86_64-baseos-rpms
   $ sudo dnf install -y libvirt qemu-kvm mkisofs python3-devel jq ipmitool
   $ sudo usermod --append --groups libvirt <user>
   
   **NOTE**
   
   For more information about Red Hat Subscription Manager, see Using and Configuring Red Hat Subscription Manager.
   
   6. Install the following packages:

   ```
   $ sudo dnf install -y libvirt qemu-kvm mkisofs python3-devel jq ipmitool
   ```

   7. Modify the user to add the **libvirt** group to the newly created user:

   ```
   $ sudo usermod --append --groups libvirt <user>
   ```

   8. Restart **firewalld** and enable the **http** service:
9. Start and enable the `libvirtd` service:

```bash
$ sudo systemctl start firewalld
$ sudo firewall-cmd --zone=public --add-service=http --permanent
$ sudo firewall-cmd --reload
$ sudo systemctl enable libvirtd --now
```

10. Create the `default` storage pool and start it:

```bash
$ sudo virsh pool-define-as --name default --type dir --target /var/lib/libvirt/images
$ sudo virsh pool-start default
$ sudo virsh pool-autostart default
```

11. Configure networking.

```bash
$ export PUB_CONN=<baremetal_nic_name>
$ sudo nohup bash -c "
   nmcli con down "$PUB_CONN"
   nmcli con delete "$PUB_CONN"
   # RHEL 8.1 appends the word \"System\" in front of the connection, delete in case it exists
   nmcli con down \"System $PUB_CONN\"
   nmcli con delete \"System $PUB_CONN\"
   nmcli connection add ifname baremetal type bridge con-name baremetal
   nmcli con add type bridge-slave ifname \"$PUB_CONN\" master baremetal
   pkill dhclient; dhclient baremetal
   "
```

If you are deploying with a `provisioning` network, export the `provisioning` network NIC name:

```bash
$ export PROV_CONN=<prov_nic_name>
```

If you are deploying with a `provisioning` network, configure the `provisioning` network:

```bash
$ sudo nohup bash -c "
   nmcli con down \"$PROV_CONN\"
   nmcli con delete \"$PROV_CONN\"
   nmcli connection add ifname provisioning type bridge con-name provisioning
   nmcli con add type bridge-slave ifname \"$PROV_CONN\" master provisioning
   nmcli connection modify provisioning ipv6.addresses fd00:1101::1/64 ipv6.method manual
   nmcli con down provisioning
   nmcli con up provisioning
   "
```
NOTE

The ssh connection might disconnect after executing these steps.

The IPv6 address can be any address as long as it is not routable via the baremetal network.

Ensure that UEFI is enabled and UEFI PXE settings are set to the IPv6 protocol when using IPv6 addressing.

12. Configure the IPv4 address on the provisioning network connection.

   $ nmcli connection modify provisioning ipv4.addresses 172.22.0.254/24 ipv4.method manual

13. ssh back into the provisioner node (if required).

   # ssh kni@provisioner.<cluster-name>.<domain>

14. Verify the connection bridges have been properly created.

   $ sudo nmcli con show

   NAME               UUID                                  TYPE      DEVICE
   baremetal          4d5133a5-8351-4bb9-bfd4-3af264801530  bridge baremetal
   provisioning       43942805-017f-4d7d-a2c2-7cb3324482ed bridge provisioning
   virbr0             d9bca40f-eee1-410b-8879-a2d4bb0465e7  bridge virbr0
   bridge-slave-eno1  76a8ed50-c7e5-4999-b4f6-6d9014dd0812 ethernet eno1
   bridge-slave-eno2  f31c3353-54b7-48de-893a-02d2b34c4736  ethernet eno2

15. Create a pull-secret.txt file.

   $ vim pull-secret.txt

In a web browser, navigate to Install OpenShift on Bare Metal with installer-provisioned infrastructure, and scroll down to the Downloads section. Click Copy pull secret. Paste the contents into the pull-secret.txt file and save the contents in the kni user’s home directory.

8.3.3. Retrieving the OpenShift Container Platform installer

Use the latest-4.x version of the installer to deploy the latest generally available version of OpenShift Container Platform:

   $ export VERSION=latest-4.7
   export RELEASE_IMAGE=$(curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/release.txt | grep 'Pull From: quay.io' | awk -F ' ' '{print $3}')

Additional resources

- See OpenShift Container Platform upgrade channels and releases for an explanation of the different release channels.

8.3.4. Extracting the OpenShift Container Platform installer
After retrieving the installer, the next step is to extract it.

**Procedure**

1. Set the environment variables:

   ```bash
   $ export cmd=openshift-baremetal-install
   $ export pullsecret_file=~/pull-secret.txt
   $ export extract_dir=$(pwd)
   ``

2. Get the `oc` binary:

   ```bash
   $ curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/openshift-client-
   linux.tar.gz | tar zxvf - oc
   ```

3. Extract the installer:

   ```bash
   $ sudo cp oc /usr/local/bin
   $ oc adm release extract --registry-config "$\{pullsecret_file\}" --command="$cmd" --to "$\{extract_dir\}" $\{RELEASE_IMAGE\}
   $ sudo cp openshift-baremetal-install /usr/local/bin
   ``

**8.3.5. Creating an RHCOS images cache (optional)**

To employ image caching, you must download two images: the Red Hat Enterprise Linux CoreOS (RHCOS) image used by the bootstrap VM and the RHCOS image used by the installer to provision the different nodes. Image caching is optional, but especially useful when running the installer on a network with limited bandwidth.

If you are running the installer on a network with limited bandwidth and the RHCOS images download takes more than 15 to 20 minutes, the installer will time out. Caching images on a web server will help in such scenarios.

Use the following steps to install a container that contains the images.

1. Install `podman`.

   ```bash
   $ sudo dnf install -y podman
   ``

2. Open firewall port **8080** to be used for RHCOS image caching.

   ```bash
   $ sudo firewall-cmd --add-port=8080/tcp --zone=public --permanent
   $ sudo firewall-cmd --reload
   ```

3. Create a directory to store the `bootstraposimage` and `clusterosimage`.

   ```bash
   $ mkdir /home/kni/rhcos_image_cache
   ```

4. Set the appropriate SELinux context for the newly created directory.
$ sudo semanage fcontext -a -t httpd_sys_content_t "/home/kni/rhcos_image_cache(/.*)?"
$ sudo restorecon -Rv rhcos_image_cache/

5. Get the commit ID from the installer. The ID determines which images the installer needs to download.

$ export COMMIT_ID=$(/usr/local/bin/openshift-baremetal-install version | grep "^built from commit" | awk '{print $4}')

6. Get the URI for the RHCOS image that the installer will deploy on the nodes.

$ export RHCOS_OPENSTACK_URI=$(curl -s -S \nhttps://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json \n| jq .images.openstack.path | sed 's//"//g')

7. Get the URI for the RHCOS image that the installer will deploy on the bootstrap VM.

$ export RHCOS_QEMU_URI=$(curl -s -S \nhttps://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json \n| jq .images.qemu.path | sed 's//"//g')

8. Get the path where the images are published.

$ export RHCOS_PATH=$(curl -s -S \nhttps://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json \n| jq .baseUrl | sed 's//"//g')

9. Get the SHA hash for the RHCOS image that will be deployed on the bootstrap VM.

$ export RHCOS_QEMU_SHA_UNCOMPRESSED=$(curl -s -S \nhttps://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json \n| jq -r '.images.qemu["uncompressed-sha256"]')

10. Get the SHA hash for the RHCOS image that will be deployed on the nodes.

$ export RHCOS_OPENSTACK_SHA_COMPRESSED=$(curl -s -S \nhttps://raw.githubusercontent.com/openshift/installer/$COMMIT_ID/data/data/rhcos.json \n| jq -r '.images.openstack.sha256')

11. Download the images and place them in the /home/kni/rhcos_image_cache directory.

$ curl -L ${RHCOS_PATH}${RHCOS_QEMU_URI} -o /home/kni/rhcos_image_cache/${RHCOS_QEMU_URI}
$ curl -L ${RHCOS_PATH}${RHCOS_OPENSTACK_URI} -o /home/kni/rhcos_image_cache/${RHCOS_OPENSTACK_URI}

12. Confirm SELinux type is of httpd_sys_content_t for the newly created files.

$ ls -Z /home/kni/rhcos_image_cache

13. Create the pod.
8.3.6. Configuration files

8.3.6.1. Configuring the install-config.yaml file

The install-config.yaml file requires some additional details. Most of the information is teaching the installer and the resulting cluster enough about the available hardware so that it is able to fully manage it.

1. Configure install-config.yaml. Change the appropriate variables to match the environment, including pullSecret and sshKey.

```yaml
apiVersion: v1
baseDomain: <domain>
metadata:
  name: <cluster-name>
networking:
  machineCIDR: <public-cidr>
  networkType: OVNKubernetes
compute:
  - name: worker
    replicas: 2
controlPlane:
  name: master
  replicas: 3
  platform:
    baremetal: {}
platform:
  baremetal:
    apiVIP: <api-ip>
    ingressVIP: <wildcard-ip>
    provisioningNetworkInterface: <NIC1>
    provisioningNetworkCIDR: <CIDR>
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: ipmi://<out-of-band-ip>
      username: <user>
      password: <password>
      bootMACAddress: <NIC1-mac-address>
    hardwareProfile: default
  - name: <openshift-master-1>
    role: master
    bmc:
      address: ipmi://<out-of-band-ip>
      username: <user>
      password: <password>
      bootMACAddress: <NIC1-mac-address>
    hardwareProfile: default
```

$ podman run -d --name rhcos_image_cache \
  -v /home/kni/rhcos_image_cache:/var/www/html \
  -p 8080:8080/tcp \
  quay.io/centos7/httpd-24-centos7:latest
Scale the worker machines based on the number of worker nodes that are part of the OpenShift Container Platform cluster.

Refer to the BMC addressing sections for more options.

2. Create a directory to store cluster configs.

   ```bash
   $ mkdir ~/clusterconfigs
   $ cp install-config.yaml ~/clusterconfigs
   ```

3. Ensure all bare metal nodes are powered off prior to installing the OpenShift Container Platform cluster.

   ```bash
   $ ipmitool -I lanplus -U <user> -P <password> -H <management-server-ip> power off
   ```

4. Remove old bootstrap resources if any are left over from a previous deployment attempt.

   ```bash
   for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk '{print $2}'); do
     sudo virsh destroy $i;
     sudo virsh undefine $i;
     sudo virsh vol-delete $i --pool $i;
     sudo virsh vol-delete $i.ign --pool $i;
     sudo virsh pool-destroy $i;
     sudo virsh pool-undefine $i;
   done
   ```
8.3.6.2. Setting proxy settings within the install-config.yaml file (optional)

To deploy an OpenShift Container Platform cluster using a proxy, make the following changes to the install-config.yaml file.

```yaml
apiVersion: v1
baseDomain: <domain>
proxy:
  httpProxy: http://USERNAME:PASSWORD@proxy.example.com:PORT
  httpsProxy: https://USERNAME:PASSWORD@proxy.example.com:PORT
noProxy: <WILDCARD_OF_DOMAIN>,<PROVISIONING_NETWORK/CIDR>,
        <BMC_ADDRESS_RANGE/CIDR>
```

The following is an example of noProxy with values.

```yaml
noProxy: .example.com,172.22.0.0/24,10.10.0.0/24
```

With a proxy enabled, set the appropriate values of the proxy in the corresponding key/value pair.

Key considerations:

- If the proxy does not have an HTTPS proxy, change the value of httpsProxy from https:// to http://.
- If using a provisioning network, include it in the noProxy setting, otherwise the installer will fail.
- Set all of the proxy settings as environment variables within the provisioner node. For example, HTTP_PROXY, HTTPS_PROXY, and NO_PROXY.

**NOTE**

When provisioning with IPv6, you cannot define a CIDR address block in the noProxy settings. You must define each address separately.

8.3.6.3. Modifying the install-config.yaml file for no provisioning network (optional)

To deploy an OpenShift Container Platform cluster without a provisioning network, make the following changes to the install-config.yaml file.

```yaml
platform:
baremetal:
  apiVIP: <apiVIP>
  ingressVIP: <ingress/wildcard VIP>
  provisioningNetwork: "Disabled"
```

8.3.6.4. Configuring managed Secure Boot in the install-config.yaml file (optional)

You can enable managed Secure Boot when deploying an installer-provisioned cluster using Redfish BMC addressing, such as redfish, redfish-virtualmedia, or idrac-virtualmedia. To enable managed Secure Boot, add the bootMode configuration setting to each node:

```yaml
Example

hosts:
```
Ensure the `bmc.address` setting uses `redfish`, `redfish-virtualmedia`, or `idrac-virtualmedia` as the protocol. For additional information, see "BMC addressing for HPE iLO" or "BMC addressing for Dell iDRAC".

The `bootMode` setting is `UEFI` by default. To enable managed Secure Boot, change it to `UEFISecureBoot`.

**NOTE**

To ensure the nodes can support managed Secure Boot, see "Configuring nodes" in the "Prerequisites". If the nodes do not support managed Secure Boot, see "Configuring nodes for Secure Boot manually" in the "Configuring nodes" section. Configuring Secure Boot manually requires Redfish virtual media.

**NOTE**

Red Hat does not support Secure Boot with IPMI because IPMI does not provide Secure Boot management facilities.

### 8.3.6.5. Additional install-config parameters

See the following tables for the required parameters, the `hosts` parameter, and the `bmc` parameter for the `install-config.yaml` file.

#### Table 8.2. Required parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>baseDomain</code></td>
<td></td>
<td>The domain name for the cluster. For example, <code>example.com</code>.</td>
</tr>
<tr>
<td><code>sshKey</code></td>
<td></td>
<td>The <code>sshKey</code> configuration setting contains the key in the <code>~/.ssh/id_rsa.pub</code> file required to access the control plane nodes and worker nodes. Typically, this key is from the <code>provisioner</code> node.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pullSecret</td>
<td></td>
<td>The <code>pullSecret</code> configuration setting contains a copy of the pull secret downloaded from the Install OpenShift on Bare Metal page when preparing the provisioner node.</td>
</tr>
<tr>
<td>metadata:</td>
<td></td>
<td>The name to be given to the OpenShift Container Platform cluster. For example, <code>openshift</code>.</td>
</tr>
<tr>
<td>network:</td>
<td></td>
<td>The public CIDR (Classless Inter-Domain Routing) of the external network. For example, <code>10.0.0.0/24</code>.</td>
</tr>
<tr>
<td>compute:</td>
<td></td>
<td>The OpenShift Container Platform cluster requires a name be provided for worker (or compute) nodes even if there are zero nodes.</td>
</tr>
<tr>
<td></td>
<td>- name:</td>
<td>worker</td>
</tr>
<tr>
<td></td>
<td>replicas:</td>
<td>2</td>
</tr>
<tr>
<td>controlPlane:</td>
<td></td>
<td>The OpenShift Container Platform cluster requires a name for control plane (master) nodes.</td>
</tr>
<tr>
<td></td>
<td>name:</td>
<td>master</td>
</tr>
<tr>
<td></td>
<td>replicas:</td>
<td>3</td>
</tr>
<tr>
<td>defaultMachinePlatform</td>
<td></td>
<td>The default configuration used for machine pools without a platform configuration.</td>
</tr>
<tr>
<td>apiVIP</td>
<td>api. &lt;clusternamem.clusterdomain&gt;</td>
<td>The VIP to use for internal API communication. This setting must either be provided or pre-configured in the DNS so that the default name resolves correctly.</td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>disableCertificateVerification</td>
<td>False</td>
<td><strong>redfish</strong> and <strong>redfish-virtualmedia</strong> need this parameter to manage BMC</td>
</tr>
<tr>
<td></td>
<td></td>
<td>addresses. The value should be <strong>True</strong> when using a self-signed certificate for BMC addresses.</td>
</tr>
<tr>
<td>ingressVIP</td>
<td>test.apps.&lt;clusternameloclusterdomain&gt;</td>
<td>The VIP to use for ingress traffic.</td>
</tr>
</tbody>
</table>

**Table 8.3. Optional Parameters**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>provisioningDHCPRange</td>
<td>172.22.0.10,172.22.0.100</td>
<td>Defines the IP range for nodes on the <strong>provisioning</strong> network.</td>
</tr>
<tr>
<td>provisioningNetworkCIDR</td>
<td>172.22.0.0/24</td>
<td>The CIDR for the network to use for provisioning. This option is required when not using the default address range on the <strong>provisioning</strong> network.</td>
</tr>
<tr>
<td>clusterProvisioningIP</td>
<td>The third IP address of the <strong>provisioningNetworkCIDR</strong>.</td>
<td>The IP address within the cluster where the provisioning services run. Defaults to the third IP address of the <strong>provisioning</strong> subnet. For example, <strong>172.22.0.3</strong>.</td>
</tr>
<tr>
<td>bootstrapProvisioningIP</td>
<td>The second IP address of the <strong>provisioningNetworkCIDR</strong>.</td>
<td>The IP address on the bootstrap VM where the provisioning services run while the installer is deploying the control plane (master) nodes. Defaults to the second IP address of the <strong>provisioning</strong> subnet. For example, <strong>172.22.0.2</strong> or <strong>2620:52:0:1307::2</strong>.</td>
</tr>
<tr>
<td>externalBridge</td>
<td>baremetal</td>
<td>The name of the <strong>baremetal</strong> bridge of the hypervisor attached to the <strong>baremetal</strong> network.</td>
</tr>
<tr>
<td>provisioningBridge</td>
<td>provisioning</td>
<td>The name of the <strong>provisioning</strong> bridge on the <strong>provisioner</strong> host attached to the <strong>provisioning</strong> network.</td>
</tr>
<tr>
<td>defaultMachinePlatform</td>
<td></td>
<td>The default configuration used for machine pools without a platform configuration.</td>
</tr>
<tr>
<td>bootstrapOSImage</td>
<td></td>
<td>A URL to override the default operating system image for the bootstrap node. The URL must contain a SHA-256 hash of the image. For example: <strong><a href="https://mirror.openshift.com/rhcos-">https://mirror.openshift.com/rhcos-</a>&lt;version&gt;-qemu.qcow2.gz?sha256=&lt;uncompressed_sha256&gt;</strong>.</td>
</tr>
</tbody>
</table>
**clusterOSImage**

A URL to override the default operating system for cluster nodes. The URL must include a SHA-256 hash of the image. For example, `https://mirror.openshift.com/images/rhcos-<version>-openstack.qcow2.gz?sha256=<compressed_sha256>`.

**provisioningNetwork**

Set this parameter to **Disabled** to disable the requirement for a provisioning network. User may only do virtual media based provisioning, or bring up the cluster using assisted installation. If using power management, BMC’s must be accessible from the machine networks. User must provide two IP addresses on the external network that are used for the provisioning services. Set this parameter to **managed**, which is the default, to fully manage the provisioning network, including DHCP, TFTP, and so on.

Set this parameter to **unmanaged** to still enable the provisioning network but take care of manual configuration of DHCP. Virtual Media provisioning is recommended but PXE is still available if required.

**httpProxy**

Set this parameter to the appropriate HTTP proxy used within your environment.

**httpsProxy**

Set this parameter to the appropriate HTTPS proxy used within your environment.

**noProxy**

Set this parameter to the appropriate list of exclusions for proxy usage within your environment.

**Hosts**

The **hosts** parameter is a list of separate bare metal assets used to build the cluster.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong></td>
<td></td>
<td>The name of the BareMetalHost resource to associate with the details. For example, <strong>openshift-master-0</strong>.</td>
</tr>
<tr>
<td><strong>role</strong></td>
<td></td>
<td>The role of the bare metal node. Either <strong>master</strong> or <strong>worker</strong>.</td>
</tr>
</tbody>
</table>
### 8.3.6.6. BMC addressing

Most vendors support BMC addressing with the Intelligent Platform Management Interface (IPMI). IPMI does not encrypt communications. It is suitable for use within a data center over a secured or dedicated management network. Check with your vendor to see if they support Redfish network boot. Redfish delivers simple and secure management for converged, hybrid IT and the Software Defined Data Center (SDDC). Redfish is human readable and machine capable, and leverages common Internet and web services standards to expose information directly to the modern tool chain. If your hardware does not support Redfish network boot, use IPMI.

**IPMI**

Hosts using IPMI use the `ipmi://<out-of-band-ip>:<port>` address format, which defaults to port 623 if not specified. The following example demonstrates an IPMI configuration within the `install-config.yaml` file.

```yaml
platform:
baremetal:
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: ipmi://<out-of-band-ip>
      username: <user>
      password: <password>
```

**Redfish network boot**

To enable Redfish, use `redfish://` or `redfish+http://` to disable TLS. The installer requires both the

---

**NOTE**

You must provide a valid MAC address from the host if you disabled the `provisioning` network.
To enable Redfish, use `redfish://` or `redfish+http://` to disable TLS. The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the `install-config.yaml` file.

```yaml
platform:
baremetal:
hosts:
- name: openshift-master-0
  role: master
  bmc:
    address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
    username: <user>
    password: <password>

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the `disableCertificateVerification: True` configuration parameter within the `install-config.yaml` file.

```yaml
platform:
baremetal:
hosts:
- name: openshift-master-0
  role: master
  bmc:
    address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
    username: <user>
    password: <password>
    disableCertificateVerification: True

8.3.6.7. BMC addressing for Dell

The `address` field for each `bmc` entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

```yaml
platform:
baremetal:
hosts:
- name: <hostname>
  role: <master | worker>
  bmc:
    address: <address>
    username: <user>
    password: <password>

For Dell hardware, Red Hat supports Redfish virtual media, Redfish network boot, and IPMI.

Table 8.4. BMC address formats for Dell hardware

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redfish virtual media</td>
<td>idrac-virtualmedia://&lt;out-of-band-ip&gt;/redfish/v1/Systems/System.Embedded.1</td>
</tr>
</tbody>
</table>
### Protocol and Address Format

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redfish network boot</td>
<td><code>redfish://&lt;out-of-band-ip&gt;/redfish/v1/Systems/System.Embedded.1</code></td>
</tr>
<tr>
<td>IPMI</td>
<td><code>ipmi://&lt;out-of-band-ip&gt;</code></td>
</tr>
</tbody>
</table>

**IMPORTANT**

Use `idrac-virtualmedia` as the protocol for Redfish virtual media. `redfish-virtualmedia` will not work on Dell hardware. Dell’s `idrac-virtualmedia` uses the Redfish standard with Dell’s OEM extensions.

See the following sections for additional details.

**Redfish virtual media for Dell**

For Redfish virtual media on Dell servers, use `idrac-virtualmedia://` in the `address` setting. Using `redfish-virtualmedia://` will not work.

The following example demonstrates using iDRAC virtual media within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
    - name: openshift-master-0
      role: master
      bmc:
        address: idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
        username: <user>
        password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the `disableCertificateVerification: True` configuration parameter within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
    - name: openshift-master-0
      role: master
      bmc:
        address: idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
        username: <user>
        password: <password>
        disableCertificateVerification: True
```
NOTE

Currently, Redfish is only supported on Dell with iDRAC firmware versions 4.20.20.20 through 04.40.00.00 for installer-provisioned installations on bare metal deployments. There is a known issue with version 04.40.00.00. With iDRAC 9 firmware version 04.40.00.00, the Virtual Console plug-in defaults to eHTML5, which causes problems with the InsertVirtualMedia workflow. Set the plug-in to HTML5 to avoid this issue. The menu path is: Configuration → Virtual console → Plug-in Type → HTML5.

Ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: Configuration → Virtual Media → Attach Mode → AutoAttach.

Use idrac-virtualmedia:// as the protocol for Redfish virtual media. Using redfish-virtualmedia:// will not work on Dell hardware, because the idrac-virtualmedia:// protocol corresponds to the idrac hardware type and the Redfish protocol in Ironic. Dell’s idrac-virtualmedia:// protocol uses the Redfish standard with Dell’s OEM extensions. Ironic also supports the idrac type with the WSMAN protocol. Therefore, you must specify idrac-virtualmedia:// to avoid unexpected behavior when electing to use Redfish with virtual media on Dell hardware.

Redfish network boot for Dell

To enable Redfish, use redfish:// or redfish+http:// to disable transport layer security (TLS). The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the install-config.yaml file.

```yaml
platform:
baremetal:
  hosts:
    - name: openshift-master-0
      role: master
      bmc:
        address: redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
        username: <user>
        password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include disableCertificateVerification: True in the bmc configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the disableCertificateVerification: True configuration parameter within the install-config.yaml file.

```yaml
platform:
baremetal:
  hosts:
    - name: openshift-master-0
      role: master
      bmc:
        address: redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
        username: <user>
        password: <password>
        disableCertificateVerification: True
```
NOTE

Currently, Redfish is only supported on Dell with iDRAC firmware versions 4.20.20.20 through 04.40.00.00 for installer-provisioned installations on bare metal deployments. There is a known issue with version 04.40.00.00. With iDRAC 9 firmware version 04.40.00.00, the Virtual Console plug-in defaults to eHTML5, which causes problems with the InsertVirtualMedia workflow. Set the plug-in to HTML5 to avoid this issue. The menu path is: Configuration → Virtual console → Plug-in Type → HTML5.

Ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: Configuration → Virtual Media → Attach Mode → AutoAttach.

The redfish:// URL protocol corresponds to the redfish hardware type in Ironic.

8.3.6.8. BMC addressing for HPE

The address field for each bmc entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

Table 8.5. BMC address formats for HPE hardware

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redfish virtual media</td>
<td>redfish-virtualmedia://&lt;out-of-band-ip&gt;/redfish/v1/Systems/1</td>
</tr>
<tr>
<td>Redfish network boot</td>
<td>redfish://&lt;out-of-band-ip&gt;/redfish/v1/Systems/1</td>
</tr>
<tr>
<td>IPMI</td>
<td>ipmi://&lt;out-of-band-ip&gt;</td>
</tr>
</tbody>
</table>

See the following sections for additional details.

Redfish virtual media for HPE

To enable Redfish virtual media for HPE servers, use redfish-virtualmedia:// in the address setting. The following example demonstrates using Redfish virtual media within the install-config.yaml file.
- name: openshift-master-0
  role: master
  bmc:
    address: redfish-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/1
    username: <user>
    password: <password>

NOTE

Redfish virtual media is not supported on 9th generation systems running iLO4, because Ironic does not support iLO4 with virtual media.

Redfish network boot for HPE

To enable Redfish, use redfish:// or redfish+http:// to disable TLS. The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the install-config.yaml file.

platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>
          disableCertificateVerification: True

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include disableCertificateVerification: True in the bmc configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the disableCertificateVerification: True configuration parameter within the install-config.yaml file.

platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>
          disableCertificateVerification: True
8.3.6.9. Root device hints

The rootDeviceHints parameter enables the installer to provision the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. The installer examines the devices in the order it discovers them, and compares the discovered values with the hint values. The installer uses the first discovered device that matches the hint value. The configuration can combine multiple hints, but a device must match all hints for the installer to select it.

<table>
<thead>
<tr>
<th>Subfield</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>deviceName</strong></td>
<td>A string containing a Linux device name like /dev/vda. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>hctl</strong></td>
<td>A string containing a SCSI bus address like 0:0:0:0. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>model</strong></td>
<td>A string containing a vendor-specific device identifier. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td><strong>vendor</strong></td>
<td>A string containing the name of the vendor or manufacturer of the device. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td><strong>serialNumber</strong></td>
<td>A string containing the device serial number. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>minSizeGigabytes</strong></td>
<td>An integer representing the minimum size of the device in gigabytes.</td>
</tr>
<tr>
<td><strong>wwn</strong></td>
<td>A string containing the unique storage identifier. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>wwnWithExtension</strong></td>
<td>A string containing the unique storage identifier with the vendor extension appended. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>wwnVendorExtension</strong></td>
<td>A string containing the unique vendor storage identifier. The hint must match the actual value exactly.</td>
</tr>
</tbody>
</table>
A boolean indicating whether the device should be a rotating disk (true) or not (false).

Example usage

```yaml
- name: master-0
  role: master
  bmc:
    address: ipmi://10.10.0.3:6203
    username: admin
    password: redhat
  bootMACAddress: de:ad:be:ef:00:40
  rootDeviceHints:
    deviceName: "/dev/sda"
```

8.3.6.10. Creating the OpenShift Container Platform manifests

1. Create the OpenShift Container Platform manifests.

   ```bash
   $ ./openshift-baremetal-install --dir ~/clusterconfigs create manifests
  INFO Consuming Install Config from target directory
   WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings
   WARNING Discarding the OpenShift Manifest that was provided in the target directory because its dependencies are dirty and it needs to be regenerated
   ```

8.3.7. Creating a disconnected registry (optional)

In some cases, you might want to install an OpenShift Container Platform cluster using a local copy of the installation registry. This could be for enhancing network efficiency because the cluster nodes are on a network that does not have access to the internet.

A local, or mirrored, copy of the registry requires the following:

- A certificate for the registry node. This can be a self-signed certificate.
- A web server that a container on a system will serve.
- An updated pull secret that contains the certificate and local repository information.

**NOTE**

Creating a disconnected registry on a registry node is optional. The subsequent sections indicate that they are optional since they are steps you need to execute only when creating a disconnected registry on a registry node. You should execute all of the subsequent sub-sections labeled “(optional)” when creating a disconnected registry on a registry node.
8.3.7.1. Preparing the registry node to host the mirrored registry (optional)

Make the following changes to the registry node.

Procedure

1. Open the firewall port on the registry node.
   
   $ sudo firewall-cmd --add-port=5000/tcp --zone=libvirt --permanent
   $ sudo firewall-cmd --add-port=5000/tcp --zone=public --permanent
   $ sudo firewall-cmd --reload

2. Install the required packages for the registry node.

   $ sudo yum -y install python3 podman httpd httpd-tools jq

3. Create the directory structure where the repository information will be held.

   $ sudo mkdir -p /opt/registry/{auth,certs,data}

8.3.7.2. Generating the self-signed certificate (optional)

Generate a self-signed certificate for the registry node and put it in the /opt/registry/certs directory.

Procedure

1. Adjust the certificate information as appropriate.

   $ host_fqdn=$( hostname --long )
   $ cert_c="<Country Name>" # Country Name (C, 2 letter code)
   $ cert_s="<State>" # Certificate State (S)
   $ cert_l="<Locality>" # Certificate Locality (L)
   $ cert_o="<Organization>" # Certificate Organization (O)
   $ cert_ou="<Org Units>" # Certificate Organizational Unit (OU)
   $ cert_cn="$host_fqdn" # Certificate Common Name (CN)

   $ openssl req
   -newkey rsa:4096
   -nodes
   -sha256
   -keyout /opt/registry/certs/domain.key
   -x509
   -days 365
   -out /opt/registry/certs/domain.crt
   -addext "subjectAltName = DNS:$host_fqdn"
   -subj "/C=$cert_c/ST=$cert_s/L=$cert_l/O=$cert_o/OU=$cert_ou/CN=$cert_cn"

   NOTE

   When replacing <Country Name>, ensure that it only contains two letters. For example, US.

2. Update the registry node’s ca-trust with the new certificate.
8.3.7.3. Creating the registry podman container (optional)

The registry container uses the `/opt/registry` directory for certificates, authentication files, and to store its data files. The registry container uses `httpd` and needs an `htpasswd` file for authentication.

Procedure

1. Create an `htpasswd` file in `/opt/registry/auth` for the container to use.
   
   ```bash
   $ htpasswd -bBc /opt/registry/auth/htpasswd <user> <passwd>
   
   Replace `<user>` with the user name and `<passwd>` with the password.
   
2. Create and start the registry container.
   
   ```bash
   $ podman create \
   --name ocpdiscon-registry \
   -p 5000:5000 \
   -e "REGISTRY_AUTH=htpasswd" \
   -e "REGISTRY_AUTH_HTPASSWD_REALM=Registry" \
   -e "REGISTRY_HTTP_SECRET=ALongRandomSecretForRegistry" \
   -e "REGISTRY_HTTP_SECRET=ALongRandomSecretForRegistry" \
   -e "REGISTRY_HTTP_TLS_CERTIFICATE=/certs/domain.crt" \
   -e "REGISTRY_HTTP_TLS_KEY=/certs/domain.key" \
   -e "REGISTRY_COMPATIBILITY_SCHEMA1_ENABLED=true" \
   -v /opt/registry/data:/var/lib/registry:z \
   -v /opt/registry/auth:/auth:z \
   docker.io/library/registry:2
   
   $ podman start ocpdiscon-registry
   
   8.3.7.4. Copy and update the pull-secret (optional)

Copy the pull secret file from the provisioner node to the registry node and modify it to include the authentication information for the new registry node.

Procedure

1. Copy the `pull-secret.txt` file.
   
   ```bash
   $ scp kni@provisioner:/home/kni/pull-secret.txt pull-secret.txt
   
   2. Update the `host_fqdn` environment variable with the fully qualified domain name of the registry node.
   
   ```bash
   $ host_fqdn=$( hostname --long )
3. Update the `b64auth` environment variable with the base64 encoding of the `http` credentials used to create the `htpasswd` file.

   ```bash
   $ b64auth=$( echo -n '<username>:<passwd>' | openssl base64 )
   ``

   Replace `<username>` with the user name and `<passwd>` with the password.

4. Set the `AUTHSTRING` environment variable to use the base64 authorization string. The `$USER` variable is an environment variable containing the name of the current user.

   ```bash
   $ AUTHSTRING="\{"$host_fqdn:5000\": \{"auth": "$b64auth", \"email\": \"$USER@redhat.com\"\}\}"
   ``

5. Update the `pull-secret.txt` file.

   ```bash
   $ jq ".auths += $AUTHSTRING" < pull-secret.txt > pull-secret-update.txt
   ``

### 8.3.7.5. Mirroring the repository (optional)

**Procedure**

1. Copy the `oc` binary from the provisioner node to the registry node.

   ```bash
   $ sudo scp kni@provisioner:/usr/local/bin/oc /usr/local/bin
   ``

2. Set the required environment variables.

   a. Set the release version:

      ```bash
      $ VERSION=<release_version>
      ``

      For `<release_version>`, specify the tag that corresponds to the version of OpenShift Container Platform to install, such as 4.7.

   b. Set the local registry name and host port:

      ```bash
      $ LOCAL_REG='<local_registry_host_name>:<local_registry_host_port>'
      ``

      For `<local_registry_host_name>`, specify the registry domain name for your mirror repository, and for `<local_registry_host_port>`, specify the port that it serves content on.

   c. Set the local repository name:

      ```bash
      $ LOCAL_REPO='<local_repository_name>'
      ``

      For `<local_repository_name>`, specify the name of the repository to create in your registry, such as `ocp4/openshift4`.

3. Mirror the remote install images to the local repository.

   ```bash
   $ /usr/local/bin/oc adm release mirror \
   -a pull-secret-update.txt \
   --from=$UPSTREAM_REPO \
   ```
8.3.7.6. Modify the install-config.yaml file to use the disconnected registry (optional)

On the provisioner node, the install-config.yaml file should use the newly created pull-secret from the pull-secret-update.txt file. The install-config.yaml file must also contain the disconnected registry node’s certificate and registry information.

Procedure

1. Add the disconnected registry node’s certificate to the install-config.yaml file. The certificate should follow the "additionalTrustBundle: |" line and be properly indented, usually by two spaces.

   $ echo "additionalTrustBundle: |" >> install-config.yaml
   $ sed -e 's/^/  /' /opt/registry/certs/domain.crt >> install-config.yaml

2. Add the mirror information for the registry to the install-config.yaml file.

   $ echo "imageContentSources:" >> install-config.yaml
   $ echo "- mirrors:" >> install-config.yaml
   $ echo "  - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
   $ echo "    source: quay.io/openshift-release-dev/ocp-release" >> install-config.yaml
   $ echo "  - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
   $ echo "    source: quay.io/openshift-release-dev/ocp-v4.0-art-dev" >> install-config.yaml

   NOTE
   Replace registry.example.com with the registry’s fully qualified domain name.

8.3.8. Deploying routers on worker nodes

During installation, the installer deploys router pods on worker nodes. By default, the installer installs two router pods. If the initial cluster has only one worker node, or if a deployed cluster requires additional routers to handle external traffic loads destined for services within the OpenShift Container Platform cluster, you can create a yaml file to set an appropriate number of router replicas.

NOTE
By default, the installer deploys two routers. If the cluster has at least two worker nodes, you can skip this section.

NOTE
If the cluster has no worker nodes, the installer deploys the two routers on the control plane nodes by default. If the cluster has no worker nodes, you can skip this section.

Procedure

1. Create a router-replicas.yaml file.
NOTE

Replace `<num-of-router-pods>` with an appropriate value. If working with just one worker node, set `replicas:` to 1. If working with more than 3 worker nodes, you can increase `replicas:` from the default value 2 as appropriate.

2. Save and copy the `router-replicas.yaml` file to the `clusterconfigs/openshift` directory.

```bash
cp ~/router-replicas.yaml clusterconfigs/openshift/99_router-replicas.yaml
```

8.3.9. Validation checklist for installation

☐ OpenShift Container Platform installer has been retrieved.

☐ OpenShift Container Platform installer has been extracted.

☐ Required parameters for the `install-config.yaml` have been configured.

☐ The `hosts` parameter for the `install-config.yaml` has been configured.

☐ The `bmc` parameter for the `install-config.yaml` has been configured.

☐ Conventions for the values configured in the `bmc address` field have been applied.

☐ Created a disconnected registry (optional).

☐ (optional) Validate disconnected registry settings if in use.

☐ (optional) Deployed routers on worker nodes.

8.3.10. Deploying the cluster via the OpenShift Container Platform installer

Run the OpenShift Container Platform installer:

```bash
$ ./openshift-baremetal-install --dir ~/clusterconfigs --log-level debug create cluster
```

8.3.11. Following the installation
During the deployment process, you can check the installation’s overall status by issuing the `tail` command to the `.openshift_install.log` log file in the install directory folder.

```
$ tail -f /path/to/install-dir/.openshift_install.log
```

### 8.3.12. Preparing to reinstall a cluster on bare metal

Before you reinstall a cluster on bare metal, you must perform cleanup operations.

**Procedure**

1. Remove or reformat the disks for the bootstrap, control plane (also known as master) node, and worker nodes. If you are working in a hypervisor environment, you must add any disks you removed.

2. Delete the artifacts that the previous installation generated:

   ```
   $ cd ; /bin/rm -rf auth/ bootstrap.ign master.ign worker.ign metadata.json .openshift_install.log .openshift_install_state.json
   ```

3. Generate new manifests and Ignition config files. See “Creating the Kubernetes manifest and Ignition config files” for more information.

4. Upload the new bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. This will overwrite the previous Ignition files.

### 8.4. EXPANDING THE CLUSTER

After deploying an installer-provisioned OpenShift Container Platform cluster, you can use the following procedures to expand the number of worker nodes. Ensure that each prospective worker node meets the prerequisites.

**NOTE**

Expanding the cluster using RedFish Virtual Media involves meeting minimum firmware requirements. See [Firmware requirements for installing with virtual media](#) in the **Prerequisites** section for additional details when expanding the cluster using RedFish Virtual Media.

### 8.4.1. Preparing the bare metal node

Expanding the cluster requires a DHCP server. Each node must have a DHCP reservation.
RESERVING IP ADDRESSES SO THEY BECOME STATIC IP ADDRESSES

Some administrators prefer to use static IP addresses so that each node's IP address remains constant in the absence of a DHCP server. To use static IP addresses in the OpenShift Container Platform cluster, reserve the IP addresses in the DHCP server with an infinite lease. After the installer provisions the node successfully, the dispatcher script will check the node's network configuration. If the dispatcher script finds that the network configuration contains a DHCP infinite lease, it will recreate the connection as a static IP connection using the IP address from the DHCP infinite lease. NICs without DHCP infinite leases will remain unmodified.

Setting IP addresses with an infinite lease is incompatible with network configuration deployed by using the Machine Config Operator.

Preparing the bare metal node requires executing the following procedure from the provisioner node.

Procedure

1. Get the oc binary, if needed. It should already exist on the provisioner node.

   ```
   [kni@provisioner ~]$ curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/openshift-client-linux-$VERSION.tar.gz | tar zxvf - oc
   ```

   ```
   [kni@provisioner ~]$ sudo cp oc /usr/local/bin
   ```

2. Power off the bare metal node via the baseboard management controller and ensure it is off.

3. Retrieve the user name and password of the bare metal node's baseboard management controller. Then, create base64 strings from the user name and password. In the following example, the user name is root and the password is calvin.

   ```
   [kni@provisioner ~]$ echo -ne "root" | base64
   ```

   ```
   [kni@provisioner ~]$ echo -ne "calvin" | base64
   ```

4. Create a configuration file for the bare metal node.

   ```
   [kni@provisioner ~]$ vim bmh.yaml
   ```

   ```yaml
   ---
   apiVersion: v1
   kind: Secret
   metadata:
     name: openshift-worker-<num>-bmc-secret
   type: Opaque
   data:
     username: <base64-of-uid>
     password: <base64-of-pwd>
   ---
   apiVersion: metal3.io/v1alpha1
   kind: BareMetalHost
   metadata:
     name: openshift-worker-<num>
   ```
spec:
  online: true
  bootMACAddress: <NIC1-mac-address>
  bmc:
    address: <protocol>://<bmc-ip>
    credentialsName: openshift-worker-<num>-bmc-secret

Replace `<num>` for the worker number of the bare metal node in the two `name` fields and the `credentialsName` field. Replace `<base64-of-uid>` with the base64 string of the user name. Replace `<base64-of-pwd>` with the base64 string of the password. Replace `<NIC1-mac-address>` with the MAC address of the bare metal node's first NIC.

Refer to the BMC addressing section for additional BMC configuration options. Replace `<protocol>` with the BMC protocol, such as IPMI, RedFish, or others. Replace `<bmc-ip>` with the IP address of the bare metal node's baseboard management controller.

**NOTE**

If the MAC address of an existing bare metal node matches the MAC address of a bare metal host that you are attempting to provision, then the Ironic installation will fail. If the host enrollment, inspection, cleaning, or other Ironic steps fail, the Bare Metal Operator retries the installation continuously. See Diagnosing a host duplicate MAC address for more information.

5. Create the bare metal node.

```
[kni@provisioner ~]$ oc -n openshift-machine-api create -f bmh.yaml
```

```
secret/openshift-worker-<num>-bmc-secret created
baremetalhost.metal3.io/openshift-worker-<num> created
```

Where `<num>` will be the worker number.

6. Power up and inspect the bare metal node.

```
[kni@provisioner ~]$ oc -n openshift-machine-api get bmh openshift-worker-<num>
```

Where `<num>` is the worker node number.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>PROVISIONING STATUS</th>
<th>CONSUMER</th>
<th>BMC</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-worker-&lt;num&gt;</td>
<td>OK</td>
<td>ready</td>
<td></td>
<td>ipmi://&lt;out-of-band-ip&gt;</td>
</tr>
<tr>
<td>true</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

8.4.1.1. Diagnosing a duplicate MAC address when provisioning a new host in the cluster

If the MAC address of an existing bare-metal node in the cluster matches the MAC address of a bare-metal host you are attempting to add to the cluster, the Bare Metal Operator associates the host with the existing node. If the host enrollment, inspection, cleaning, or other Ironic steps fail, the Bare Metal Operator retries the installation continuously. A registration error is displayed for the failed bare-metal host.
You can diagnose a duplicate MAC address by examining the bare-metal hosts that are running in the `openShift-machine-api` namespace.

**Prerequisites**

- Install an OpenShift Container Platform cluster on bare metal.
- Install the OpenShift Container Platform CLI `oc`.
- Log in as a user with `cluster-admin` privileges.

**Procedure**

To determine whether a bare-metal host that fails provisioning has the same MAC address as an existing node, do the following:

1. Get the bare-metal hosts running in the `openShift-machine-api` namespace:

   ```bash
   $ oc get bmh -n openShift-machine-api
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>PROVISIONING STATUS</th>
<th>CONSUMER</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-master-0</td>
<td>OK</td>
<td>externally provisioned</td>
<td>openshift-zpwpq-master-0</td>
</tr>
<tr>
<td>openshift-master-1</td>
<td>OK</td>
<td>externally provisioned</td>
<td>openshift-zpwpq-master-1</td>
</tr>
<tr>
<td>openshift-master-2</td>
<td>OK</td>
<td>externally provisioned</td>
<td>openshift-zpwpq-master-2</td>
</tr>
<tr>
<td>openshift-worker-0</td>
<td>OK</td>
<td>provisioned</td>
<td>openshift-zpwpq-worker-0-lv84n</td>
</tr>
<tr>
<td>openshift-worker-1</td>
<td>OK</td>
<td>provisioned</td>
<td>openshift-zpwpq-worker-0-zd8lm</td>
</tr>
<tr>
<td>openshift-worker-2</td>
<td>error</td>
<td>registering</td>
<td></td>
</tr>
</tbody>
</table>

2. To see more detailed information about the status of the failing host, run the following command replacing `<bare_metal_host_name>` with the name of the host:

   ```bash
   $ oc get -n openShift-machine-api bmh <bare_metal_host_name> -o yaml
   ```

   **Example output**

   ```yaml
   ...
   status:
   errorCount: 12
   errorMessage: MAC address b4:96:1d:7c:20 conflicts with existing node openshift-worker-1
   errorType: registration error
   ...
   ```

8.4.2. Provisioning the bare metal node

Provisioning the bare metal node requires executing the following procedure from the provisioner node.

**Procedure**

1. Ensure the `PROVISIONING STATUS` is `ready` before provisioning the bare metal node.

   ```bash
   $ oc -n openShift-machine-api get bmh openshift-worker-<num>
   ```
2. Get a count of the number of worker nodes.

```bash
$ oc get nodes
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>provisioner.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-1.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-2.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-3.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-worker-0.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-worker-1.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
</tbody>
</table>

3. Get the machine set.

```bash
$ oc get machinesets -n openshift-machine-api
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>READY</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-worker-0.example.com</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>55m</td>
</tr>
<tr>
<td>openshift-worker-1.example.com</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>55m</td>
</tr>
</tbody>
</table>

4. Increase the number of worker nodes by one.

```bash
$ oc scale --replicas=<num> machineset <machineset> -n openshift-machine-api
```

Replace `<num>` with the new number of worker nodes. Replace `<machineset>` with the name of the machine set from the previous step.

5. Check the status of the bare metal node.

```bash
$ oc -n openshift-machine-api get bmh openshift-worker-<num>
```

Where `<num>` is the worker node number. The status changes from ready to provisioning.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>PROVISIONING STATUS</th>
<th>CONSUMER</th>
<th>BMC</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-worker-&lt;num&gt;</td>
<td>OK</td>
<td>provisioning</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ipmi://&lt;out-of-band-ip&gt;</td>
<td>unknown</td>
<td>true</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The provisioning status remains until the OpenShift Container Platform cluster provisions the node. This can take 30 minutes or more. Once complete, the status will change to provisioned.

```bash
$ oc -n openshift-machine-api get bmh openshift-worker-<num>
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>PROVISIONING STATUS</th>
<th>CONSUMER</th>
<th>BMC</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-worker-&lt;num&gt;</td>
<td>OK</td>
<td>provisioned</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ipmi://&lt;out-of-band-ip&gt;</td>
<td>unknown</td>
<td>true</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Once provisioned, ensure the bare metal node is ready.

You can also check the kubelet.

8.5. TROUBLESHOOTING

8.5.1. Troubleshooting the installer workflow

Prior to troubleshooting the installation environment, it is critical to understand the overall flow of the installer-provisioned installation on bare metal. The diagrams below provide a troubleshooting flow with a step-by-step breakdown for the environment.

Workflow 1 of 4 illustrates a troubleshooting workflow when the `install-config.yaml` file has errors or the Red Hat Enterprise Linux CoreOS (RHCOS) images are inaccessible. Troubleshooting suggestions can be found at Troubleshooting `install-config.yaml`.
Workflow 2 of 4 illustrates a troubleshooting workflow for bootstrap VM issues, bootstrap VMs that cannot boot up the cluster nodes, and inspecting logs. When installing an OpenShift Container Platform cluster without the provisioning network, this workflow does not apply.
Workflow 3 of 4 illustrates a troubleshooting workflow for cluster nodes that will not PXE boot. If installing using RedFish Virtual Media, each node must meet minimum firmware requirements for the installer to deploy the node. See Firmware requirements for installing with virtual media in the Prerequisites section for additional details.

Workflow 4 of 4 illustrates a troubleshooting workflow from a non-accessible API to a validated installation.

8.5.2. Troubleshooting install-config.yaml

The install-config.yaml configuration file represents all of the nodes that are part of the OpenShift Container Platform cluster. The file contains the necessary options consisting of but not limited to apiVersion, baseDomain, imageContentSources and virtual IP addresses. If errors occur early in the deployment of the OpenShift Container Platform cluster, the errors are likely in the install-config.yaml configuration file.

Procedure

1. Use the guidelines in YAML-tips.

2. Verify the YAML syntax is correct using syntax-check.

3. Verify the Red Hat Enterprise Linux CoreOS (RHCOS) QEMU images are properly defined and accessible via the URL provided in the install-config.yaml. For example:
8.5.3. Bootstrap VM issues

The OpenShift Container Platform installer spawns a bootstrap node virtual machine, which handles provisioning the OpenShift Container Platform cluster nodes.

Procedure

1. About 10 to 15 minutes after triggering the installer, check to ensure the bootstrap VM is operational using the `virsh` command:

   ```bash
   $ curl -s -o /dev/null -w "%{http_code}\n" http://webserver.example.com:8080/rhcos-44.81.202004250133-0-qemu.x86_64.qcow2.gz?
   sha256=7d884b46ee54fe87bbc3893bf2aa9af3b2d31f2e19ab5529c60636fb0f1ce7
   
   If the output is **200**, there is a valid response from the webserver storing the bootstrap VM image.

2. Verify `libvirtd` is running on the system:

   ```bash
   $ sudovirsh list
   
   Id    Name                           State
   --------------------------------------------
   12    openshift-xf6fq-bootstrap      running
   
   $ systemctl status libvirtd
   ● libvirtd.service - Virtualization daemon
     Loaded: loaded (/usr/lib/systemd/system/libvirtd.service; enabled; vendor preset: enabled)
     Active: active (running) since Tue 2020-03-03 21:21:07 UTC; 3 weeks 5 days ago
       Docs: man:libvirtd(8)
             https://libvirt.org
     Main PID: 9850 (libvirtd)
     Tasks: 20 (limit: 32768)
     Memory: 74.8M
     CGroup: /system.slice/libvirtd.service
     └─ 9850 /usr/sbin/libvirtd
   
   If the bootstrap VM is operational, log in to it.

3. Use the `virsh console` command to find the IP address of the bootstrap VM:

   ```bash
   $ sudo virsh console example.com
   ```

**NOTE**

The name of the bootstrap VM is always the cluster name followed by a random set of characters and ending in the word "bootstrap."

If the bootstrap VM is not running after 10-15 minutes, troubleshoot why it is not running. Possible issues include:

Preliminary Procedure

1. If the webserver is not responding:

   ```bash
   $ curl -s -o /dev/null -w "%{http_code}\n" http://webserver.example.com:8080/rhcos-44.81.202004250133-0-qemu.x86_64.qcow2.gz?
   sha256=7d884b46ee54fe87bbc3893bf2aa9af3b2d31f2e19ab5529c60636fb0f1ce7
   
   If the output is **200**, there is a valid response from the webserver storing the bootstrap VM image.

2. Verify `libvirtd` is running on the system:

   ```bash
   $ sudovirsh list
   
   Id    Name                           State
   --------------------------------------------
   12    openshift-xf6fq-bootstrap      running
   
   $ systemctl status libvirtd
   ● libvirtd.service - Virtualization daemon
     Loaded: loaded (/usr/lib/systemd/system/libvirtd.service; enabled; vendor preset: enabled)
     Active: active (running) since Tue 2020-03-03 21:21:07 UTC; 3 weeks 5 days ago
       Docs: man:libvirtd(8)
             https://libvirt.org
     Main PID: 9850 (libvirtd)
     Tasks: 20 (limit: 32768)
     Memory: 74.8M
     CGroup: /system.slice/libvirtd.service
     └─ 9850 /usr/sbin/libvirtd
   
   If the bootstrap VM is operational, log in to it.

3. Use the `virsh console` command to find the IP address of the bootstrap VM:

   ```bash
   $ sudo virsh console example.com
   ```
IMPORTANT

When deploying a OpenShift Container Platform cluster without the *provisioning* network, you must use a public IP address and not a private IP address like *172.22.0.2*.

4. Once you obtain the IP address, log in to the bootstrap VM using the *ssh* command:

```bash
$ ssh core@172.22.0.2
```

If you are not successful logging in to the bootstrap VM, you have likely encountered one of the following scenarios:

- You cannot reach the *172.22.0.0/24* network. Verify network connectivity on the provisioner host specifically around the *provisioning* network bridge. This will not be the issue if you are not using the *provisioning* network.

- You cannot reach the bootstrap VM via the public network. When attempting to SSH via *baremetal* network, verify connectivity on the *provisioner* host specifically around the *baremetal* network bridge.

- You encountered *Permission denied (publickey,password,keyboard-interactive)*. When attempting to access the bootstrap VM, a *Permission denied* error might occur. Verify that the SSH key for the user attempting to log into the VM is set within the *install-config.yaml* file.

### 8.5.3.1. Bootstrap VM cannot boot up the cluster nodes

During the deployment, it is possible for the bootstrap VM to fail to boot the cluster nodes, which prevents the VM from provisioning the nodes with the RHCOS image. This scenario can arise due to:

- A problem with the *install-config.yaml* file.

- Issues with out-of-band network access via the baremetal network.

To verify the issue, there are three containers related to *ironic*:

- *ironic-api*
• ironic-conductor
• ironic-inspector

Procedure

1. Log in to the bootstrap VM:
   ```
   $ ssh core@172.22.0.2
   ```

2. To check the container logs, execute the following:
   ```
   [core@localhost ~]$ sudo podman logs -f <container-name>
   ```

Replace `<container-name>` with one of ironic-api, ironic-conductor, or ironic-inspector. If you encounter an issue where the control plane nodes are not booting up via PXE, check the ironic-conductor pod. The ironic-conductor pod contains the most detail about the attempt to boot the cluster nodes, because it attempts to log in to the node over IPMI.

Potential reason
The cluster nodes might be in the ON state when deployment started.

Solution
Power off the OpenShift Container Platform cluster nodes before you begin the installation over IPMI:
```
$ ipmitool -I lanplus -U root -P <password> -H <out-of-band-ip> power off
```

8.5.3.2. Inspecting logs

When experiencing issues downloading or accessing the RHCOS images, first verify that the URL is correct in the install-config.yaml configuration file.

Example of internal webserver hosting RHCOS images

```
bootstrapOSImage: http://<ip:port>/rhcos-43.81.202001142154.0-qemu.x86_64.qcow2.gz?
sha256=9d999f55ff1d447ed7c106508e5deecd04dc3c06095d34d36bf1cd127837e0c
clusterOSImage: http://<ip:port>/rhcos-43.81.202001142154.0-openstack.x86_64.qcow2.gz?
sha256=a1bda656fa0892f7b936fd6b6a6086bdaed5dafacedcd7a1e811abb78fe3b0
```

The `ipa-downloader` and `coreos-downloader` containers download resources from a webserver or the external quay.io registry, whichever the install-config.yaml configuration file specifies. Verify the following two containers are up and running and inspect their logs as needed:

• ipa-downloader
• coreos-downloader

Procedure

1. Log in to the bootstrap VM:
   ```
   $ ssh core@172.22.0.2
   ```
2. Check the status of the ipa-downloader and coreos-downloader containers within the bootstrap VM:

   [core@localhost ~]$ sudo podman logs -f ipa-downloader
   [core@localhost ~]$ sudo podman logs -f coreos-downloader

   If the bootstrap VM cannot access the URL to the images, use the curl command to verify that the VM can access the images.

3. To inspect the bootkube logs that indicate if all the containers launched during the deployment phase, execute the following:

   [core@localhost ~]$ journalctl -xe
   [core@localhost ~]$ journalctl -b -f -u bootkube.service

4. Verify all the pods, including dnsmasq, mariadb, httpd, and ironic, are running:

   [core@localhost ~]$ sudo podman ps

5. If there are issues with the pods, check the logs of the containers with issues. To check the log of the ironic-api, execute the following:

   [core@localhost ~]$ sudo podman logs <ironic-api>

8.5.4. Cluster nodes will not PXE boot

When OpenShift Container Platform cluster nodes will not PXE boot, execute the following checks on the cluster nodes that will not PXE boot. This procedure does not apply when installing a OpenShift Container Platform cluster without the provisioning network.

Procedure

1. Check the network connectivity to the provisioning network.

2. Ensure PXE is enabled on the NIC for the provisioning network and PXE is disabled for all other NICs.

3. Verify that the install-config.yaml configuration file has the proper hardware profile and boot MAC address for the NIC connected to the provisioning network. For example:

   control plane node settings
   bootMACAddress: 24:6E:96:1B:96:90 # MAC of bootable provisioning NIC
   hardwareProfile: default  #control plane node settings

   Worker node settings
   bootMACAddress: 24:6E:96:1B:96:90 # MAC of bootable provisioning NIC
   hardwareProfile: unknown  #worker node settings
8.5.5. The API is not accessible

When the cluster is running and clients cannot access the API, domain name resolution issues might impede access to the API.

Procedure

1. **Hostname Resolution**: Check the cluster nodes to ensure they have a fully qualified domain name, and not just `localhost.localdomain`. For example:

   ```bash
   $ hostname
   
   If a hostname is not set, set the correct hostname. For example:
   
   ```bash
   $ hostnamectl set-hostname <hostname>
   ```

2. **Incorrect Name Resolution**: Ensure that each node has the correct name resolution in the DNS server using `dig` and `nslookup`. For example:

   ```bash
   $ dig api.<cluster-name>.example.com
   
   ; <<>> DiG 9.11.4-P2-RedHat-9.11.4-26.P2.el8 <<>> api.<cluster-name>.example.com
   ;;; global options: +cmd
   ;;; Got answer:
   ;;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 37551
   ;;; flags: qr aa rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 1, ADDITIONAL: 2
   ;;; OPT PSEUDOSECTION:
   ;;; EDNS: version: 0, flags:; udp: 4096
   ;;; COOKIE: 866929d2f8e8563582af23f05ec44203d313e50948d43f60 (good)
   ;;; QUESTION SECTION:
   ;api.<cluster-name>.example.com. IN A
   
   ;;; ANSWER SECTION:
   api.<cluster-name>.example.com. 10800 IN A 10.19.13.86
   
   ;;; AUTHORITY SECTION:
   <cluster-name>.example.com. 10800 IN NS <cluster-name>.example.com.
   
   ;;; ADDITIONAL SECTION:
   
   ; Query time: 0 msec
   ; WHEN: Tue May 19 20:30:59 UTC 2020
   ; MSG SIZE  rcvd: 140
   ```

The output in the foregoing example indicates that the appropriate IP address for the `api.<cluster-name>.example.com` VIP is `10.19.13.86`. This IP address should reside on the `baremetal` network.

8.5.6. Cleaning up previous installations
In the event of a previous failed deployment, remove the artifacts from the failed attempt before attempting to deploy OpenShift Container Platform again.

**Procedure**

1. Power off all bare metal nodes prior to installing the OpenShift Container Platform cluster:

   ```bash
   $ ipmitool -I lanplus -U <user> -P <password> -H <management-server-ip> power off
   ```

2. Remove all old bootstrap resources if any are left over from a previous deployment attempt:

   ```bash
   for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk '{print $2}'); do
       sudo virsh destroy $i;
       sudo virsh undefine $i;
       sudo virsh vol-delete $i --pool $i;
       sudo virsh vol-delete $i.ign --pool $i;
       sudo virsh pool-destroy $i;
       sudo virsh pool-undefined $i;
   done
   ```

3. Remove the following from the `clusterconfigs` directory to prevent Terraform from failing:

   ```bash
   $ rm -rf ~/clusterconfigs/auth ~/clusterconfigs/terraform* ~/clusterconfigs/tls ~/clusterconfigs/metadata.json
   ```

**8.5.7. Issues with creating the registry**

When creating a disconnected registry, you might encounter a "User Not Authorized" error when attempting to mirror the registry. This error might occur if you fail to append the new authentication to the existing `pull-secret.txt` file.

**Procedure**

1. Check to ensure authentication is successful:

   ```bash
   $ /usr/local/bin/oc adm release mirror \
   -a pull-secret-update.json \
   --from=$UPSTREAM_REPO \
   --to-release-image=$LOCAL_REG/$LOCAL_REPO:${VERSION} \ 
   --to=$LOCAL_REG/$LOCAL_REPO
   ```

   **NOTE**

   Example output of the variables used to mirror the install images:

   ```bash
   UPSTREAM_REPO=${RELEASE_IMAGE} 
   LOCAL_REG=<registry_FQDN>:<registry_port> 
   LOCAL_REPO='ocp4/openshift4'
   ```

   The values of `RELEASE_IMAGE` and `VERSION` were set during the Retrieving OpenShift Installer step of the Setting up the environment for an OpenShift installation section.
2. After mirroring the registry, confirm that you can access it in your disconnected environment:

$$
curl -k -u <user>:<password> https://registry.example.com:<registry-port>/v2/_catalog
["repositories": ["<Repo-Name>"]]
$$

8.5.8. Miscellaneous issues

8.5.8.1. Addressing the runtime network not ready error

After the deployment of a cluster you might receive the following error:

```
```

The Cluster Network Operator is responsible for deploying the networking components in response to a special object created by the installer. It runs very early in the installation process, after the control plane (master) nodes have come up, but before the bootstrap control plane has been torn down. It can be indicative of more subtle installer issues, such as long delays in bringing up control plane (master) nodes or issues with `apiserver` communication.

Procedure

1. Inspect the pods in the `openshift-network-operator` namespace:

$$
oc get all -n openshift-network-operator
$$

```
NAME                                    READY STATUS            RESTARTS   AGE
pod/network-operator-69dfd7b577-bg89v   0/1   ContainerCreating 0          149m
```

2. On the `provisioner` node, determine that the network configuration exists:

$$
kubectl get network.config.openshift.io cluster -oyaml
$$

```
apiVersion: config.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  serviceNetwork:
    - 172.30.0.0/16
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  networkType: OpenShiftSDN
```

If it does not exist, the installer did not create it. To determine why the installer did not create it, execute the following:

$$
openshift-install create manifests
$$

3. Check that the `network-operator` is running:
$ kubectl -n openshift-network-operator get pods

4. Retrieve the logs:

$ kubectl -n openshift-network-operator logs -l "name=network-operator"

On high availability clusters with three or more control plane (master) nodes, the Operator will perform leader election and all other Operators will sleep. For additional details, see Troubleshooting.

8.5.8.2. Cluster nodes not getting the correct IPv6 address over DHCP

If the cluster nodes are not getting the correct IPv6 address over DHCP, check the following:

1. Ensure the reserved IPv6 addresses reside outside the DHCP range.

2. In the IP address reservation on the DHCP server, ensure the reservation specifies the correct DHCP Unique Identifier (DUID). For example:

   # This is a dnsmasq dhcp reservation, 'id:00:03:00:01' is the client id and '18:db:f2:8c:d5:9f' is the MAC Address for the NIC
   id:00:03:00:01:18:db:f2:8c:d5:9f,openshift-master-1,[2620:52:0:1302::6]

3. Ensure that route announcements are working.

4. Ensure that the DHCP server is listening on the required interfaces serving the IP address ranges.

8.5.8.3. Cluster nodes not getting the correct hostname over DHCP

During IPv6 deployment, cluster nodes must get their hostname over DHCP. Sometimes the NetworkManager does not assign the hostname immediately. A control plane (master) node might report an error such as:

Failed Units: 2
NetworkManager-wait-online.service
nodeip-configuration.service

This error indicates that the cluster node likely booted without first receiving a hostname from the DHCP server, which causes kubelet to boot with a localhost.localdomain hostname. To address the error, force the node to renew the hostname.

Procedure

1. Retrieve the hostname:

   [core@master-X ~]$ hostname

   If the hostname is localhost, proceed with the following steps.

   NOTE

   Where X is the control plane node (also known as the master node) number.
2. Force the cluster node to renew the DHCP lease:
   
   [core@master-X ~]$ sudo nmcli con up "<bare-metal-nic>"
   
   Replace `<bare-metal-nic>` with the wired connection corresponding to the `baremetal` network.

3. Check `hostname` again:
   
   [core@master-X ~]$ hostname

4. If the hostname is still `localhost.localdomain`, restart `NetworkManager`:
   
   [core@master-X ~]$ sudo systemctl restart NetworkManager

5. If the hostname is still `localhost.localdomain`, wait a few minutes and check again. If the hostname remains `localhost.localdomain`, repeat the previous steps.

6. Restart the `nodeip-configuration` service:
   
   [core@master-X ~]$ sudo systemctl restart nodeip-configuration.service

   This service will reconfigure the `kubelet` service with the correct hostname references.

7. Reload the unit files definition since the kubelet changed in the previous step:
   
   [core@master-X ~]$ sudo systemctl daemon-reload

8. Restart the `kubelet` service:
   
   [core@master-X ~]$ sudo systemctl restart kubelet.service

9. Ensure `kubelet` booted with the correct hostname:
   
   [core@master-X ~]$ sudo journalctl -fu kubelet.service

If the cluster node is not getting the correct hostname over DHCP after the cluster is up and running, such as during a reboot, the cluster will have a pending `csr`. Do not approve a `csr`, or other issues might arise.

**Addressing a csr**

1. Get CSRs on the cluster:
   
   $ oc get csr

2. Verify if a pending `csr` contains `Subject Name: localhost.localdomain`:
   
   $ oc get csr <pending_csr> -o jsonpath='{.spec.request}' | base64 --decode | openssl req -noout -text

3. Remove any `csr` that contains `Subject Name: localhost.localdomain`:
8.5.8.4. Routes do not reach endpoints

During the installation process, it is possible to encounter a Virtual Router Redundancy Protocol (VRRP) conflict. This conflict might occur if a previously used OpenShift Container Platform node that was once part of a cluster deployment using a specific cluster name is still running but not part of the current OpenShift Container Platform cluster deployment using that same cluster name. For example, a cluster was deployed using the cluster name `openshift`, deploying three control plane (master) nodes and three worker nodes. Later, a separate install uses the same cluster name `openshift`, but this redeployment only installed three control plane (master) nodes, leaving the three worker nodes from a previous deployment in an ON state. This might cause a Virtual Router Identifier (VRID) conflict and a VRRP conflict.

1. Get the route:

   ```
   $ oc get route oauth-openshift
   ```

2. Check the service endpoint:

   ```
   $ oc get svc oauth-openshift
   ```

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>oauth-openshift</td>
<td>ClusterIP</td>
<td>172.30.19.162</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>59m</td>
</tr>
</tbody>
</table>

3. Attempt to reach the service from a control plane (master) node:

   ```
   [core@master0 ~]$ curl -k https://172.30.19.162
   ```

   ```json
   {
   "kind": "Status",
   "apiVersion": "v1",
   "metadata": {
   },
   "status": "Failure",
   "message": "forbidden: User "system:anonymous" cannot get path "/\"",
   "reason": "Forbidden",
   "details": {
   },
   "code": 403
   }
   ```

4. Identify the `authentication-operator` errors from the `provisioner` node:

   ```
   $ oc logs deployment/authentication-operator -n openshift-authentication-operator
   ```

Solution

1. Ensure that the cluster name for every deployment is unique, ensuring no conflict.

2. Turn off all the rogue nodes which are not part of the cluster deployment that are using the same cluster name. Otherwise, the authentication pod of the OpenShift Container Platform cluster might never start successfully.

8.5.8.5. Failed Ignition during Firstboot

During the Firstboot, the Ignition configuration may fail.

Procedure

1. Connect to the node where the Ignition configuration failed:

   Failed Units: 1
   machine-config-daemon-firstboot.service

2. Restart the machine-config-daemon-firstboot service:

   [core@worker-X ~]$ sudo systemctl restart machine-config-daemon-firstboot.service

8.5.8.6. NTP out of sync

The deployment of OpenShift Container Platform clusters depends on NTP synchronized clocks among the cluster nodes. Without synchronized clocks, the deployment may fail due to clock drift if the time difference is greater than two seconds.

Procedure

1. Check for differences in the AGE of the cluster nodes. For example:

   $ oc get nodes

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0.cloud.example.com</td>
<td>Ready</td>
<td>master</td>
<td>145m</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>master-1.cloud.example.com</td>
<td>Ready</td>
<td>master</td>
<td>135m</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>master-2.cloud.example.com</td>
<td>Ready</td>
<td>master</td>
<td>145m</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>worker-2.cloud.example.com</td>
<td>Ready</td>
<td>worker</td>
<td>100m</td>
<td>v1.16.2</td>
</tr>
</tbody>
</table>

2. Check for inconsistent timing delays due to clock drift. For example:

   $ oc get bmh -n openshift-machine-api

   master-1   error registering master-1  ipmi://<out-of-band-ip>

   $ sudo timedatectl

   Local time: Tue 2020-03-10 18:20:02 UTC
   Universal time: Tue 2020-03-10 18:20:02 UTC
   RTC time: Tue 2020-03-10 18:36:53
Addressing clock drift in existing clusters

1. Create a `chrony.conf` file and encode it as `base64` string. For example:

```bash
$ cat << EOF | base64
server <NTP-server> iburst
stratumweight 0
driftfile /var/lib/chrony/drift
rtcsync
makestep 10 3
bindcmdaddress 127.0.0.1
bindcmdaddress ::1
keyfile /etc/chrony.keys
commandkey 1
generatecommandkey
noclientlog
logchange 0.5
logdir /var/log/chrony
EOF
```

Replace `<NTP-server>` with the IP address of the NTP server. Copy the output.

```
[text-in-base-64]
```

2. Create a `MachineConfig` object, replacing the `base64` string with the `[text-in-base-64]` string generated in the output of the previous step. The following example adds the file to the control plane (master) nodes. You can modify the file for worker nodes or make an additional machine config for the worker role.

```yaml
$ cat << EOF > /99_masters-chrony-configuration.yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  creationTimestamp: null
labels:
  machineconfiguration.openshift.io/role: master
name: 99-master-etc-chrony-conf
spec:
  config:
    ignition:
      config: {}
    security:
      tls: {}
    timeouts: {}
    version: 3.1.0
  networkd: {}
  passwd: {}
  storage:
    files:
```

Time zone: UTC (UTC, +0000)
System clock synchronized: no
NTP service: active
RTC in local TZ: no
3. Make a backup copy of the configuration file. For example:

   $ cp 99_masters-chrony-configuration.yaml 99_masters-chrony-configuration.yaml.backup

4. Apply the configuration file:

   $ oc apply -f ./masters-chrony-configuration.yaml

5. Ensure the **System clock synchronized** value is **yes**:

   $ sudo timedatectl

   Local time: Tue 2020-03-10 19:10:02 UTC
   Universal time: Tue 2020-03-10 19:10:02 UTC
   RTC time: Tue 2020-03-10 19:36:53
   Time zone: UTC (UTC, +0000)
   System clock synchronized: yes
   NTP service: active
   RTC in local TZ: no

   To setup clock synchronization prior to deployment, generate the manifest files and add this file to the **openshift** directory. For example:

   $ cp chrony-masters.yaml ~/clusterconfigs/openshift/99_masters-chrony-configuration.yaml

   Then, continue to create the cluster.

8.5.9. **Reviewing the installation**

After installation, ensure the installer deployed the nodes and pods successfully.

**Procedure**

1. When the OpenShift Container Platform cluster nodes are installed appropriately, the following **Ready** state is seen within the **STATUS** column:

   $ oc get nodes

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
</table>

Replace [text-in-base-64] with the base64 string.
2. Confirm the installer deployed all pods successfully. The following command removes any pods that are still running or have completed as part of the output.

```bash
$ oc get pods --all-namespaces | grep -iv running | grep -iv complete
```
CHAPTER 9. INSTALLING WITH Z/VM ON IBM Z AND LINUXONE

9.1. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND LINUXONE

In OpenShift Container Platform version 4.7, you can install a cluster on IBM Z or LinuxONE infrastructure that you provision.

**NOTE**

While this document refers only to IBM Z, all information in it also applies to LinuxONE.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

9.1.1. Prerequisites

- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.

- Provision **persistent storage using NFS** for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.

- Review details about the OpenShift Container Platform installation and update processes.

- If you use a firewall, you must **configure it to allow the sites** that your cluster requires access to.

  **NOTE**

  Be sure to also review this site list if you are configuring a proxy.

9.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access **Quay.io** to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.
IMPORTANT
If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

9.1.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

9.1.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.

NOTE

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

9.1.3.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

9.1.3.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
• A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

### 9.1.3.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

**Table 9.1. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

### 9.1.3.5. Minimum IBM Z system environment

You can install OpenShift Container Platform version 4.7 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s
- LinuxONE, any version

**Hardware requirements**

- The equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

**NOTE**

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

**IMPORTANT**

Since the overall performance of the cluster can be impacted, the LPARs that are used to setup the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

**Operating system requirements**

- One instance of z/VM 7.1 or later
On your z/VM instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

**IBM Z network connectivity requirements**
To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

**Disk storage for the z/VM guest virtual machines**

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV to ensure optimal performance.
- FCP attached disk storage

**Storage / Main Memory**

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

**9.1.3.6. Preferred IBM Z system environment**

**Hardware requirements**

- 3 LPARS that each have the equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- Two network connections to connect to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.
- HiperSockets, which are attached to a node either directly as a device or by bridging with one z/VM VSwitch to be transparent to the z/VM guest. To directly connect HiperSockets to a node, you must set up a gateway to the external network via a RHEL 8 guest to bridge to the HiperSockets network.

**Operating system requirements**

- 2 or 3 instances of z/VM 7.1 or later for high availability

On your z/VM instances, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines, one per z/VM instance.
- At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the z/VM instances.
IBM Z network connectivity requirements
To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV and High Performance FICON (zHPF) to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

9.1.3.7. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- See [Bridging a HiperSockets LAN with a z/VM Virtual Switch](#) in IBM Documentation.
- See [Scaling HyperPAV alias devices on Linux guests on z/VM](#) for performance optimization.
- See [Topics in LPAR performance](#) for LPAR weight management and entitlements.
- See [Recommended host practices for IBM Z & LinuxONE environments](#)

9.1.4. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.
Prerequisites

- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the supporting infrastructure for your cluster.

Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

9.1.4.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

Table 9.2. All machines to all machines

### Table 9.3. All machines to control plane

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6443</td>
<td>Kubernetes API</td>
</tr>
</tbody>
</table>

### Table 9.4. Control plane machines to control plane machines

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

### Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**
OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**
Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:
Table 9.5. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application Ingress load balancer: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

Table 9.6. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
TIP

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

NTP configuration

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

Additional resources

- Configuring chrony time service

9.1.4.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

Table 9.7. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

### Routes

Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

### Bootstrap

Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.

### Master hosts

DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.

### Worker hosts

Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

---

**Example 9.1. Sample DNS zone database**
The following example BIND zone file shows sample PTR records for reverse name resolution.

### Example 9.2. Sample DNS zone database for reverse records

```dns
$TTL 1W
@ IN SOA ns1.example.com. root (  
  2019070700 ; serial  
  3H ; refresh (3 hours)  
  30M ; retry (30 minutes)  
  2W ; expiry (2 weeks)  
  1W ) ; minimum (1 week) 
IN NS ns1.example.com.

worker1.ocp4 IN A 192.168.1.7 
; 
;EOF
```

The following example BIND zone file shows sample PTR records for reverse name resolution.
9.1.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

$ eval "$(ssh-agent -s)"

Example output

Agent pid 31874

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

$ ssh-add <path>/<file_name>  

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

9.1.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

9.1.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

9.1.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:
5. Place the `oc` binary in a directory that is on your PATH. To check your PATH, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

9.1.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.7 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

9.1.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.7 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

```
$ echo $PATH
```

```
$ oc <command>
```
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 9.1.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

### 9.1.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for
the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 9.1.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

#### Table 9.8. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere**. For additional information about platform.<platform> parameters, consult the table for your specific platform that follows.

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

### 9.1.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 9.9. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the **networking** object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>

### 9.1.8.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 9.10. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>additionalTrustBundle</code></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>compute</code></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>

<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

**NOTE**
If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). <td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. The default value is External. Setting this field to Internal is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

**IMPORTANT**

If the value of the field is set to Internal, the cluster will become non-functional. For more information, refer to BZ#1953035.

### 9.1.8.2. Sample install-config.yaml file for IBM Z

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture : s390x
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture : s390x
metadata:
  name: test
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The \texttt{controlPlane} section is a single mapping, but the \texttt{compute} section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the \texttt{compute} section must begin with a hyphen, -, and the first line of the \texttt{controlPlane} section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading (SMT), or \texttt{hyperthreading}. By default, SMT is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to \texttt{Disabled}. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

\textbf{NOTE}

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the \texttt{hyperthreading} parameter has no effect.

\textbf{IMPORTANT}

If you disable \texttt{hyperthreading}, whether in the BIOS or in the \texttt{install-config.yaml}, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set the value of the \texttt{replicas} parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.
NOTE

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \((2^{32} - 23) - 2\) pod IPs addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to `none`. You cannot provide additional platform configuration variables for IBM Z infrastructure.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to `none`, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).
NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

9.1.9. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE
The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> ①
     httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
     noProxy: example.com ③
   additionalTrustBundle: | ④
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
     ...
   ```

   ① A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   ② A proxy URL to use for creating HTTPS connections outside the cluster.
A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster` Proxy object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

9.1.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites
• You obtained the OpenShift Container Platform installation program.
• You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   
   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.
   ```

   **WARNING**

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

   **IMPORTANT**

   When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   
   For `<installation_directory>`, specify the same installation directory.
   ```

   The following files are generated in the directory:

   ```
   ├── auth
   │   ├── kubeadm-password
   ```
9.1.11. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines

Before you install a cluster on IBM Z infrastructure that you provision, you must install RHCOS on z/VM guest virtual machines for the cluster to use. Complete the following steps to create the machines.

Prerequisites

- An HTTP or HTTPS server running on your provisioning machine that is accessible to the machines you create.

Procedure

1. Log in to Linux on your provisioning machine.

2. Obtain the Red Hat Enterprise Linux CoreOS (RHCOS) kernel, initramfs, and rootfs files from the RHCOS image mirror.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - **kernel**: `rhcos-<version>-live-kernel-<architecture>`
   - **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
   - **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

   **NOTE**

   The rootfs image is the same for FCP and DASD.

3. Create parameter files. The following parameters are specific for a particular virtual machine:

   - For `ip=`, specify the following seven entries:
     
     i. The IP address for the machine.
     
     ii. An empty string.
     
     iii. The gateway.
iv. The netmask.

v. The machine host and domain name in the form `hostname.domainname`. Omit this value to let RHCOS decide.

vi. The network interface name. Omit this value to let RHCOS decide.

vii. If you use static IP addresses, specify `none`.

- For `coreos.inst.ignition_url=`, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

- For `coreos.live.rootfs_url=`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

- For installations on DASD-type disks, complete the following tasks:
  
  i. For `coreos.inst.install_dev=`, specify `dasda`.

  ii. Use `rd.dasd=` to specify the DASD where RHCOS is to be installed.

  iii. Leave all other parameters unchanged.

  Example parameter file, `bootstrap-0.parm`, for the bootstrap machine:

  ```
  rd.neednet=1 \
  console=ttysc0p0 \
  coreos.inst.install_dev=dasda \
  coreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img \
  coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/bootstrap.ign \
  ip=172.18.78.2::172.18.78.1:255.255.255.0:::none nameserver=172.18.78.1 \
  rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 \
  zfcp.allow_lun_scan=0 \
  rd.dasd=0.0.3490
  ```

  Write all options in the parameter file as a single line and make sure you have no newline characters.

- For installations on FCP-type disks, complete the following tasks:

  i. Use `rd.zfcp=<adapter>,<wwpn>,<lun>` to specify the FCP disk where RHCOS is to be installed. For multipathing repeat this step for each additional path.

  ii. For multipathing, set the following parameter: `rd.multipath=default`.

  iii. For multipathing, set the install device as:

  `coreos.inst.install_dev=/dev/mapper/mpatha`.

  iv. For single-path installation, set the install device as: `coreos.inst.install_dev=sda`.

**NOTE**

If additional LUNs are configured with NPIV, FCP requires `zfcp.allow_lun_scan=0`. If you must enable `zfcp.allow_lun_scan=1` because you use a CSI driver, for example, you must configure your NPIV so that each node cannot access the boot partition of another node.
v. Leave all other parameters unchanged.

**IMPORTANT**

Additional post-installation steps are required to fully enable multipathing. For more information, see “Enabling multipathing with kernel arguments on RHCOS” in *Post-installation machine configuration tasks*.

The following is an example parameter file `worker-1.parm` for a worker node with multipathing:

```
rd.neednet=1 \
console=ttySCLP0 \
coreos.inst.install_dev=sda \
coreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img \
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/worker.ign \
ip=172.18.78.2::172.18.78.1:255.255.255.0:::none nameserver=172.18.78.1 \
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,porto=0 \
zfcp.allow_lun_scan=0 \nrd.zfcp=0.0.1987,0x50050763070bc5e3,0x4008400B00000000 \nrd.zfcp=0.0.19C7,0x50050763070bc5e3,0x4008400B00000000 \nrd.zfcp=0.0.1987,0x50050763071bc5e3,0x4008400B00000000 \nrd.zfcp=0.0.19C7,0x50050763071bc5e3,0x4008400B00000000
```

Write all options in the parameter file as a single line and make sure you have no newline characters.

4. Transfer the initramfs, kernel, parameter files, and RHCOS images to z/VM, for example with FTP. For details about how to transfer the files with FTP and boot from the virtual reader, see *Installing under Z/VM*.

5. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node.
   See [PUNCH](https://www.ibm.com/support/knowledgecenter/en/SSTPSW_8.4.0/books/h浪潮zvm02/guide/gsdhp0064.html) in IBM Documentation.

**TIP**

You can use the CP `PUNCH` command or, if you use Linux, the `vmur` command to transfer files between two z/VM guest virtual machines.

7. IPL the bootstrap machine from the reader:

   ```
   $ ipl c
   ```
   
   See [IPL](https://www.ibm.com/support/knowledgecenter/en/SSTPSW_8.4.0/books/h浪潮zvm02/guide/gsdhp0064.html) in IBM Documentation.

8. Repeat this procedure for the other machines in the cluster.

**9.1.11.1. Advanced RHCOS installation reference**
This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

Routing and bonding options at RHCOS boot prompt
If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node’s networking. If no networking arguments are used, the installation defaults to using DHCP.

**IMPORTANT**

When adding networking arguments, you must also add the `rd.neednet=1` kernel argument.

The following table describes how to use `ip=`, `nameserver=`, and `bond=` kernel arguments for live ISO installs.

**NOTE**

Ordering is important when adding kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

Routing and bonding options for ISO
The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

<td><code>nameserver=1.1.1.1</code></td>
</tr>
<tr>
<td></td>
<td><code>nameserver=8.8.8.8</code></td>
</tr>
</tbody>
</table>
Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples:

- The syntax for configuring a bonded interface is:
  
  ```
  bond=name[:network_interfaces][:options]
  ```

  - `name` is the bonding device name (`bond0`), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.

Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>To configure the bonded interface to use DHCP, set the bond's IP address to <code>dhcp</code>. For example:</td>
<td><code>bond=bond0:em1,em2:mode=active-backup</code> <code>ip=bond0:dhcp</code></td>
</tr>
<tr>
<td>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</td>
<td><code>bond=bond0:em1,em2:mode=active-backup</code> <code>ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:bond0:none</code></td>
</tr>
<tr>
<td>Optional: You can configure VLANs on bonded interfaces by using the <code>vlan=</code> parameter.</td>
<td>To configure the bonded interface with a VLAN and to use DHCP:</td>
</tr>
<tr>
<td></td>
<td><code>ip=bond0.100:dhcp</code> <code>bond=bond0:em1,em2:mode=active-backup</code> <code>vlan=bond0.100:bond0</code></td>
</tr>
<tr>
<td></td>
<td>To configure the bonded interface with a VLAN and to use a static IP address:</td>
</tr>
<tr>
<td></td>
<td><code>ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:bond0.100:none</code> <code>bond=bond0:em1,em2:mode=active-backup</code> <code>vlan=bond0.100:bond0</code></td>
</tr>
</tbody>
</table>
Optional: Network teaming can be used as an alternative to bonding by using the \texttt{team=} parameter. In this example:

- The syntax for configuring a team interface is: \texttt{team=\texttt{name[:network\_interfaces]}}
  \texttt{name} is the team device name (team0) and \texttt{network\_interfaces} represents a comma-separated list of physical (ethernet) interfaces (em1, em2).

\textbf{NOTE}

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

To configure a network team:

\begin{verbatim}
team=team0:em1,em2
ip=team0:dhcp
\end{verbatim}

### 9.1.12. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

**Procedure**

1. Monitor the bootstrap process:

\begin{verbatim}
$ ./openshift-install --dir <installation\_directory> wait-for bootstrap-complete \ 
--log-level=info
\end{verbatim}

   \textbf{1} For \texttt{<installation\_directory>}, specify the path to the directory that you stored the installation files in.

   \textbf{2} To view different installation details, specify \texttt{warn}, \texttt{debug}, or \texttt{error} instead of \texttt{info}.

**Example output**

\begin{verbatim}
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.20.0 up
\end{verbatim}
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT
You must remove the bootstrap machine from the load balancer at this point.
You can also remove or reformat the machine itself.

9.1.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

9.1.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.
Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the *Pending* or *Approved* status for each machine that you added to the cluster:

   $ oc get csr

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in *Pending* status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the *machine-approver* if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  
  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  
  <csr_name> is the name of a CSR from the list of current CSRs.
  ```
• To approve all pending CSRs, run the following command:

\[
\text{
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{\"\n\"}}{{end}}{{end}}'| xargs oc adm certificate approve
\]

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

\[
\text{
$ oc get nodes
\}
\]

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

• For more information on CSRs, see [Certificate Signing Requests](#).

**9.1.15. Initial Operator configuration**

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

• Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

\[
\text{
$ watch -n5 oc get clusteroperators
\}
\]

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>
2. Configure the Operators that are not available.

9.1.15.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

9.1.15.1.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on IBM Z.
- Persistent storage provisioned for your cluster.
IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the spec.storage.pvc in the configs.imageregistry/cluster resource.

   **NOTE**
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   ```

   No resources found in openshift-image-registry namespace

   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   ```

   storage:
   pvc:
   claim:

   Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   ```bash
   $ oc get clusteroperator image-registry
   
   Example output
5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:
     
     ```
     $ oc edit configs.imageregistry/cluster
     
     Then, change the line
     
     managementState: Removed
     
     to
     
     managementState: Managed
     ```

9.1.15.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

   - To set the image registry storage to an empty directory:

     ```
     $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
     
     "storage":{"emptyDir":{}}}'
     ```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

9.1.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**
Your control plane has initialized.

You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

</tbody>
</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>Running</td>
<td>9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apisher-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>3m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td></td>
</tr>
<tr>
<td>Running</td>
<td>0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.
If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.

   a. All the worker nodes are restarted. To monitor the process, enter the following command:

   ```
   $ oc get nodes -w
   ```

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

9.1.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

9.1.18. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

**Prerequisites**

- The oc CLI tool installed.

**Procedure**

1. Log in to the cluster:

   ```
   $ oc login -u <username>
   ```

2. On the node you want to gather hardware information about, start a debugging container:

   ```
   $ oc debug node/<nodename>
   ```

3. Change to the /host file system and start toolbox:
$ chroot /host
$ toolbox

4. Collect the `dbginfo` data:

```bash
$ dbginfo.sh
```

5. You can then retrieve the data, for example, using `scp`.

**Additional resources**

- See [How to generate SOSREPORT within OpenShift4 nodes without SSH](#).

**9.1.19. Next steps**

- [Enabling multipathing with kernel arguments on RHCOS](#).
- Customize your cluster.
- If necessary, you can [opt out of remote health reporting](#).

**9.2. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND LINUXONE IN A RESTRICTED NETWORK**

In OpenShift Container Platform version 4.7, you can install a cluster on IBM Z and LinuxONE infrastructure that you provision in a restricted network.

**NOTE**

While this document refers to only IBM Z, all information in it also applies to LinuxONE.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

**Prerequisites**

- Create a mirror registry for installation in a restricted network and obtain the `imageContentSources` data for your version of OpenShift Container Platform.

- Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

**IMPORTANT**

Ensure that installation steps are done from a machine with access to the installation media.
• Provision persistent storage using NFS for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

• Review details about the OpenShift Container Platform installation and update processes.

• If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.

NOTE
Be sure to also review this site list if you are configuring a proxy.

9.2.1. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT
Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

9.2.1.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

• The ClusterVersion status includes an Unable to retrieve available updates error.

• By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

9.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:
• Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

IMPORTANT
If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

9.2.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

9.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

• One temporary bootstrap machine

• Three control plane, or master, machines

• At least two compute machines, which are also known as worker machines.

NOTE
The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT
To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits .

9.2.3.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP
addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

9.2.3.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

9.2.3.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Table 9.11. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>

<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

9.2.3.5. Minimum IBM Z system environment

You can install OpenShift Container Platform version 4.7 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s
- LinuxONE, any version

Hardware requirements

- The equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

**NOTE**

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.
IMPORTANT

Since the overall performance of the cluster can be impacted, the LPARs that are used to setup the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One instance of z/VM 7.1 or later

On your z/VM instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

9.2.3.6. Preferred IBM Z system environment

Hardware requirements

- 3 LPARS that each have the equivalent of 6 IFLs, which are SMT2 enabled, for each cluster.
- Two network connections to connect to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.
- HiperSockets, which are attached to a node either directly as a device or by bridging with one z/VM VSWITCH to be transparent to the z/VM guest. To directly connect HiperSockets to a node, you must set up a gateway to the external network via a RHEL 8 guest to bridge to the HiperSockets network.
Operating system requirements

- 2 or 3 instances of z/VM 7.1 or later for high availability

On your z/VM instances, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines, one per z/VM instance.
- At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the z/VM instances.
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.
- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using the CP command `SET SHARE`. Do the same for infrastructure nodes, if they exist. See `SET SHARE` in IBM Documentation.

IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV and High Performance FICON (zHPF) to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

9.2.3.7. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- See Bridging a HiperSockets LAN with a z/VM Virtual Switch in IBM Documentation.
9.2.4. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

Prerequisites

- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the supporting infrastructure for your cluster.

Procedure

1. Configure DHCP or set static IP addresses on each node.
2. Provision the required load balancers.
3. Configure the ports for your machines.
4. Configure DNS.
5. Ensure network connectivity.

9.2.4.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require either a DHCP server or that static IP addresses be set on each host in the cluster to establish a network connection, which allows them to download their Ignition config files.

It is recommended to use the DHCP server to manage the machines for the cluster long-term. Ensure that the DHCP server is configured to provide persistent IP addresses and host names to the cluster machines.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.
IMPORTANT

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

Table 9.15. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application Ingress load balancer: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

Table 9.16. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
</tbody>
</table>
The machines that run the Ingress router pods, compute, or worker, by default.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**

- Configuring chrony time service

**9.2.4.2. User-provisioned DNS requirements**

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

**Table 9.17. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>APIs</td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

**Example 9.3. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root (...
```
The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 9.4. Sample DNS zone database for reverse records

```dns
$TTL 1W
@ IN SOA ns1.example.com. root ( 
  2019070700 ; serial 
  3H ; refresh (3 hours) 
  30M ; retry (30 minutes) 
  2W ; expiry (2 weeks) 
  1W ) ; minimum (1 week) 
IN NS ns1.example.com. 
IN MX 10 smtp.example.com. 
; 
ns1 IN A 192.168.1.5 
smtpp IN A 192.168.1.5 
; 
helper IN A 192.168.1.5 
helper.ocp4 IN A 192.168.1.5 
; 
; The api identifies the IP of your load balancer. 
api.ocp4 IN A 192.168.1.5 
api-int.ocp4 IN A 192.168.1.5 
; 
; The wildcard also identifies the load balancer. 
*.apps.ocp4 IN A 192.168.1.5 
; 
; Create an entry for the bootstrap host. 
bootstrap.ocp4 IN A 192.168.1.96 
; 
; Create entries for the master hosts. 
master0.ocp4 IN A 192.168.1.97 
master1.ocp4 IN A 192.168.1.98 
master2.ocp4 IN A 192.168.1.99 
; 
; Create entries for the worker hosts. 
worker0.ocp4 IN A 192.168.1.11 
worker1.ocp4 IN A 192.168.1.17 
; 
; EOF
```

The syntax is "last octet" and the host must have an FQDN with a trailing dot.
9.2.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" \n -f <path>/<file_name>
```

   **1** Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.
2. Start the *ssh-agent* process as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the *ssh-agent*:

```bash
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 9.2.6. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```bash
$ mkdir <installation_directory>
```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

9.2.6.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the `install-config.yaml` file.

IMPORTANT

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

9.2.6.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 9.18. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

OpenShift Container Platform 4.7 Installing
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>, <code>{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
9.2.6.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 9.19. Network parameters

<table>
<thead>
<tr>

|                    |                                  |     "email":"you@example.com"  
|                    |                                  | }  
|                    |                                  | } |
| networking          | The configuration for the cluster network. | Object |
| networking.network | The cluster network provider Container Network Interface (CNI) plug-in to install. | Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN. |
| networking.clusterNetwork | The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example: networking: clusterNetwork:  
|                                    |                                  | - cidr: 10.128.0.0/14  
|                                    |                                  | hostPrefix: 23
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the <code>machineNetwork.cidr</code> value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

### 9.2.6.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
Table 9.20. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>

<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>controlPlane.hypertreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td><code>controlPlane.name</code></td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td><code>master</code></td>
</tr>
<tr>
<td><code>controlPlane.platform</code></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td><code>controlPlane.replicas</code></td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is <code>3</code>, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
</tbody>
</table>

**NOTE**
Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the [Cloud Credential Operator entry in the Cluster Operators reference content](#).  

**IMPORTANT**
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.  

**NOTE**
If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. The default value is <strong>External</strong>. Setting this field to <strong>Internal</strong> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</td>
</tr>
</tbody>
</table>

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

**IMPORTANT**
If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to BZ#1953035.

### 9.2.6.2. Sample install-config.yaml file for IBM Z

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 2
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading (SMT), or **hyperthreading**. By default, SMT is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.
IMPORTANT

If you disable hyperthreading, whether in the BIOS or in the install-config.yaml, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4 You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8 The cluster name that you specified in your DNS records.

9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

10 The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{(32 - 23) - 2}\) pod IPs addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

12 You must set the platform to none. You cannot provide additional platform configuration variables for IBM Z infrastructure.
WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as **installing a cluster on any platform**, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

---

9.2.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy. By default, the cluster-wide proxy is disabled. To configure it, modify the cluster configuration and restart the kube-proxy service. The following example sets the proxy configuration:

```
cloud: proxy:
  enabled: true
  proxyType: transparent
  proxyHost: proxy.example.com
  proxyPort: 9193
```

---

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

The public portion of the default SSH key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

Add the `additionalTrustBundle` parameter and value. The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.
Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
noProxy: example.com ³
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
  ...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations.
4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the Proxy object is configured to reference the `user-ca-bundle` config map in the trustedCA field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents...
specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

9.2.7. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

IMPORTANT
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

NOTE
The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the install-config.yaml installation configuration file.

Procedure
1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

```
. ├── auth
    │   └── kubeadm-password
    │       └── kubeconfig
    │   └── bootstrap.ign
    └── master.ign
        └── metadata.json
            └── worker.ign
```
9.2.8. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines

Before you install a cluster on IBM Z infrastructure that you provision, you must install RHCOS on z/VM guest virtual machines for the cluster to use. Complete the following steps to create the machines.

Prerequisites

- An HTTP or HTTPS server running on your provisioning machine that is accessible to the machines you create.

Procedure

1. Log in to Linux on your provisioning machine.

2. Obtain the Red Hat Enterprise Linux CoreOS (RHCOS) kernel, initramfs, and rootfs files from the RHCOS image mirror.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - kernel: `rhcos-<version>-live-kernel-<architecture>`
   - initramfs: `rhcos-<version>-live-initramfs.<architecture>.img`
   - rootfs: `rhcos-<version>-live-rootfs.<architecture>.img`

   **NOTE**

   The rootfs image is the same for FCP and DASD.

3. Create parameter files. The following parameters are specific for a particular virtual machine:

   - For `ip=`, specify the following seven entries:
     i. The IP address for the machine.
     ii. An empty string.
     iii. The gateway.
     iv. The netmask.
     v. The machine host and domain name in the form `hostname.domainname`. Omit this value to let RHCOS decide.
     vi. The network interface name. Omit this value to let RHCOS decide.
If you use static IP addresses, specify none.

- For `coreos.inst.ignition_url=`, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

- For `coreos.live.rootfs_url=`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

- For installations on DASD-type disks, complete the following tasks:
  1. For `coreos.inst.install_dev=`, specify `dasda`.
  2. Use `rd.dasd=` to specify the DASD where RHCOS is to be installed.
  3. Leave all other parameters unchanged.

  Example parameter file, `bootstrap-0.parm`, for the bootstrap machine:

  ```
  rd.neednet=1 \n  console=ttyscp0 \n  coreos.inst.install_dev=dasda \n  coreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img \n  coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/bootstrap.ign \n  ip=172.18.78.2::172.18.78.1:255.255.255.0:: none nameserver=172.18.78.1 \n  rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 \n  zfcp.allow_lun_scan=0 \n  rd.dasd=0.0.3490
  ```

  Write all options in the parameter file as a single line and make sure you have no newline characters.

- For installations on FCP-type disks, complete the following tasks:
  1. Use `rd.zfcp=<adapter>,<wwpn>,<lun>` to specify the FCP disk where RHCOS is to be installed. For multipathing repeat this step for each additional path.
  2. For multipathing, set the following parameter: `rd.multipath=default`.
  3. For multipathing, set the install device as:
     
     `coreos.inst.install_dev=/dev/mapper/mpatha`.
  4. For single-path installation, set the install device as: `coreos.inst.install_dev=sda`.

  **NOTE**

  If additional LUNs are configured with NPIV, FCP requires `zfcp.allow_lun_scan=0`. If you must enable `zfcp.allow_lun_scan=1` because you use a CSI driver, for example, you must configure your NPIV so that each node cannot access the boot partition of another node.

  v. Leave all other parameters unchanged.
IMPORTANT

Additional post-installation steps are required to fully enable multipathing. For more information, see "Enabling multipathing with kernel arguments on RHCOS" in Post-installation machine configuration tasks.

The following is an example parameter file worker-1.parm for a worker node with multipathing:

```
rd.neednet=1 \
console=ttyscp0 \
coreos.inst.install_dev=sda \
coreos.live.rootsfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-rootsfs.s390x.img \
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/worker.ign \
ip=172.18.78.2::172.18.78.1:255.255.255.0:::none nameserver=172.18.78.1 \
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 \
zfcp.allow_lun_scan=0 \
rdfcp=0.0.1987,0x50050763070bc5e3,0x4008400B00000000 \
rdfcp=0.0.19c7,0x50050763070bc5e3,0x4008400B00000000 \
rdfcp=0.0.1987,0x50050763071bc5e3,0x4008400B00000000 \
rdfcp=0.0.19c7,0x50050763071bc5e3,0x4008400B00000000
```

Write all options in the parameter file as a single line and make sure you have no newline characters.

4. Transfer the initramfs, kernel, parameter files, and RHCOS images to z/VM, for example with FTP. For details about how to transfer the files with FTP and boot from the virtual reader, see Installing under Z/VM.

5. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node.
   See PUNCH in IBM Documentation.

   TIP

   You can use the CP PUNCH command or, if you use Linux, the vmur command to transfer files between two z/VM guest virtual machines.

7. IPL the bootstrap machine from the reader:

   `$ ipl c`

   See IPL in IBM Documentation.

8. Repeat this procedure for the other machines in the cluster.

9.2.8.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables
describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

**Routing and bonding options at RHCOS boot prompt**

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node’s networking. If no networking arguments are used, the installation defaults to using DHCP.

**IMPORTANT**

When adding networking arguments, you must also add the `rd.neednet=1` kernel argument.

The following table describes how to use `ip=`, `nameserver=`, and `bond=` kernel arguments for live ISO installs.

**NOTE**

Ordering is important when adding kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

**Routing and bonding options for ISO**

The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>To configure an IP address, either use DHCP (<code>ip= dhcp</code>) or set an individual static IP address (<code>ip= &lt;host_ip&gt;</code>). Then identify the DNS server IP address (<code>nameserver=&lt;dns_ip&gt;</code>) on each node. This example sets:</td>
<td><code>ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code></td>
</tr>
<tr>
<td>- The node’s IP address to 10.10.10.2</td>
<td>nameserver=4.4.4.41</td>
</tr>
<tr>
<td>- The gateway address to 10.10.10.254</td>
<td></td>
</tr>
<tr>
<td>- The netmask to 255.255.255.0</td>
<td></td>
</tr>
<tr>
<td>- The hostname to core0.example.com</td>
<td></td>
</tr>
<tr>
<td>- The DNS server address to 4.4.4.41</td>
<td></td>
</tr>
</tbody>
</table>

Specify multiple network interfaces by specifying multiple `ip=` entries.  

<table>
<thead>
<tr>
<th>Examples</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code></td>
<td></td>
</tr>
<tr>
<td><code>ip=10.10.10.3::10.10.254:255.255.255.0:core0.example.com:enp2s0:none</code></td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>Examples</td>
</tr>
<tr>
<td>-------------</td>
<td>----------</td>
</tr>
</tbody>
</table>
| Optional: You can configure routes to additional networks by setting an `rd.route=` value. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway. | To configure the default gateway:  
`ip=:10.10.10.254:::`
To configure the route for the additional network:  
`rd.route=20.20.20.0/24:20.20.20.254:enp2s0`
|
| Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. | ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none  
`ip=:::core0.example.com:enp2s0:none`
|
| You can combine DHCP and static IP configurations on systems with multiple network interfaces. | ip=enp1s0:dhcp  
ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0:none |
| Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter. | To configure a VLAN on a network interface and use a static IP address:  
`ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none  
vlan=enp2s0.100:enp2s0`
To configure a VLAN on a network interface and to use DHCP:  
`ip=enp2s0.100:dhcp  
vlan=enp2s0.100:enp2s0`
|
| You can provide multiple DNS servers by adding a `nameserver=` entry for each server. | nameserver=1.1.1.1  
nameserver=8.8.8.8 |
<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional: Bonding multiple network interfaces to a single interface is supported using the <code>bond=</code> option. In these two examples:</td>
<td>To configure the bonded interface to use DHCP, set the bond’s IP address to <code>dhcp</code>. For example:</td>
</tr>
<tr>
<td>• The syntax for configuring a bonded interface is: <code>bond=name[:network_interfaces] [:options]</code></td>
<td><code>bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</code></td>
</tr>
<tr>
<td>• <code>name</code> is the bonding device name (<code>bond0</code>), <code>network_interfaces</code> represents a comma-separated list of physical (ethernet) interfaces (<code>em1,em2</code>), and <code>options</code> is a comma-separated list of bonding options. Enter <code>modinfo bonding</code> to see available options.</td>
<td>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</td>
</tr>
<tr>
<td>• When you create a bonded interface using <code>bond=</code>, you must specify how the IP address is assigned and other information for the bonded interface.</td>
<td><code>bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none</code></td>
</tr>
<tr>
<td>Optional: You can configure VLANs on bonded interfaces by using the <code>vlan=</code> parameter.</td>
<td>To configure the bonded interface with a VLAN and to use DHCP:</td>
</tr>
<tr>
<td></td>
<td><code>ip=bond0.100:dhcp</code></td>
</tr>
<tr>
<td></td>
<td><code>bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0</code></td>
</tr>
<tr>
<td></td>
<td>To configure the bonded interface with a VLAN and to use a static IP address:</td>
</tr>
<tr>
<td></td>
<td><code>ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:bond0.100:none</code></td>
</tr>
<tr>
<td></td>
<td><code>bond=bond0:em1,em2:mode=active-backup vlan=bond0.100:bond0</code></td>
</tr>
</tbody>
</table>
Optional: Network teaming can be used as an alternative to bonding by using the `team=` parameter. In this example:

- The syntax for configuring a team interface is: `team=name[:network_interfaces]`
  - `name` is the team device name (team0) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (em1, em2).

**NOTE**
Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

### 9.2.9. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

#### Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.

#### Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 1
   --log-level=info 2
   
   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   
   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.
   
   **Example output**
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.20.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```
The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.

### 9.2.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 9.2.11. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**
1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  63m  v1.20.0
master-1  Ready     master  63m  v1.20.0
master-2  Ready     master  64m  v1.20.0
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME        AGE     REQUESTOR                                                                   CONDITION
csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
... 
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
CHAPTER 9. INSTALLING WITH Z/VM ON IBM Z AND LINUXONE

NOTE
For clusters running on platforms that are not machine API enabled, such as bare
metal and other user-provisioned infrastructure, you must implement a method
of automatically approving the kubelet serving certificate requests (CSRs). If a
request is not approved, then the oc exec, oc rsh, and oc logs commands
cannot succeed, because a serving certificate is required when the API server
connects to the kubelet. Any operation that contacts the Kubelet endpoint
requires this certificate approval to be in place. The method must watch for new
CSRs, confirm that the CSR was submitted by the node-bootstrapper service
account in the system:node or system:admin groups, and confirm the identity
of the node.
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

NOTE
Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

1383


To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME     STATUS    ROLES   AGE   VERSION
master-0 Ready  master  73m   v1.20.0
master-1 Ready  master  73m   v1.20.0
master-2 Ready  master  74m   v1.20.0
worker-0 Ready  worker  11m   v1.20.0
worker-1 Ready  worker  11m   v1.20.0
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 9.2.12. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

```
NAME           VERSION AVAILABLE PROGRESSING DEGRADED SINCE
authentication  4.7.0 True False False 3h56m
baremetal      4.7.0 True False False 29h
cloud-credential 4.7.0 True False False 29h
cluster-autoscaler 4.7.0 True False False 29h
config-operator 4.7.0 True False False 6h39m
```
2. Configure the Operators that are not available.

### 9.2.12.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '[["op": "add", "path": "/spec/disableAllDefaultSources", "value": true]]'
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

### 9.2.12.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

9.2.12.2.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on IBM Z.
- Persistent storage provisioned for your cluster.

IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   NOTE

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   Example output

   ```
   No resources found in openshift-image-registry namespace
   ```

   NOTE

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:
$ oc edit configs.imageregistry.operator.openshift.io

**Example output**

```
storage:
pvc:
  claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage PVC**.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

**Example output**

```
NAME             VERSION                              AVAILABLE   PROGRESSING   DEGRADED
SINCE   MESSAGE
image-registry   4.7                                  True        False         False      6h50m
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:
  
  ```
  $ oc edit configs.imageregsitry/cluster
  
  Then, change the line
  
  managementState: Removed
  
  to
  
  managementState: Managed
  ```

### 9.2.12.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  
  
  "storage":{"emptyDir":{}}}'}
  ```
WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

9.2.13. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n 5 oc get clusteroperators
```

Example output

<table>
<thead>
<tr>

</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```
**Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>Running 0 5m</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

1 Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.

   a. All the worker nodes are restarted. To monitor the process, enter the following command:

   ```
   $ oc get nodes -w
   ```

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

4. Register your cluster on the Cluster registration page.

**9.2.14. Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](https://openshift.io/cluster-manager).

After you confirm that your [OpenShift Cluster Manager](https://openshift.io/cluster-manager) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.
Additional resources

- See About remote health monitoring for more information about the Telemetry service

9.2.15. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

Prerequisites

- The oc CLI tool installed.

Procedure

1. Log in to the cluster:

   $ oc login -u <username>

2. On the node you want to gather hardware information about, start a debugging container:

   $ oc debug node/<nodename>

3. Change to the /host file system and start toolbox:

   $ chroot /host
   $ toolbox

4. Collect the dbginfo data:

   $ dbginfo.sh

5. You can then retrieve the data, for example, using scp.

Additional resources

- See How to generate SOSREPORT within OpenShift Container Platform version 4 nodes without SSH.

9.2.16. Next steps

- Customize your cluster.

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
CHAPTER 10. INSTALLING WITH RHEL KVM ON IBM Z AND LINUXONE

10.1. INSTALLING A CLUSTER WITH RHEL KVM ON IBM Z AND LINUXONE

In OpenShift Container Platform version 4.7, you can install a cluster on IBM Z or LinuxONE infrastructure that you provision.

NOTE
While this document refers only to IBM Z, all information in it also applies to LinuxONE.

IMPORTANT
Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

10.1.1. Prerequisites

- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- Provision persistent storage using NFS for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- RHEL Kernel Virtual Machine (KVM) system that is hosted on the logical partition (LPAR) and based on RHEL 8.4 or later

NOTE
Be sure to also review this site list if you are configuring a proxy.

10.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

10.1.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

One or more KVM host machines based on RHEL 8.4 or later. Each RHEL KVM host machine must have libvirt installed and running. The virtual machines are provisioned under each RHEL KVM host machine.

10.1.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following nodes:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines

NOTE

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different RHEL instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

See Red Hat Enterprise Linux technology capabilities and limits.

10.1.3.2. Network connectivity requirements

The OpenShift Container Platform installer creates the Ignition files, which are necessary for all the Red Hat Enterprise Linux CoreOS (RHCOS) virtual machines. The automated installation of OpenShift Container Platform is performed by the bootstrap machine. It starts the installation of OpenShift Container Platform on each node, starts the Kubernetes cluster, and then finishes. During this bootstrap, the virtual machine must have an established network connection either through a Dynamic Host Configuration Protocol (DHCP) server or static IP address.

10.1.3.3. IBM Z network connectivity requirements
To install on IBM Z under RHEL KVM, you need:

- A RHEL KVM host configured with an OSA or RoCE network adapter.
- Either a RHEL KVM host that is configured to use bridged networking in libvirt or MacVTap to connect the network to the guests. See Types of virtual network connections.

10.1.3.4. Host machine resource requirements

The RHEL KVM host in your environment must meet the following requirements to host the virtual machines that you plan for the OpenShift Container Platform environment. See Getting started with virtualization.

You can install OpenShift Container Platform version 4.7 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s
- LinuxONE, any version

10.1.3.5. Minimum IBM Z system environment

Hardware requirements

- The equivalent of six IFLs, which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

NOTE

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

IMPORTANT

Since the overall performance of the cluster can be impacted, the LPARs that are used to setup the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One LPAR running RHEL 8.4 or later with KVM, which is managed by libvirt

On your RHEL KVM host, set up:

- Three guest virtual machines for OpenShift Container Platform control plane machines
- Two guest virtual machines for OpenShift Container Platform compute machines
- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine
10.1.3.6. Minimum resource requirements

Each cluster virtual machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

10.1.3.7. Preferred IBM Z system environment

**Hardware requirements**

- Three LPARS that each have the equivalent of six IFLs, which are SMT2 enabled, for each cluster.
- Two network connections to connect to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.

**Operating system requirements**

- For high availability, two or three LPARs running RHEL 8.4 or later with KVM, which are managed by libvirt.

On your RHEL KVM host, set up:

- Three guest virtual machines for OpenShift Container Platform control plane machines, distributed across the RHEL KVM host machines.
- At least six guest virtual machines for OpenShift Container Platform compute machines, distributed across the RHEL KVM host machines.
- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.
- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using `cpu_shares`. Do the same for infrastructure nodes, if they exist. See `schedinfo` in IBM Documentation.

10.1.3.8. Preferred resource requirements

The preferred requirements for each cluster virtual machine are:

<table>
<thead>
<tr>
<th>Virtual Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>
### 10.1.3.9. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

**Additional resources**

- [Recommended host practices for IBM Z & LinuxONE environments](#)

### 10.1.4. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

**Prerequisites**

- Review the [OpenShift Container Platform 4.x Tested Integrations](#) page before you create the supporting infrastructure for your cluster.

**Procedure**

1. Configure DHCP or set static IP addresses on each node.

2. Choose to perform either a fast track installation of Red Hat Enterprise Linux CoreOS (RHCOS) or a full installation of Red Hat Enterprise Linux CoreOS (RHCOS). For the full installation you must set up an HTTP or HTTPS server to provide Ignition files and install images to the cluster nodes. For the fast track installation an HTTP or HTTPS server is not required, however, a DHCP server is required. See sections "Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines" and "Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines".

3. Provision the required load balancers.

4. Configure the ports for your machines.

5. Configure DNS.

### 10.1.4.1. Networking requirements for user-provisioned infrastructure

---

**Virtual Machine** | **Operating System** | **vCPU** | **Virtual RAM** | **Storage**
--- | --- | --- | --- | ---
Control plane | RHCOS | 8 | 16 GB | 120 GB
Compute | RHCOS | 6 | 8 GB | 120 GB
All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require either a DHCP server or that static IP addresses be set on each host in the cluster to establish a network connection, which allows them to download their Ignition config files.

It is recommended to use the DHCP server to manage the machines for the cluster long-term. Ensure that the DHCP server is configured to provide persistent IP addresses and host names to the cluster machines.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

NOTE
The RHEL KVM host must be configured to use bridged networking in libvirt or MacVTap to connect the network to the virtual machines. The virtual machines must have access to the network, which is attached to the RHEL KVM host. Virtual Networks, for example network address translation (NAT), within KVM are not a supported configuration.

</tbody>
</table>

### Network topology requirements

The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Load balancers

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

### Table 10.4. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

### Table 10.5. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.
**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**

- Configuring chrony time service

### 10.1.4.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
### Compartment | Record | Description
--- | --- | ---
Routes | `.apps.<cluster_name>.<base_domain>` | Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

Bootstrap | `bootstrap.<cluster_name>.<base_domain>` | Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.

Master hosts | `<master><n>.<cluster_name>.<base_domain>` | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.

Worker hosts | `<worker><n>.<cluster_name>.<base_domain>` | Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

**Example 10.1. Sample DNS zone database**

```sh
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
;
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
;
; The api identifies the IP of your load balancer.
```
The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 10.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
            3H ; refresh (3 hours)
            30M ; retry (30 minutes)
            2W ; expiry (2 weeks)
            1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
; The syntax is "last octet" and the host must have an FQDN
; with a trailing dot.
97 IN PTR master0.ocp4.example.com.
98 IN PTR master1.ocp4.example.com.
99 IN PTR master2.ocp4.example.com.
;
96 IN PTR bootstrap.ocp4.example.com.
;
5 IN PTR api.ocp4.example.com.
5 IN PTR api-int.ocp4.example.com.
;
11 IN PTR worker0.ocp4.example.com.
7 IN PTR worker1.ocp4.example.com.
;
;EOF
```

10.1.5. Generating an SSH private key and adding it to the agent
If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "\n-f <path>/<file_name>
```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. Start the `ssh-agent` process as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.
3. Add your SSH private key to the `ssh-agent`

```
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**10.1.6. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:
$ tar xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

10.1.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

10.1.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 Linux Client** entry and save the file.

4. Unpack the archive:

   $ tar xzvf <file>

5. Place the oc binary in a directory that is on your **PATH**.

   To check your **PATH**, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

10.1.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:
   
   ```
   C:\> path
   ```

   After you install the OpenShift CLI, it is available using the **oc** command:
   
   ```
   C:\> oc <command>
   ```

10.1.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:
   
   ```
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the **oc** command:
   
   ```
   $ oc <command>
   ```

10.1.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:
$ mkdir <installation_directory>

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

### NOTE

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

### IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

#### 10.1.8.1. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: s390x
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: s390x
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE
Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the `hyperthreading` parameter has no effect.

IMPORTANT
If you disable `hyperthreading`, whether in the BIOS or in the `install-config.yaml`, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set the value of the `replicas` parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE
Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 ($2^{32} - 2^{23} - 2$) pod IP addresses. If you require more, you must provide enough space to cover the need for external networks.
pod IP’s addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

11. The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

12. You must set the platform to none. You cannot provide additional platform configuration variables for IBM Z infrastructure.

**WARNING**

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to none, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

13. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

14. The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15. The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
10.1.9. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**
The `Proxy` object’s `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object’s `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
     ...
   
   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations.
   4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to...
reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 10.1.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**
1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

```
├── auth
│   ├── kubeadm-password
│   └── kubectlconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```
10.1.11. Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines

Before you install a cluster on IBM Z infrastructure that you provision, you must install RHCOS as Red Hat Enterprise Linux (RHEL) guest virtual machines for the cluster to use. Complete the following steps to create the machines in a fast-track installation of Red Hat Enterprise Linux CoreOS (RHCOS), importing a prepackaged Red Hat Enterprise Linux CoreOS (RHCOS) QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least one LPAR running RHEL 8.4 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- A DHCP server that provides IP addresses.

Procedure

1. Obtain the RHEL QEMU copy-on-write (QCOW2) disk image file from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   IMPORTANT

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

2. Download the QCOW2 disk image and Ignition files to a common directory on the RHEL KVM host.
   For example: /var/lib/libvirt/images

   NOTE

   The Ignition files are generated by the OpenShift Container Platform installer.

3. Create a new disk image with the QCOW2 disk image backing file for each KVM guest node.

   $ qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/{source_rhcos_qemu} /var/lib/libvirt/images/{vmname}.qcow2 {size}

4. Create the new KVM guest nodes using the Ignition file and the new disk image.

   $ virt-install --noautoconsole \
      --connect qemu:///system \
      --name {vn_name} \
      --memory {memory} \
      --vcpus {vcpus} \
      --disk {disk} \
      --import \
      --network network={network},mac={mac} \

10.1.12. Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines

Before you install a cluster on IBM Z infrastructure that you provision, you must install RHCOS as Red Hat Enterprise Linux (RHEL) guest virtual machines for the cluster to use. Complete the following steps to create the machines in a full installation on a new QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- An HTTP or HTTPS server is set up.

Procedure

1. Obtain the RHEL kernel, initramfs, and rootfs files from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   IMPORTANT

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure. The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - kernel: rhcos-<version>-live-kernel-<architecture>
   - initramfs: rhcos-<version>-live-initramfs.<architecture>.img
   - rootfs: rhcos-<version>-live-rootfs.<architecture>.img

2. Move the downloaded RHEL live kernel, initramfs, and rootfs as well as the Ignition files to an HTTP or HTTPS server before you launch virt-install.

   NOTE

   The Ignition files are generated by the OpenShift Container Platform installer.

3. Create the new KVM guest nodes using the RHEL kernel, initramfs, and Ignition files, the new disk image, and adjusted parm line arguments.

   - For --location, specify the location of the kernel/initrd on the HTTP or HTTPS server.
For `coreos.inst.ignition_url=`, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

For `coreos.live.rootfs_url=`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

```bash
$ virt-install \
  --connect qemu:///system \
  --name {vn_name} \
  --vcpus {vcpus} \
  --memory {memory_mb} \
  --disk {vn_name}.qcow2,size={image_size| default(10,true)} \
  --network network={virt_network_parm} \
  --boot hd \
  --location {media_location},kernel={rhcos_kernel},initrd={rhcos_initrd} \
  --extra-args "rd.neednet=1 dfltcc=off coreos.inst=yes coreos.inst.install_dev=vda \
  coreos.live.rootfs_url={rhcos_liveos} ip={ip}::{default_gateway}:{subnet_mask_length}:: \
  {vn_name}:enc1:none;{MTU} nameserver={dns} coreos.inst.ignition_url={rhcos_ign}" \
  --noautoconsole \
  --wait
```

**NOTE**

*dfltcc=off* is required for IBM z15 and LinuxONE III.

### 10.1.13. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

**Procedure**

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \
   --log-level=info
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`. 

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \
   --log-level=info
   ```
10.1.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   system:admin

10.1.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.
Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
OpenShift Container Platform 4.7 Installing

NOTE
For clusters running on platforms that are not machine API enabled, such as bare
metal and other user-provisioned infrastructure, you must implement a method
of automatically approving the kubelet serving certificate requests (CSRs). If a
request is not approved, then the oc exec, oc rsh, and oc logs commands
cannot succeed, because a serving certificate is required when the API server
connects to the kubelet. Any operation that contacts the Kubelet endpoint
requires this certificate approval to be in place. The method must watch for new
CSRs, confirm that the CSR was submitted by the node-bootstrapper service
account in the system:node or system:admin groups, and confirm the identity
of the node.
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

NOTE
Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

1418

<csr_name> is the name of a CSR from the list of current CSRs.


To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template=’{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}’ | xargs oc adm certificate approve
```

After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME     STATUS   ROLES     AGE   VERSION
master-0 Ready   master  73m   v1.20.0
master-1 Ready   master  73m   v1.20.0
master-2 Ready   master  74m   v1.20.0
worker-0 Ready   worker  11m   v1.20.0
worker-1 Ready   worker  11m   v1.20.0
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see **Certificate Signing Requests**.

### 10.1.16. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

```
NAME        VERSION AVAILABLE PROGRESSING DEGRADED SINCE
authentication 4.7.0  True False False 3h56m
baremetal 4.7.0  True False False 29h
cloud-credential 4.7.0  True False False 29h
cluster-autoscaler 4.7.0  True False False 29h
config-operator 4.7.0  True False False 6h39m
```
2. Configure the Operators that are not available.

10.1.16.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

10.1.16.1.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on IBM Z.
- Persistent storage provisioned for your cluster.
IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imagerepository.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim:
   
   Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

   ```
   $ oc get clusteroperator image-registry
   
   Example output
5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

  ```bash
  $ oc edit configs.imageregistry/cluster
  ```

  Then, change the line

  ```plaintext
  managementState: Removed
  ```

  to

  ```plaintext
  managementState: Managed
  ```

10.1.16.12. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  "{storage":{"emptyDir":{}}}'}
  ```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```plaintext
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

10.1.17. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**
Your control plane has initialized.
You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>Running 1</td>
<td></td>
<td>9m</td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>3m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>1m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>2m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>Running 0</td>
<td></td>
<td>5m</td>
<td></td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.
If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.

   a. All the worker nodes are restarted. To monitor the process, enter the following command:

   ```
   $ oc get nodes -w
   ```

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

10.1.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

10.1.19. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

**Prerequisites**

- The oc CLI tool installed.

**Procedure**

1. Log in to the cluster:

   ```
   $ oc login -u <username>
   ```

2. On the node you want to gather hardware information about, start a debugging container:

   ```
   $ oc debug node/<nodename>
   ```

3. Change to the /host file system and start **toolbox**: 

   ```
   $ oc get nodes -w
   ```
$ chroot /host
$ toolbox

4. Collect the `dbginfo` data:

$ dbginfo.sh

5. You can then retrieve the data, for example, using `scp`.

Additional resources

- See also [How to generate SOSREPORT within OpenShift4 nodes without SSH](#).

### 10.1.20. Next steps

- Customize your cluster.
- If necessary, you can [opt out of remote health reporting](#).

## 10.2. INSTALLING A CLUSTER WITH RHEL KVM ON IBM Z AND LINUXONE IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.7, you can install a cluster on IBM Z and LinuxONE infrastructure that you provision in a restricted network.

**NOTE**

While this document refers to only IBM Z, all information in it also applies to LinuxONE.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

### 10.2.1. Prerequisites

- Create a registry on your mirror host and obtain the `imageContentSources` data for your version of OpenShift Container Platform.
- Move or remove any existing installation files, before you begin the installation process. This ensures that the required installation files are created and updated during the installation process.

**IMPORTANT**

Ensure that installation steps are done from a machine with access to the installation media.

- You provisioned [persistent storage using NFS](#) for your cluster. To deploy a private image registry, you must set up persistent storage with `ReadWriteMany` access.
Review details about the OpenShift Container Platform installation and update processes.

If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

You provisioned a RHEL Kernel Virtual Machine (KVM) system that is hosted on the logical partition (LPAR) and based on RHEL 8.4 or later.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 10.2.2. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

### 10.2.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

### 10.2.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

One or more KVM host machines based on RHEL 8.4 or later. Each RHEL KVM host machine must have libvirt installed and running. The virtual machines are provisioned under each RHEL KVM host machine.

#### 10.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following nodes:
One temporary bootstrap machine

Three control plane, or master, machines

At least two compute machines, which are also known as worker machines

**NOTE**

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different RHEL instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

See *Red Hat Enterprise Linux technology capabilities and limits*.

### 10.2.3.2. Network connectivity requirements

The OpenShift Container Platform installer creates the Ignition files, which are necessary for all the Red Hat Enterprise Linux CoreOS (RHCOS) virtual machines. The automated installation of OpenShift Container Platform is performed by the bootstrap machine. It starts the installation of OpenShift Container Platform on each node, starts the Kubernetes cluster, and then finishes. During this bootstrap, the virtual machine must have an established network connection either through a Dynamic Host Configuration Protocol (DHCP) server or static IP address.

### 10.2.3.3. IBM Z network connectivity requirements

To install on IBM Z under RHEL KVM, you need:

- A RHEL KVM host configured with an OSA or RoCE network adapter.

- Either a RHEL KVM host that is configured to use bridged networking in libvirt or MacVTap to connect the network to the guests.

  See *Types of virtual network connections*.

### 10.2.3.4. Host machine resource requirements

The RHEL KVM host in your environment must meet the following requirements to host the virtual machines that you plan for the OpenShift Container Platform environment. See *Getting started with virtualization*.

You can install OpenShift Container Platform version 4.7 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s

- LinuxONE, any version

### 10.2.3.5. Minimum IBM Z system environment
Hardware requirements

- The equivalent of six IFLs, which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

**NOTE**

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

**IMPORTANT**

Since the overall performance of the cluster can be impacted, the LPARs that are used to setup the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One LPAR running RHEL 8.4 or later with KVM, which is managed by libvirt

On your RHEL KVM host, set up:

- Three guest virtual machines for OpenShift Container Platform control plane machines
- Two guest virtual machines for OpenShift Container Platform compute machines
- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

### 10.2.3.6. Minimum resource requirements

Each cluster virtual machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

[^1]: One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

### 10.2.3.7. Preferred IBM Z system environment

Hardware requirements
Three LPARS that each have the equivalent of six IFLs, which are SMT2 enabled, for each cluster.

Two network connections to connect to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

Operating system requirements

- For high availability, two or three LPARs running RHEL 8.4 or later with KVM, which are managed by libvirt.

On your RHEL KVM host, set up:

- Three guest virtual machines for OpenShift Container Platform control plane machines, distributed across the RHEL KVM host machines.

- At least six guest virtual machines for OpenShift Container Platform compute machines, distributed across the RHEL KVM host machines.

- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.

- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using cpu_shares. Do the same for infrastructure nodes, if they exist. See schedinfo in IBM Documentation.

10.2.3.8. Preferred resource requirements

The preferred requirements for each cluster virtual machine are:

<table>
<thead>
<tr>
<th>Virtual Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>8</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>6</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

10.2.3.9. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

10.2.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:
Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

Access Quay.io to obtain the packages that are required to install your cluster.

Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

Additional resources

- Recommended host practices for IBM Z & LinuxONE environments

### 10.2.5. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

**Prerequisites**

- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the supporting infrastructure for your cluster.

**Procedure**

1. Set up static IP addresses.

2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.

3. Choose to perform either a fast track installation of Red Hat Enterprise Linux CoreOS (RHCOS) or a full installation of Red Hat Enterprise Linux CoreOS (RHCOS). For the full installation you must set up an HTTP or HTTPS server to provide Ignition files and install images to the cluster nodes. For the fast track installation an HTTP or HTTPS server is not required, however, a DHCP server is required. See sections "Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines" and "Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines".

4. Provision the required load balancers.

5. Configure the ports for your machines.

6. Configure DNS.

7. Ensure network connectivity.

### 10.2.5.1. Networking requirements for user-provisioned infrastructure
All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in *initramfs* during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

**Table 10.7. All machines to all machines**

</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6443</td>
<td>Kubernetes API</td>
</tr>
</tbody>
</table>

**Table 10.9. Control plane machines to control plane machines**
Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**
OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 10.10. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

**Additional resources**

- Configuring chrony time service
10.2.5.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

Table 10.12. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

TIP

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

**Example 10.3. Sample DNS zone database**

```bash
$TTL 1W

**10.2.6. Generating an SSH private key and adding it to the agent**

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.
Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "\n   -f <path>/<file_name>
   ```
   
   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.
10.2.7. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

10.2.7.1. Sample install-config.yaml file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: s390x
controlPlane:
```

1 2 3 4 5
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading (SMT), or **hyperthreading**. By default, SMT is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

**IMPORTANT**

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml**, ensure that your capacity planning accounts for the dramatically decreased machine performance.
You must set the value of the `replicas` parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

**NOTE**

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 ($2^{32 - 23} - 2$) pod IPs addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to `none`. You cannot provide additional platform configuration variables for IBM Z infrastructure.

**WARNING**

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to `none`, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

For <local_registry>, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, registry.example.com or registry.example.com:5000. For <credentials>, specify the base64-encoded user name and password for your mirror registry.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

Add the additionalTrustBundle parameter and value. The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

Provide the imageContentSources section from the output of the command to mirror the repository.

10.2.7.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).
Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
  additionalTrustBundle:
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**
The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

10.2.8. Creating the Kubernetes manifest and Ignition config files
Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the mastersSchedulable parameter in the
   `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the mastersSchedulable parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory> 1
```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   ```
   ├── auth
   │    └── kubeadmin-password
   │          └── kubectlconfig
   │    └── bootstrap.ign
   │    └── master.ign
   │    └── metadata.json
   │    └── worker.ign
   ```

10.2.9. Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines

Before you install a cluster on IBM Z infrastructure that you provision, you must install RHCOS as Red Hat Enterprise Linux (RHEL) guest virtual machines for the cluster to use. Complete the following steps to create the machines in a fast-track installation of Red Hat Enterprise Linux CoreOS (RHCOS), importing a prepackaged Red Hat Enterprise Linux CoreOS (RHCOS) QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least one LPAR running RHEL 8.4 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- A DHCP server that provides IP addresses.
Procedure

1. Obtain the RHEL QEMU copy-on-write (QCOW2) disk image file from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

2. Download the QCOW2 disk image and Ignition files to a common directory on the RHEL KVM host.
   For example: /var/lib/libvirt/images

**NOTE**

The Ignition files are generated by the OpenShift Container Platform installer.

3. Create a new disk image with the QCOW2 disk image backing file for each KVM guest node.

   ```bash
   $ qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/{source_rhcos_qemu}
   /var/lib/libvirt/images/{vmname}.qcow2 {size}
   ```

4. Create the new KVM guest nodes using the Ignition file and the new disk image.

   ```bash
   $ virt-install --noautoconsole \
   --connect qemu:///system \
   --name {vn_name} \
   --memory {memory} \
   --vcpus {vcpus} \
   --disk {disk} \
   --import \
   --network network={network},mac={mac} \
   --qemu-commandline="-drive \ 
   if=none,id=ignition,format=raw,file={ign_file},readonly=on -device virtio-block,serial=ignition,drive=ignition"
   ```

10.2.10. Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines

Before you install a cluster on IBM Z infrastructure that you provision, you must install RHCOS as Red Hat Enterprise Linux (RHEL) guest virtual machines for the cluster to use. Complete the following steps to create the machines in a full installation on a new QEMU copy-on-write (QCOW2) disk image.

**Prerequisites**

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
An HTTP or HTTPS server is set up.

Procedure

1. Obtain the RHEL kernel, initramfs, and rootfs files from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   IMPORTANT
   
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - kernel: rhcos-<version>-live-kernel-<architecture>
   - initramfs: rhcos-<version>-live-initramfs.<architecture>.img
   - rootfs: rhcos-<version>-live-rootfs.<architecture>.img

2. Move the downloaded RHEL live kernel, initramfs, and rootfs as well as the Ignition files to an HTTP or HTTPS server before you launch virt-install.

   NOTE
   
   The Ignition files are generated by the OpenShift Container Platform installer.

3. Create the new KVM guest nodes using the RHEL kernel, initramfs, and Ignition files, the new disk image, and adjusted parm line arguments.

   - For --location, specify the location of the kernel/initrd on the HTTP or HTTPS server.

   - For coreos.inst.ignition_url=, specify the Ignition file for the machine role. Use bootstrap.ign, master.ign, or worker.ign. Only HTTP and HTTPS protocols are supported.

   - For coreos.live.rootfs_url=, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

   ```bash
   $ virt-install
   --connect qemu:///system
   --name {vn_name}
   --vcpus {vcpus}
   --memory {memory_mb}
   --disk {vn_name}.qcow2,size={image_size|default(10,true)}
   --network network={virt_network_parm}
   --boot hd
   --location {media_location},kernel={rhcos_kernel},initrd={rhcos_initrd}
   --extra-args "rd.neednet=1 dfltc=off coreos.inst=yes coreos.inst.install_dev=vda
   coreos.live.rootfs_url={rhcos_liveos} ip={ip}::{default_gateway}:{subnet_mask_length}:
   {vn_name}:enc1:none:{MTU} nameserver={dns} coreos.inst.ignition_url={rhcos_ign}"
   --noautoconsole
   --wait
   ```
NOTE

dfltc=off is required for IBM z15 and LinuxONE III.

10.2.11. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info
   
   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   
   2 To view different installation details, specify warn, debug, or error instead of info.
   
   Example output
   
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.20.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   
   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.
   
2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**
   
   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.

10.2.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the
correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

10.2.13. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.
The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```bash
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

$ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  $ oc adm certificate approve <csr_name> 1

  - **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

$ oc get nodes

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

10.2.14. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>

2. Configure the Operators that are not available.

### 10.2.14.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the OperatorHub object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  
  **TIP**

  Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

### 10.2.14.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

#### 10.2.14.2.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on IBM Z.
- Persistent storage provisioned for your cluster.
IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

    **NOTE**

    When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

    ```
    $ oc get pod -n openshift-image-registry -l docker-registry=default
    ``

    **Example output**

    No resources found in openshift-image-registry namespace

    **NOTE**

    If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

    ```
    $ oc edit configs.imagerepository.operator.openshift.io
    ``

    **Example output**

    ```
    storage:
    pvc:
    claim:
    Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.
    ```

4. Check the **clusteroperator** status:

    ```
    $ oc get clusteroperator image-registry
    ``

    **Example output**
5. Ensure that your registry is set to managed to enable building and pushing of images.
   
   - Run:
     
     ```bash
     $ oc edit configs.imageregistry/cluster
     
     Then, change the line
     
     managementState: Removed
     
     to
     
     managementState: Managed
     
   10.2.14.2.2. Configuring storage for the image registry in non-production clusters

   You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

   Procedure
   
   - To set the image registry storage to an empty directory:
     
     ```bash
     $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'
     
     WARNING
     Configure this option for only non-production clusters.

     If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

     ```bash
     Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
     ```

     Wait a few minutes and run the command again.

   10.2.15. Completing installation on user-provisioned infrastructure

   After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

   Prerequisites
• Your control plane has initialized.
• You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```bash
$ watch -n5 oc get clusteroperators
```

Example output

```

</tr>
</tbody>
</table>
```

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> 1
```

Specify the pod name and namespace, as shown in the output of the previous command.
If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.

   a. All the worker nodes are restarted. To monitor the process, enter the following command:

   ```bash
   $ oc get nodes -w
   ```

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

10.2.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

10.2.17. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

**Prerequisites**

- The oc CLI tool installed.

**Procedure**

1. Log in to the cluster:

   ```bash
   $ oc login -u <username>
   ```

2. On the node you want to gather hardware information about, start a debugging container:

   ```bash
   $ oc debug node/<nodename>
   ```

3. Change to the /host file system and start toolbox:
$ chroot /host
$ toolbox

4. Collect the **dbginfo** data:

   $ dbginfo.sh

5. You can then retrieve the data, for example, using **scp**.

**Additional resources**

- How to generate SOSREPORT within OpenShift Container Platform version 4 nodes without SSH.

**10.2.18. Next steps**

- Customize your cluster.

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
CHAPTER 11. INSTALLING ON IBM POWER SYSTEMS

11.1. INSTALLING A CLUSTER ON IBM POWER SYSTEMS

In OpenShift Container Platform version 4.7, you can install a cluster on IBM Power Systems infrastructure that you provision.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

Prerequisites

- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- Provision persistent storage using NFS for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

11.1.1. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.
11.1.2. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

11.1.2.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.

**NOTE**

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

11.1.2.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in *initramfs* during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

11.1.2.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

11.1.2.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

**Table 11.1. Minimum resource requirements**

---

1461
<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>IOPS</th>
</tr>
</thead>
<tbody>
<tr>

<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

### 11.1.2.5. Minimum IBM Power Systems requirements

You can install OpenShift Container Platform version 4.7 on the following IBM hardware:

- IBM POWER8 or POWER9 processor-based systems

#### Hardware requirements

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

#### Operating system requirements

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

#### Disk storage for the IBM Power guest virtual machines

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

#### Network for the PowerVM guest virtual machines

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM vNIC

#### Storage / main memory

- 100 GB / 16 GB for OpenShift Container Platform control plane machines
- 100 GB / 8 GB for OpenShift Container Platform compute machines
- 100 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine
Hardware requirements
- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

Operating system requirements
- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:
- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

Disk storage for the IBM Power guest virtual machines
- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines
- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM vNIC

Storage / main memory
- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

11.1.2.7. Certificate signing requests management
Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

11.1.3. Creating the user-provisioned infrastructure
Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

Prerequisites
- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the supporting infrastructure for your cluster.

Procedure
1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

### 11.1.3.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in *initramfs* during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

Network topology requirements

The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 11.5. API load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You</td>

<td>machine initializes the cluster control plane. You must configure the</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>/readyz endpoint for the API server</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>health check probe.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
<tr>
<td></td>
<td>remove the bootstrap machine from</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>the load balancer after the bootstrap</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>machine initializes the cluster control plane.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

**Table 11.6. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td></td>
<td>router pods, compute, or worker, by default.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
<tr>
<td></td>
<td>router pods, compute, or worker, by default.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
TIP
If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

NOTE
A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

NTP configuration
OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

Additional resources
- Configuring chrony time service

11.1.3.2. User-provisioned DNS requirements
DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

**Table 11.7. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</strong></td>
<td></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td><strong>Routes</strong></td>
<td><em>.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</em>*</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td><strong>Bootstrap</strong></td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td><strong>Master hosts</strong></td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td><strong>Worker hosts</strong></td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

---

**Example 11.1. Sample DNS zone database**
The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 11.2. Sample DNS zone database for reverse records

```

The syntax is "last octet" and the host must have an FQDN with a trailing dot.
97 IN PTR master0.ocp4.example.com.
11.4. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user's `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.
NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the **ssh-agent** process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

**Example output**

   ```
   Agent pid 31874
   ```

**NOTE**
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the **ssh-agent**:

   ```
   $ ssh-add <path>/<file_name>
   ```

**Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**11.1.5. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 11.1.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of **oc**.

#### 11.1.6.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 Linux Client** entry and save the file.

4. Unpack the archive:
5. Place the **oc** binary in a directory that is on your **PATH**. To check your **PATH**, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### 11.1.6.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**. To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### 11.1.6.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your **PATH**. To check your **PATH**, open a terminal and execute the following command:

```
$ tar xvzf <file>
$ echo $PATH
$ oc <command>
```

```
C:\> path
C:\> oc <command>
```
After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

11.1.7. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

11.1.7.1. Sample `install-config.yaml` file for IBM Z

11.1.7.2. Sample `install-config.yaml` file for IBM Power Systems

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: ppc64le
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: ppc64le
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
  platform:
    none: {}
  fips: false
  pullSecret: '{"auths": ...}'
  sshKey: 'ssh-ed25519 AAAA…'

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2-5. The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

3-6. Whether to enable or disable simultaneous multithreading (SMT), or **hyperthreading**. By default, SMT is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

**IMPORTANT**

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml**, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4. You must set the value of the **replicas** parameter to 0. This parameter controls the number of
7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines.

8 The cluster name that you specified in your DNS records.

9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

**NOTE**

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

10 The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \(2^{32 - 23} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

12 You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z infrastructure. IBM Power Systems infrastructure.

**WARNING**

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

13 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

11.1.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster` Proxy object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 11.1.8. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.
IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on ppc64le only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>  1
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

   **WARNING**

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
### IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │                     kubeconfig
   │      bootstraps.ign
   │      master.ign
   │      metadata.json
   └── worker.ign
   ```

### 11.1.9. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines

Before you install a cluster on IBM Power Systems infrastructure that you provision, you must create RHCOS machines for it to use. Follow either the steps to use an ISO image or network PXE booting to create the machines.

#### 11.1.9.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image

Before you install a cluster on IBM Power Systems infrastructure that you provision, you must create RHCOS machines for it to use. You can use an ISO image to create the machines.

**Prerequisites**

- Obtain the Ignition config files for your cluster.
- Have access to an HTTP server that can be accessed from your computer, and from the machines that you create.
Procedure

1. Upload the control plane, compute, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

   ISO file names resemble the following example:

   ```
   rhcos-<version>-live.<architecture>.iso
   ```

3. Use the ISO to start the RHCOS installation. Use one of the following installation options:
   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection via a LOM interface.

4. Boot the ISO image. You can interrupt the installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command instead of adding kernel arguments. If you run the live installer without options or interruption, the installer boots up to a shell prompt on the live system, ready for you to install RHCOS to disk.

5. Review the [Advanced RHCOS installation reference](#) section for different ways of configuring features, such as networking and disk partitions, before running the `coreos-installer`.

6. Run the `coreos-installer` command. At a minimum, you must identify the Ignition config file location for your node type, and the location of the disk you are installing to. Here is an example:

   ```
   $ sudo coreos-installer install \
   --ignition-url=https://host/worker.ign /dev/sda
   ```

7. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

8. Continue to create the other machines for your cluster.
11.1.9.1.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

**Routing and bonding options at RHCOS boot prompt**

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node's networking. If no networking arguments are used, the installation defaults to using DHCP.

**IMPORTANT**

When adding networking arguments, you must also add the `rd.neednet=1` kernel argument.

The following table describes how to use `ip=`, `nameserver=`, and `bond=` kernel arguments for live ISO installs.

**NOTE**

Ordering is important when adding kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

**Routing and bonding options for ISO**

The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.
### Description

To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). Then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:

- The node’s IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The hostname to **core0.example.com**
- The DNS server address to **4.4.4.41**

### Examples

| ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none |
| nameserver=4.4.4.41 |

### Examples

Specify multiple network interfaces by specifying multiple ip= entries.

| ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none |
| ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none |

### Optional: You can configure routes to additional networks by setting an rd.route= value.

If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

To configure the default gateway:

| ip=::10.10.10.254::: |

To configure the route for the additional network:

| rd.route=20.20.20.0/24:20.20.20.254:enp2s0 |

### Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used.

| ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none |
| ip=:::core0.example.com:enp2s0:none |

### You can combine DHCP and static IP configurations on systems with multiple network interfaces.

<p>| ip=enp1s0:dhcp |
| ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none |</p>
<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional: You can configure VLANs on individual interfaces by using the <code>vlan=</code> parameter.</td>
<td>To configure a VLAN on a network interface and use a static IP address:</td>
</tr>
<tr>
<td></td>
<td>ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none vlan=enp2s0.100:enp2s0</td>
</tr>
<tr>
<td></td>
<td>To configure a VLAN on a network interface and to use DHCP:</td>
</tr>
<tr>
<td></td>
<td>ip=enp2s0.100:dhcp vlan=enp2s0.100:enp2s0</td>
</tr>
<tr>
<td>You can provide multiple DNS servers by adding a <code>nameserver=</code> entry for each server.</td>
<td>nameserver=1.1.1.1 nameserver=8.8.8.8</td>
</tr>
<tr>
<td>Optional: Bonding multiple network interfaces to a single interface is supported using the <code>bond=</code> option. In these two examples:</td>
<td>To configure the bonded interface to use DHCP, set the bond’s IP address to <code>dhcp</code>. For example:</td>
</tr>
<tr>
<td></td>
<td>bond=bond0:em1,em2:mode=active-backup ip=bond0:dhcp</td>
</tr>
<tr>
<td></td>
<td>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</td>
</tr>
<tr>
<td></td>
<td>bond=bond0:em1,em2:mode=active-backup ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:bond0:none</td>
</tr>
</tbody>
</table>

- The syntax for configuring a bonded interface is: `bond=name[::network_interfaces] [::options]`
  - `name` is the bonding device name (`bond0`), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.
  - When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

```bash
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup_vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use DHCP:

```bash
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup_vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:

```bash
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup_vlan=bond0.100:bond0
```

Optional: Network teaming can be used as an alternative to bonding by using the `team=` parameter. In this example:

- The syntax for configuring a team interface is: `team=name:[network_interfaces]`
  - `name` is the team device name (team0) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1`, `em2`).

**NOTE**

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

### 11.1.9.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting

Before you install a cluster that uses manually-provisioned RHCOS nodes, such as bare metal, you must create RHCOS machines for it to use. You can use PXE or iPXE booting to create the machines.

**Prerequisites**

- Obtain the Ignition config files for your cluster.
- Configure suitable PXE or iPXE infrastructure.
- Have access to an HTTP server that you can access from your computer.

**Procedure**
1. Upload the master, worker, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

**IMPORTANT**

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS qcow2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

3. Upload the additional files that are required for your booting method:

- For traditional PXE, upload the **kernel** and **initramfs** files to your TFTP server and the **rootfs** file to your HTTP server.
- For iPXE, upload the **kernel**, **initramfs**, and **rootfs** files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

4. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

5. Configure PXE or iPXE installation for the RHCOS images.

Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
```
KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign

1 Specify the location of the live kernel file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2 If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3 Specify locations of the RHCOS files that you uploaded to your HTTP server. The initrd parameter value is the location of the initramfs file, the coreos.live.rootsfs_url parameter value is the location of the rootsfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the APPEND line to configure networking or other boot options.

NOTE
This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more console= arguments to the APPEND line. For example, add console=tty0 console=ttyS0 to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?.

For iPXE:

kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
<architecture>.img

1 Specify locations of the RHCOS files that you uploaded to your HTTP server. The kernel parameter value is the location of the kernel file, the initrd=main argument is needed for booting on UEFI systems, the coreos.live.rootsfs_url parameter value is the location of the rootsfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file.

2 If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3 Specify the location of the initramfs file that you uploaded to your HTTP server.
NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `kernel` line. For example, add `console=tty0` `console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?

6. If you use PXE UEFI, perform the following actions:

   a. Provide the `shimx64.efi` and `grubx64.efi` EFI binaries and the `grub.cfg` file that are required for booting the system.

      • Extract the necessary EFI binaries by mounting the RHCOS ISO to your host and then mounting the `images/efiboot.img` file to your host:

      ```
      $ mkdir -p /mnt/iso
      $ mkdir -p /mnt/efiboot
      $ mount -o loop rhcos-installer.x86_64.iso /mnt/iso
      $ mount -o loop,ro /mnt/iso/images/efiboot.img /mnt/efiboot
      
      • From the `efiboot.img` mount point, copy the `EFI/redhat/shimx64.efi` and `EFI/redhat/grubx64.efi` files to your TFTP server:

      ```
      $ cp /mnt/efiboot/EFI/redhat/shimx64.efi .
      $ cp /mnt/efiboot/EFI/redhat/grubx64.efi .
      $ umount /mnt/efiboot
      $ umount /mnt/iso
      
      • Copy the `EFI/redhat/grub.cfg` file that is included in the RHCOS ISO to your TFTP server.

   b. Edit the `grub.cfg` file to include arguments similar to the following:

      ```
      menuentry 'Install Red Hat Enterprise Linux CoreOS' --class fedora --class gnu-linux --class gnu --class os {
      linuxefi rhcos=<version>-live-kernel=<architecture> coreos.inst.install_dev=/dev/sda
      <architecture>.img coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
      initrdelf rhcos=<version>-live-initramfs.<architecture>.img
      }
      ```

      where:
rhcos-<version>-live-kernel-<architecture>
  Specifies the kernel file that you uploaded to your TFTP server.

http://<HTTP_server>/rhcos-<version>-live-rootfs.<architecture>.img
  Specifies the location of the live rootfs image that you uploaded to your HTTP server.

http://<HTTP_server>/bootstrap.ign
  Specifies the location of the bootstrap Ignition config file that you uploaded to your HTTP server.

rhcos-<version>-live-initramfs.<architecture>.img
  Specifies the location of the initramfs file that you uploaded to your TFTP server.

NOTE
For more information on how to configure a PXE server for UEFI boot, see the Red Hat Knowledgebase article: How to configure/setup a PXE server for UEFI boot for Red Hat Enterprise Linux?

7. Continue to create the machines for your cluster.

IMPORTANT
You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

11.1.10. Creating the cluster
To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites
- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure
1. Monitor the bootstrap process:

```bash
$ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
  --log-level=info
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`. 
1.1.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

11.1.12. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.
Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ``

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ``

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
OpenShift Container Platform 4.7 Installing

NOTE
For clusters running on platforms that are not machine API enabled, such as bare
metal and other user-provisioned infrastructure, you must implement a method
of automatically approving the kubelet serving certificate requests (CSRs). If a
request is not approved, then the oc exec, oc rsh, and oc logs commands
cannot succeed, because a serving certificate is required when the API server
connects to the kubelet. Any operation that contacts the Kubelet endpoint
requires this certificate approval to be in place. The method must watch for new
CSRs, confirm that the CSR was submitted by the node-bootstrapper service
account in the system:node or system:admin groups, and confirm the identity
of the node.
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

NOTE
Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

1492

<csr_name> is the name of a CSR from the list of current CSRs.


To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the `Ready` status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  73m  v1.20.0
master-1  Ready     master  73m  v1.20.0
master-2  Ready     master  74m  v1.20.0
worker-0  Ready     worker  11m  v1.20.0
worker-1  Ready     worker  11m  v1.20.0
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the `Ready` status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 11.1.13. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

```
NAME                                       VERSION AVAILABLE PROGRESSING DEGRADED SINCE
authentication                             4.7.0   True    False    False  3h56m
baremetal                                  4.7.0   True    False    False  29h
cloud-credential                           4.7.0   True    False    False  29h
cluster-autoscaler                         4.7.0   True    False    False  29h
config-operator                            4.7.0   True    False    False  6h39m
```
2. Configure the Operators that are not available.

11.1.13.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

11.1.13.1.1. Configuring registry storage for IBM Z

11.1.13.1.2. Configuring registry storage for IBM Power Systems

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on IBM Z. on IBM Power Systems.
- Persistent storage provisioned for your cluster.
IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   Example output
   No resources found in openshift-image-registry namespace
   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   Example output
   storage:
   pvc:
   claim:
   Leave the `claim` field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

   ```
   $ oc get clusteroperator image-registry
   Example output
   ```
5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

  ```bash
  $ oc edit configs.imageregistry/cluster
  
  Then, change the line
  
  managementState: Removed
  
  to
  
  managementState: Managed
  ```

### 11.1.13.13. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {
  "storage":{"emptyDir":{}}}}'
  ```

  **WARNING**

  Configure this option for only non-production clusters.

  If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  ```
  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
  ```

  Wait a few minutes and run the command again.

### 11.1.14. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**
- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

</tbody>
</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```shell
   $ oc get pods --all-namespaces
   ```

   **Example output**

   ```
   NAMESPACE                         NAME                                            READY   STATUS
   RESTARTS   AGE
   openshift-apiserver-operator      openshift-apiserver-operator-85cb746d-55-zqhs8   1/1     Running     0
                              Running     1          9m
   openshift-apiserver               apiserver-67b9g                                 1/1     Running     0
                              3m
   openshift-apiserver               apiserver-ljcmx                                 1/1     Running     0
                              1m
   openshift-apiserver               apiserver-z25h4                                 1/1     Running     0
                              2m
   openshift-authentication-operator authentication-operator-69d5d8bf84-vh2n8     1/1     Running     0
                              Running     0          5m
   ...
   ```

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```shell
   $ oc logs <pod_name> -n <namespace>
   ```

   **Example output**

   ```
   OpenShift Container Platform 4.7 Installing
   INFO Waiting up to 30m0s for the cluster to initialize...
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.
If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.

a. To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

   ```
   $ bootlist -m normal -o sda
   ```

b. To update the boot list for normal mode and add alternate device names, enter the following command:

   ```
   $ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
   ```

   If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

c. All the worker nodes are restarted. To monitor the process, enter the following command:

   ```
   $ oc get nodes -w
   ```

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

11.1.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

11.1.16. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
11.2. INSTALLING A CLUSTER ON IBM POWER SYSTEMS IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.7, you can install a cluster on IBM Power Systems infrastructure that you provision in a restricted network.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

Prerequisites

- Create a mirror registry for installation in a restricted network and obtain the `imageContentSources` data for your version of OpenShift Container Platform.

- Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

**IMPORTANT**

Ensure that installation steps are performed on a machine with access to the installation media.

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide `ReadWriteMany` access modes.

- Review details about the [OpenShift Container Platform installation and update](#) processes.

- If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

11.2.1. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.
IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

11.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an *Unable to retrieve available updates* error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

11.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

11.2.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

11.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.
NOTE

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

11.2.3.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

11.2.3.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

11.2.3.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Table 11.8. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>

<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

11.2.3.5. Minimum IBM Power Systems requirements
You can install OpenShift Container Platform version 4.7 on the following IBM hardware:

- IBM POWER8 or POWER9 processor-based systems

**Hardware requirements**

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

**Operating system requirements**

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

**Disk storage for the IBM Power guest virtual machines**

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM vNIC

**Storage / main memory**

- 100 GB / 16 GB for OpenShift Container Platform control plane machines
- 100 GB / 8 GB for OpenShift Container Platform compute machines
- 100 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

11.2.3.6. Recommended IBM Power system requirements

**Hardware requirements**

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

**Operating system requirements**

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

**Disk storage for the IBM Power guest virtual machines**
- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines
- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM vNIC

Storage / main memory
- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

11.2.3.7. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

11.2.4. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

Prerequisites
- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the supporting infrastructure for your cluster.

Procedure
1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

11.2.4.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.
During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   Do not configure session persistence for an API load balancer.

   Configure the following ports on both the front and back of the load balancers:

   **Table 11.12. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

   **NOTE**
   The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:
- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

### Table 11.13. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

**Additional resources**

- Configuring chrony time service

**11.2.4.2. User-provisioned DNS requirements**

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.-<cluster_name>.-<base_domain>.-.`
Table 11.14. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.
Example 11.3. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (
  2019070700 ; serial
  3H ; refresh (3 hours)
  30M ; retry (30 minutes)
  2W ; expiry (2 weeks)
  1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
;
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
;
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5
;
apps.ocp4 IN A 192.168.1.5
;
bootstrap.ocp4 IN A 192.168.1.96
;
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
master2.ocp4 IN A 192.168.1.99
;
worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.7
;
;EOF
```

The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 11.4. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (
  2019070700 ; serial
  3H ; refresh (3 hours)
  30M ; retry (30 minutes)
  2W ; expiry (2 weeks)
  1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
; The syntax is "last octet" and the host must have an FQDN
```
11.2.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "\n   -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

Running this command generates an SSH key that does not require a password in the location that you specified.
NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   $ eval "$(ssh-agent -s)"

   Example output

   Agent pid 31874

   NOTE
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> ¹

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

¹ Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

11.2.6. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following install-config.yaml file template and save it in the <installation_directory>.

NOTE

You must name this configuration file install-config.yaml.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the next step of the installation process. You must back it up now.

11.2.6.1. Sample install-config.yaml file for IBM Z

11.2.6.2. Sample install-config.yaml file for IBM Power Systems

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: ppc64le
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: ppc64le
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the hyperthreading parameter has no effect.

IMPORTANT

If you disable hyperthreading, whether in the BIOS or in the install-config.yaml, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to
manage the traffic.

**NOTE**

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to **23**, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \(2^{(32 - 23)} - 2\) pod IPs addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z infrastructure. IBM Power Systems infrastructure.

**WARNING**

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.
The public portion of the default SSH key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

Add the `additionalTrustBundle` parameter and value. The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

### 11.2.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
     noProxy: example.com
   additionalTrustBundle: |
   ```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

The installation program does not support the proxy readinessEndpoints field.

Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

Only the Proxy object named cluster is supported, and no additional proxies can be created.

11.2.7. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.
IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on ppc64le only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the install-config.yaml installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   $ ./openshift-install create manifests --dir <installation_directory>  

   For <installation_directory>, specify the installation directory that contains the install-config.yaml file you created.

   WARNING

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   ```
   ├── auth
   │   └── kubeadm-password
   │
   ├── bootstrap.ign
   │
   ├── master.ign
   │
   └── metadata.json
   ```

11.2.8. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines

Before you install a cluster on IBM Power Systems infrastructure that you provision, you must create RHCOS machines for it to use. Follow either the steps to use an ISO image or network PXE booting to create the machines.

11.2.8.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image

Before you install a cluster on IBM Power Systems infrastructure that you provision, you must create RHCOS machines for it to use. You can use an ISO image to create the machines.

Prerequisites

- Obtain the Ignition config files for your cluster.
- Have access to an HTTP server that can be accessed from your computer, and from the machines that you create.
Procedure

1. Upload the control plane, compute, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

   ISO file names resemble the following example:

   `rhcos-<version>-live.<architecture>.iso`

3. Use the ISO to start the RHCOS installation. Use one of the following installation options:
   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection via a LOM interface.

4. Boot the ISO image. You can interrupt the installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command instead of adding kernel arguments. If you run the live installer without options or interruption, the installer boots up to a shell prompt on the live system, ready for you to install RHCOS to disk.

5. Review the Advanced RHCOS installation reference section for different ways of configuring features, such as networking and disk partitions, before running the `coreos-installer`.

6. Run the `coreos-installer` command. At a minimum, you must identify the Ignition config file location for your node type, and the location of the disk you are installing to. Here is an example:

   ```bash
   $ sudo coreos-installer install \
   --ignition-url=https://host/worker.ign /dev/sda
   ```

7. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

8. Continue to create the other machines for your cluster.
IMPORTANT
You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

11.2.8.1.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the coreos-installer command.

Routing and bonding options at RHCOS boot prompt
If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node’s networking. If no networking arguments are used, the installation defaults to using DHCP.

IMPORTANT
When adding networking arguments, you must also add the rd.neednet=1 kernel argument.

The following table describes how to use ip=, nameserver=, and bond= kernel arguments for live ISO installs.

NOTE
Ordering is important when adding kernel arguments: ip=, nameserver=, and then bond=.

Routing and bonding options for ISO
The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the dracut tool during system boot. For more information about the networking options supported by dracut, see the dracut.cmdline manual page.
### Description

To configure an IP address, either use DHCP (\texttt{ip=\texttt{dhcp}}) or set an individual static IP address (\texttt{ip=\texttt{<host_ip>}}). Then identify the DNS server IP address (\texttt{nameserver=\texttt{<dns_ip>}}) on each node. This example sets:

- The node’s IP address to \texttt{10.10.10.2}
- The gateway address to \texttt{10.10.10.254}
- The netmask to \texttt{255.255.255.0}
- The hostname to \texttt{core0.example.com}
- The DNS server address to \texttt{4.4.4.41}

### Examples

\begin{itemize}
  \item \texttt{ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none}
  \item \texttt{nameserver=4.4.4.41}
\end{itemize}

Specify multiple network interfaces by specifying multiple \texttt{ip=} entries.

\begin{itemize}
  \item \texttt{ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none}
  \item \texttt{ip=10.10.10.3::10.10.254:255.255.255.0:core0.example.com:enp2s0:none}
\end{itemize}

Optional: You can configure routes to additional networks by setting an \texttt{rd.route=} value.

If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

To configure the default gateway:

\begin{itemize}
  \item \texttt{ip=:10.10.10.254:}
\end{itemize}

To configure the route for the additional network:

\begin{itemize}
  \item \texttt{rd.route=20.20.20.0/24:20.20.20.254:enp2s0}
\end{itemize}

Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used.

\begin{itemize}
  \item \texttt{ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none}
  \item \texttt{ip=:core0.example.com:enp2s0:none}
\end{itemize}

You can combine DHCP and static IP configurations on systems with multiple network interfaces.

\begin{itemize}
  \item \texttt{ip=enp1s0:dhcp}
  \item \texttt{ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0:none}
\end{itemize}

</tr>
<tr>
<td></td>
<td>To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:</td>
</tr>
<tr>
<td></td>
<td><code>bond=bond0:em1,em2:mode=active-backup</code></td>
</tr>
<tr>
<td></td>
<td><code>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none</code></td>
</tr>
</tbody>
</table>
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface with a VLAN and to use DHCP:

```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

Optional: Network teaming can be used as an alternative to bonding by using the `team=` parameter. In this example:

- The syntax for configuring a team interface is: `team=name[:network_interfaces]`
  - `name` is the team device name (`team0`) and
  - `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1, em2`).

**NOTE**

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

### 11.2.8.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting

Before you install a cluster that uses manually-provisioned RHCOS nodes, such as bare metal, you must create RHCOS machines for it to use. You can use PXE or iPXE booting to create the machines.

**Prerequisites**

- Obtain the Ignition config files for your cluster.
- Configure suitable PXE or iPXE infrastructure.
- Have access to an HTTP server that you can access from your computer.

**Procedure**
1. Upload the master, worker, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

**IMPORTANT**

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS qcow2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-%version%-live-kernel-%architecture`
- **initramfs**: `rhcos-%version%-live-initramfs.%architecture%.img`
- **rootfs**: `rhcos-%version%-live-rootfs.%architecture%.img`

3. Upload the additional files that are required for your booting method:

- For traditional PXE, upload the **kernel** and **initramfs** files to your TFTP server and the **rootfs** file to your HTTP server.
- For iPXE, upload the **kernel**, **initramfs**, and **rootfs** files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

4. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

5. Configure PXE or iPXE installation for the RHCOS images.

Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

```plaintext
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
```
KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>  1
<architecture>.img coreos.live.rootsfs_url=http://<HTTP_server>/rhcos-<version>-live-
rootsfs.<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign  2  3

1 Specify the location of the live kernel file that you uploaded to your HTTP server. The
URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2 If you use multiple NICs, specify a single interface in the ip option. For example, to use
DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3 Specify locations of the RHCOS files that you uploaded to your HTTP server. The
initrd parameter value is the location of the initramfs file, the coreos.live.rootsfs_url
parameter value is the location of the rootfs file, and the coreos.inst.ignition_url
parameter value is the location of the bootstrap Ignition config file. You can also add
more kernel arguments to the APPEND line to configure networking or other boot
options.

NOTE
This configuration does not enable serial console access on machines with a
graphical console. To configure a different console, add one or more
console= arguments to the APPEND line. For example, add console=tty0
console=ttyS0 to set the first PC serial port as the primary console and the
graphical console as a secondary console. For more information, see How
does one set up a serial terminal and/or console in Red Hat Enterprise Linux?.

• For iPXE:

kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign  1  2
<architecture>.img  3
boot

1 Specify locations of the RHCOS files that you uploaded to your HTTP server. The
kernel parameter value is the location of the kernel file, the initrd=main argument is
needed for booting on UEFI systems, the coreos.live.rootsfs_url parameter value is
the location of the rootfs file, and the coreos.inst.ignition_url parameter value is the
location of the bootstrap Ignition config file.

2 If you use multiple NICs, specify a single interface in the ip option. For example, to use
DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3 Specify the location of the initramfs file that you uploaded to your HTTP server.
NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `kernel` line. For example, add `console=tty0 console=ttys0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?.

6. If you use PXE UEFI, perform the following actions:

   a. Provide the `shimx64.efi` and `grubx64.efi` EFI binaries and the `grub.cfg` file that are required for booting the system.

      • Extract the necessary EFI binaries by mounting the RHCOS ISO to your host and then mounting the `images/efiboot.img` file to your host:

        ```
        $ mkdir -p /mnt/iso
        $ mkdir -p /mnt/efiboot
        $ mount -o loop rhcos-installer.x86_64.iso /mnt/iso
        $ mount -o loop,ro /mnt/iso/images/efiboot.img /mnt/efiboot
        ```

      • From the `efiboot.img` mount point, copy the `EFI/redhat/shimx64.efi` and `EFI/redhat/grubx64.efi` files to your TFTP server:

        ```
        $ cp /mnt/efibootEFI/redhat/shimx64.efi .
        $ cp /mnt/efibootEFI/redhat/grubx64.efi .
        $ umount /mnt/efiboot
        $ umount /mnt/iso
        ```

      • Copy the `EFI/redhat/grub.cfg` file that is included in the RHCOS ISO to your TFTP server.

   b. Edit the `grub.cfg` file to include arguments similar to the following:

        ```
        menuentry 'Install Red Hat Enterprise Linux CoreOS' --class fedora --class gnu-linux --class gnu --class os {
        linuxefi rhcos-<version>-live-kernel-<architecture> coreos.inst.install_dev=/dev/sda
        <architecture>.img coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
        initrdelfi rhcos-<version>-live-initramfs.<architecture>.img
        }
        ```

        where:
rhcos-<version>-live-kernel-<architecture>
   Specifies the kernel file that you uploaded to your TFTP server.

http://<HTTP_server>/rhcos-<version>-live-rootfs.<architecture>.img
   Specifies the location of the live rootfs image that you uploaded to your HTTP server.

http://<HTTP_server>/bootstrap.ign
   Specifies the location of the bootstrap Ignition config file that you uploaded to your HTTP server.

rhcos-<version>-live-initramfs.<architecture>.img
   Specifies the location of the initramfs file that you uploaded to your TFTP server.

**NOTE**

For more information on how to configure a PXE server for UEFI boot, see the Red Hat Knowledgebase article: How to configure/setup a PXE server for UEFI boot for Red Hat Enterprise Linux?.

7. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

11.2.9. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.

**Procedure**

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   ![Image](image_url)
Example output

INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.20.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   IMPORTANT
   You must remove the bootstrap machine from the load balancer at this point.
   You can also remove or reformat the machine itself.

11.2.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami

   Example output
   
   system:admin

11.2.11. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.
Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the `machine-approver` if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  $ oc adm certificate approve <csr_name> ①

  ① `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the `Pending` status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  $ oc adm certificate approve <csr_name> ①

  ① `<csr_name>` is the name of a CSR from the list of current CSRs.
To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 11.2.12. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>3h56m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>6h39m</td>
</tr>
</tbody>
</table>
### 11.2.12.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

### 11.2.12.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

11.2.12.2.1. Changing the image registry’s management state

To start the image registry, you must change the Image Registry Operator configuration’s `managementState` from `Removed` to `Managed`.

Procedure

- Change `managementState` Image Registry Operator configuration from `Removed` to `Managed`. For example:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"managementState": "Managed"}}'
  ```

11.2.12.2.2. Configuring registry storage for IBM Z

11.2.12.2.3. Configuring registry storage for IBM Power Systems

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on IBM Z. on IBM Power Systems.
- Persistent storage provisioned for your cluster.

**IMPORTANT**

OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

**NOTE**

When using shared storage, review your security settings to prevent outside access.
2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

**Example output**

```
No resources found in openshift-image-registry namespace
```

**NOTE**

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

**Example output**

```
storage:
pvc:
  claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

**Example output**

```
NAME             VERSION                              AVAILABLE   PROGRESSING   DEGRADED
SINCE   MESSAGE
image-registry   4.7                                  True        False         False      6h50m
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:
  
  ```
  $ oc edit configs.imageregistry/cluster
  ```

  Then, change the line

  ```
  managementState: Removed
  ```

  to

  ```
  managementState: Managed
  ```

11.2.12.2.4. Configuring storage for the image registry in non-production clusters
You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'
  ```

  **WARNING**
  Configure this option for only non-production clusters.

  If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  ```
  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
  ```

  Wait a few minutes and run the command again.

**11.2.13. Completing installation on user-provisioned infrastructure**

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>console</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1</td>
<td>9m</td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apisher-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>3m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apisher-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>1m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apisher-z25h4</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>2m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0</td>
<td>5m</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```bash
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.
a. To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```bash
$ bootlist -m normal -o sda
```

b. To update the boot list for normal mode and add alternate device names, enter the following command:

```bash
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
```

If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

c. All the worker nodes are restarted. To monitor the process, enter the following command:

```bash
$ oc get nodes -w
```

**NOTE**

If you have additional machine types such as infrastructure nodes, repeat the process for these types.

4. Register your cluster on the [Cluster registration](#) page.

### 11.2.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

### 11.2.15. Next steps

- [Customize your cluster](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).
12.1. INSTALLING A CLUSTER ON OPENSTACK WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.7, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP). To customize the installation, modify parameters in the `install-config.yaml` before you install the cluster.

12.1.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
  - Verify that OpenShift Container Platform 4.7 is compatible with your RHOSP version by using the "Supported platforms for OpenShift clusters" section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

- Verify that your network configuration does not rely on a provider network. Provider networks are not supported.

- Have a storage service installed in RHOSP, like block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.

- Have metadata service enabled in RHOSP

12.1.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 12.1. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 12.1.2.1. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

### 12.1.2.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory, 2 vCPUs, and 100 GB storage space
TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

12.1.2.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

12.1.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.1.4. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.
IMPORTANT

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On Ceph RGW, the account in url option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the swiftoperator role to the account that will access Swift:

   $ openstack role add --user <user> --project <project> swiftoperator

Your RHOSP deployment can now use Swift for the image registry.

12.1.5. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the ’External’ network:

   $ openstack network list --long -c ID -c Name -c "Router Type"

Example output

+-------------------------------+--------------------+-------------+
| ID                           | Name               | Router Type |
+-------------------------------+--------------------+-------------+
| 148a8023-62a7-4672-b018-003462f8d7dc | public_network     | External    |
A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

**IMPORTANT**

If the external network’s CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the `install-config.yaml` file before you start the installation process.

The default network ranges are:

<table>
<thead>
<tr>
<th>Network</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>machineNetwork</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td>serviceNetwork</td>
<td>172.30.0.0/16</td>
</tr>
<tr>
<td>clusterNetwork</td>
<td>10.128.0.0/14</td>
</tr>
</tbody>
</table>

**WARNING**

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

**NOTE**

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

### 12.1.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

   **IMPORTANT**

   Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`. 
- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
    dev-env:
      region_name: RegionOne
      auth:
        username: 'devuser'
        password: XXX
        project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

   a. Copy the certificate authority file to your machine.

   b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```yaml
   clouds:
     shiftstack:
       ...
       cacert: '/etc/pki/ca-trust/source/anchors/ca.crt.pem'
   ```

   **TIP**

   After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

   ```bash
   $ oc edit configmap -n openshift-config cloud-provider-config
   ```

3. Place the `clouds.yaml` file in one of the following locations:

   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable

   b. The current directory

   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

   The installation program searches for `clouds.yaml` in that order.

### 12.1.7. Obtaining the installation program
Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

**12.1.8. Creating the installation configuration file**

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

- Obtain service principal permissions at the subscription level.
Procedure

1. Create the install-config.yaml file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   1 For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

   ii. Select openstack as the platform to target.

   iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

   iv. Specify the floating IP address to use for external access to the OpenShift API.

   v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

   vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

   vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

   viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.
IMPORTANT

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

See `Installation configuration parameters` section for more information about the available parameters.

12.1.8.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:@<ip>:<port>
     httpsProxy: https://<username>:@<ip>:<port>
     noProxy: example.com
   additionalTrustBundle: |----BEGIN CERTIFICATE----<MY_TRUSTED_CA_CERT>----END CERTIFICATE----
   ...
   ``

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**
Only the Proxy object named cluster is supported, and no additional proxies can be created.

### 12.1.9. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

**NOTE**
After installation, you cannot modify these parameters in the install-config.yaml file.

**IMPORTANT**
The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 12.1.9.1. Required configuration parameters

Required installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>. <code>&lt;baseDomain&gt;</code></td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
pullSecret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{  
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

12.1.9.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.3. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>NOTE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the networking object after installation.</td>
</tr>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^((32 - 23) - 2)) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>machineNetwork:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>- cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block.</td>
<td>An IP network block in CIDR notation.</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>For example, 10.0.0.0/16.</td>
</tr>
<tr>
<td></td>
<td>NOTE</td>
<td>Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</td>
</tr>
</tbody>
</table>

### 12.1.9.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <strong>MachinePool</strong> objects. For details, see the following “Machine-pool” table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <strong>compute</strong>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <strong>controlPlane.platform</strong> parameter value.</td>
<td><strong>aws, azure, gcp, openstack, ovirt, vsphere,</strong> or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
### 12.1.9.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. The default value is External. Setting this field to Internal is not supported on non-cloud platforms. IMPORTANT If the value of the field is set to Internal, the cluster will become non-functional. For more information, refer to BZ#1953035.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.size</code></td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.type</code></td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><code>platform.openstack.cloud</code></td>
<td>The name of the RHOSP cloud to use from the list of clouds in the <code>clouds.yaml</code> file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td><code>platform.openstack.externalNetwork</code></td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td><code>platform.openstack.computeFlavor</code></td>
<td>The RHOSP flavor to use for control plane and compute machines.</td>
<td>String, for example m1.xlarge.</td>
</tr>
<tr>
<td></td>
<td>This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the <code>type</code> key in the <code>platform.openstack.defaultMachinePlatform</code> property. You can also set a flavor value for each machine pool individually.</td>
<td></td>
</tr>
</tbody>
</table>

### 12.1.9.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 12.6. Optional RHOSP parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.platform.openstack.additionalNetworkIDs</strong></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><strong>compute.platform.openstack.additionalSecurityGroupIDs</strong></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><strong>compute.platform.openstack.zones</strong></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.additionalNetworkIDs</strong></td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.additionalSecurityGroupIDs</strong></td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.zones</td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, ['zone-1', 'zone-2'].</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImage</td>
<td>The location from which the installer downloads the RH COS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f7f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f7f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
</tbody>
</table>
### Platform.openstack.clusterOSImageProperties

Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if `platform.openstack.clusterOSImage` is set to an existing Glance image.

You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the `hw_scsi_model` property value to `virtio-scsi` and the `hw_disk_bus` value to `scsi`.

You can also use this property to enable the QEMU guest agent by including the `hw_qemu_guest_agent` property with a value of `yes`.

A list of key-value string pairs. For example, 
`["hw_scsi_model": "virtio-scsi", "hw_disk_bus": "scsi"]`.  

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>
| platform.openstack.defaultMachinePlatform | The default machine pool platform configuration. | `{  
| | | "type": "ml.large",  
| | | "rootVolume": {  
| | | "size": 30,  
| | | "type": "performance"  
| | | }  
| } |
| platform.openstack.ingressFloatingIP | An existing floating IP address to associate with the Ingress port. To use this property, you must also define the `platform.openstack.externalNetwork` property. | An IP address, for example 128.0.0.1. |
| platform.openstack.apiFloatingIP | An existing floating IP address to associate with the API load balancer. To use this property, you must also define the `platform.openstack.externalNetwork` property. | An IP address, for example 128.0.0.1. |
| platform.openstack.externalDNS | IP addresses for external DNS servers that cluster instances use for DNS resolution. | A list of IP addresses as strings. For example, ["8.8.8.8", "192.168.1.12"] |
### Platform.openstack.machinesSubnet

The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.

The first item in `networking.machineNetwork` must match the value of `machinesSubnet`.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

A UUID as a string. For example, `fa806b2f-ac49-4bce-b9db-124bc64209bf`.

#### 12.1.9.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.
NOTE
By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

12.1.9.7. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `install-config.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

NOTE
Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

Prerequisites

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an `install-config.yaml` file as part of the OpenShift Container Platform installation process.

Procedure

1. In the `install-config.yaml` file, edit the flavors for machines:
   a. If you want to use bare-metal control plane machines, change the value of `controlPlane.platform.openstack.type` to a bare metal flavor.
   b. Change the value of `compute.platform.openstack.type` to a bare metal flavor.
   c. If you want to deploy your machines on a pre-existing network, change the value of `platform.openstack.machinesSubnet` to the RHOSP subnet UUID of the network. Control plane and compute machines must use the same subnet.

An example bare metal `install-config.yaml` file

```
controlPlane:
  platform:
    openstack:
```
If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

Change this value to a bare metal flavor to use for compute machines.

If you want to use a pre-existing network, change this value to the UUID of the RHOSP subnet.

Use the updated `install-config.yaml` file to complete the installation process. The compute machines that are created during deployment use the flavor that you added to the file.

**NOTE**

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

### 12.1.9.8. Sample customized `install-config.yaml` file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
```
12.1.10. Setting compute machine affinity

Optionally, you can set the affinity policy for compute machines during installation. The installer does not select an affinity policy for compute machines by default.

You can also create machine sets that use particular RHOSP server groups after installation.

**NOTE**

Control plane machines are created with a `soft-anti-affinity` policy.

**TIP**

You can learn more about RHOSP instance scheduling and placement in the RHOSP documentation.

**Prerequisites**

- Create the `install-config.yaml` file and complete any modifications to it.

**Procedure**

1. Using the RHOSP command-line interface, create a server group for your compute machines. For example:

   ```bash
   $ openstack
```
For more information, see the `server group create` command documentation.

2. Change to the directory that contains the installation program and create the manifests:

```bash
$ ./openshift-install create manifests --dir=<installation_directory>
```

where:

**installation_directory**

Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

3. Open `manifests/99_openshift-cluster-api_worker-machineset-0.yaml`, the `MachineSet` definition file.

4. Add the property `serverGroupID` to the definition beneath the `spec.template.spec.providerSpec.value` property. For example:

```yaml
apiVersion: machine.openshift.io/v1beta1
kind: MachineSet
metadata:
  labels:
    machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
    machine.openshift.io/cluster-api-machine-role: <node_role>
    machine.openshift.io/cluster-api-machine-type: <node_role>
    name: <infrastructure_ID>-<node_role>
    namespace: openshift-machine-api
spec:
  replicas: <number_of_replicas>
  selector:
    matchLabels:
      machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
      machine.openshift.io/cluster-api-machine-role: <node_role>
      machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
    template:
      metadata:
        labels:
          machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
          machine.openshift.io/cluster-api-machine-role: <node_role>
          machine.openshift.io/cluster-api-machine-type: <node_role>
          machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
      spec:
        providerSpec:
          value:
            apiVersion: openstackproviderconfig.openshift.io/v1alpha1
cloudName: openstack
        cloudsSecret:
          name: openstack-cloud-credentials
          namespace: openshift-machine-api
          flavor: <nova_flavor>
          image: <glance_image_name_or_location>
```
Add the UUID of your server group here.

5. Optional: Back up the manifests/99_openshift-cluster-api_worker-machineset-0.yaml file. The installation program deletes the manifests/ directory when creating the cluster.

When you install the cluster, the installer uses the MachineSet definition that you modified to create compute machines within your RHOSP server group.

### 12.1.11. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

    ```bash
    ssh-keygen
    ```

    **NOTE**

    Ensure you have the correct permissions to generate an SSH key.

    **IMPORTANT**

    If you generate multiple keys, only one will be used.

    **NOTE**

    You may need to adjust the key generation process for your specific environment.
Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   **NOTE**

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**12.1.12. Enabling access to the environment**

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.
You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

### 12.1.12.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```bash
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```bash
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```text
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

**NOTE**

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your `/etc/hosts` file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the `/etc/hosts` file grant access to the web console and the monitoring interface of your cluster locally. You can also use the `kubectl` or `oc`. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.
4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:
   - `platform.openstack.ingressFloatingIP`
   - `platform.openstack.apiFloatingIP`

If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 12.1.12.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 12.1.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   
   1 For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
   
   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.
   
   NOTE
   
   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.
   
   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   Example output

   ... INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s
   
   NOTE
   
   The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

12.1.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster’s version:

   $ oc get clusterversion

4. View your Operators’ status:

   $ oc get clusteroperator

5. View all running pods in the cluster:

   $ oc get pods -A
12.1.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output
   
   system:admin

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

12.1.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

12.1.17. Next steps

- Customize your cluster.
• If necessary, you can opt out of remote health reporting.

• If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.

• If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.2. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR

In OpenShift Container Platform version 4.7, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP) that uses Kuryr SDN. To customize the installation, modify parameters in the install-config.yaml before you install the cluster.

12.2.1. Prerequisites

• Review details about the OpenShift Container Platform installation and update processes.
  
  • Verify that OpenShift Container Platform 4.7 is compatible with your RHOSP version by using the “Supported platforms for OpenShift clusters” section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

• Verify that your network configuration does not rely on a provider network. Provider networks are not supported.

• Have a storage service installed in RHOSP, like block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.

12.2.2. About Kuryr SDN

Kuryr is a container network interface (CNI) plug-in solution that uses the Neutron and Octavia Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the openshift-kuryr namespace:

• kuryr-controller - a single service instance installed on a master node. This is modeled in OpenShift Container Platform as a Deployment object.

• kuryr-cni - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a DaemonSet object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.
Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The `ovn-octavia` Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

### 12.2.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster’s minimum requirements:

**Table 12.7. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3 - plus the expected number of Services of LoadBalancer type</td>
</tr>
<tr>
<td>Ports</td>
<td>1500 - 1 needed per Pod</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>Networks</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Resource</td>
<td>Value</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Security groups</td>
<td>250 - 1 needed per Service and per NetworkPolicy</td>
</tr>
<tr>
<td>Security group rules</td>
<td>1000</td>
</tr>
<tr>
<td>Load balancers</td>
<td>100 - 1 needed per Service</td>
</tr>
<tr>
<td>Load balancer listeners</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
<tr>
<td>Load balancer pools</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**IMPORTANT**

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods’ booting time.

- Each network policy is mapped into an RHOSP security group, and depending on the `NetworkPolicy` spec, one or more rules are added to the security group.

- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota. If you are using RHOSP version 15 or earlier, or the `ovn-octavia driver`, each load balancer has a security group with the user project.

- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment’s size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them. If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.
To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
- Use `openvswitch` firewall driver if ML2/OVS Neutron driver is used instead of `ovs-hybrid`.

### 12.2.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

**Procedure**

- Increase the quotas for a project by running the following command:

  ```bash
  $ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
  ```

### 12.2.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the `trunks` extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to `openvswitch` instead of `ovs_hybrid` so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

### 12.2.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)’s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

**NOTE**

The following steps only capture the key pieces required during the deployment of RHOSP when dealing with Octavia. It is also important to note that registry methods vary.

This example uses the local registry method.

**Procedure**

1. If you are using the local registry, create a template to upload the images to the registry. For example:

   ```bash
   (undercloud) $ openstack overcloud container image prepare
   ```
2. Verify that the `local_registry_images.yaml` file contains the Octavia images. For example:

```yaml
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
  push_destination: <local-ip-from-undercloud.conf>:8787
```

**NOTE**

The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from `registry.redhat.io` to the Undercloud node:

```bash
(undercloud) $ sudo openstack overcloud container image upload
  --config-file /home/stack/local_registry_images.yaml
  --verbose
```

This may take some time depending on the speed of your network and Undercloud disk.

4. Since an Octavia load balancer is used to access the OpenShift Container Platform API, you must increase their listeners' default timeouts for the connections. The default timeout is 50 seconds. Increase the timeout to 20 minutes by passing the following file to the Overcloud deploy command:

```bash
(undercloud) $ cat octavia_timeouts.yaml
parameter_defaults:
  OctaviaTimeoutClientData: 1200000
  OctaviaTimeoutMemberData: 1200000
```

**NOTE**

This is not needed for RHOSP 13.0.13+.

5. Install or update your Overcloud environment with Octavia:

```bash
$ openstack overcloud deploy --templates
  -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml
  -e octavia_timeouts.yaml
```
This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see installation of Octavia using Director.

When leveraging Kuryr SDN, the Overcloud installation requires the Neutron trunk extension. This is available by default on director deployments. Use the openvswitch firewall instead of the default ovs-hybrid when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

6. In RHOSP versions earlier than 13.0.13, add the project ID to the octavia.conf configuration file after you create the project.
   - To enforce network policies across services, like when traffic goes through the Octavia load balancer, you must ensure Octavia creates the Amphora VM security groups on the user project. This change ensures that required load balancer security groups belong to that project, and that they can be updated to enforce services isolation.

   This task is unnecessary in RHOSP version 13.0.13 or later.

   Octavia implements a new ACL API that restricts access to the load balancers VIP.

   a. Get the project ID

   $ openstack project show <project>

   Example output

   +-------------+----------------------------------+
   | Field       | Value                            |
   +-------------+----------------------------------+
   | description |                                  |
   | domain_id   | default                          |
   | enabled     | True                             |
   | id          | PROJECT_ID                       |
   | is_domain   | False                            |
   | name        | "<project>"                      |
   | parent_id   | default                          |
   | tags        | []                               |
   +-------------+----------------------------------+

   b. Add the project ID to octavia.conf for the controllers.

      i. Source the stackrc file:
$ source stackrc  # Undercloud credentials

ii. List the Overcloud controllers:

$ openstack server list

Example output

+--------------------------------------+--------------+--------+-----------------------+-------
| ID                                   | Name         | Status | Networks              |       |
| Image                                | Flavor       |        |                       |       |
+--------------------------------------+--------------+--------+-----------------------+-------
| 6bef8e73-2ba5-4860-a0b1-3937f8ca7e01 | controller-0 | ACTIVE | overcloud-full        | controller |
| dda3173a-ab26-47f8-a2dc-8473b4a67ab9 | compute-0    | ACTIVE | overcloud-full        | compute |
+--------------------------------------+--------------+--------+-----------------------+-------

iii. SSH into the controller(s).

$ ssh heat-admin@192.168.24.8

controller-0$ sudo docker restart octavia_worker

iv. Edit the `octavia.conf` file to add the project into the list of projects where Amphora security groups are on the user’s account.

```bash
# List of project IDs that are allowed to have Load balancer security groups
# belonging to them.
amp_secgroup_allowed_projects = PROJECT_ID
```

c. Restart the Octavia worker so the new configuration loads.

controller-0$ sudo docker restart octavia_worker

NOTE

Depending on your RHOSP environment, Octavia might not support UDP listeners. If you use Kuryr SDN on RHOSP version 13.0.13 or earlier, UDP services are not supported. RHOSP version 16 or later support UDP.

12.2.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:
Beginning with RHOSP version 16, the Octavia OVN provider driver (ovn) is supported on OpenShift Container Platform on RHOSP deployments.

*ovn* is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If *ovn* is enabled, however, Kuryr uses it.

If Kuryr uses *ovn* instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

You can configure your cluster to use the Octavia OVN driver after your RHOSP cloud is upgraded from version 13 to version 16.

### 12.2.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

#### RHOSP general limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.
- Clusters that use the OVN Octavia provider driver support **Service** objects for which the **.spec.selector** property is unspecified only if the **.subsetsaddresses** property of the **Endpoints** object includes the subnet of the nodes or pods.
- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.
- Configuring the **sessionAffinity=ClientIP** property on **Service** objects does not have an effect. Kuryr does not support this setting.

#### RHOSP version limitations

```bash
$ openstack loadbalancer provider list
```

<table>
<thead>
<tr>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amphora</td>
<td>The Octavia Amphora driver.</td>
</tr>
<tr>
<td>octavia</td>
<td>Deprecated alias of the Octavia Amphora driver.</td>
</tr>
<tr>
<td>ovn</td>
<td>Octavia OVN driver.</td>
</tr>
</tbody>
</table>
Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources. Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.

- Octavia RHOSP versions before 13.0.13 do not support UDP listeners. Therefore, OpenShift Container Platform UDP services are not supported.

- Octavia RHOSP versions before 13.0.13 cannot listen to multiple protocols on the same port. Services that expose the same port to different protocols, like TCP and UDP, are not supported.

- Kuryr SDN does not support automatic unidling by a service.

**RHOSP environment limitations**

There are limitations when using Kuryr SDN that depend on your deployment environment.

Because of Octavia’s lack of support for the UDP protocol and multiple listeners, if the RHOSP version is earlier than 13.0.13, Kuryr forces pods to use TCP for DNS resolution.

In Go versions 1.12 and earlier, applications that are compiled with CGO support disabled use UDP only. In this case, the native Go resolver does not recognize the `use-vc` option in `resolv.conf`, which controls whether TCP is forced for DNS resolution. As a result, UDP is still used for DNS resolution, which fails.

To ensure that TCP forcing is allowed, compile applications either with the environment variable `CGO_ENABLED` set to 1, i.e. `CGO_ENABLED=1`, or ensure that the variable is absent.

In Go versions 1.13 and later, TCP is used automatically if DNS resolution using UDP fails.

**NOTE**

musl-based containers, including Alpine-based containers, do not support the `use-vc` option.

**RHOSP upgrade limitations**

As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a load balancer failover.

- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.
IMPORTANT

If OpenShift Container Platform detects a new Octavia version that supports UDP load balancing, it recreates the DNS service automatically. The service recreation ensures that the service default supports UDP load balancing.

The recreation causes the DNS service approximately one minute of downtime.

12.2.3.5. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines. Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

12.2.3.6. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines. Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory, 2 vCPUs, and 100 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

12.2.3.7. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

12.2.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:
• Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 12.2.5. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.

**IMPORTANT**

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

**Prerequisites**

• You have a RHOSP administrator account on the target environment.

• The Swift service is installed.

• On Ceph RGW, the **account in url** option is enabled.

**Procedure**

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

   ```bash
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

Your RHOSP deployment can now use Swift for the image registry.

### 12.2.6. Verifying external network access

...
The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   **Example output**

   ```
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

**IMPORTANT**

If the external network’s CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the `install-config.yaml` file before you start the installation process.

The default network ranges are:

<table>
<thead>
<tr>
<th>Network</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>machineNetwork</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td>serviceNetwork</td>
<td>172.30.0.0/16</td>
</tr>
<tr>
<td>clusterNetwork</td>
<td>10.128.0.0/14</td>
</tr>
</tbody>
</table>

**WARNING**

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.
NOTE

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

12.2.7. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called clouds.yaml. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the clouds.yaml file:
   - If your RHOSP distribution includes the Horizon web UI, generate a clouds.yaml file in it.
     
     IMPORTANT
     
     Remember to add a password to the auth field. You can also keep secrets in a separate file from clouds.yaml.
     
     - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
  dev-env:
    region_name: RegionOne
    auth:
      username: 'devuser'
      password: XXX
      project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   
   a. Copy the certificate authority file to your machine.
   
   b. Add the cacerts key to the clouds.yaml file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
  shiftstack:
    ... 
  cacert: /etc/pki/ca-trust/source/anchors/ca.crt.pem
```
TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```bash
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:
   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for `clouds.yaml` in that order.

12.2.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.
4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 12.2.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the install-config.yaml file.
   a. Change to the directory that contains the installation program and run the following command:

      ```bash
      $ ./openshift-install create install-config --dir <installation_directory>
      ```

     **IMPORTANT**

     Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

     b. At the prompts, provide the configuration details for your cloud:
        i. Optional: Select an SSH key to use to access your cluster machines.

     **NOTE**

     For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.
ii. Select openstack as the platform to target.

iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

iv. Specify the floating IP address to use for external access to the OpenShift API.

v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

12.2.9.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

**Prerequisites**

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

   **NOTE**

   The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

   For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**
1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with a . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RH COS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RH COS trust bundle.

**NOTE**
The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 12.2.10. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for
the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the install-config.yaml file.

**IMPORTANT**

The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.2.10.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>apiVersion</strong></td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td><strong>baseDomain</strong></td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;. &lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td><strong>metadata</strong></td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>metadata.name</strong></td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere.**

For additional information about `platform.<platform>` parameters, consult the table for your specific platform that follows.

---

### pullSecret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

---

### 12.2.10.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 12.9. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td>The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>hostPrefix is set to 23 then each node is assigned a /23 subnet out of the</td>
<td>The default value is 23.</td>
</tr>
<tr>
<td></td>
<td>given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP</td>
<td></td>
</tr>
<tr>
<td></td>
<td>addresses.</td>
<td></td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>IP address block for the service network.</td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP kernel arguments, the machineNetwork.cidr value</td>
<td>machineNetwork:</td>
</tr>
<tr>
<td></td>
<td>must be the CIDR of the primary network.</td>
<td>- cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
### networking.machin

Network.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is **10.0.0.0/16** for all platforms other than libvirt. For libvirt, the default value is **192.168.126.0/24**.

An IP network block in CIDR notation.

For example, **10.0.0.0/16**.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.machin</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>additionalTrustBundle</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>compute.architectu</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><code>worker</code></td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following “Machine-pool” table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

### controlPlane.name

Required if you use `controlPlane`. The name of the machine pool.

- `master`

### controlPlane.platform

Required if you use `controlPlane`. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the `compute.platform` parameter value.

- `aws`, `azure`, `gcp`, `openstack`, `ovirt`, `vsphere`, or `{}`

### controlPlane.replicas

The number of control plane machines to provision.

- The only supported value is 3, which is the default value.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <em>source</em> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Values**

- **Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to **BZ#1953035**.

### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

**Values**

- One or more keys. For example:

  ```
  sshKey:
  <key1>
  <key2>
  <key3>
  ```

#### 12.2.10.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 12.11. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.size</code></td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.type</code></td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example <code>performance</code>.</td>
</tr>
<tr>
<td><code>platform.openstack.cloud</code></td>
<td>The name of the RHOSP cloud to use from the list of clouds in the <code>clouds.yaml</code> file.</td>
<td>String, for example <code>MyCloud</code>.</td>
</tr>
<tr>
<td><code>platform.openstack.externalNetwork</code></td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example <code>external</code>.</td>
</tr>
<tr>
<td><code>platform.openstack.computeFlavor</code></td>
<td>The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the <code>type</code> key in the <code>platform.openstack.defaultMachinePlatform</code> property. You can also set a flavor value for each machine pool individually.</td>
<td>String, for example <code>m1.xlarge</code>.</td>
</tr>
</tbody>
</table>

### 12.2.10.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

#### Table 12.12. Optional RHOSP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>

|                                               | the hw_qemu_guest_agent property with a value of yes.                      |                                                                       |
| platform.openstack.defaultMachinePlatform     | The default machine pool platform configuration.                            | {                                                                       |
|                                               |                                                                             |   "type": "ml.large",
<p>|                                               |                                                                             |   &quot;rootVolume&quot;: {                                                     |
|                                               |                                                                             |     &quot;size&quot;: 30,                                                        |
|                                               |                                                                             |     &quot;type&quot;: &quot;performance&quot;                                             |
|                                               |                                                                             | }                                                                      |
| platform.openstack.ingressFloatingIP          | An existing floating IP address to associate with the Ingress port. To use  | An IP address, for example 128.0.0.1.                                    |
|                                               | this property, you must also define the platform.openstack.externalNetwork  |                                                                       |
|                                               | property.                                                                   |                                                                       |
| platform.openstack.apiFloatingIP              | An existing floating IP address to associate with the API load balancer.    | An IP address, for example 128.0.0.1.                                    |
|                                               | To use this property, you must also define the platform.openstack.externalNetwork property. |                                                                       |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.openstack.externalDNS</code></td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;].</td>

<tr>
<td><code>platform.openstack.machinesSubnet</code></td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet. The first item in <code>networking.machineNetwork</code> must match the value of <code>machinesSubnet</code>. If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</td>
<td>A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
</tbody>
</table>

### 12.2.10.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

12.2.10.7. Sample customized `install-config.yaml` file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OpenShift SDN, you must modify the `install-config.yaml` file to include *Kuryr* as the desired `networking.networkType` and proceed with the default OpenShift Container Platform SDN installation steps. This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: m1.large
        replicas: 3
    metadata:
      name: example
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  serviceNetwork:
    - 172.30.0.0/16
  networkType: Kuryr
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
    trunkSupport: true
```
The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `serviceNetwork` property. The larger range is required to prevent IP address conflicts.

Both `trunkSupport` and `octaviaSupport` are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

12.2.10.8. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation.

Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the `cluster-network-03-config.yml` manifest file to configure ports pool behavior:

- The `enablePortPoolsPrepopulation` parameter controls pool prepopulation, which forces Kuryr to add ports to the pool when it is created, such as when a new host is added, or a new namespace is created. The default value is `false`.

- The `poolMinPorts` parameter is the minimum number of free ports that are kept in the pool. The default value is `1`.

- The `poolMaxPorts` parameter is the maximum number of free ports that are kept in the pool. A value of `0` disables that upper bound. This is the default setting. If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.

- The `poolBatchPorts` parameter defines the maximum number of Neutron ports that can be created at once. The default value is `3`.

12.2.10.9. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the `install-config.yaml` file.

Procedure

```yaml
octaviaSupport: true
pullSecret: {'auths': ...}
sshKey: ssh-ed25519 AAAA...
```
1. From a command line, create the manifest files:

   ```sh
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

For `<installation_directory>`, specify the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a file that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```sh
   $ touch <installation_directory>/manifests/cluster-network-03-config.yml
   ```

For `<installation_directory>`, specify the directory name that contains the `manifests/` directory for your cluster.

After creating the file, several network configuration files are in the `manifests/` directory, as shown:

   ```sh
   $ ls <installation_directory>/manifests/cluster-network-*
   ```

   Example output

   ```
   cluster-network-01-crd.yml
   cluster-network-02-config.yml
   cluster-network-03-config.yml
   ```

3. Open the `cluster-network-03-config.yml` file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

   ```sh
   $ oc edit networks.operator.openshift.io cluster
   ```

4. Edit the settings to meet your requirements. The following file is provided as an example:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     clusterNetwork:
       - cidr: 10.128.0.0/14
         hostPrefix: 23
     serviceNetwork:
       - 172.30.0.0/16
     defaultNetwork:
       type: Kuryr
       kuryrConfig:
         enablePortPoolsPrepopulation: false
         poolMinPorts: 1
         poolBatchPorts: 3
         poolMaxPorts: 5
         openstackServiceNetwork: 172.30.0.0/15
   ```
Set the value of `enablePortPoolsPrepopulation` to `true` to make Kuryr create new Neutron ports after a namespace is created or a new node is added to the cluster. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is `false`.

Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of `poolMinPorts`. The default value is `1`.

`poolBatchPorts` controls the number of new ports that are created if the number of free ports is lower than the value of `poolMinPorts`. The default value is `3`.

If the number of free ports in a pool is higher than the value of `poolMaxPorts`, Kuryr deletes them until the number matches that value. Setting this value to `0` disables this upper bound, preventing pools from shrinking. The default value is `0`.

The `openStackServiceNetwork` parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia’s LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of `openStackServiceNetwork` must be at least twice the size of the value of `serviceNetwork`, and the value of `serviceNetwork` must overlap entirely with the range that is defined by `openStackServiceNetwork`.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the `serviceNetwork` parameter.

If this parameter is not set, the CNO uses an expanded value of `serviceNetwork` that is determined by decrementing the prefix size by `1`.

Save the `cluster-network-03-config.yml` file, and exit the text editor.

Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory while creating the cluster.

### 12.2.11. Setting compute machine affinity

Optionally, you can set the affinity policy for compute machines during installation. The installer does not select an affinity policy for compute machines by default.

You can also create machine sets that use particular RHOSP server groups after installation.

**NOTE**

Control plane machines are created with a `soft-anti-affinity` policy.

**TIP**

You can learn more about *RHOSP instance scheduling and placement* in the RHOSP documentation.

**Prerequisites**

- Create the `install-config.yaml` file and complete any modifications to it.
Procedure

1. Using the RHOSP command-line interface, create a server group for your compute machines. For example:

```bash
$ openstack \
   --os-compute-api-version=2.15 \
server group create \
   --policy anti-affinity \
my-openshift-worker-group
```

For more information, see the server group create command documentation.

2. Change to the directory that contains the installation program and create the manifests:

```bash
$ ./openshift-install create manifests --dir=<installation_directory>
```

where:

**installation_directory**

Specifies the name of the directory that contains the install-config.yaml file for your cluster.

3. Open manifests/99_openshift-cluster-api_worker-machineset-0.yaml, the MachineSet definition file.

4. Add the property serverGroupID to the definition beneath the spec.template.spec.providerSpec.value property. For example:

```yaml
apiVersion: machine.openshift.io/v1beta1
kind: MachineSet
metadata:
  labels:
    machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
    machine.openshift.io/cluster-api-machine-role: <node_role>
    machine.openshift.io/cluster-api-machine-type: <node_role>
    name: <infrastructure_ID>-<node_role>
    namespace: openshift-machine-api
spec:
  replicas: <number_of_replicas>
  selector:
    matchLabels:
      machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
      machine.openshift.io/cluster-api-machine-role: <node_role>
      machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
  template:
    metadata:
      labels:
        machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
        machine.openshift.io/cluster-api-machine-role: <node_role>
        machine.openshift.io/cluster-api-machine-type: <node_role>
        machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
    spec:
      providerSpec:
        value:
          apiVersion: openstackproviderconfig.openshift.io/v1alpha1
          cloudName: openstack
```
Add the UUID of your server group here.

5. Optional: Back up the manifests/99_openshift-cluster-api_worker-machineset-0.yaml file. The installation program deletes the manifests/ directory when creating the cluster.

When you install the cluster, the installer uses the MachineSet definition that you modified to create compute machines within your RHOSP server group.

12.2.12. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.
1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "\n-f <path>/<file_name>
```

1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. Start the `ssh-agent` process as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

Agent pid 31874

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

**Example output**

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**12.2.13. Enabling access to the environment**
At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

### 12.2.13.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```
NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your `/etc/hosts` file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the `/etc/hosts` file grant access to the web console and the monitoring interface of your cluster locally. You can also use the `kubectl` or `oc`. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.2.13.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for
you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

12.2.14. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \1
   --log-level=info 2
   ```

   1 For `<installation_directory>`, specify the location of your customized `/install-config.yaml` file.
   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   NOTE

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.
When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

### Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using `oc`, run `export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig`
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

#### NOTE

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.

#### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for `Recovering from expired control plane certificates` for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

#### IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### 12.2.15. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

#### Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig ①
   ```
   
   ① For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```shell
   $ oc get nodes
   ```

3. View your cluster’s version:

   ```shell
   $ oc get clusterversion
   ```

4. View your Operators’ status:

   ```shell
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:

   ```shell
   $ oc get pods -A
   ```

### 12.2.16. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```shell
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```shell
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

**Additional resources**
• See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

12.2.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

• See About remote health monitoring for more information about the Telemetry service

12.2.18. Next steps

• Customize your cluster.

• If necessary, you can opt out of remote health reporting.

• If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.

• If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.3. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.7, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

12.3.1. Prerequisites

• Review details about the OpenShift Container Platform installation and update processes.

  • Verify that OpenShift Container Platform 4.7 is compatible with your RHOSP version by using the “Supported platforms for OpenShift clusters” section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

  • Verify that your network configuration does not rely on a provider network. Provider networks are not supported.

  • Have an RHOSP account where you want to install OpenShift Container Platform.

  • On the machine from which you run the installation program, have:
A single directory in which you can keep the files you create during the installation process

Python 3

12.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.3.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

**Table 12.13. Recommended resources for a default OpenShift Container Platform cluster on RHOSP**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Resource</td>
<td>Value</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 12.3.3.1. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines. Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

### 12.3.3.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines. Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory, 2 vCPUs, and 100 GB storage space
TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

12.3.3.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

12.3.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:
   a. Register with Red Hat Subscription Manager:
      
      ```
      $ sudo subscription-manager register # If not done already
      ```
   b. Pull the latest subscription data:
      
      ```
      $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
      ```
   c. Disable the current repositories:
      
      ```
      $ sudo subscription-manager repos --disable=* # If not done already
      ```
   d. Add the required repositories:
      
      ```
      $ sudo subscription-manager repos \ 
      --enable=rhel-8-for-x86_64-baseos-rpms \ 
      --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
      ```
2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
```

3. Ensure that the `python` command points to `python3`:

```
$ sudo alternatives --set python /usr/bin/python3
```

### 12.3.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

**Prerequisites**

- The `curl` command-line tool is available on your machine.

**Procedure**

- To download the playbooks to your working directory, run the following script from a command line:

```
$ xargs -n 1 curl -O <<< ' 
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/bootstrap.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/common.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/compute-nodes.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/control-plane.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/inventory.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/network.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/security-groups.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/downbootstrap.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/downcompute-nodes.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/downcontrol-plane.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/download-balancers.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/downnetwork.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/downsecurity-groups.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/downcontainers.yaml'
```
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 12.3.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.
4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 12.3.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " \n-f <path>/<file_name>
```

   1. Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 12.3.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

**Prerequisites**

- The RHOSP CLI is installed.

**Procedure**

2. Under **Version**, select the most recent release of OpenShift Container Platform 4.7 for Red Hat Enterprise Linux (RHEL) 8.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.
3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (Qcow).

4. Decompress the image.

   **NOTE**
   
   You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like `.gz` or `.tgz`. To find out if or how the file is compressed, in a command line, enter:

   ```bash
   file <name_of_downloaded_file>
   ```

5. From the image that you downloaded, create an image that is named `rhcos` in your cluster by using the RHOSP CLI:

   ```bash
   openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-
   [RHCOS_VERSION]-openstack.qcow2 rhcos
   ```

   **IMPORTANT**
   
   Depending on your RHOSP environment, you might be able to upload the image in either `.raw` or `.qcow2` formats. If you use Ceph, you must use the `.raw` format.

   **WARNING**
   
   If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

12.3.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```bash
   openstack network list --long -c ID -c Name -c "Router Type"
   ```
Example output

| ID                                   | Name           | Router Type |
|--------------------------------------+----------------+-------------|
| 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |

A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

NOTE
If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

12.3.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

12.3.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   ```
   $ openstack floating ip create --description "bootstrap machine" <external_network>
   ```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

OpenShift Container Platform 4.7 Installing
NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your `/etc/hosts` file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the `/etc/hosts` file grant access to the web console and the monitoring interface of your cluster locally. You can also use the `kubectl` or `oc`. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:
   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.3.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `inventory.yaml` file, do not define the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
• **os_ingress_fip**

If you cannot provide an external network, you can also leave **os_external_network** blank. If you do not provide a value for **os_external_network**, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the **wait-for** command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```text
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 12.3.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the **clouds.yaml** file:
   - If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

      **IMPORTANT**

      Remember to add a password to the **auth** field. You can also keep secrets in a separate file from **clouds.yaml**.

      - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see Config files in the RHOSP documentation.

      ```yaml
      clouds:
      shiftstack:
      auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
      ```
If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

a. Copy the certificate authority file to your machine.

b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

```yaml
clouds:
  shiftstack:
    ...
  cacert: /etc/pki/ca-trust/source/anchors/ca.crt.pem
```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```bash
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:

a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable

b. The current directory

c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for `clouds.yaml` in that order.

### 12.3.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

- Obtain service principal permissions at the subscription level.

**Procedure**
1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

         **NOTE**

         For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `openstack` as the platform to target.

      iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

      iv. Specify the floating IP address to use for external access to the OpenShift API.

      v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

      vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

      vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

      viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters” section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
You now have the file `install-config.yaml` in the directory that you specified.

12.3.13. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.3.13.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 12.14. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
</tbody>
</table>
### metadata

Kubernetes resource **ObjectMeta**, from which only the *name* parameter is consumed.

#### metadata.name

The name of the cluster. DNS records for the cluster are all subdomains of `{{.metadata.name}}.{{.baseDomain}}`.

String of lowercase letters, hyphens (-), and periods (.), such as `dev`. The string must be 14 characters or fewer long.

#### platform

The configuration for the specific platform upon which to perform the installation: *aws*, *baremetal*, *azure*, *openstack*, *ovirt*, *vsphere*.

For additional information about *platform.<platform>* parameters, consult the table for your specific platform that follows.

#### pullSecret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
    "auths":{
        "cloud.openshift.com":{
            "auth":"b3Blb=",
            "email":"you@example.com"
        },
        "quay.io":{
            "auth":"b3Blb=",
            "email":"you@example.com"
        }
    }
}
```

### 12.3.13.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 12.15. Network parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the networking object after installation.</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>cidr: <strong>10.128.0.0/14</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: <strong>23</strong></td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>23</strong>.</td>
<td></td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <strong>172.30.0.0/16</strong>.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>172.30.0.0/16</strong></td>
</tr>
</tbody>
</table>
networking.machine
Network
The IP address blocks for machines.
If you specify multiple IP address blocks, the blocks must not overlap.
If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network.

networking.machineNetwork.cidr
Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than `libvirt`. For `libvirt`, the default value is `192.168.126.0/24`.

NOTE
Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

12.3.13.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 12.16. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td>on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or **hyperthreading**, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>controlPlane.hypertreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td></td>
</tr>
<tr>
<td><strong>controlPlane.name</strong></td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td><strong>controlPlane.platform</strong></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td><strong>controlPlane.replicas</strong></td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;').</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.
Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to **BZ#1953035**.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>sshKey</strong></td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>sshKey:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&lt;key1&gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&lt;key2&gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&lt;key3&gt;</td>
</tr>
</tbody>
</table>

### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

12.3.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 12.17. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.platform.openstack.rootVolume.size</strong></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><strong>compute.platform.openstack.rootVolume.type</strong></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example <strong>performance</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.platfrom.openstack.rootVolume.size</td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td>controlPlane.platfrom.openstack.rootVolume.type</td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>platform.openstack.cloud</td>
<td>The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td>platform.openstack.externalNetwork</td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td>platform.openstack.computeFlavor</td>
<td>The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.</td>
<td>String, for example m1.xlarge.</td>
</tr>
</tbody>
</table>

12.3.13.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 12.18. Optional RHOSP parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.zones</td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffe8eb9f28a1f2a245ca19522c16c86f17f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffe8eb9f28a1f2a245ca19522c16c86f17f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
</tbody>
</table>
### platform.openstack.clusterOSImageProperties

Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if `platform.openstack.clusterOSImage` is set to an existing Glance image.

You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the `hw_scsi_model` property value to `virtio-scsi` and the `hw_disk_bus` value to `scsi`.

You can also use this property to enable the QEMU guest agent by including the `hw_qemu_guest_agent` property with a value of `yes`.

A list of key-value string pairs. For example, 
```
["hw_scsi_model": "virtio-scsi",
 "hw_disk_bus": "scsi"]
```

### platform.openstack.defaultMachinePlatform

The default machine pool configuration.

```
{
  "type": "ml.large",
  "rootVolume": {
    "size": 30,
    "type": "performance"
  }
}
```

### platform.openstack.ingressFloatingIP

An existing floating IP address to associate with the Ingress port. To use this property, you must also define the `platform.openstack.externalNetwork` property.

An IP address, for example `128.0.0.1`.

### platform.openstack.apiFloatingIP

An existing floating IP address to associate with the API load balancer. To use this property, you must also define the `platform.openstack.externalNetwork` property.

An IP address, for example `128.0.0.1`. 
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.openstack.externalDNS</td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;].</td>
</tr>
<tr>
<td>platform.openstack.machinesSubnet</td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</td>
<td>A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
</tbody>
</table>

### 12.3.13.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

12.3.13.7. Sample customized `install-config.yaml` file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
      replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16
networkType: OpenShiftSDN
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
    fips: false
    pullSecret: '{"auths": ...}'
    sshKey: ssh-ed25519 AAAA...
```

12.3.13.8. Setting a custom subnet for machines
The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

**Prerequisites**

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:

   - To set the value by using a script, run:

     ```bash
     $ python -c "import yaml; path = "install-config.yaml"; data = yaml.safe_load(open(path));
     data["networking"]["machineNetwork"] = [{'cidr': '192.168.0.0/18'}];
     open(path, "w").write(yaml.dump(data, default_flow_style=False))"
     
     1 Insert a value that matches your intended Neutron subnet, e.g. `192.0.2.0/24`.

   - To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.

**12.3.13.9. Emptying compute machine pools**

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

**Prerequisites**

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:

   - To set the value by using a script, run:

     ```bash
     $ python -c "import yaml; path = "install-config.yaml"; data = yaml.safe_load(open(path));
     data["networking"]["machineNetwork"] = [{'cidr': '192.168.0.0/18'}];
     open(path, "w").write(yaml.dump(data, default_flow_style=False))"
     ```

     1 Insert a value that matches your intended Neutron subnet, e.g. `192.0.2.0/24`. 

   - To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.
To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to 0.

12.3.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ``

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*yaml
   ```
Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   ```
   ├── auth
   │   └── kubeadm-password
   │       └── kubeconfig
   ├── bootstrap.ign
   ├── master.ign
   ├── metadata.json
   └── worker.ign
   ```

5. Export the metadata file’s `infraID` key as an environment variable:
$ export INFRA_ID=$(jq -r .infraId metadata.json)

TIP

Extract the infraID key from metadata.json and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

12.3.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, bootstrap.ign.
- The infrastructure ID from the installer’s metadata file is set as an environment variable ($INFRA_ID).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()
files.append(
    {'path': '/etc/hostname',
     'mode': 420,
     'contents':
        {'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64}
    })
```
Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```python
ca_cert_path = os.environ.get('OS_CACERT', '')
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

    files.append(
        {
            'path': '/opt/openshift/tls/cloud-ca-cert.pem',
            'mode': 420,
            'contents': {
                'source': 'data:text/plain;charset=utf-8;base64,\n                ' + ca_cert_b64
            }
        }
    )

ignition['storage']['files'] = files;
with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)
```

2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
```

3. Get the image’s details:

```
$ openstack image show <image_name>
```

Make a note of the file value; it follows the pattern v2/images/<image_ID>/file.

**NOTE**

Verify that the image you created is active.

4. Retrieve the image service’s public address:

```
$ openstack catalog show image
```

5. Combine the public address with the image file value and save the result as the storage location. The location follows the pattern <image_service_public_URL>/v2/images/<image_ID>/file.

6. Generate an auth token and save the token ID:

```
$ openstack token issue -c id -f value
```

7. Insert the following content into a file called $INFRA_ID-bootstrap-ignition.json and edit the placeholders to match your own values:

```json
{
    "ignition": {
```

1648
Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.

Set `name` in `httpHeaders` to "X-Auth-Token".

Set `value` in `httpHeaders` to your token’s ID.

If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

WARNING

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

12.3.16. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

NOTE

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.
Prerequisites

- The infrastructure ID from the installation program’s metadata file is set as an environment variable ($INFRA_ID).
  - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

```bash
for index in $(seq 0 2); do
  MASTER_HOSTNAME="$INFRA_ID-master-$index"
  python -c "import base64, json, sys;
  ignition = json.load(sys.stdin);
  storage = ignition.get('storage', {});
  files = storage.get('files', []);
  files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source': 'data:text/plain;charset=utf-8;base64,' + base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}}, 'filesystem': 'root'});
  storage['files'] = files;
  ignition['storage'] = storage
  json.dump(ignition, sys.stdout)"
  <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: `<INFRA_ID>-master-0-ignition.json`, `<INFRA_ID>-master-1-ignition.json`, and `<INFRA_ID>-master-2-ignition.json`.

12.3.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the `inventory.yaml` playbook:

   **Example external network value in the inventory.yaml Ansible playbook**

   ```
   ...
   # The public network providing connectivity to the cluster. If not
   # provided, the cluster external connectivity must be provided in another
   # way.
   ```
# Required for `os_api_fip`, `os_ingress_fip`, `os_bootstrap_fip`.
```
os_external_network: "external"
```

**IMPORTANT**

If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

   **Example FIP values in the `inventory.yaml` Ansible playbook**

   ```yaml
   # OpenShift API floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the Control Plane to
   # serve the OpenShift API.
   os_api_fip: '203.0.113.23'

   # OpenShift Ingress floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the worker nodes to serve
   # the applications.
   os_ingress_fip: '203.0.113.19'

   # If this value is non-empty, the corresponding floating IP will be
   # attached to the bootstrap machine. This is needed for collecting logs
   # in case of install failure.
   os_bootstrap_fip: '203.0.113.20'
   ```

**IMPORTANT**

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform post-installation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See “Enabling access to the environment” for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml security-groups.yaml
   ```

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml network.yaml
   ```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:
Optionally, you can use the `inventory.yaml` file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

### 12.3.17.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an `inventory.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `inventory.yaml` file, edit the flavors for machines:
   
   a. If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.
   
   b. Change the value of `os_flavor_worker` to a bare metal flavor.

   **An example bare metal inventory.yaml file**

   ```yaml
   all:
   hosts:
     localhost:
       ansible_connection: local
       ansible_python_interpreter: "{{ansible_playbook_python}}"
   ```

   ```bash
   $ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
   ```
If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

Change this value to a bare metal flavor to use for compute machines.

Use the updated inventory.yaml file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

NOTE

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```bash
./openshift-install wait-for install-complete --log-level debug
```

12.3.18. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The inventory.yaml, common.yaml, and bootstrap.yaml Ansible playbooks are in a common directory.
- The metadata.json file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the bootstrap.yaml playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml bootstrap.yaml
   ```

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

   ```bash
   $ openstack console log show "$INFRA_ID-bootstrap"
   ```
12.3.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program’s metadata file is set as an environment variable (\$INFRA_ID).
- The `inventory.yaml`, `common.yaml`, and `control-plane.yaml` Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.
2. If the control plane Ignition config files aren’t already in your working directory, copy them into it.
3. On a command line, run the `control-plane.yaml` playbook:
   
   ```bash
   $ ansible-playbook -i inventory.yaml control-plane.yaml
   ```
4. Run the following command to monitor the bootstrapping process:

   ```bash
   $ openshift-install wait-for bootstrap-complete
   ```

   You will see messages that confirm that the control plane machines are running and have joined the cluster:

   ```text
   INFO API v1.14.6+f9b5405 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   ...
   INFO It is now safe to remove the bootstrap resources
   ```

12.3.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   
   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   
   2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   
   Example output
   
   system:admin
   ```

**12.3.21. Deleting bootstrap resources from RHOSP**

Delete the bootstrap resources that you no longer need.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **down-bootstrap.yaml** Ansible playbooks are in a common directory.
- The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the **down-bootstrap.yaml** playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml
   
   The bootstrap port, server, and floating IP address are deleted.
12.3.22. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `compute-nodes.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the playbook:
   ```bash
   $ ansible-playbook -i inventory.yaml compute-nodes.yaml
   ```

Next steps

- Approve the certificate signing requests for the machines.

12.3.23. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:
   ```bash
   $ oc get nodes
   ```
The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rlh</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.
To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

* `<csr_name>` is the name of a CSR from the list of current CSRs.*

To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

* `<csr_name>` is the name of a CSR from the list of current CSRs.*

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**
It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

### 12.3.24. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

**Prerequisites**

- You have the installation program (`openshift-install`)

**Procedure**

- On a command line, enter:

  ```bash
  $ openshift-install --log-level debug wait-for install-complete
  ```

The program outputs the console URL, as well as the administrator’s login information.

### 12.3.25. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 12.3.26. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.

If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.4. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.7, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

12.4.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
  - Verify that OpenShift Container Platform 4.7 is compatible with your RHOSP version by using the “Supported platforms for OpenShift clusters” section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

- Verify that your network configuration does not rely on a provider network. Provider networks are not supported.

- Have an RHOSP account where you want to install OpenShift Container Platform.

- On the machine from which you run the installation program, have:
  - A single directory in which you can keep the files you create during the installation process
  - Python 3

12.4.2. About Kuryr SDN

Kuryr is a container network interface (CNI) plug-in solution that uses the Neutron and Octavia Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the openshift-kuryr namespace:

- **kuryr-controller** - a single service instance installed on a master node. This is modeled in OpenShift Container Platform as a Deployment object.

- **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a DaemonSet object.
The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The `ovn-octavia` Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

### 12.4.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster's minimum requirements:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3 - plus the expected number of Services of LoadBalancer type</td>
</tr>
<tr>
<td>Ports</td>
<td>1500 - 1 needed per Pod</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>Networks</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>Resource</td>
<td>Value</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>250 - 1 needed per Service and per NetworkPolicy</td>
</tr>
<tr>
<td>Security group rules</td>
<td>1000</td>
</tr>
<tr>
<td>Load balancers</td>
<td>100 - 1 needed per Service</td>
</tr>
<tr>
<td>Load balancer listeners</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
<tr>
<td>Load balancer pools</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**IMPORTANT**

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods' booting time.

- Each network policy is mapped into an RHOSP security group, and depending on the `NetworkPolicy` spec, one or more rules are added to the security group.

- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota. If you are using RHOSP version 15 or earlier, or the `ovn-octavia driver`, each load balancer has a security group with the user project.

- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment’s size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate
If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
- Use `openvswitch` firewall driver if ML2/OVS Neutron driver is used instead of `ovs-hybrid`.

### 12.4.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

**Procedure**

- Increase the quotas for a project by running the following command:

  ```
  $ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
  ```

### 12.4.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the `trunks` extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to `openvswitch` instead of `ovs_hybrid` so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

### 12.4.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)'s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

**NOTE**

The following steps only capture the key pieces required during the deployment of RHOSP when dealing with Octavia. It is also important to note that registry methods vary.

This example uses the local registry method.
Procedure

1. If you are using the local registry, create a template to upload the images to the registry. For example:

   (undercloud) $ openstack overcloud container image prepare \
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
   --namespace=registry.access.redhat.com/rhosp13 \
   --push-destination=<local-ip-from-undercloud.conf>:8787 \n   --tag-from-label {version}-{product-version} \
   --output-env-file=/home/stack/templates/overcloud_images.yaml \
   --output-images-file /home/stack/local_registry_images.yaml

2. Verify that the `local_registry_images.yaml` file contains the Octavia images. For example:

   ... 
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43 
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45 
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45 
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44 
     push_destination: <local-ip-from-undercloud.conf>:8787

   NOTE
   The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from `registry.redhat.io` to the Undercloud node:

   (undercloud) $ sudo openstack overcloud container image upload \
   --config-file /home/stack/local_registry_images.yaml \
   --verbose

   This may take some time depending on the speed of your network and Undercloud disk.

4. Since an Octavia load balancer is used to access the OpenShift Container Platform API, you must increase their listeners' default timeouts for the connections. The default timeout is 50 seconds. Increase the timeout to 20 minutes by passing the following file to the Overcloud deploy command:

   (undercloud) $ cat octavia_timeouts.yaml
   parameter_defaults:
     OctaviaTimeoutClientData: 1200000
     OctaviaTimeoutMemberData: 1200000

   NOTE
   This is not needed for RHOSP 13.0.13+.
5. Install or update your Overcloud environment with Octavia:

```bash
$ openstack overcloud deploy --templates \\
- e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \\
- e octavia_timeouts.yaml
```

**NOTE**

This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see installation of Octavia using Director.

**NOTE**

When leveraging Kuryr SDN, the Overcloud installation requires the Neutron `trunk` extension. This is available by default on director deployments. Use the `openvswitch` firewall instead of the default `ovs-hybrid` when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

6. In RHOSP versions earlier than 13.0.13, add the project ID to the `octavia.conf` configuration file after you create the project.

- To enforce network policies across services, like when traffic goes through the Octavia load balancer, you must ensure Octavia creates the Amphora VM security groups on the user project.
  
  This change ensures that required load balancer security groups belong to that project, and that they can be updated to enforce services isolation.

**NOTE**

This task is unnecessary in RHOSP version 13.0.13 or later.

Octavia implements a new ACL API that restricts access to the load balancers VIP.

a. Get the project ID

```bash
$ openstack project show <project>
```

**Example output**

```
+-------------+----------------------------------+
| Field       | Value                            |
+-------------+----------------------------------+
| description |                                  |
| domain_id   | default                          |
| enabled     | True                             |
| id          | PROJECT_ID                       |
| is_domain   | False                            |
| name        | *<project>*                      |
```
b. Add the project ID to `octavia.conf` for the controllers.
   i. Source the `stackrc` file:
      
      ```bash
      $ source stackrc  # Undercloud credentials
      ```
   
   ii. List the Overcloud controllers:
      
      ```bash
      $ openstack server list
      ```
      
      **Example output**
      
      ```plaintext
      +--------------------------------------+--------------+--------+-----------------------+-------
      | ID                                   | Name         | Status | Networks              |
      | Image | Flavor          |
      +--------------------------------------+--------------+--------+-----------------------+-------
      +--------------------------------------+--------------+--------+-----------------------+-------
      | 6bef8e73-2ba5-4860-a0b1-3937f8ca7e01 | controller-0 | ACTIVE | overcloud-full | controller |
      | ctlplane=192.168.24.8 | controller |
      | dda3173a-ab26-47f8-a2dc-8473b4a67ab9 | compute-0    | ACTIVE | overcloud-full | compute |
      | ctlplane=192.168.24.6 | compute      |
      +--------------------------------------+--------------+--------+-----------------------+-------
      ```
   
   iii. SSH into the controller(s).
      
      ```bash
      $ ssh heat-admin@192.168.24.8
      ```
   
   iv. Edit the `octavia.conf` file to add the project into the list of projects where Amphora security groups are on the user's account.
      
      ```bash
      # List of project IDs that are allowed to have Load balancer security groups belonging to them.
      amp_secgROUP_allowed_projects = PROJECT_ID
      ```
   
   c. Restart the Octavia worker so the new configuration loads.
      
      ```bash
      controller-0$ sudo docker restart octavia_worker
      ```
NOTE

Depending on your RHOSP environment, Octavia might not support UDP listeners. If you use Kuryr SDN on RHOSP version 13.0.13 or earlier, UDP services are not supported. RHOSP version 16 or later support UDP.

12.4.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```bash
$ openstack loadbalancer provider list
```

Example output

```
+---------+-------------------------------------------------+
| name    | description                                     |
+---------+-------------------------------------------------+
| amphora | The Octavia Amphora driver.                     |
| octavia | Deprecated alias of the Octavia Amphora driver. |
| ovn     | Octavia OVN driver.                             |
+---------+-------------------------------------------------+
```

Beginning with RHOSP version 16, the Octavia OVN provider driver (**ovn**) is supported on OpenShift Container Platform on RHOSP deployments.

**ovn** is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If **ovn** is enabled, however, Kuryr uses it.

If Kuryr uses **ovn** instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

12.4.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

**RHOSP general limitations**

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.
Clusters that use the OVN Octavia provider driver support Service objects for which the .spec.selector property is unspecified only if the .subsets.addresses property of the Endpoints object includes the subnet of the nodes or pods.

If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for Service objects with type LoadBalancer.

Configuring the sessionAffinity=ClientIP property on Service objects does not have an effect. Kuryr does not support this setting.

**RHOSP version limitations**
Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources. Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.

- Octavia RHOSP versions before 13.0.13 do not support UDP listeners. Therefore, OpenShift Container Platform UDP services are not supported.

- Octavia RHOSP versions before 13.0.13 cannot listen to multiple protocols on the same port. Services that expose the same port to different protocols, like TCP and UDP, are not supported.

- Kuryr SDN does not support automatic unidling by a service.

**RHOSP environment limitations**
There are limitations when using Kuryr SDN that depend on your deployment environment.

Because of Octavia’s lack of support for the UDP protocol and multiple listeners, if the RHOSP version is earlier than 13.0.13, Kuryr forces pods to use TCP for DNS resolution.

In Go versions 1.12 and earlier, applications that are compiled with CGO support disabled use UDP only. In this case, the native Go resolver does not recognize the use-vc option in resolv.conf, which controls whether TCP is forced for DNS resolution. As a result, UDP is still used for DNS resolution, which fails.

To ensure that TCP forcing is allowed, compile applications either with the environment variable CGO_ENABLED set to 1, i.e. CGO_ENABLED=1, or ensure that the variable is absent.

In Go versions 1.13 and later, TCP is used automatically if DNS resolution using UDP fails.

**NOTE**

musl-based containers, including Alpine-based containers, do not support the use-vc option.

**RHOSP upgrade limitations**
As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.
If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a load balancer failover.
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

**IMPORTANT**

If OpenShift Container Platform detects a new Octavia version that supports UDP load balancing, it recreates the DNS service automatically. The service recreation ensures that the service default supports UDP load balancing.

The recreation causes the DNS service approximately one minute of downtime.

### 12.4.3.5. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

### 12.4.3.6. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory, 2 vCPUs, and 100 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 12.4.3.7. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:
• An instance from the RHOSP quota
• A port from the RHOSP quota
• A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

12.4.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

• Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
• Access Quay.io to obtain the packages that are required to install your cluster.
• Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.4.5. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules’ repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

• Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

   a. Register with Red Hat Subscription Manager:

      $ sudo subscription-manager register # If not done already

   b. Pull the latest subscription data:
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already

c. Disable the current repositories:

$ sudo subscription-manager repos --disable=* # If not done already

d. Add the required repositories:

$ sudo subscription-manager repos \
   --enable=rhel-8-for-x86_64-baseos-rpms \
   --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
   --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
   --enable=rhel-8-for-x86_64-appstream-rpms

2. Install the modules:

$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr

3. Ensure that the python command points to python3:

   $ sudo alternatives --set python /usr/bin/python3

12.4.6. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

```bash
$ xargs -n 1 curl -O <<< ' 
https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/bootstrap.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/common.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/compute-nodes.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/control-plane.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/inventory.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/network.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/security-groups.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.7/upi/openstack/down-bootstrap.yaml
'`
```
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 12.4.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.
The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

12.4.8. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your *ssh-agent* and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user *core*. When you deploy the cluster, the key is added to the *core* user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" \
   -f <path>/<file_name>
   ```

   **Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.**
Running this command generates an SSH key that does not require a password in the location that you specified.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the **ssh-agent** process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the **ssh-agent**:

   ```bash
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

12.4.9. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

**Prerequisites**

- The RHOSP CLI is installed.

**Procedure**

2. Under Version, select the most recent release of OpenShift Container Platform 4.7 for Red Hat Enterprise Linux (RHEL) 8.

   **IMPORTANT**
   
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the *Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)*.

4. Decompress the image.

   **NOTE**
   
   You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like `.gz` or `.tgz`. To find out if or how the file is compressed, in a command line, enter:

   ```bash
   $ file <name_of_downloaded_file>
   ```

5. From the image that you downloaded, create an image that is named `rhcos` in your cluster by using the RHOSP CLI:

   ```bash
   $ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-${RHCOS_VERSION}-openstack.qcow2 rhcos
   ```

   **IMPORTANT**
   
   Depending on your RHOSP environment, you might be able to upload the image in either `.raw` or `.qcow2` formats. If you use Ceph, you must use the `.raw` format.

   **WARNING**
   
   If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

**12.4.10. Verifying external network access**
The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the ‘External’ network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

   **NOTE**

   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

12.4.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

12.4.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```
2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   ```
   $ openstack floating ip create --description "bootstrap machine" <external_network>
   ```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

   **NOTE**

   If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your `/etc/hosts` file:

   - `<api_floating_ip> api.<cluster_name>.<base_domain>`
   - `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
   - `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
   - `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
   - `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
   - `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

   The cluster domain names in the `/etc/hosts` file grant access to the web console and the monitoring interface of your cluster locally. You can also use the `kubectl` or `oc` command. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:

   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

   If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.
TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.4.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `inventory.yaml` file, do not define the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
- `os_ingress_fip`

If you cannot provide an external network, you can also leave `os_external_network` blank. If you do not provide a value for `os_external_network`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the `wait-for` command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

12.4.12. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.
IMPORTANT

Remember to add a password to the auth field. You can also keep secrets in a separate file from clouds.yaml.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
    dev-env:
      region_name: RegionOne
      auth:
        username: 'devuser'
        password: XXX
        project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   
   a. Copy the certificate authority file to your machine.
   
   b. Add the cacerts key to the clouds.yaml file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```yaml
   clouds:
     shiftstack:
       ...
       cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
   ```

   TIP

   After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the ca-cert.pem key in the cloud-provider-config keymap. On a command line, run:

   ```bash
   $ oc edit configmap -n openshift-config cloud-provider-config
   ```

3. Place the clouds.yaml file in one of the following locations:
   
   a. The value of the OS_CLIENT_CONFIG_FILE environment variable
   
   b. The current directory
   
   c. A Unix-specific user configuration directory, for example ~/.config/openstack/clouds.yaml
12.4.13. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the install-config.yaml file.

   a. Change to the directory that contains the installation program and run the following command:

      ```
      $ ./openshift-install create install-config --dir <installation_directory>
      ```

      For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

      IMPORTANT

      Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      NOTE

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

      ii. Select openstack as the platform to target.

      iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

      iv. Specify the floating IP address to use for external access to the OpenShift API.
v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

    **IMPORTANT**
    
    The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file `install-config.yaml` in the directory that you specified.

### 12.4.14. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

#### NOTE

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 12.4.14.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (_), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
| pullSecret | Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io. | { "auths":{
  "cloud.openshift.com":{
    "auth":"b3Blb=",
    "email":"you@example.com"
  },
  "quay.io":{
    "auth":"b3Blb=",
    "email":"you@example.com"
  }
} }
12.4.14.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.21. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>
|                            | **NOTE** You cannot modify parameters specified by the networking object after installation.
| networking.networkType     | The cluster network provider Container Network Interface (CNI) plug-in to install. | Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN. |
| networking.clusterNetwork  | The IP address blocks for pods.                                             | An array of objects. For example:                                         |
|                            | The default value is **10.128.0.0/14** with a host prefix of **/23**.       | networking:                                                            |
|                            | If you specify multiple IP address blocks, the blocks must not overlap.     | clusterNetwork:                                                         |
|                            |                                                                           | - cidr: **10.128.0.0/14**                                               |
|                            |                                                                           | hostPrefix: **23**                                                       |
| networking.clusterNetwork.cidr | Required if you use networking.clusterNetwork. An IP address block.         | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. |
|                            | An IPv4 network.                                                           |                                                                       |
| networking.clusterNetwork.hostPrefix | The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses. | A subnet prefix. The default value is 23. |
### 12.4.14.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <code>hyperthreading</code>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>IMPORTANT</td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hypertreading</strong>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td><strong>master</strong></td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is <strong>3</strong>, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;').</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.</td>
<td></td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. The default value is <code>External</code>. Setting this field to <code>Internal</code> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: <code>sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</code></td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

**IMPORTANT**

If the value of the field is set to `Internal`, the cluster will become non-functional. For more information, refer to BZ#1953035.

### 12.4.14.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 12.23. Additional RHOSP parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.rootVolume.size</td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td>compute.platform.openstack.rootVolume.type</td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.rootVolume.size</td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.rootVolume.type</td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>platform.openstack.cloud</td>
<td>The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td>platform.openstack.externalNetwork</td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td>platform.openstack.computeFlavor</td>
<td>The RHOSP flavor to use for control plane and compute machines.</td>
<td>String, for example m1.xlarge.</td>
</tr>
<tr>
<td></td>
<td>This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.</td>
<td></td>
</tr>
</tbody>
</table>

12.4.14.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 12.24. Optional RHOSP parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.additionalNetworkIDs</td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>compute.platform.openstack.additionalSecurityGroupIDs</td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>compute.platform.openstack.zones</td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphor provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.additionalNetworkIDs</td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.additionalSecurityGroupIDs</td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.platForm.openstack.zones</td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImageProperties</td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image. You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi. You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;].</td>
</tr>
<tr>
<td>platform.openstack.defaultMachinePlatform</td>
<td>The default machine pool platform configuration.</td>
<td>{&quot;type&quot;: &quot;ml.large&quot;, &quot;rootVolume&quot;: { &quot;size&quot;: 30, &quot;type&quot;: &quot;performance&quot; }}</td>
</tr>
<tr>
<td>platform.openstack.ingressFloatingIP</td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.apiFloatingIP</td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.externalDNS</td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;].</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>platform.openstack.machinesSubnet</code></td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet. The first item in <code>networking.machineNetwork</code> must match the value of <code>machinesSubnet</code>. If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</td>
<td>A UUID as a string. For example, <code>fa806b2f-ac49-4bce-b9db-124bc64209bf</code>.</td>
</tr>
</tbody>
</table>

### 12.4.14.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.
NOTE

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

12.4.14.7. Sample customized `install-config.yaml` file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OpenShift SDN, you must modify the `install-config.yaml` file to include `Kuryr` as the desired `networking.networkType` and proceed with the default OpenShift Container Platform SDN installation steps. This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: ml.large
        replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  serviceNetwork:
    - 172.30.0.0/16
  networkType: Kuryr
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
    trunkSupport: true
    octaviaSupport: true
    pullSecret: '{"auths": ...}'
    sshKey: ssh-ed25519 AAAA...
```
The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `serviceNetwork` property. The larger range is required to prevent IP address conflicts.

Both `trunkSupport` and `octaviaSupport` are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

A Kuryr ports pool maintains a number of ports on standby for pod creation.

Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the `cluster-network-03-config.yml` manifest file to configure ports pool behavior:

- The `enablePortPoolsPrepopulation` parameter controls pool prepopulation, which forces Kuryr to add ports to the pool when it is created, such as when a new host is added, or a new namespace is created. The default value is `false`.

- The `poolMinPorts` parameter is the minimum number of free ports that are kept in the pool. The default value is `1`.

- The `poolMaxPorts` parameter is the maximum number of free ports that are kept in the pool. A value of `0` disables that upper bound. This is the default setting. If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.

- The `poolBatchPorts` parameter defines the maximum number of Neutron ports that can be created at once. The default value is `3`.

12.4.14.9. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the `install-config.yaml` file.

Procedure

1. From a command line, create the manifest files:

```
$ ./openshift-install create manifests --dir <installation_directory>
```
1. For `<installation_directory>`, specify the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a file that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```
   $ touch <installation_directory>/manifests/cluster-network-03-config.yml
   ```

3. Open the `cluster-network-03-config.yml` file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     clusterNetwork:
       - cidr: 10.128.0.0/14
         hostPrefix: 23
     serviceNetwork:
       - 172.30.0.0/16
     defaultNetwork:
       type: Kuryr
       kuryrConfig:
         enablePortPoolsPrepopulation: false
         poolMinPorts: 1
         poolBatchPorts: 3
         poolMaxPorts: 5
         openstackServiceNetwork: 172.30.0.0/15
   ```

4. Edit the settings to meet your requirements. The following file is provided as an example:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     clusterNetwork:
       - cidr: 10.128.0.0/14
         hostPrefix: 23
     serviceNetwork:
       - 172.30.0.0/16
     defaultNetwork:
       type: Kuryr
       kuryrConfig:
         enablePortPoolsPrepopulation: true
         poolMinPorts: 1
         poolBatchPorts: 3
         poolMaxPorts: 5
         openstackServiceNetwork: 172.30.0.0/15
   ```

   Set the value of `enablePortPoolsPrepopulation` to `true` to make Kuryr create new Neutron ports after a namespace is created or a new node is added to the cluster. This setting raises the Neutron ports quota but can reduce the time that is required to spawn
pods. The default value is `false`.

2. Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of `poolMinPorts`. The default value is `1`.

3. `poolBatchPorts` controls the number of new ports that are created if the number of free ports is lower than the value of `poolMinPorts`. The default value is `3`.

4. If the number of free ports in a pool is higher than the value of `poolMaxPorts`, Kuryr deletes them until the number matches that value. Setting this value to `0` disables this upper bound, preventing pools from shrinking. The default value is `0`.

5. The `openStackServiceNetwork` parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia’s LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of `openStackServiceNetwork` must be at least twice the size of the value of `serviceNetwork`, and the value of `serviceNetwork` must overlap entirely with the range that is defined by `openStackServiceNetwork`.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the `serviceNetwork` parameter.

If this parameter is not set, the CNO uses an expanded value of `serviceNetwork` that is determined by decrementing the prefix size by 1.

5. Save the `cluster-network-03-config.yml` file, and exit the text editor.

6. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory while creating the cluster.

12.4.14.10. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

**Prerequisites**

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:

   ```bash
   $ python -c '...
   ```
1. Insert a value that matches your intended Neutron subnet, e.g. 192.0.2.0/24.

- To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.

### 12.4.14.11. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

**Prerequisites**

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:

   - To set the value by using a script, run:

     ```
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["compute"][0]["replicas"] = 0;
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```

   - To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to 0.

### 12.4.14.12. Modifying the network type

By default, the installation program selects the OpenShiftSDN network type. To use Kuryr instead, change the value in the installation configuration file that the program generated.

**Prerequisites**

- You have the file `install-config.yaml` that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. In a command prompt, browse to the directory that contains `install-config.yaml`.
2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:

- To set the value by using a script, run:

  ```
  $ python -c 'import yaml;
  path = "install-config.yaml";
  data = yaml.safe_load(open(path));
  data["networking"]['networkType'] = "Kuryr";
  open(path, "w").write(yaml.dump(data, default_flow_style=False))'
  ``

- To set the value manually, open the file and set `networking.networkType` to "Kuryr".

### 12.4.15. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.
2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   $ ./openshift-install create ignition-configs --dir <installation_directory>  

   For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

- auth
  - kubeadmin-password
  - kubeconfig
- bootstrap.ign
5. Export the metadata file’s `infraID` key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

**TIP**

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

### 12.4.16. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

**Prerequisites**

- You have the bootstrap Ignition file that the installer program generates, `bootstrap.ign`.
- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

**Procedure**

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()
files.append(
```

```python
    {
```
2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```bash
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
```

3. Get the image’s details:

```bash
$ openstack image show <image_name>
```

Make a note of the file value; it follows the pattern v2/images/<image_ID>/file.

**NOTE**
Verify that the image you created is active.

4. Retrieve the image service’s public address:

```bash
$ openstack catalog show image
```

5. Combine the public address with the image file value and save the result as the storage location. The location follows the pattern <image_service_public_URL>/v2/images/<image_ID>/file.

6. Generate an auth token and save the token ID:

```bash
$ openstack token issue -c id -f value
```
7. Insert the following content into a file called $INFRA_ID-bootstrap-ignition.json and edit the placeholders to match your own values:

```json
{
  "ignition": {
    "config": {
      "merge": [
        {
          "source": "<storage_url>",
          "httpHeaders": [
            {
              "name": "X-Auth-Token",
              "value": "<token_ID>"
            }
          ]
        }
      ],
      "security": {
        "tls": {
          "certificateAuthorities": [
            {
              "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>"
            }
          ]
        }
      },
      "version": "3.2.0"
    }
  }
}
```

1. Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.
2. Set `name` in `httpHeaders` to "X-Auth-Token".
3. Set `value` in `httpHeaders` to your token’s ID.
4. If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

**WARNING**

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

12.4.17. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.
NOTE

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

Prerequisites

- The infrastructure ID from the installation program’s metadata file is set as an environment variable ($INFRA_ID).
  - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

```bash
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index"
    python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
    'data:text/plain;charset=utf-8;base64,' +
    base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
    'filesystem': 'root'});
    storage['files'] = files;
    ignition['storage'] = storage
    json.dump(ignition, sys.stdout)"
    <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: <INFRA_ID>-master-0-ignition.json, <INFRA_ID>-master-1-ignition.json, and <INFRA_ID>-master-2-ignition.json.

12.4.18. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the inventory.yaml playbook:

   Example external network value in the inventory.yaml Ansible playbook

   ```yaml
   ...
   ```
If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

Example FIP values in the `inventory.yaml` Ansible playbook

```yaml
# The public network providing connectivity to the cluster. If not provided, the cluster external connectivity must be provided in another way.

# Required for `os_api_fip`, `os_ingress_fip`, `os_bootstrap_fip`.

os_external_network: 'external'

...  

# OpenShift API floating IP address. If this value is non-empty, the corresponding floating IP will be attached to the Control Plane to serve the OpenShift API.

os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the corresponding floating IP will be attached to the worker nodes to serve the applications.

os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be attached to the bootstrap machine. This is needed for collecting logs in case of install failure.

os_bootstrap_fip: '203.0.113.20'
```

**IMPORTANT**

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform post-installation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See “Enabling access to the environment” for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml network.yaml
```
5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
```

12.4.19. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `bootstrap.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `bootstrap.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml bootstrap.yaml
```

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

```
$ openstack console log show "$INFRA_ID-bootstrap"
```

12.4.20. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program's metadata file is set as an environment variable (`$INFRA_ID`).
- The `inventory.yaml`, `common.yaml`, and `control-plane.yaml` Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".
Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. If the control plane Ignition config files aren’t already in your working directory, copy them into it.

3. On a command line, run the `control-plane.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml control-plane.yaml
   ```

4. Run the following command to monitor the bootstrapping process:

   ```bash
   $ openshift-install wait-for bootstrap-complete
   ```

   You will see messages that confirm that the control plane machines are running and have joined the cluster:

   ```
   INFO API v1.14.6+f9b5405 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   ... INFO It is now safe to remove the bootstrap resources
   ```

12.4.21. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```
12.4.22. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `down-bootstrap.yaml` Ansible playbooks are in a common directory.
- The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the `down-bootstrap.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml down-bootstrap.yaml
```

The bootstrap port, server, and floating IP address are deleted.

**WARNING**

If you did not disable the bootstrap Ignition file URL earlier, do so now.

12.4.23. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `compute-nodes.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

Procedure
1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the playbook:

   ```
   $ ansible-playbook -i inventory.yaml compute-nodes.yaml
   ```

Next steps

- Approve the certificate signing requests for the machines.

**12.4.24. Approving the certificate signing requests for your machines**

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mdflf</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved, Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved, Issued</td>
</tr>
</tbody>
</table>
3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name> 1
  
  1  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>
5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     ```
     $ oc adm certificate approve <csr_name>
     ```

     `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     ```
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
     ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

   ```
   $ oc get nodes
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

   **NOTE**

   It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

   **Additional information**

   - For more information on CSRs, see [Certificate Signing Requests](#).

### 12.4.25. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

**Prerequisites**

- You have the installation program (**openshift-install**)

**Procedure**

- On a command line, enter:
$ openshift-install --log-level debug wait-for install-complete

The program outputs the console URL, as well as the administrator’s login information.

12.4.26. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the [OpenShift Cluster Manager](https://docs.openshift.com/container-platform/4.7/high_availability/telemetry.html).

After you confirm that your [OpenShift Cluster Manager](https://docs.openshift.com/container-platform/4.7/high_availability/telemetry.html) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](https://docs.openshift.com/container-platform/4.7/high_availability/telemetry.html) for more information about the Telemetry service

12.4.27. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.5. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN SR-IOV INFRASTRUCTURE

In OpenShift Container Platform 4.7, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure and uses single-root input/output virtualization (SR-IOV) networks to run compute machines.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, such as Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

12.5.1. Prerequisites

  - Verify that OpenShift Container Platform 4.7 is compatible with your RHOSP version by using the "Supported platforms for OpenShift clusters" section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](https://docs.openshift.com/container-platform/4.7/installcatalog/index.html).
  - Verify that your network configuration does not rely on a provider network. Provider networks are not supported.
- Have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine where you run the installation program, have:
  - A single directory in which you can keep the files you create during the installation process
  - Python 3

### 12.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 12.5.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

#### Table 12.25. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 12.5.3.1. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

### 12.5.3.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory, 2 vCPUs, and 100 GB storage space
TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

Additionally, for clusters that use single-root input/output virtualization (SR-IOV), RHOSP compute nodes require a flavor that supports huge pages.

IMPORTANT

SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

Additional resources

- For more information about configuring performant RHOSP compute nodes, see Configuring Compute nodes for performance.

12.5.3.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

12.5.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

   a. Register with Red Hat Subscription Manager:

   ```bash
   $ sudo subscription-manager register # If not done already
   ```
b. Pull the latest subscription data:

```bash
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
```

c. Disable the current repositories:

```bash
$ sudo subscription-manager repos --disable=* # If not done already
```

d. Add the required repositories:

```bash
$ sudo subscription-manager repos\
   --enable=rhel-8-for-x86_64-baseos-rpms\
   --enable=openstack-16-tools-for-rhel-8-x86_64-rpms\
   --enable=ansible-2.9-for-rhel-8-x86_64-rpms\
   --enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```bash
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
```

3. Ensure that the `python` command points to `python3`:

```bash
$ sudo alternatives --set python /usr/bin/python3
```

### 12.5.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

#### Prerequisites

- The `curl` command-line tool is available on your machine.

#### Procedure

- To download the playbooks to your working directory, run the following script from a command line:

```bash
```
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 12.5.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the *Infrastructure Provider* page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

12.5.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

IMPORTANT

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "\n-f <path>/<file_name>  
```

1 Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
Running this command generates an SSH key that does not require a password in the location that you specified.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   $ eval "$\$(ssh-agent -s)"

   Example output

   Agent pid 31874

   NOTE

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   $ ssh-add /home/<you>/<path>/<file_name>

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

12.5.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

2. Under **Version**, select the most recent release of OpenShift Container Platform 4.7 for Red Hat Enterprise Linux (RHEL) 8.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the *Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)*.

4. Decompress the image.

   **NOTE**
   You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like `.gz` or `.tgz`. To find out if or how the file is compressed, in a command line, enter:

   ```
   $ file <name_of_downloaded_file>
   ```

5. From the image that you downloaded, create an image that is named **rhcos** in your cluster by using the RHOSP CLI:

   ```
   $ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-
   ${RHCOS_VERSION}-openstack.qcow2 rhcos
   ```

   **IMPORTANT**
   Depending on your RHOSP environment, you might be able to upload the image in either `.raw` or `.qcow2` formats. If you use Ceph, you must use the `.raw` format.

   **WARNING**
   If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

**12.5.9. Verifying external network access**
The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

### Prerequisites
- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

### Procedure
1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   +-------------------+----------------+-------------+
   | ID                | Name           | Router Type |
   +-------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External |
   +-------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

   **NOTE**
   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

### 12.5.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

#### 12.5.10.1. Enabling access with floating IP addresses
Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

**Procedure**
1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```
2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   
   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   ```
   $ openstack floating ip create --description "bootstrap machine" <external_network>
   ```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

   **NOTE**

   If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your /etc/hosts file:

   ```
   * <api_floating_ip> api.<cluster_name>.<base_domain>
   * <application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>
   * <application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>
   * <application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>
   * <application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
   * <application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>
   ```

   The cluster domain names in the /etc/hosts file grant access to the web console and the monitoring interface of your cluster locally. You can also use the kubectl or oc. You can access the user applications by using the additional entries pointing to the <application_floating_ip>. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

5. Add the FIPs to the inventory.yaml file as the values of the following variables:

   ```
   * os_api_fip
   * os_bootstrap_fip
   * os_ingress_fip
   ```

   If you use these values, you must also enter an external network as the value of the os_external_network variable in the inventory.yaml file.
TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.5.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `inventory.yaml` file, do not define the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
- `os_ingress_fip`

If you cannot provide an external network, you can also leave `os_external_network` blank. If you do not provide a value for `os_external_network`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the `wait-for` command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

12.5.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.
IMPORTANT

Remember to add a password to the auth field. You can also keep secrets in a separate file from clouds.yaml.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
  dev-env:
    region_name: RegionOne
    auth:
      username: 'devuser'
      password: XXX
      project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   a. Copy the certificate authority file to your machine.
   b. Add the cacerts key to the clouds.yaml file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
  shiftstack:
    ...
  cacert: '/etc/pki/ca-trust/source/anchors/ca.crt.pem'
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the ca-cert.pem key in the cloud-provider-config keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the clouds.yaml file in one of the following locations:
   a. The value of the OS_CLIENT_CONFIG_FILE environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example ~/.config/openstack/clouds.yaml
12.5.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the *install-config.yaml* file.
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:
      i. Optional: Select an SSH key to use to access your cluster machines.

         **NOTE**

         For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your *ssh-agent* process uses.

      ii. Select `openstack` as the platform to target.

      iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

      iv. Specify the floating IP address to use for external access to the OpenShift API.
v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file install-config.yaml in the directory that you specified.

12.5.13. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the install-config.yaml file.

IMPORTANT

The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.5.13.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{ &quot;auths&quot;:{ &quot;cloud.openshift.com&quot;:{ &quot;auth&quot;:&quot;b3Blb=&quot;, &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot; }, &quot;quay.io&quot;:{ &quot;auth&quot;:&quot;b3Blb=&quot;, &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot; } } }</td>
</tr>
</tbody>
</table>
12.5.13.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 12.27. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <em>10.128.0.0/14</em> with a host prefix of <em>/23</em>.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td>An IP address block.</td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given cidr. A <code>hostPrefix</code> value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>The default value is 23.</td>
<td></td>
</tr>
</tbody>
</table>
### networking.serviceNetwork

The IP address block for services. The default value is **172.30.0.0/16**.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.serviceNetwork</td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
</tbody>
</table>

### networking.machineNetwork

The IP address blocks for machines.

- If you specify multiple IP address blocks, the blocks must not overlap.
- If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.machineNetwork</td>
<td>An array of objects. For example:</td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>

### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is **10.0.0.0/16** for all platforms other than libvirt. For libvirt, the default value is **192.168.126.0/24**.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
<td>NOTE</td>
</tr>
<tr>
<td></td>
<td>Set the <code>networking.machineNetwork</code> to match the CIDR that the preferred NIC resides in.</td>
<td></td>
</tr>
</tbody>
</table>

#### 12.5.13.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision. A positive integer greater than or equal to 2. The default value is 3.</td>
<td></td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane. Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <em>hypertreading</em>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
### credentialsMode

The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.

### fips

Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><code>false</code> or <code>true</code></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>imageContentSources</code></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><code>imageContentSources.source</code></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><code>imageContentSources.mirrors</code></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><code>publish</code></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. The default value is <code>External</code>. Setting this field to <code>Internal</code> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If the value of the field is set to <code>Internal</code>, the cluster will become non-functional. For more information, refer to <code>BZ#1953035</code>.</td>
<td></td>
</tr>
<tr>
<td><code>sshKey</code></td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example:</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <code>ssh-agent</code> process uses.</td>
<td></td>
</tr>
</tbody>
</table>

12.5.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

Table 12.29. Additional RHOSP parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.platform.openstack.rootVolume.size</strong></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><strong>compute.platform.openstack.rootVolume.type</strong></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.rootVolume.size</strong></td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.rootVolume.type</strong></td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><strong>platform.openstack.cloud</strong></td>
<td>The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td><strong>platform.openstack.externalNetwork</strong></td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td><strong>platform.openstack.computeFlavor</strong></td>
<td>The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.</td>
<td>String, for example m1.xlarge.</td>
</tr>
</tbody>
</table>

### 12.5.13.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

<p>| Table 12.30. Optional RHOSP parameters |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.zones</td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td></td>
<td>On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td></td>
</tr>
<tr>
<td>platform.openstack.clusterOSImage</td>
<td>The location from which the installer downloads the RHCO5 image.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum.</td>
</tr>
<tr>
<td></td>
<td>You must set this parameter to perform an installation in a restricted network.</td>
<td>For example, [<a href="http://mirror.example.com/images/rhcos-43.81.20191210630.0-openstack.x86_64.qcow2.gz?sha256=dfebbd688a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b06b1b7f265d">http://mirror.example.com/images/rhcos-43.81.20191210630.0-openstack.x86_64.qcow2.gz?sha256=dfebbd688a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b06b1b7f265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImageProperties</td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image. You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi. You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;].</td>
</tr>
<tr>
<td>platform.openstack.defaultMachinePlatform</td>
<td>The default machine pool platform configuration.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;type&quot;: &quot;ml.large&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;rootVolume&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;size&quot;: 30,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;type&quot;: &quot;performance&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td>platform.openstack.ingressFloatingIP</td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.apiFloatingIP</td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.externalDNS</td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;].</td>
</tr>
</tbody>
</table>
**platform.openstack.machinesSubnet**
The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.

The first item in `networking.machineNetwork` must match the value of `machinesSubnet`.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

A UUID as a string. For example, `fa806b2f-ac49-4bce-b9db-124bc64209bf`.

---

**12.5.13.6. Sample customized install-config.yaml file for RHOSP**

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

---

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
  compute:
    - name: worker
      platform:
        openstack:
          type: ml.large
          replicas: 3
      metadata:
        name: example
      networking:
        clusterNetwork:
          - cidr: 10.128.0.0/14
          hostPrefix: 23
        machineNetwork:
          - cidr: 10.0.0.0/16
        serviceNetwork:
          - 172.30.0.0/16
      networkType: OpenShiftSDN
```
12.5.13.7. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

12.5.13.8. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.
Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```
     $ python -c 'import yaml; path = "install-config.yaml"; data = yaml.safe_load(open(path)); data["networking"]["machineNetwork"] = ["cidr": "192.168.0.0/18"]';
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```
     Insert a value that matches your intended Neutron subnet, e.g. `192.0.2.0/24`.
   - To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.

12.5.13.9. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```
     $ python -c 'import yaml; path = "install-config.yaml"; data = yaml.safe_load(open(path)); data["compute"][0]["replicas"] = 0;
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```
   - To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to 0.
12.5.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>  
   ``

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-* .yaml openshift/99_openshift-cluster-api_worker-machineset-* .yaml
   
   Because you create and manage these resources yourself, you do not have to initialize them.
   ```

   - You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.
WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

+ IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the mastersSchedulable parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   
   b. Locate the mastersSchedulable parameter and ensure that it is set to `false`.
   
   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

5. Export the metadata file’s `infraID` key as an environment variable:

   ```bash
   $ export INFRA_ID=$(jq -r .infraID metadata.json)
   ```
TIP

Extract the infralD key from metadata.json and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

12.5.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, bootstrap.ign.
- The infrastructure ID from the installer’s metadata file is set as an environment variable ($INFRA_ID).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()
files.append(
    {'path': '/etc/hostname',
     'mode': 420,
     'contents': {
         'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
     }
    })

cert_path = os.environ.get('OS_CACERT', '')
if cert_path:
    ca_cert_path = cert_path
```
2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
```

3. Get the image’s details:

```
$ openstack image show <image_name>
```

Make a note of the `file` value; it follows the pattern `v2/images/<image_ID>/file`.

**NOTE**
Verify that the image you created is active.

4. Retrieve the image service’s public address:

```
$ openstack catalog show image
```

5. Combine the public address with the image `file` value and save the result as the storage location. The location follows the pattern `<image_service_public_URL>/v2/images/<image_ID>/file`.

6. Generate an auth token and save the token ID:

```
$ openstack token issue -c id -f value
```

7. Insert the following content into a file called `$INFRA_ID-bootstrap-ignition.json` and edit the placeholders to match your own values:

```json
{
    "ignition": {
        "config": {
            "merge": [{
                "source": "<storage_url>",
```
Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.

Set `name` in `httpHeaders` to "X-Auth-Token".

Set `value` in `httpHeaders` to your token's ID.

If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

**WARNING**

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

**12.5.16. Creating control plane Ignition config files on RHOSP**

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

**NOTE**

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

**Prerequisites**
The infrastructure ID from the installation program’s metadata file is set as an environment variable (\$INFRA_ID).

- If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

**Procedure**

- On a command line, run the following Python script:

```bash
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index"
    python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
        'data:text/plain;charset=utf-8;base64,' +
        base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
        'filesystem': 'root'});
    storage['files'] = files;
    ignition['storage'] = storage
    json.dump(ignition, sys.stdout)"
    <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: `<INFRA_ID>-master-0-ignition.json`, `<INFRA_ID>-master-1-ignition.json`, and `<INFRA_ID>-master-2-ignition.json`.

### 12.5.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

**Prerequisites**

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

**Procedure**

1. Optional: Add an external network value to the `inventory.yaml` playbook:

   **Example external network value in the inventory.yaml Ansible playbook**

   ```yaml
   ...
   
   # The public network providing connectivity to the cluster. If not
   # provided, the cluster external connectivity must be provided in another
   # way.
   
   # Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
   os_external_network: "external"
   
   ...
   ```
IMPORTANT

If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

Example FIP values in the `inventory.yaml` Ansible playbook

```yaml
...
# OpenShift API floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the Control Plane to
# serve the OpenShift API.
os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the worker nodes to serve
# the applications.
os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
os_bootstrap_fip: '203.0.113.20'
```

IMPORTANT

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform post-installation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See “Enabling access to the environment” for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml network.yaml
```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
```
Optionally, you can use the `inventory.yaml` file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

12.5.17.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP **Bare Metal service (Ironic)** is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an `inventory.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `inventory.yaml` file, edit the flavors for machines:

   a. If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.

   b. Change the value of `os_flavor_worker` to a bare metal flavor.

   **An example bare metal inventory.yaml file**

   ```yaml
   all:
   hosts:
   localhost:
   ansible_connection: local
   ansible_python_interpreter: "{{ansible_playbook_python}}"

   # User-provided values
   os_subnet_range: '10.0.0.0/16'
   os_flavor_master: 'my-bare-metal-flavor'
   os_flavor_worker: 'my-bare-metal-flavor'
   ```
If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

Change this value to a bare metal flavor to use for compute machines.

Use the updated `inventory.yaml` file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

**NOTE**

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

### 12.5.18. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `bootstrap.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the `bootstrap.yaml` playbook:
   
   ```
   $ ansible-playbook -i inventory.yaml bootstrap.yaml
   ```
3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:
   
   ```
   $ openstack console log show "$INFRA_ID-bootstrap"
   ```

### 12.5.19. Creating the control plane machines on RHOSP
Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
- The `inventory.yaml`, `common.yaml`, and `control-plane.yaml` Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. If the control plane Ignition config files aren't already in your working directory, copy them into it.

3. On a command line, run the `control-plane.yaml` playbook:

   ```
   $ ansible-playbook -i inventory.yaml control-plane.yaml
   ```

4. Run the following command to monitor the bootstrapping process:

   ```
   $ openshift-install wait-for bootstrap-complete
   ```

   You will see messages that confirm that the control plane machines are running and have joined the cluster:

   ```
   INFO API v1.14.6+f9b5405 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   ... INFO It is now safe to remove the bootstrap resources
   ```

12.5.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.
Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

Example output

   system:admin

12.5.21. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The inventory.yaml, common.yaml, and down-bootstrap.yaml Ansible playbooks are in a common directory.
- The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the down-bootstrap.yaml playbook:

   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml

The bootstrap port, server, and floating IP address are deleted.

WARNING

If you did not disable the bootstrap Ignition file URL earlier, do so now.
12.5.22. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports single root I/O virtualization (SR-IOV), you can provision SR-IOV networks that compute machines run on.

**NOTE**

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.

**Prerequisites**

- Your cluster supports SR-IOV.

**NOTE**

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.

- You created radio and uplink provider networks as part of your RHOSP deployment. The names **radio** and **uplink** are used in all example commands to represent these networks.

**Procedure**

1. On a command line, create a radio RHOSP network:

   ```bash
   $ openstack network create radio --provider-physical-network radio --provider-network-type flat --external
   ```

2. Create an uplink RHOSP network:

   ```bash
   $ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
   ```

3. Create a subnet for the radio network:

   ```bash
   $ openstack subnet create --network radio --subnet-range <radio_network_subnet_range>
   ```

4. Create a subnet for the uplink network:

   ```bash
   $ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range>
   ```

12.5.23. Creating compute machines that run on SR-IOV networks

After standing up the control plane, create compute machines that run on the SR-IOV networks that you created in “Creating SR-IOV networks for compute machines”.

**Prerequisites**
You downloaded the modules in "Downloading playbook dependencies".

You downloaded the playbooks in "Downloading the installation playbooks".

The metadata.yaml file that the installation program created is in the same directory as the Ansible playbooks.

The control plane is active.

You created radio and uplink SR-IOV networks as described in "Creating SR-IOV networks for compute machines".

Procedure

1. On a command line, change the working directory to the location of the inventory.yaml and common.yaml files.

2. Add the radio and uplink networks to the end of the inventory.yaml file by using the additionalNetworks parameter:

   ```yaml
   additionalNetworks:
   - id: radio
     count: 4
     type: direct
     port_security_enabled: no
   - id: uplink
     count: 4
     type: direct
     port_security_enabled: no
   ```

   The count parameter defines the number of SR-IOV virtual functions (VFs) to attach to each worker node. In this case, each network has four VFs.

3. Replace the content of the compute-nodes.yaml file with the following text:

   ```yaml
   - hosts: all
     gather_facts: no
   
   vars:
     worker_list: []
     port_name_list: []
     nic_list: []
   
   tasks:
     # Create the SDN/primary port for each worker node
   ```
- name: 'Create the Compute ports'
  os_port:
    name: "{{ item.1 }}-{{ item.0 }}"
    network: "{{ os_network }}"
    security_groups:
      - "{{ os_sg_worker }}"
    allowed_address_pairs:
      - ip_address: "{{ os_ingressVIP }}"
    with_indexed_items: "{{ [os_port_worker] * os_compute_nodes_number }}"
  register: ports

# Tag each SDN/primary port with cluster name
- name: 'Set Compute ports tag'
  command:
    cmd: "openstack port set --tag {{ cluster_id_tag }} {{ item.1 }}-{{ item.0 }}"
  with_indexed_items: "{{ [os_port_worker] * os_compute_nodes_number }}"

- name: 'List the Compute Trunks'
  command:
    cmd: "openstack network trunk list"
  when: os_networking_type == "Kuryr"
  register: compute_trunks

- name: 'Create the Compute trunks'
  command:
    cmd: "openstack network trunk create --parent-port {{ item.1.id }} {{ os_compute_trunk_name }}-{{ item.0 }}"
  with_indexed_items: "{{ ports.results }}"
  when:
    - os_networking_type == "Kuryr"
    - "os_compute_trunk_name|string not in compute_trunks.stdout"

- name: 'Call additional-port processing'
  include_tasks: additional-ports.yaml

# Create additional ports in OpenStack
- name: 'Create additionalNetworks ports'
  os_port:
    name: "{{ item.0 }}-{{ item.1.name }}"
    vnic_type: "{{ item.1.type }}"
    network: "{{ item.1.uuid }}"
    port_security_enabled: "{{ item.1.port_security_enabled|default(omit) }}"
    no_security_groups: "{{ 'true' if item.1.security_groups is not defined else omit }}"
    security_groups: "{{ item.1.security_groups | default(omit) }}"
  with_nested:
    - "{{ worker_list }}"
    - "{{ port_name_list }}"

# Tag the ports with the cluster info
- name: 'Set additionalNetworks ports tag'
  command:
    cmd: "openstack port set --tag {{ cluster_id_tag }} {{ item.0 }}-{{ item.1.name }}"
  with_nested:
    - "{{ worker_list }}"
    - "{{ port_name_list }}"
# Build the nic list to use for server create
- name: Build nic list
  set_fact:
    nic_list: "{{ nic_list | default([]) + [ item.name ] }}"
  with_items: "{{ port_name_list }}"

# Create the servers
- name: 'Create the Compute servers'
  vars:
    worker_nics: "{{ [ item.1 ] | product(nic_list) | map('join','-') | map('regex_replace', '(\.)', 'port-name=\1') | list }}"

  # Create the Compute servers
  - name: Create the Compute servers
    vars:
      worker_nics: "{{ [ item.1 ] | product(nic_list) | map('join','-') | map('regex_replace', '(\.)', 'port-name=\1') | list }}"
      worker_list: "{{ worker_list | default([]) + [ item.1 + '-' + item.0 | string ] }}"
    with_indexed_items: "{{ [ os_compute_server_name ] * os_compute_nodes_number }}"

# Ensure that each network specified in additionalNetworks exists
- name: 'Verify additionalNetworks'
  with_items: "{{ additionalNetworks }}"
  register: network_info

# Expand additionalNetworks by the count parameter in each network definition
- name: 'Build port and port index list for additionalNetworks'
  set_fact:
    port_list: "{{ port_list | default([]) + [ { 'net_name': item.1.id, 'uuid': network_info.results[item.0].openstack_networks[0].id, 'type': item.1.type|default('normal'), 'security_groups': item.1.security_groups|default(omit), 'port_security_enabled': item.1.port_security_enabled|default(omit) } ] + item.1.count|default(1) }}"
    index_list: "{{ index_list | default([]) + range(item.1.count|default(1)) | list }}"
  with_indexed_items: "{{ additionalNetworks }}"

# Calculate and save the name of the port
# The format of the name is cluster_name-worker-workerID-networkUUID(partial)-count
# i.e. fdp-nz995-worker-1-99bcd111-1

4. Insert the following content into a local file that is called additional-ports.yaml:

Example 12.2. additional-ports.yaml

# Build a list of worker nodes with indexes
- name: 'Build worker list'
  set_fact:
    worker_list: "{{ worker_list | default([]) + [ item.1 + '-' + item.0 | string ] }}"
  with_indexed_items: "{{ [ os_compute_server_name ] * os_compute_nodes_number }}"

# Ensure that each network specified in additionalNetworks exists
- name: 'Verify additionalNetworks'
  with_items: "{{ additionalNetworks }}"
  register: network_info

# Expand additionalNetworks by the count parameter in each network definition
- name: 'Build port and port index list for additionalNetworks'
  set_fact:
    port_list: "{{ port_list | default([]) + [ { 'net_name': item.1.id, 'uuid': network_info.results[item.0].openstack_networks[0].id, 'type': item.1.type|default('normal'), 'security_groups': item.1.security_groups|default(omit), 'port_security_enabled': item.1.port_security_enabled|default(omit) } ] + item.1.count|default(1) }}"
    index_list: "{{ index_list | default([]) + range(item.1.count|default(1)) | list }}"
  with_indexed_items: "{{ additionalNetworks }}"

# Calculate and save the name of the port
# The format of the name is cluster_name-worker-workerID-networkUUID(partial)-count
# i.e. fdp-nz995-worker-1-99bcd111-1
5. On a command line, run the `compute-nodes.yaml` playbook:

```bash
$ ansible-playbook -i inventory.yaml compute-nodes.yaml
```

### 12.5.24. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.20.0
   master-1  Ready     master  63m  v1.20.0
   master-2  Ready     master  64m  v1.20.0
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   ```

   **Example output**

   ```
   NAME        AGE   REQUESTOR                                   CONDITION
   csr-mddf5   20m   system:node:master-01.example.com   Approved,Issued
   csr-z5rln   16m   system:node:worker-21.example.com   Approved,Issued
   ```
3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  
  ```
  $ oc adm certificate approve <csr_name> 1
  
  1  
  
  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td></td>
</tr>
</tbody>
</table>
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>  # 1
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE   VERSION
master-0  Ready     master  73m   v1.20.0
master-1  Ready     master  73m   v1.20.0
master-2  Ready     master  74m   v1.20.0
worker-0  Ready     worker  11m   v1.20.0
worker-1  Ready     worker  11m   v1.20.0
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

**Additional information**

- For more information on CSRs, see Certificate Signing Requests.

**12.5.25. Verifying a successful installation**

Verify that the OpenShift Container Platform installation is complete.

**Prerequisites**

- You have the installation program *(openshift-install)*

**Procedure**
On a command line, enter:

```
$ openshift-install --log-level debug wait-for install-complete
```

The program outputs the console URL, as well as the administrator’s login information.

The cluster is operational. Before you can configure it for SR-IOV networks though, you must perform additional tasks.

### 12.5.26. Preparing a cluster that runs on RHOSP for SR-IOV

Before you use **single root I/O virtualization (SR-IOV)** on a cluster that runs on Red Hat OpenStack Platform (RHOSP), make the RHOSP metadata service mountable as a drive and enable the No-IOMMU Operator for the virtual function I/O (VFIO) driver.

#### 12.5.26.1. Enabling the RHOSP metadata service as a mountable drive

You can apply a machine config to your machine pool that makes the Red Hat OpenStack Platform (RHOSP) metadata service available as a mountable drive.

The following machine config enables the display of RHOSP network UUIDs from within the SR-IOV Network Operator. This configuration simplifies the association of SR-IOV resources to cluster SR-IOV resources.

**Procedure**

1. Create a machine config file from the following template:

   **A mountable metadata service machine config file**

   ```yaml
   kind: MachineConfig
   apiVersion: machineconfiguration.openshift.io/v1
   metadata:
     name: 20-mount-config
   labels:
     machineconfiguration.openshift.io/role: worker
   spec:
     config:
       ignition:
         version: 3.2.0
       systemd:
         units:
           - name: create-mountpoint-var-config.service
             enabled: true
             contents: |
             [Unit]
             Description=Create mountpoint /var/config
             Before=kubelet.service

             [Service]
             ExecStart=/bin/mkdir -p /var/config

             [Install]
             WantedBy=var-config.mount
   ```
1. You can substitute a name of your choice.

2. From a command line, apply the machine config:

   ```bash
   $ oc apply -f <machine_config_file_name>.yaml
   ```

### 12.5.26.2. Enabling the No-IOMMU feature for the RHOSP VFIO driver

You can apply a machine config to your machine pool that enables the No-IOMMU feature for the Red Hat OpenStack Platform (RHOSP) virtual function I/O (VFIO) driver. The RHOSP vfio-pci driver requires this feature.

**Procedure**

1. Create a machine config file from the following template:

   **A No-IOMMU VFIO machine config file**

   ```yaml
   kind: MachineConfig
   apiVersion: machineconfiguration.openshift.io/v1
   metadata:
     name: 99-vfio-noiommu
     labels:
       machineconfiguration.openshift.io/role: worker
   spec:
     config:
       ignition:
         version: 3.2.0
     storage:
       files:
         - path: /etc/modprobe.d/vfio-noiommu.conf
           mode: 0644
           contents:
             source:
               data:b3B0aW9ucyB2ZmlvIGVuYWJsZV91bnNhZmVfdmFyOm9pb21vd2VhbkR1PEZMYjIzNjMzMTMzMTY5NDUzNjUwNjM3NTc4MTc4Mzg4NzE0NjI0Mzc2ODkwOTEK
   ```

   You can substitute a name of your choice.

2. From a command line, apply the machine config:

   ```bash
   $ oc apply -f <machine_config_file_name>.yaml
   ```
NOTE

After you apply the machine config to the machine pool, you can watch the machine config pool status to see when the machines are available.

The cluster is installed and prepared for SR-IOV configuration. You must now perform the SR-IOV configuration tasks in "Next steps".

12.5.27. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

12.5.28. Additional resources

- See Performance Addon Operator for low latency nodes for information about configuring your deployment for real-time running and low latency.

12.5.29. Next steps

- To complete SR-IOV configuration for your cluster:
  - Install the Performance Addon Operator.
  - Configure the Performance Addon Operator with huge pages support.
  - Install the SR-IOV Operator.
  - Configure your SR-IOV network device.

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.

- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.

- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.6. INSTALLING A CLUSTER ON OPENSTACK IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.7, you can install a cluster on Red Hat OpenStack Platform (RHOSP) in a restricted network by creating an internal mirror of the installation release content.
Prerequisites

- **Create a registry on your mirror host** and obtain the `imageContentSources` data for your version of OpenShift Container Platform.

  **IMPORTANT**

  Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- Review details about the **OpenShift Container Platform installation and update processes**.
  - Verify that OpenShift Container Platform 4.7 is compatible with your RHOSP version by using the "Supported platforms for OpenShift clusters" section. You can also compare platform support across different versions by viewing the **OpenShift Container Platform on RHOSP support matrix**.

- Verify that your network configuration does not rely on a provider network. Provider networks are not supported.

- Have the metadata service enabled in RHOSP.

### 12.6.1. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

#### 12.6.1.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an **Unable to retrieve available updates** error.

- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

### 12.6.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

**Table 12.31. Recommended resources for a default OpenShift Container Platform cluster on RHOSP**
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

**12.6.2.1. Control plane machines**

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

### 12.6.2.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory, 2 vCPUs, and 100 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 12.6.2.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 100 GB storage space

### 12.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT
If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.6.4. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.

IMPORTANT
If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On Ceph RGW, the **account in url** option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

```
$ openstack role add --user <user> --project <project> swiftoperator
```

Your RHOSP deployment can now use Swift for the image registry.

12.6.5. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:

   - If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.
IMPORTANT

Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
    dev-env:
      region_name: RegionOne
      auth:
        username: 'devuser'
        password: XXX
        project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   a. Copy the certificate authority file to your machine.
   b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
cclouds:
  shiftstack:
    ...
  cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:
   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
d. A Unix-specific site configuration directory, for example /etc/openstack/clouds.yaml
The installation program searches for clouds.yaml in that order.

12.6.6. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network Red Hat OpenStack Platform (RHOSP) environment.

Prerequisites

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

Procedure

2. Under Version, select the most recent release of OpenShift Container Platform 4.7 for RHEL 8.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW) image.

4. Decompress the image.

   **NOTE**

   You must decompress the image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

   ```
   $ file <name_of_downloaded_file>
   ```

5. Upload the image that you decompressed to a location that is accessible from the bastion server, like Glance. For example:

   ```
   $ openstack image create --file rhcos-44.81.202003110027-0-openstack.x86_64.qcow2 --disk-format qcow2 rhcos-$(RHCOS_VERSION)
   ```

   **IMPORTANT**

   Depending on your RHOSP environment, you might be able to upload the image in either .raw or .qcow2 formats. If you use Ceph, you must use the .raw format.
The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

12.6.7. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the `imageContentSources` values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory> 1
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.
b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `openstack` as the platform to target.

iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

iv. Specify the floating IP address to use for external access to the OpenShift API.

v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the `install-config.yaml` file, set the value of `platform.openstack.clusterOSImage` to the image location or name. For example:

```
platform:
  openstack:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?
    sha256=f8ebdd68a8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
```

3. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

a. Update the `pullSecret` value to contain the authentication information for your registry:

```
pullSecret: {"auths":{"<mirror_host_name>:5000": {"auth": ","credentials","email": "you@example.com"}}}
```

For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
    -----END CERTIFICATE-----
```
The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Add the image content resources, which look like this excerpt:

```
imageContentSources:
  - mirrors:
    - <mirror_host_name>:5000/<repo_name>/release
      source: quay.example.com/openshift-release-dev/ocp-release
    - mirrors:
      - <mirror_host_name>:5000/<repo_name>/release
      source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 12.6.7.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**
1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
noProxy: example.com
additionalTrustBundle:
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 12.6.7.2. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for...
the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the install-config.yaml file.

**IMPORTANT**

The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.6.7.2.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 12.32. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere**. For additional information about `platform.<platform>` parameters, consult the table for your specific platform that follows.

### pullSecret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
   "auths":{
      "cloud.openshift.com":{
         "auth":"b3Blb=",
         "email":"you@example.com"
      },
      "quay.io":{
         "auth":"b3Blb=",
         "email":"you@example.com"
      }
   }
}
```

### 12.6.7.2.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.33. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>machineNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

**NOTE**
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

### 12.6.7.2.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 12.34. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or **hyperthreading**, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <em>hypertreading</em>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or { }</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
**publish**

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Values**

Internal or External. The default value is External.

Setting this field to Internal is not supported on non-cloud platforms.

**IMPORTANT**

If the value of the field is set to Internal, the cluster will become non-functional. For more information, refer to BZ#1953035.

**sshKey**

The SSH key or keys to authenticate access your cluster machines.

**Values**

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

12.6.7.2.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 12.35. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.rootVolume.size</td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td>compute.platform.openstack.rootVolume.type</td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
</tbody>
</table>
### Optional RHOSP Configuration Parameters

Optional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>controlPlane.platform.openstack.rootVolume.size</strong></td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.rootVolume.type</strong></td>
<td>For control plane machines, the root volume's type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><strong>platform.openstack.cloud</strong></td>
<td>The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td><strong>platform.openstack.externalNetwork</strong></td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td><strong>platform.openstack.computeFlavor</strong></td>
<td>The RHOSP flavor to use for control plane and compute machines.</td>
<td>String, for example m1.xlarge.</td>
</tr>
</tbody>
</table>

This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.additionalNetworkIDs</td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>compute.platform.openstack.additionalSecurityGroupIDs</td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>compute.platform.openstack.zones</td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.additionalNetworkIDs</td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.additionalSecurityGroupIDs</td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>platform.openstack.clusterOSImage</code></td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example <code>my-rhcos</code>.</td>
</tr>
</tbody>
</table>
OpenShift Container Platform 4.7 Installing

Parameter

Description

Values

platform.openst
ack.clusterOSI
mageProperties

Properties to add to the
installer-uploaded
ClusterOSImage in Glance.
This property is ignored if

A list of key-value string pairs. For example,

["hw_scsi_model": "virtio-scsi",
"hw_disk_bus": "scsi"] .

platform.openstack.clust
erOSImage is set to an
existing Glance image.
You can use this property to
exceed the default persistent
volume (PV) limit for RHOSP
of 26 PVs per node. To
exceed the limit, set the
hw_scsi_model property
value to virtio-scsi and the
hw_disk_bus value to scsi.
You can also use this property
to enable the QEMU guest
agent by including the

hw_qemu_guest_agent
property with a value of yes.
platform.openst
ack.defaultMach
inePlatform

The default machine pool
platform configuration.

{
"type": "ml.large",
"rootVolume": {
"size": 30,
"type": "performance"
}
}

platform.openst
ack.ingressFloa
tingIP

An existing floating IP address
to associate with the Ingress
port. To use this property, you
must also define the

An IP address, for example 128.0.0.1.

platform.openstack.exter
nalNetwork property.
platform.openst
ack.apiFloatingI
P

An existing floating IP address
to associate with the API load
balancer. To use this property,
you must also define the

platform.openstack.exter
nalNetwork property.

1784

An IP address, for example 128.0.0.1.


<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.openstack.externalDNS</code></td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;]].</td>
</tr>
<tr>
<td><code>platform.openstack.machinesSubnet</code></td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</td>
<td>A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
</tbody>
</table>

The first item in `networking.machineNetwork` must match the value of `machinesSubnet`.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

### 12.6.7.3. Sample customized `install-config.yaml` file for restricted OpenStack installations

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:  
  name: master
  platform: {} 
  replicas: 3
compute:  
- name: worker
  platform:  
    openstack:  
      type: ml.large
      replicas: 3
  metadata:  
    name: example
  networking:  
    clusterNetwork:  
      - cidr: 10.128.0.0/14
        hostPrefix: 23
    machineCIDR: 10.0.0.0/16
```
Setting compute machine affinity

12.6.8. Setting compute machine affinity

Optionally, you can set the affinity policy for compute machines during installation. The installer does not select an affinity policy for compute machines by default.

You can also create machine sets that use particular RHOSP server groups after installation.

**NOTE**

Control plane machines are created with a soft-anti-affinity policy.

**TIP**

You can learn more about RHOSP instance scheduling and placement in the RHOSP documentation.

**Prerequisites**

- Create the `install-config.yaml` file and complete any modifications to it.

**Procedure**

1. Using the RHOSP command-line interface, create a server group for your compute machines. For example:

   ```
   $ openstack \
   ```
2. Change to the directory that contains the installation program and create the manifests:

   $ ./openshift-install create manifests --dir=<installation_directory>

   where:

   **installation_directory**
   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

3. Open `manifests/99_openshift-cluster-api_worker-machineset-0.yaml`, the **MachineSet** definition file.

4. Add the property **serverGroupID** to the definition beneath the `spec.template.spec.providerSpec.value` property. For example:

```yaml
apiVersion: machine.openshift.io/v1beta1
kind: MachineSet
metadata:
  labels:
    machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
    machine.openshift.io/cluster-api-machine-role: <node_role>
    machine.openshift.io/cluster-api-machine-type: <node_role>
  name: <infrastructure_ID>-<node_role>
  namespace: openshift-machine-api
spec:
  replicas: <number_of_replicas>
  selector:
    matchLabels:
      machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
      machine.openshift.io/cluster-api-machine-role: <node_role>
      machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
  template:
    metadata:
      labels:
        machine.openshift.io/cluster-api-cluster: <infrastructure_ID>
        machine.openshift.io/cluster-api-machine-role: <node_role>
        machine.openshift.io/cluster-api-machine-type: <node_role>
        machine.openshift.io/cluster-api-machineset: <infrastructure_ID>-<node_role>
    spec:
      providerSpec:
        value:
          apiVersion: openstackproviderconfig.openshift.io/v1alpha1
          cloudName: openstack
          cloudsSecret:
            name: openstack-cloud-credentials
            namespace: openshift-machine-api
          flavor: <nova_flavor>
          image: <glance_image_name_or_location>
```

For more information, see the **server group create** command documentation.
Add the UUID of your server group here.

5. Optional: Back up the `manifests/99_openshift-cluster-api_worker-machineset-0.yaml` file. The installation program deletes the `manifests/` directory when creating the cluster.

When you install the cluster, the installer uses the `MachineSet` definition that you modified to create compute machines within your RHOSP server group.

### 12.6.9. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```bash
ssh-keygen
```
Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

2. Start the ssh-agent process as a background task:

Example output

Agent pid 31874

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

12.6.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.
You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

12.6.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your `/etc/hosts` file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the `/etc/hosts` file grant access to the web console and the monitoring interface of your cluster locally. You can also use the `kubectl` or `oc`. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.
4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 12.6.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 12.6.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   Example output

   ```
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s
   ```

   **NOTE**

   The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

12.6.12. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:
   
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:
   
   $ oc get nodes

3. View your cluster’s version:
   
   $ oc get clusterversion

4. View your Operators’ status:
   
   $ oc get clusteroperator

5. View all running pods in the cluster:
   
   $ oc get pods -A
12.6.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:
   
   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   ```

2. Verify you can run `oc` commands successfully using the exported configuration:
   
   ```bash
   $ oc whoami
   
   system:admin
   ```

Example output

Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

12.6.14. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \\
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

12.6.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

12.6.16. Next steps

- Customize your cluster.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.7. UNINSTALLING A CLUSTER ON OPENSTACK

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP).

12.7.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites

- Have a copy of the installation program that you used to deploy the cluster.
Have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$ ./openshift-install destroy cluster \n--dir <installation_directory> --log-level info
```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2. To view different details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

12.8. UNINSTALLING A CLUSTER ON RHOSP FROM YOUR OWN INFRASTRUCTURE

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP) on user-provisioned infrastructure.

12.8.1. Downloading playbook dependencies

The Ansible playbooks that simplify the removal process on user-provisioned infrastructure require several Python modules. On the machine where you will run the process, add the modules' repositories and then download them.

**NOTE**

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

   a. Register with Red Hat Subscription Manager:

```
$ sudo subscription-manager register # If not done already
```
b. Pull the latest subscription data:

```
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
```

c. Disable the current repositories:

```
$ sudo subscription-manager repos --disable=* # If not done already
```

d. Add the required repositories:

```
$ sudo subscription-manager repos \
  --enable=rhel-8-for-x86_64-baseos-rpms \
  --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
  --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
  --enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk
```

3. Ensure that the `python` command points to `python3`:

```
$ sudo alternatives --set python /usr/bin/python3
```

### 12.8.2. Removing a cluster from RHOSP that uses your own infrastructure

You can remove an OpenShift Container Platform cluster on Red Hat OpenStack Platform (RHOSP) that uses your own infrastructure. To complete the removal process quickly, run several Ansible playbooks.

**Prerequisites**

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies."
- You have the playbooks that you used to install the cluster.
- You modified the playbooks that are prefixed with `down-` to reflect any changes that you made to their corresponding installation playbooks. For example, changes to the `bootstrap.yaml` file are reflected in the `down-bootstrap.yaml` file.
- All of the playbooks are in a common directory.

**Procedure**

1. On a command line, run the playbooks that you downloaded:

```
$ ansible-playbook -i inventory.yaml \
  down-bootstrap.yaml \  
  down-control-plane.yaml \  
  down-compute-nodes.yaml \  
  
```

2. Remove any DNS record changes you made for the OpenShift Container Platform installation.

OpenShift Container Platform is removed from your infrastructure.
13.1. INSTALLING A CLUSTER QUICKLY ON RHV

You can quickly install a default, non-customized, OpenShift Container Platform cluster on a Red Hat Virtualization (RHV) cluster, similar to the one shown in the following diagram.

The installation program uses installer-provisioned infrastructure to automate creating and deploying the cluster.

To install a default cluster, you prepare the environment, run the installation program and answer its prompts. Then, the installation program creates the OpenShift Container Platform cluster.

For an alternative to installing a default cluster, see Installing a cluster with customizations.

NOTE

This installation program is available for Linux and macOS only.

13.1.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on Red Hat Virtualization (RHV).
- If you use a firewall, configure it to allow the sites that your cluster requires access to.
13.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access **Quay.io** to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

13.1.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.7 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

**Requirements**

- The RHV version is 4.4.

- The RHV environment has one data center whose state is **Up**.

- The RHV data center contains an RHV cluster.

- The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
- Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
- 112 GiB RAM or more, including:
  - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
  - 16 GiB or more for each of the three control plane machines which provide the control plane.
  - 16 GiB or more for each of the three compute machines, which run the application workloads.
- The RHV storage domain must meet these etcd backend performance requirements.
- In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.
- To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.
- The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.
- A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:
  - DiskOperator
  - DiskCreator
  - UserTemplateBasedVm
  - TemplateOwner
  - TemplateCreator
  - ClusterAdmin on the target cluster

**WARNING**

Apply the principle of least privilege: Avoid using an administrator account with SuperUser privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary ovirt-config.yaml file that might be compromised.

13.1.4. Verifying the requirements for the RHV environment
Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

**IMPORTANT**

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

**Procedure**

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.7.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version.
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see [Support Matrix for OpenShift Container Platform on RHV](#).

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
   c. Click the name of that data center.
   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.
   e. Record the Domain Name for use later on.
   f. Confirm Free Space has at least 230 GiB.
   g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.
   h. In the data center details, click the Clusters tab.
   i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.
   a. In the RHV Administration Portal, click Compute > Clusters.
   b. Click the cluster where you plan to install OpenShift Container Platform.
   c. In the cluster details, click the Hosts tab.
   d. Inspect the hosts and confirm they have a combined total of at least 28 Logical CPU Cores available exclusively for the OpenShift Container Platform cluster.
e. Record the number of available **Logical CPU Cores** for use later on.

f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.

g. Confirm that, all together, the hosts have 112 GiB of **Max free Memory for scheduling new virtual machines** distributed to meet the requirements for each of the following OpenShift Container Platform machines:

- 16 GiB required for the bootstrap machine
- 16 GiB required for each of the three control plane machines
- 16 GiB for each of the three compute machines

h. Record the amount of **Max free Memory for scheduling new virtual machines** for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

```
$ curl -k -u <username>@<profile>:<password> \  
https://<engine-fqdn>/ovirt-engine/api
```

1. For `<username>`, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the **Profile** dropdown list. For `<password>`, specify the password for that user name.

2. For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

For example:

```
$ curl -k -u ocpadmin@internal:pw123 \  
https://rhv-env.virtlab.example.com/ovirt-engine/api
```

### 13.1.5. Preparing the network environment on RHV

Configure two static IP addresses for the OpenShift Container Platform cluster and create DNS entries using these addresses.

**Procedure**

1. Reserve two static IP addresses
   
   a. On the network where you plan to install OpenShift Container Platform, identify two static IP addresses that are outside the DHCP lease pool.

   b. Connect to a host on this network and verify that each of the IP addresses is not in use. For example, use Address Resolution Protocol (ARP) to check that none of the IP addresses have entries:
$ arp 10.35.1.19

Example output

10.35.1.19 (10.35.1.19) -- no entry

c. Reserve two static IP addresses following the standard practices for your network environment.

d. Record these IP addresses for future reference.

2. Create DNS entries for the OpenShift Container Platform REST API and apps domain names using this format:

   api.<cluster-name>.<base-domain>   <ip-address>  
   *.apps.<cluster-name>.<base-domain>   <ip-address>

   For <cluster-name>, <base-domain>, and <ip-address>, specify the cluster name, base domain, and static IP address of your OpenShift Container Platform API.

   Specify the cluster name, base domain, and static IP address of your OpenShift Container Platform apps for Ingress and the load balancer.

   For example:

   api.my-cluster.virtlab.example.com 10.35.1.19
   *.apps.my-cluster.virtlab.example.com 10.35.1.20

13.1.6. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in insecure mode.

WARNING

Installing in insecure mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.

Procedure

1. Create a file named ~/.ovirt/ovirt-config.yaml.

2. Add the following content to ovirt-config.yaml:
Specify the hostname or address of your oVirt engine.

Specify the fully qualified domain name of your oVirt engine.

Specify the admin password for your oVirt engine.

3. Run the installer.

13.1.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" \
   -f <path>/<file_name>
   ```

   **1** Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

```bash
$ ssh-add <path>/<file_name>
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

13.1.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 13.1.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Open the `ovirt-imageio` port to the Manager from the machine running the installer. By default, the port is `54322`.

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```bash
$ ./openshift-install create cluster --dir <installation_directory> \  
--log-level=info
```
For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

Respond to the installation program prompts.

a. Optional: For **SSH Public Key**, select a password-less public key, such as `~/.ssh/id_rsa.pub`. This key authenticates connections with the new OpenShift Container Platform cluster.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, select an SSH key that your `ssh-agent` process uses.

b. For **Platform**, select `ovirt`.

c. For **Engine FQDN[:PORT]**, enter the fully qualified domain name (FQDN) of the RHV environment.
   For example:
   ```
rhv-env.virtlab.example.com:443
   ```

d. The installer automatically generates a CA certificate. For **Would you like to use the above certificate to connect to the Manager?**, answer `y` or `N`. If you answer `N`, you must install OpenShift Container Platform in insecure mode.

e. For **Engine username**, enter the user name and profile of the RHV administrator using this format:
   ```
   <username>@<profile>  1
   ```

   **1** For `<username>`, specify the user name of an RHV administrator. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the `Profile` dropdown list. For example: `admin@internal`.

f. For **Engine password**, enter the RHV admin password.

g. For **Cluster**, select the RHV cluster for installing OpenShift Container Platform.
h. For **Storage domain**, select the storage domain for installing OpenShift Container Platform.

i. For **Network**, select a virtual network that has access to the RHV Manager REST API.

j. For **Internal API Virtual IP**, enter the static IP address you set aside for the cluster’s REST API.

k. For **Ingress virtual IP**, enter the static IP address you reserved for the wildcard apps domain.

l. For **Base Domain**, enter the base domain of the OpenShift Container Platform cluster. If this cluster is exposed to the outside world, this must be a valid domain recognized by DNS infrastructure. For example, enter: `virtlab.example.com`

m. For **Cluster Name**, enter the name of the cluster. For example, `my-cluster`. Use cluster name from the externally registered/resolvable DNS entries you created for the OpenShift Container Platform REST API and apps domain names. The installation program also gives this name to the cluster in the RHV environment.

n. For **Pull Secret**, copy the pull secret from the `pull-secret.txt` file you downloaded earlier and paste it here. You can also get a copy of the same pull secret from the Red Hat OpenShift Cluster Manager.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

You have completed the steps required to install the cluster. The remaining steps show you how to verify the cluster and troubleshoot the installation.

### 13.1.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of **oc**.

#### 13.1.10.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.7 Linux Client** entry and save the file.
4. Unpack the archive:

   ```bash
   $ tar xvzf <file>
   ```
5. Place the `oc` binary in a directory that is on your `PATH`. To check your `PATH`, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 13.1.10.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the `Version` drop-down menu.
3. Click `Download Now` next to the OpenShift v4.7 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`. To check your `PATH`, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 13.1.10.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the `Version` drop-down menu.
3. Click `Download Now` next to the OpenShift v4.7 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your `PATH`. To check your `PATH`, open a terminal and execute the following command:

```
$ echo $PATH
```

$ oc <command>
After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

To learn more, see Getting started with the OpenShift CLI.

### 13.1.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```text
   system:admin
   ```

**Additional resources**

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

### 13.1.12. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```
   $ oc get nodes
   ```

3. View your cluster’s version:

   ```
   $ oc get clusterversion
   ```

4. View your Operators’ status:

   ```
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:

   ```
   $ oc get pods -A
   ```

**Troubleshooting**

If the installation fails, the installation program times out and displays an error message. To learn more, see [Troubleshooting installation issues](#).

### 13.1.13. Accessing the OpenShift Container Platform web console on RHV

After the OpenShift Container Platform cluster initializes, you can log in to the OpenShift Container Platform web console.

**Procedure**

1. Optional: In the Red Hat Virtualization (RHV) Administration Portal, open **Compute → Cluster**.

2. Verify that the installation program creates the virtual machines.

3. Return to the command line where the installation program is running. When the installation program finishes, it displays the user name and temporary password for logging into the OpenShift Container Platform web console.

4. In a browser, open the URL of the OpenShift Container Platform web console. The URL uses this format:

   ```
   console-openshift-console.apps.<clustername>.<basedomain>
   ```

   For `<clustername>.<basedomain>`, specify the cluster name and base domain.

   For example:

   ```
   console-openshift-console.apps.my-cluster.virtlab.example.com
   ```
13.1.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.

13.1.15. Troubleshooting common issues with installing on Red Hat Virtualization (RHV)

Here are some common issues you might encounter, along with proposed causes and solutions.

13.1.15.1. CPU load increases and nodes go into a Not Ready state

- **Symptom:** CPU load increases significantly and nodes start going into a Not Ready state.

- **Cause:** The storage domain latency might be too high, especially for control plane nodes (also known as the master nodes).

- **Solution:**
  Make the nodes ready again by restarting the kubelet service:

  ```
  $ systemctl restart kubelet
  ```

  Inspect the OpenShift Container Platform metrics service, which automatically gathers and reports on some valuable data such as the etcd disk sync duration. If the cluster is operational, use this data to help determine whether storage latency or throughput is the root issue. If so, consider using a storage resource that has lower latency and higher throughput.

  To get raw metrics, enter the following command as kubeadmin or user with cluster-admin privileges:

  ```
  ```

  To learn more, see Exploring Application Endpoints for the purposes of Debugging with OpenShift 4.x.

13.1.15.2. Trouble connecting the OpenShift Container Platform cluster API

- **Symptom:** The installation program completes but the OpenShift Container Platform cluster API is not available. The bootstrap virtual machine remains up after the bootstrap process is complete. When you enter the following command, the response will time out.

  ```
  $ oc login -u kubeadmin -p *** <apiurl>
  ```

- **Cause:** The bootstrap VM was not deleted by the installation program and has not released the cluster’s API IP address.
- **Solution**: Use the `wait-for` subcommand to be notified when the bootstrap process is complete:

  ```bash
  $ ./openshift-install wait-for bootstrap-complete
  $$
  When the bootstrap process is complete, delete the bootstrap virtual machine:

  ```bash
  $ ./openshift-install destroy bootstrap
  $$

### 13.1.16. Post-installation tasks

After the OpenShift Container Platform cluster initializes, you can perform the following tasks.

- **Optional**: After deployment, add or replace SSH keys using the Machine Config Operator (MCO) in OpenShift Container Platform.

- **Optional**: Remove the `kubeadmin` user. Instead, use the authentication provider to create a user with cluster-admin privileges.

### 13.2. INSTALLING A CLUSTER ON RHV WITH CUSTOMIZATIONS

You can customize and install an OpenShift Container Platform cluster on Red Hat Virtualization (RHV), similar to the one shown in the following diagram.

The installation program uses installer-provisioned infrastructure to automate creating and deploying the cluster.

To install a customized cluster, you prepare the environment and perform the following steps:
1. Create an installation configuration file, the `install-config.yaml` file, by running the installation program and answering its prompts.

2. Inspect and modify parameters in the `install-config.yaml` file.

3. Make a working copy of the `install-config.yaml` file.

4. Run the installation program with a copy of the `install-config.yaml` file.

Then, the installation program creates the OpenShift Container Platform cluster.

For an alternative to installing a customized cluster, see Installing a default cluster.

**NOTE**

This installation program is available for Linux and macOS only.

### 13.2.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.

- You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on Red Hat Virtualization (RHV).

- If you use a firewall, configure it to allow the sites that your cluster requires access to.

### 13.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 13.2.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.7 cluster, the RHV environment must meet the following requirements.
Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

Requirements

- The RHV version is 4.4.
- The RHV environment has one data center whose state is Up.
- The RHV data center contains an RHV cluster.
- The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
  - Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
  - 112 GiB RAM or more, including:
    - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
    - 16 GiB or more for each of the three control plane machines which provide the control plane.
    - 16 GiB or more for each of the three compute machines, which run the application workloads.
- The RHV storage domain must meet these etcd backend performance requirements.
- In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.
- To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.
- The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.
A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:

- **DiskOperator**
- **DiskCreator**
- **UserTemplateBasedVm**
- **TemplateOwner**
- **TemplateCreator**
- **ClusterAdmin** on the target cluster

**WARNING**

Apply the principle of least privilege: Avoid using an administrator account with SuperUser privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary ovirt-config.yaml file that might be compromised.

### 13.2.4. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

**IMPORTANT**

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

**Procedure**

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.7.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select **About**.
   b. In the window that opens, make a note of the **RHV Software Version**
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see [Support Matrix for OpenShift Container Platform on RHV](#).

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click **Compute → Data Centers**.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
c. Click the name of that data center.

d. In the data center details, on the **Storage** tab, confirm the storage domain where you plan to install OpenShift Container Platform is **Active**.

e. Record the **Domain Name** for use later on.

f. Confirm **Free Space** has at least 230 GiB.

g. Confirm that the storage domain meets **these etcd backend performance requirements**, which you can measure by using the fio performance benchmarking tool.

h. In the data center details, click the **Clusters** tab.

i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.

   a. In the RHV Administration Portal, click **Compute > Clusters**.

   b. Click the cluster where you plan to install OpenShift Container Platform.

   c. In the cluster details, click the **Hosts** tab.

   d. Inspect the hosts and confirm they have a combined total of at least 28 **Logical CPU Cores** available **exclusively** for the OpenShift Container Platform cluster.

   e. Record the number of available **Logical CPU Cores** for use later on.

   f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.

   g. Confirm that, all together, the hosts have 112 GiB of **Max free Memory for scheduling new virtual machines** distributed to meet the requirements for each of the following OpenShift Container Platform machines:

   - 16 GiB required for the bootstrap machine
   - 16 GiB required for each of the three control plane machines
   - 16 GiB for each of the three compute machines

   h. Record the amount of **Max free Memory for scheduling new virtual machines** for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

```
$ curl -k -u <username>@<profile>:<password> \
https://<engine-fqdn>/ovirt-engine/api
```

For `<username>`, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the **Profile** dropdown list. For `<password>`, specify the password for that user.
name.

2. For <engine-fqdn>, specify the fully qualified domain name of the RHV environment.

For example:

```
$ curl -k -u ocpadmin@internal:pw123 \  
https://rhv-env.virtlab.example.com/ovirt-engine/api
```

### 13.2.5. Preparing the network environment on RHV

Configure two static IP addresses for the OpenShift Container Platform cluster and create DNS entries using these addresses.

**Procedure**

1. Reserve two static IP addresses
   
   a. On the network where you plan to install OpenShift Container Platform, identify two static IP addresses that are outside the DHCP lease pool.
   
   b. Connect to a host on this network and verify that each of the IP addresses is not in use. For example, use Address Resolution Protocol (ARP) to check that none of the IP addresses have entries:

   ```
   $ arp 10.35.1.19
   ```

   **Example output**

   ```
   10.35.1.19 (10.35.1.19) -- no entry
   ```

   c. Reserve two static IP addresses following the standard practices for your network environment.

   d. Record these IP addresses for future reference.

2. Create DNS entries for the OpenShift Container Platform REST API and apps domain names using this format:

   ```
   api.<cluster-name>.<base-domain> <ip-address> 1
   *.apps.<cluster-name>.<base-domain> <ip-address> 2
   ```

   1. For <cluster-name>, <base-domain>, and <ip-address>, specify the cluster name, base domain, and static IP address of your OpenShift Container Platform API.

   2. Specify the cluster name, base domain, and static IP address of your OpenShift Container Platform apps for Ingress and the load balancer.

   For example:

   ```
   api.my-cluster.virtlab.example.com 10.35.1.19
   *.apps.my-cluster.virtlab.example.com 10.35.1.20
   ```
13.2.6. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in insecure mode.

**WARNING**

Installing in insecure mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.

**Procedure**

1. Create a file named ~/.ovirt/ovirt-config.yaml.

2. Add the following content to ovirt-config.yaml:

```
ovirt_url: https://ovirt.example.com/ovirt-engine/api
ovirt_fqdn: ovirt.example.com
ovirt_pem_url: ""
ovirt_username: ocpadmin@internal
ovirt_password: super-secret-password
ovirt_insecure: true
```

   1. Specify the hostname or address of your oVirt engine.
   2. Specify the fully qualified domain name of your oVirt engine.
   3. Specify the admin password for your oVirt engine.

3. Run the installer.

13.2.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.
IMPORTANT

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "\n   -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. Start the `ssh-agent` process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

   ```bash
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

13.2.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
13.2.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat Virtualization (RHV).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   
   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. Respond to the installation program prompts.
      i. For **SSH Public Key**, select a password-less public key, such as `~/.ssh/id_rsa.pub`. This key authenticates connections with the new OpenShift Container Platform cluster.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, select an SSH key that your **ssh-agent** process uses.

      ii. For **Platform**, select `ovirt`.

      iii. For **Enter oVirt’s API endpoint URL**, enter the URL of the RHV API using this format:

      ```
      https://<engine-fqdn>/ovirt-engine/api
      ```

      For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.
For example:

```bash
$ curl -k -u ocpadmin@internal:pw123 
https://rhv-env.virtlab.example.com/ovirt-engine/api
```

iv. For **Is the oVirt CA trusted locally?**, enter **Yes**, because you have already set up a CA certificate. Otherwise, enter **No**.

v. For **oVirt’s CA bundle**, if you entered **Yes** for the preceding question, copy the certificate content from `/etc/pki/ca-trust/source/anchors/ca.pem` and paste it here. Then, press **Enter** twice. Otherwise, if you entered **No** for the preceding question, this question does not appear.

vi. For **oVirt engine username**, enter the user name and profile of the RHV administrator using this format:

```
<username>@<profile>
```

For **<username>**, specify the user name of an RHV administrator. For **<profile>**, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the **Profile** dropdown list. Together, the user name and profile should look similar to this example:

```
ocpadmin@internal
```

vii. For **oVirt engine password**, enter the RHV admin password.

viii. For **oVirt cluster**, select the cluster for installing OpenShift Container Platform.

ix. For **oVirt storage domain**, select the storage domain for installing OpenShift Container Platform.

x. For **oVirt network**, select a virtual network that has access to the RHV Manager REST API.

xi. For **Internal API Virtual IP**, enter the static IP address you set aside for the cluster’s REST API.

xii. For **Ingress virtual IP**, enter the static IP address you reserved for the wildcard apps domain.

xiii. For **Base Domain**, enter the base domain of the OpenShift Container Platform cluster. If this cluster is exposed to the outside world, this must be a valid domain recognized by DNS infrastructure. For example, enter: `virtlab.example.com`

xiv. For **Cluster Name**, enter the name of the cluster. For example, `my-cluster`. Use cluster name from the externally registered/resolvable DNS entries you created for the OpenShift Container Platform REST API and apps domain names. The installation program also gives this name to the cluster in the RHV environment.

xv. For **Pull Secret**, copy the pull secret from the `pull-secret.txt` file you downloaded earlier and paste it here. You can also get a copy of the same pull secret from the Red Hat OpenShift Cluster Manager.
2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

**NOTE**

If you have any intermediate CA certificates on the Manager, verify that the certificates appear in the `ovirt-config.yaml` file and the `install-config.yaml` file. If they do not appear, add them as follows:

1. In the `~/.ovirt/ovirt-config.yaml` file:

   ```yaml
   [ovirt_ca_bundle]: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA>
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   <INTERMEDIATE_CA>
   -----END CERTIFICATE-----
   ``

2. In the `install-config.yaml` file:

   ```yaml
   [additionalTrustBundle]: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA>
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   <INTERMEDIATE_CA>
   -----END CERTIFICATE-----
   ``

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 13.2.9.1. Example install-config.yaml files for Red Hat Virtualization (RHV)

You can customize the OpenShift Container Platform cluster the installation program creates by changing the parameters and parameter values in the `install-config.yaml` file.

The following example is specific to installing OpenShift Container Platform on RHV.

This file is located in the `<installation_directory>` you specified when you ran the following command.

```
$ ./openshift-install create install-config --dir <installation_directory>
```
NOTE

- These example files are provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

- Changing the `install-config.yaml` file can increase the resources your cluster requires. Verify that your RHV environment has those additional resources. Otherwise, the installation or cluster will fail.

Example: This is the default `install-config.yaml` file

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - architecture: amd64
    hyperthreading: Enabled
    name: worker
    platform: {}
    replicas: 3
controlPlane:
  architecture: amd64
  hyperthreading: Enabled
  name: master
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: my-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
      networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  ovirt:
    api_vip: 10.46.8.230
    ingress_vip: 192.168.1.5
    ovirt_cluster_id: 68833f9f-e89c-4891-b768-e2ba0815b76b
    ovirt_storage_domain_id: ed7b0f4e-0e96-492a-8fff-279213ee1468
    ovirt_network_name: ovirtmgmt
    vnicProfileID: 3fa86930-0be5-4052-b667-b79f0a729692
  publish: External
pullSecret: '{"auths": ...}'
sshKey: ssh-ed12345 AAAA...
```

Example: A minimal `install-config.yaml` file

```yaml
apiVersion: v1
baseDomain: example.com
metadata:
  name: test-cluster
```
platform:
  ovirt:
    api_vip: 10.46.8.230
    ingress_vip: 10.46.8.232
    ovirt_cluster_id: 68833f9f-e89c-4891-b768-e2ba0815b76b
    ovirt_storage_domain_id: ed7b0f4e-0e96-492a-8fff-279213ee1468
    ovirt_network_name: ovirtmgmt
    vnicProfileID: 3fa86930-0be5-4052-b667-b79f0a729692
    pullSecret: '{"auths": ...}'
  sshKey: ssh-ed12345 AAAA...

Example: Custom machine pools in an install-config.yaml file

apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform:
    ovirt:
      cpu:
        cores: 4
        sockets: 2
      memoryMB: 65536
      osDisk:
        sizeGB: 100
        vmType: server
      replicas: 3
  compute:
    - name: worker
      platform:
        ovirt:
          cpu:
            cores: 4
            sockets: 4
          memoryMB: 65536
          osDisk:
            sizeGB: 200
            vmType: server
          replicas: 5
  metadata:
    name: test-cluster
    platform:
      ovirt:
        api_vip: 10.46.8.230
        ingress_vip: 10.46.8.232
        ovirt_cluster_id: 68833f9f-e89c-4891-b768-e2ba0815b76b
        ovirt_storage_domain_id: ed7b0f4e-0e96-492a-8fff-279213ee1468
        ovirt_network_name: ovirtmgmt
        vnicProfileID: 3fa86930-0be5-4052-b667-b79f0a729692
        pullSecret: '{"auths": ...}'
        sshKey: ssh-ed25519 AAAA...

13.2.9.2. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe
your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 13.2.9.2.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 13.1. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{.metadata.name}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere**. For additional information about platform parameters, consult the table for your specific platform that follows.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td></td>
</tr>
</tbody>
</table>

```json
{
    "auths":{
        "cloud.openshift.com":{
            "auth":"b3Blb=",
            "email":"you@example.com"
        },
        "quay.io":{
            "auth":"b3Blb=",
            "email":"you@example.com"
        }
    }
}
```

13.2.9.2.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 13.2. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
</tbody>
</table>
| | The default value is **10.128.0.0/14** with a host prefix of **/23**. | networking:
| | If you specify multiple IP address blocks, the blocks must not overlap. | clusterNetwork:
| | An array with an IP address block in CIDR format. For example: | - cidr: **10.128.0.0/14**
| | | hostPrefix: **23** |
| networking.clusterNetwork.cidr | Required if you use networking.clusterNetwork. An IP address block. | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between **0** and **32**. |
| | An IPv4 network. | |
| networking.clusterNetwork.hostPrefix | The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to **23** then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of **23** provides 510 (2^(32 - 23) - 2) pod IP addresses. | A subnet prefix. |
| | The default value is **23**. | |
| networking.serviceNetwork | The IP address block for services. The default value is **172.30.0.0/16**. | An array with an IP address block in CIDR format. For example: |
| | The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. | networking:
| | | serviceNetwork:
| | | - **172.30.0.0/16** |

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.

---

**Parameter** | **Description** | **Values**
---|---|---
**networking** | The configuration for the cluster network. | Object |
**networking.network** | The cluster network provider Container Network Interface (CNI) plug-in to install. | Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN. |
**networking.clusterNetwork** | The IP address blocks for pods. | An array of objects. For example: |
| | The default value is **10.128.0.0/14** with a host prefix of **/23**. | networking:
| | If you specify multiple IP address blocks, the blocks must not overlap. | clusterNetwork:
| | An array with an IP address block in CIDR format. For example: | - cidr: **10.128.0.0/14**
| | | hostPrefix: **23** |
**networking.clusterNetwork.cidr** | Required if you use networking.clusterNetwork. An IP address block. | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between **0** and **32**. |
| | An IPv4 network. | |
**networking.clusterNetwork.hostPrefix** | The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to **23** then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of **23** provides 510 (2^(32 - 23) - 2) pod IP addresses. | A subnet prefix. |
| | The default value is **23**. | |
**networking.serviceNetwork** | The IP address block for services. The default value is **172.30.0.0/16**. | An array with an IP address block in CIDR format. For example: |
| | The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. | networking:
| | | serviceNetwork:
| | | - **172.30.0.0/16** |
networking.machine

The IP address blocks for machines.

If you specify multiple IP address blocks, the blocks must not overlap.

If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network.

networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

An array of objects. For example:

```
networking:
  machineNetwork:
    - cidr: 10.0.0.0/16
```

NOTE

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

13.2.9.2.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 13.3. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. The default value is <strong>External</strong>. Setting this field to <strong>Internal</strong> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</td>
</tr>
</tbody>
</table>

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

**IMPORTANT**
If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to BZ#1953035.
13.2.9.2.4. Additional Red Hat Virtualization (RHV) configuration parameters

Additional RHV configuration parameters are described in the following table:

Table 13.4. Additional RHV parameters for clusters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.ovirt.ovirt_cluster_id</td>
<td>Required. The Cluster where the VMs will be created.</td>
<td>String. For example: 68833f9f-e89c-4891-b768-e2ba0815b76b</td>
</tr>
<tr>
<td>platform.ovirt.ovirt_storage_domain_id</td>
<td>Required. The Storage Domain ID where the VM disks will be created.</td>
<td>String. For example: ed7b0f4e-0e96-492a-8fff-279213ee1468</td>
</tr>
<tr>
<td>platform.ovirt.ovirt_network_name</td>
<td>Required. The network name where the VM nics will be created.</td>
<td>String. For example: ocpcluster</td>
</tr>
<tr>
<td>platform.ovirt.vnicProfileID</td>
<td>Required. The vNIC profile ID of the VM network interfaces. This can be inferred if the cluster network has a single profile.</td>
<td>String. For example: 3fa86930-0be5-4052-b667-b79f0a729692</td>
</tr>
<tr>
<td>platform.ovirt.api_vip</td>
<td>Required. An IP address on the machine network that will be assigned to the API virtual IP (VIP). You can access the OpenShift API at this endpoint.</td>
<td>String. Example: 10.46.8.230</td>
</tr>
<tr>
<td>platform.ovirt.ingress_vip</td>
<td>Required. An IP address on the machine network that will be assigned to the Ingress virtual IP (VIP).</td>
<td>String. Example: 10.46.8.232</td>
</tr>
</tbody>
</table>

13.2.9.2.5. Additional RHV parameters for machine pools

Additional RHV configuration parameters for machine pools are described in the following table:

Table 13.5. Additional RHV parameters for machine pools

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;machine-pool&gt;.platform.ovirt.cpu</td>
<td>Optional. Defines the CPU of the VM.</td>
<td>Object</td>
</tr>
<tr>
<td>&lt;machine-pool&gt;.platform.ovirt.cpu.cores</td>
<td>Required if you use &lt;machine-pool&gt;.platform.ovirt.cpu. The number of cores. Total virtual CPUs (vCPUs) is cores * sockets.</td>
<td>Integer</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.cpu.sockets</code></td>
<td>Required if you use <code>&lt;machine-pool&gt;.platform.ovirt.cpu</code>. The number of sockets per core. Total virtual CPUs (vCPUs) is cores * sockets.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.memoryMB</code></td>
<td>Optional. Memory of the VM in MiB.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.instanceTypeID</code></td>
<td>Optional. An instance type UUID, such as 00000009-0009-0009-0009-0000000000f1, which you can get from the https://&lt;engine-fqdn&gt;/ovirt-engine/api/instancetypes endpoint.</td>
<td>String of UUID</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.osDisk</code></td>
<td>Optional. Defines the first and bootable disk of the VM.</td>
<td>String</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.osDisk.sizeGB</code></td>
<td>Required if you use <code>&lt;machine-pool&gt;.platform.ovirt.osDisk</code>. Size of the disk in GiB.</td>
<td>Number</td>
</tr>
</tbody>
</table>
### Parameter: <machine-pool>.platform.ovirt.vmType

<table>
<thead>
<tr>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional. The VM workload type, such as high-performance, server, or desktop. By default, control plane nodes use high-performance, and worker nodes use server. For details, see Explanation of Settings in the New Virtual Machine and Edit Virtual Machine Windows and Configuring High Performance Virtual Machines, Templates, and Pools in the Virtual Machine Management Guide.</td>
<td>String</td>
</tr>
</tbody>
</table>

**NOTE**

You can replace <machine-pool> with controlPlane or compute.

### 13.2.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the create cluster command of the installation program only once, during initial installation.

**Prerequisites**

- Open the ovirt-imageio port to the Manager from the machine running the installer. By default, the port is 54322.
Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   NOTE

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   Example output

   ```
   ... INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s
   ```

   NOTE

   The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

IMPORTANT

You have completed the steps required to install the cluster. The remaining steps show you how to verify the cluster and troubleshoot the installation.

13.2.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

13.2.11.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

```bash
$ tar xvzf <file>
```
5. Place the `oc` binary in a directory that is on your `PATH`. To check your `PATH`, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 13.2.11.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the `Version` drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your `PATH`. To check your `PATH`, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 13.2.11.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the `Version` drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your `PATH`. To check your `PATH`, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
After you install the OpenShift CLI, it is available using the `oc` command:

\[
\text{
$ oc <command>
$
}
\]

### 13.2.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

\[
\text{
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
$
}
\]

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

\[
\text{
$ oc whoami
$
}
\]

**Example output**

```
system:admin
```

To learn more, see *Getting started with the OpenShift CLI*.

### 13.2.13. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s `kubeconfig` file:

\[
\text{
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
$
}
\]

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.
2. View the control plane and compute machines created after a deployment:
   
   `$ oc get nodes`

3. View your cluster’s version:
   
   `$ oc get clusterversion`

4. View your Operators’ status:
   
   `$ oc get clusteroperator`

5. View all running pods in the cluster:
   
   `$ oc get pods -A`

**Troubleshooting**

If the installation fails, the installation program times out and displays an error message. To learn more, see Troubleshooting installation issues.

### 13.2.14. Accessing the OpenShift Container Platform web console on RHV

After the OpenShift Container Platform cluster initializes, you can log in to the OpenShift Container Platform web console.

**Procedure**

1. Optional: In the Red Hat Virtualization (RHV) Administration Portal, open **Compute → Cluster**.

2. Verify that the installation program creates the virtual machines.

3. Return to the command line where the installation program is running. When the installation program finishes, it displays the user name and temporary password for logging into the OpenShift Container Platform web console.

4. In a browser, open the URL of the OpenShift Container Platform web console. The URL uses this format:
   
   ```
   console-openshift-console.apps.<clusternamel><basedomain>
   ```

   For `<clusternamel><basedomain>`, specify the cluster name and base domain.

   For example:
   
   ```
   console-openshift-console.apps.my-cluster.virtlab.example.com
   ```

### 13.2.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.
After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service.

### 13.2.16. Troubleshooting common issues with installing on Red Hat Virtualization (RHV)

Here are some common issues you might encounter, along with proposed causes and solutions.

#### 13.2.16.1. CPU load increases and nodes go into a Not Ready state

- **Symptom**: CPU load increases significantly and nodes start going into a Not Ready state.

- **Cause**: The storage domain latency might be too high, especially for control plane nodes (also known as the master nodes).

- **Solution**: Make the nodes ready again by restarting the kubelet service:

  ```
  $ systemctl restart kubelet
  ```

  Inspect the OpenShift Container Platform metrics service, which automatically gathers and reports on some valuable data such as the etcd disk sync duration. If the cluster is operational, use this data to help determine whether storage latency or throughput is the root issue. If so, consider using a storage resource that has lower latency and higher throughput.

  To get raw metrics, enter the following command as kubeadmin or user with cluster-admin privileges:

  ```
  ```

  To learn more, see Exploring Application Endpoints for the purposes of Debugging with OpenShift 4.x.

#### 13.2.16.2. Trouble connecting the OpenShift Container Platform cluster API

- **Symptom**: The installation program completes but the OpenShift Container Platform cluster API is not available. The bootstrap virtual machine remains up after the bootstrap process is complete. When you enter the following command, the response will time out.

  ```
  $ oc login -u kubeadmin -p *** <apiurl>
  ```

- **Cause**: The bootstrap VM was not deleted by the installation program and has not released the cluster’s API IP address.

- **Solution**: Use the wait-for subcommand to be notified when the bootstrap process is complete:

  ```
  $ ./openshift-install wait-for bootstrap-complete
  ```
When the bootstrap process is complete, delete the bootstrap virtual machine:

```
./openshift-install destroy bootstrap
```

### 13.2.17. Post-installation tasks

After the OpenShift Container Platform cluster initializes, you can perform the following tasks.

- Optional: After deployment, add or replace SSH keys using the Machine Config Operator (MCO) in OpenShift Container Platform.

- Optional: Remove the `kubeadmin` user. Instead, use the authentication provider to create a user with cluster-admin privileges.

### 13.2.18. Next steps

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.

### 13.3. INSTALLING A CLUSTER ON RHV WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.7, you can install a customized OpenShift Container Platform cluster on Red Hat Virtualization (RHV) and other infrastructure that you provide. The OpenShift Container Platform documentation uses the term `user-provisioned infrastructure` to refer to this infrastructure type.

The following diagram shows an example of a potential OpenShift Container Platform cluster running on a RHV cluster.
The RHV hosts run virtual machines that contain both control plane and compute pods. One of the hosts also runs a Manager virtual machine and a bootstrap virtual machine that contains a temporary control plane pod.

### 13.3.1. Prerequisites

The following items are required to install an OpenShift Container Platform cluster on a RHV environment.

- You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on RHV.
- You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on Red Hat Virtualization (RHV).
- You are familiar with the OpenShift Container Platform installation and update processes.

### 13.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 13.3.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.7 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

**Requirements**

• The RHV version is 4.4.

• The RHV environment has one data center whose state is **Up**.

• The RHV data center contains an RHV cluster.

• The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
  • Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
  • 112 GiB RAM or more, including:
    • 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
    • 16 GiB or more for each of the three control plane machines which provide the control plane.
    • 16 GiB or more for each of the three compute machines, which run the application workloads.
The RHV storage domain must meet these etcd backend performance requirements.

In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.

To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.

The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.

A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:

- **DiskOperator**
- **DiskCreator**
- **UserTemplateBasedVm**
- **TemplateOwner**
- **TemplateCreator**
- **ClusterAdmin** on the target cluster

**WARNING**

Apply the principle of least privilege: Avoid using an administrator account with **SuperUser** privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary `ovirt-config.yaml` file that might be compromised.

### 13.3.4. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

**IMPORTANT**

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

**Procedure**
1. Check that the RHV version supports installation of OpenShift Container Platform version 4.7.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version.
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
   c. Click the name of that data center.
   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.
   e. Record the Domain Name for use later on.
   f. Confirm Free Space has at least 230 GiB.
   g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.
   h. In the data center details, click the Clusters tab.
   i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.
   a. In the RHV Administration Portal, click Compute > Clusters.
   b. Click the cluster where you plan to install OpenShift Container Platform.
   c. In the cluster details, click the Hosts tab.
   d. Inspect the hosts and confirm they have a combined total of at least 28 Logical CPU Cores available exclusively for the OpenShift Container Platform cluster.
   e. Record the number of available Logical CPU Cores for use later on.
   f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.
   g. Confirm that, all together, the hosts have 112 GiB of Max free Memory for scheduling new virtual machines distributed to meet the requirements for each of the following OpenShift Container Platform machines:
      - 16 GiB required for the bootstrap machine
      - 16 GiB required for each of the three control plane machines
• 16 GiB for each of the three compute machines

h. Record the amount of Max free Memory for scheduling new virtual machines for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

```
$ curl -k -u <username>@<profile>:<password> | https://<engine-fqdn>/ovirt-engine/api
```

1 For `<username>`, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the Profile dropdown list. For `<password>`, specify the password for that user name.

2 For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

For example:

```
$ curl -k -u ocpadmin@internal:pw123 | https://rhv-env.virtlab.example.com/ovirt-engine/api
```

### 13.3.5. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in **initramfs** during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

**Firewall**

Configure your firewall so your cluster has access to required sites.

See also:

- Red Hat Virtualization Manager firewall requirements
- Host firewall requirements

**Load balancers**
Configure one or preferably two layer-4 load balancers:

- Provide load balancing for ports 6443 and 22623 on the control plane and bootstrap machines. Port 6443 provides access to the Kubernetes API server and must be reachable both internally and externally. Port 22623 must be accessible to nodes within the cluster.

- Provide load balancing for port 443 and 80 for machines that run the Ingress router, which are usually compute nodes in the default configuration. Both ports must be accessible from within and outside the cluster.

DNS

Configure infrastructure-provided DNS to allow the correct resolution of the main components and services. If you use only one load balancer, these DNS records can point to the same IP address.

- Create DNS records for api.<cluster_name>.<base_domain> (internal and external resolution) and api-int.<cluster_name>.<base_domain> (internal resolution) that point to the load balancer for the control plane machines.

- Create a DNS record for *.apps.<cluster_name>.<base_domain> that points to the load balancer for the Ingress router. For example, ports 443 and 80 of the compute machines.

</tr>
</tbody>
</table>

Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

Table 13.9. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

**13.3.6. Setting up the installation machine**
To run the binary **openshift-install** installation program and Ansible scripts, set up the RHV Manager or an Red Hat Enterprise Linux (RHEL) computer with network access to the RHV environment and the REST API on the Manager.

**Procedure**

1. Update or install Python3 and Ansible. For example:
   ```bash
   # dnf update python3 ansible
   ```

2. Install the **python3-ovirt-engine-sdk4** package to get the Python Software Development Kit.

3. Install the **ovirt.image-template** Ansible role. On the RHV Manager and other Red Hat Enterprise Linux (RHEL) machines, this role is distributed as the **ovirt-ansible-image-template** package. For example, enter:
   ```bash
   # dnf install ovirt-ansible-image-template
   ```

4. Install the **ovirt.vm-infra** Ansible role. On the RHV Manager and other RHEL machines, this role is distributed as the **ovirt-ansible-vm-infra** package.
   ```bash
   # dnf install ovirt-ansible-vm-infra
   ```

5. Create an environment variable and assign an absolute or relative path to it. For example, enter:
   ```bash
   $ export ASSETS_DIR=./wrk
   ```

**NOTE**

The installation program uses this variable to create a directory where it saves important installation-related files. Later, the installation process reuses this variable to locate those asset files. Avoid deleting this assets directory; it is required for uninstalling the cluster.

### 13.3.7. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in **insecure** mode.

**WARNING**

Installing in **insecure** mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.
Procedure

1. Create a file named ~/.ovirt/ovirt-config.yaml.

2. Add the following content to ovirt-config.yaml:

   ovirt_url: https://ovirt.example.com/ovirt-engine/api  
   ovirt_fqdn: ovirt.example.com  
   ovirt_pem_url: ""  
   ovirt_username: ocpadmin@internal  
   ovirt_password: super-secret-password

   1. Specify the hostname or address of your oVirt engine.
   2. Specify the fully qualified domain name of your oVirt engine.
   3. Specify the admin password for your oVirt engine.

3. Run the installer.

13.3.8. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N ""  
   -f <path>/<file_name>  

   1. Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
Running this command generates an SSH key that does not require a password in the location that you specified.

NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   $ eval "$(ssh-agent -s)"

Example output

Agent pid 31874

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> ①

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

① Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

13.3.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure
1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**
   
   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**
   
   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

13.3.10. Downloading the Ansible playbooks

Download the Ansible playbooks for installing OpenShift Container Platform version 4.7 on RHV.

**Procedure**

- On your installation machine, run the following commands:

  ```
  $ mkdir playbooks
  $ cd playbooks
  $ curl -s -L -X GET https://api.github.com/repos/openshift/installer/contents/upi/ovirt?ref=release-4.7 | grep 'download_url.*\.yml' | awk '{ print $2 }' | sed -r 's/(\")/,/g' | xargs -n 1 curl -O
  ```

**Next steps**
After you download these Ansible playbooks, you must also create the environment variable for the assets directory and customize the `inventory.yml` file before you create an installation configuration file by running the installation program.

13.3.11. The inventory.yml file

You use the `inventory.yml` file to define and create elements of the OpenShift Container Platform cluster you are installing. This includes elements such as the Red Hat Enterprise Linux CoreOS (RHCOS) image, virtual machine templates, bootstrap machine, control plane nodes, and worker nodes. You also use `inventory.yml` to destroy the cluster.

The following `inventory.yml` example shows you the parameters and their default values. The quantities and numbers in these default values meet the requirements for running a production OpenShift Container Platform cluster in a RHV environment.

Example inventory.yml file

```yaml
---
all:
  vars:

  ovirt_cluster: "Default"
  ocp:
    assets_dir: "{{ lookup('env', 'ASSETS_DIR') }}"
    ovirt_config_path: "{{ lookup('env', 'HOME') }}/.ovirt/ovirt-config.yaml"

# ---
# {op-system} section
# ---
  rhcos:
    image_url: "https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/4.7/latest/rhcos-openstack.x86_64.qcow2.gz"
    local_cmp_image_path: "/tmp/rhcos.qcow2.gz"
    local_image_path: "/tmp/rhcos.qcow2"

# ---
# Profiles section
# ---
  control_plane:
    cluster: "{{ ovirt_cluster }}"
    memory: 16GiB
    sockets: 4
    cores: 1
    template: rhcos_tpl
    operating_system: "rhcos_x64"
    type: high_performance
    graphical_console:
      headless_mode: false
    protocol:
      - spice
      - vnc
    disks:
      - size: 120GiB
    name: os
    interface: virtio_scsi
    storage_domain: depot_nvme
```
nics:
- name: nic1
  network: lab
  profile: lab

compute:
  cluster: "{{ ovirt_cluster }}"
  memory: 16GiB
  sockets: 4
  cores: 1
  template: worker_rhcos_tpl
  operating_system: "rhcos_x64"
  type: high_performance
  graphical_console:
    headless_mode: false
  protocol:
    - spice
    - vnc

disks:
- size: 120GiB
  name: os
  interface: virtio_scsi
  storage_domain: depot_nvme
nics:
- name: nic1
  network: lab
  profile: lab

# ---
# Virtual machines section
# ---
vms:
- name: "{{ metadata.infraID }}-bootstrap"
  ocp_type: bootstrap
  profile: "{{ control_plane }}"
  type: server
- name: "{{ metadata.infraID }}-master0"
  ocp_type: master
  profile: "{{ control_plane }}"
- name: "{{ metadata.infraID }}-master1"
  ocp_type: master
  profile: "{{ control_plane }}"
- name: "{{ metadata.infraID }}-master2"
  ocp_type: master
  profile: "{{ control_plane }}"
- name: "{{ metadata.infraID }}-worker0"
  ocp_type: worker
  profile: "{{ compute }}"
- name: "{{ metadata.infraID }}-worker1"
  ocp_type: worker
  profile: "{{ compute }}"
- name: "{{ metadata.infraID }}-worker2"
  ocp_type: worker
  profile: "{{ compute }}"
IMPORTANT

Enter values for parameters whose descriptions begin with "Enter." Otherwise, you can use the default value or replace it with a new value.

General section

- **ovirt_cluster**: Enter the name of an existing RHV cluster in which to install the OpenShift Container Platform cluster.

- **ocp.assets_dir**: The path of a directory the **openshift-install** installation program creates to store the files that it generates.

- **ocp.ovirt_config_path**: The path of the **ovirt-config.yaml** file the installation program generates, for example, `/wrk/install-config.yaml`. This file contains the credentials required to interact with the REST API of the Manager.

Red Hat Enterprise Linux CoreOS (RHCOS) section

- **image_url**: Enter the URL of the RHCOS image you specified for download.

- **local_cmp_image_path**: The path of a local download directory for the compressed RHCOS image.

- **local_image_path**: The path of a local directory for the extracted RHCOS image.

Profiles section

This section consists of two profiles:

- **control_plane**: The profile of the bootstrap and control plane nodes.

- **compute**: The profile of workers nodes in the compute plane.

These profiles have the following parameters. The default values of the parameters meet the minimum requirements for running a production cluster. You can increase or customize these values to meet your workload requirements.

- **cluster**: The value gets the cluster name from **ovirt_cluster** in the General Section.

- **memory**: The amount of memory, in GB, for the virtual machine.

- **sockets**: The number of sockets for the virtual machine.

- **cores**: The number of cores for the virtual machine.

- **template**: The name of the virtual machine template. If plan to install multiple clusters, and these clusters use templates that contain different specifications, prepend the template name with the ID of the cluster.

- **operating_system**: The type of guest operating system in the virtual machine. With oVirt/RHV version 4.4, this value must be **rhcos_x64** so the value of Ignition script can be passed to the VM.

- **type**: Enter **server** as the type of the virtual machine.
IMPORTANT

You must change the value of the type parameter from high_performance to server.

- disks: The disk specifications. The control_plane and compute nodes can have different storage domains.
- size: The minimum disk size.
- name: Enter the name of a disk connected to the target cluster in RHV.
- interface: Enter the interface type of the disk you specified.
- storage_domain: Enter the storage domain of the disk you specified.
- nics: Enter the name and network the virtual machines use. You can also specify the virtual network interface profile. By default, NICs obtain their MAC addresses from the oVirt/RHV MAC pool.

Virtual machines section

This final section, vms, defines the virtual machines you plan to create and deploy in the cluster. By default, it provides the minimum number of control plane and worker nodes for a production environment.

vms contains three required elements:

- name: The name of the virtual machine. In this case, metadata.infraID prepends the virtual machine name with the infrastructure ID from the metadata.yml file.
- ocp_type: The role of the virtual machine in the OCP cluster. Possible values are bootstrap, master, worker.
- profile: The name of the profile from which each virtual machine inherits specifications. Possible values in this example are control_plane or compute.

You can override the value a virtual machine inherits from its profile. To do this, you add the name of the profile attribute to the virtual machine in inventory.yml and assign it an overriding value. To see an example of this, examine the name: "{{ metadata.infraID }}-bootstrap" virtual machine in the preceding inventory.yml example: It has a type attribute whose value, server, overrides the value of the type attribute this virtual machine would otherwise inherit from the control_plane profile.

Metadata variables

For virtual machines, metadata.infraID prepends the name of the virtual machine with the infrastructure ID from the metadata.json file you create when you build the Ignition files.

The playbooks use the following code to read infraID from the specific file located in the ocp.assets_dir.

```yaml
---
- name: include metadata.json vars
  include_vars:
    file: "{{ ocp.assets_dir }}/metadata.json"
```
13.3.12. Specifying the RHCOS image settings

Update the Red Hat Enterprise Linux CoreOS (RHCOS) image settings of the `inventory.yml` file. Later, when you run this file one of the playbooks, it downloads a compressed Red Hat Enterprise Linux CoreOS (RHCOS) image from the `image_url` URL to the `local_cmp_image_path` directory. The playbook then uncompresses the image to the `local_image_path` directory and uses it to create oVirt/RHV templates.

**Procedure**

1. Locate the RHCOS image download page for the version of OpenShift Container Platform you are installing, such as Index of /pub/openshift-v4/dependencies/rhcos/latest/latest.

2. From that download page, copy the URL of an OpenStack qcow2 image, such as https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/4.7/latest/rhcos-openstack.x86_64.qcow2.gz.

3. Edit the `inventory.yml` playbook you downloaded earlier. In it, paste the URL as the value for `image_url`. For example:

   ```yaml
   rhcos:
     "https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/4.7/latest/rhcos-openstack.x86_64.qcow2.gz"
   ```

13.3.13. Creating the install config file

You create an installation configuration file by running the installation program, `openshift-install`, and responding to its prompts with information you specified or gathered earlier.

When you finish responding to the prompts, the installation program creates an initial version of the `install-config.yaml` file in the assets directory you specified earlier, for example, `./wrk/install-config.yaml`

The installation program also creates a file, `.$HOME/.ovirt/ovirt-config.yaml`, that contains all the connection parameters that are required to reach the Manager and use its REST API.

**NOTE:** The installation process does not use values you supply for some parameters, such as Internal API virtual IP and Ingress virtual IP, because you have already configured them in your infrastructure DNS.

It also uses the values you supply for parameters in `inventory.yml`, like the ones for oVirt cluster, oVirt storage, and oVirt network. And uses a script to remove or replace these same values from `install-config.yaml` with the previously mentioned virtual IPs.

**Procedure**

1. Run the installation program:

   ```bash
   $ openshift-install create install-config --dir $ASSETS_DIR
   ```
2. Respond to the installation program’s prompts with information about your system.

**Example output**

```
? SSH Public Key /home/user/.ssh/id_dsa.pub
? Platform <ovirt>
? Enter ovirt-engine username <ocpadmin@internal>
? Enter password <******>
? oVirt cluster <cluster>
? oVirt storage <storage>
? oVirt network <net>
? Internal API virtual IP <172.16.0.252>
? Ingress virtual IP <172.16.0.251>
? Base Domain <example.org>
? Cluster Name <ocp4>
? Pull Secret [? for help] <********>
```

For **Internal API virtual IP** and **Ingress virtual IP**, supply the IP addresses you specified when you configured the DNS service.

Together, the values you enter for the **oVirt cluster** and **Base Domain** prompts form the FQDN portion of URLs for the REST API and any applications you create, such as `https://api.ocp4.example.org:6443/` and `https://console-openshift-console.apps.ocp4.example.org`.

You can get the pull secret from the Red Hat OpenShift Cluster Manager.

### 13.3.14. Customizing install-config.yaml

Here, you use three Python scripts to override some of the installation program’s default behaviors:

- By default, the installation program uses the machine API to create nodes. To override this default behavior, you set the number of compute nodes to zero replicas. Later, you use Ansible playbooks to create the compute nodes.

- By default, the installation program sets the IP range of the machine network for nodes. To override this default behavior, you set the IP range to match your infrastructure.

- By default, the installation program sets the platform to **ovirt**. However, installing a cluster on user-provisioned infrastructure is more similar to installing a cluster on bare metal. Therefore, you delete the ovirt platform section from **install-config.yaml** and change the platform to
none. Instead, you use inventory.yml to specify all of the required settings.

**NOTE**

These snippets work with Python 3 and Python 2.

**Procedure**

1. Set the number of compute nodes to zero replicas:

   ```python
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["compute"][0]["replicas"] = 0
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
   ```

2. Set the IP range of the machine network. For example, to set the range to **172.16.0.0/16**, enter:

   ```python
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["networking"]["machineNetwork"][0]["cidr"] = "172.16.0.0/16"
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
   ```

3. Remove the ovirt section and change the platform to none:

   ```python
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   platform = conf["platform"]
   del platform["ovirt"]
   platform["none"] = {}
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
   ```

**WARNING**

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to none, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.
13.3.15. Generate manifest files

Use the installation program to generate a set of manifest files in the assets directory.

The command to generate the manifest files displays a warning message before it consumes the `install-config.yaml` file.

If you plan to reuse the `install-config.yaml` file, create a backup copy of it before you back it up before you generate the manifest files.

**Procedure**

1. Optional: Create a backup copy of the `install-config.yaml` file:

   ```bash
   $ cp install-config.yaml install-config.yaml.backup
   ```

2. Generate a set of manifests in your assets directory:

   ```bash
   $ openshift-install create manifests --dir $ASSETS_DIR
   ```

   This command displays the following messages.

**Example output**

```
INFO Consuming Install Config from target directory
WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings
```

The command generates the following manifest files:

**Example output**

```
$ tree

wrk
   └── manifests
       ├── 04-openshift-machine-config-operator.yaml
       ├── cluster-config.yaml
       ├── cluster-dns-02-config.yml
       ├── cluster-infrastrucure-02-config.yml
       ├── cluster-ingress-02-config.yml
       ├── cluster-network-01-crd.yml
       ├── cluster-network-02-config.yml
       ├── cluster-proxy-01-config.yaml
       └── cluster-scheduler-02-config.yml

   ├── cvo-overrides.yaml
   ├── etcd-ca-bundle-configmap.yaml
   ├── etcd-client-secret.yaml
   └── etcd-host-service-endpoints.yaml
```

Next steps

- Make control plane nodes non-schedulable.

### 13.3.16. Making control-plane nodes non-schedulable

Because you are manually creating and deploying the control plane machines, you must configure a manifest file to make the control plane nodes non-schedulable.

**Procedure**

1. To make the control plane nodes non-schedulable, enter:

   ```
   $ python3 -c 'import os, yaml
   path = "%s/manifests/cluster-scheduler-02-config.yml" % os.environ["ASSETS_DIR"]
   data = yaml.safe_load(open(path))
   data["spec"]['mastersSchedulable'] = False
   open(path, "w").write(yaml.dump(data, default_flow_style=False))'
   ```

### 13.3.17. Building the Ignition files

To build the Ignition files from the manifest files you just generated and modified, you run the installation program. This action creates a Red Hat Enterprise Linux CoreOS (RHCOS) machine, `initramfs`, which fetches the Ignition files and performs the configurations needed to create a node.

In addition to the Ignition files, the installation program generates the following:

- An **auth** directory that contains the admin credentials for connecting to the cluster with the `oc` and `kubectl` utilities.

- A **metadata.json** file that contains information such as the OpenShift Container Platform cluster name, cluster ID, and infrastructure ID for the current installation.

The Ansible playbooks for this installation process use the value of `infraID` as a prefix for the virtual machines they create. This prevents naming conflicts when there are multiple installations in the same oVirt/RHV cluster.
NOTE

Certificates in Ignition configuration files expire after 24 hours. Complete the cluster installation and keep the cluster running in a non-degraded state for 24 hours so that the first certificate rotation can finish.

Procedure

1. To build the Ignition files, enter:

```bash
$ openshift-install create ignition-configs --dir $ASSETS_DIR
```

Example output

```bash
$ tree
wrk
  ├── auth
  │   ├── kubeadmin-password
  │   └── kubectlconfig
  └── bootstrap.ign
  └── master.ign
  └── metadata.json
  └── worker.ign
```

13.3.18. Creating templates and virtual machines

After confirming the variables in the `inventory.yml`, you run the first Ansible provisioning playbook, `create-templates-and-vms.yml`.

This playbook uses the connection parameters for the RHV Manager from `$HOME/.ovirt/ovirt-config.yaml` and reads `metadata.json` in the assets directory.

If a local Red Hat Enterprise Linux CoreOS (RHCOS) image is not already present, the playbook downloads one from the URL you specified for `image_url` in `inventory.yml`. It extracts the image and uploads it to RHV to create templates.

The playbook creates a template based on the `control_plane` and `compute` profiles in the `inventory.yml` file. If these profiles have different names, it creates two templates.

When the playbook finishes, the virtual machines it creates are stopped. You can get information from them to help configure other infrastructure elements. For example, you can get the virtual machines’ MAC addresses to configure DHCP to assign permanent IP addresses to the virtual machines.

Procedure

1. In `inventory.yml`, under the `control_plane` and `compute` variables, change both instances of `type: high_performance` to `type: server`.

2. Optional: If you plan to perform multiple installations to the same cluster, create different templates for each OCP installation. In the `inventory.yml` file, prepend the value of `template` with `infraID`. For example:

```yaml
control_plane:
  cluster: "{{ ovirt_cluster }}"
```
Create the templates and virtual machines:

$ ansible-playbook -i inventory.yml create-templates-and-vms.yml

13.3.19. Creating the bootstrap machine

You create a bootstrap machine by running the `bootstrap.yml` playbook. This playbook starts the bootstrap virtual machine, and passes it the `bootstrap.ign` Ignition file from the assets directory. The bootstrap node configures itself so it can serve Ignition files to the control plane nodes.

To monitor the bootstrap process, you use the console in the RHV Administration Portal or connect to the virtual machine by using SSH.

Procedure

1. Create the bootstrap machine:

   $ ansible-playbook -i inventory.yml bootstrap.yml

2. Connect to the bootstrap machine using a console in the Administration Portal or SSH. Replace `<bootstrap_ip>` with the bootstrap node IP address. To use SSH, enter:

   $ ssh core@<bootstrap.ip>

3. Collect `bootkube.service` journald unit logs for the release image service from the bootstrap node:

   [core@ocp4-lk6b4-bootstrap ~]$ journalctl -b -f -u release-image.service -u bootkube.service

   **NOTE**

   The `bootkube.service` log on the bootstrap node outputs etcd `connection refused` errors, indicating that the bootstrap server is unable to connect to etcd on control plane nodes (also known as the master nodes). After etcd has started on each control plane node and the nodes have joined the cluster, the errors should stop.

13.3.20. Creating the control plane nodes

You create the control plane nodes by running the `masters.yml` playbook. This playbook passes the `master.ign` Ignition file to each of the virtual machines. The Ignition file contains a directive for the control plane node to get the Ignition from a URL such as `https://api-int.ocp4.example.org:22623/config/master`. The port number in this URL is managed by the load balancer, and is accessible only inside the cluster.

Procedure
1. Create the control plane nodes:

   $ ansible-playbook -i inventory.yml masters.yml

2. While the playbook creates your control plane, monitor the bootstrapping process:

   $ openshift-install wait-for bootstrap-complete --dir $ASSETS_DIR

   **Example output**

   - INFO API v1.18.3+b74c5ed up
   - INFO Waiting up to 40m0s for bootstrapping to complete...

3. When all the pods on the control plane nodes and etcd are up and running, the installation program displays the following output.

   **Example output**

   - INFO It is now safe to remove the bootstrap resources

### 13.3.21. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=$ASSETS_DIR/auth/kubeconfig

   The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster’s version:

   $ oc get clusterversion

4. View your Operators’ status:

   $ oc get clusteroperator

5. View all running pods in the cluster:

   $ oc get pods -A

### 13.3.22. Removing the bootstrap machine

1870
After the **wait-for** command shows that the bootstrap process is complete, you must remove the bootstrap virtual machine to free up compute, memory, and storage resources. Also, remove settings for the bootstrap machine from the load balancer directives.

**Procedure**

1. To remove the bootstrap machine from the cluster, enter:
   
   ```
   $ ansible-playbook -i inventory.yml retire-bootstrap.yml
   ```

2. Remove settings for the bootstrap machine from the load balancer directives.

### 13.3.23. Creating the worker nodes and completing the installation

Creating worker nodes is similar to creating control plane nodes. However, worker nodes do not automatically join the cluster. To add them to the cluster, you review and approve the workers’ pending CSRs (Certificate Signing Requests).

After approving the first requests, you continue approving CSR until all of the worker nodes are approved. When you complete this process, the worker nodes become **Ready** and can have pods scheduled to run on them.

Finally, monitor the command line to see when the installation process completes.

**Procedure**

1. Create the worker nodes:

   ```
   $ ansible-playbook -i inventory.yml workers.yml
   ```

2. To list all of the CSRs, enter:

   ```
   $ oc get csr -A
   ```

Eventually, this command displays one CSR per node. For example:

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-2lnxd</td>
<td>63m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master0.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hff4q</td>
<td>64m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hsn96</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master2.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-m724n</td>
<td>6m2s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-p4dz2</td>
<td>60m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-t9vfj</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master1.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>
3. To filter the list and see only pending CSRs, enter:

```bash
$ watch "oc get csr -A | grep pending -i"
```

This command refreshes the output every two seconds and displays only pending CSRs. For example:

**Example output**

Every 2.0s: oc get csr -A | grep pending -i

```bash
csr-m724n 10m kubernetes.io/kube-apiserver-client-kubelet
  system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending

csr-wcbrf 11m kubernetes.io/kube-apiserver-client-kubelet
  system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
```

4. Inspect each pending request. For example:

**Example output**

```bash
$ oc describe csr csr-m724n
```

**Example output**

Name: csr-m724n
Labels: <none>
Annotations: <none>
CreationTimestamp: Sun, 19 Jul 2020 15:59:37 +0200
Signer: kubernetes.io/kube-apiserver-client-kubelet
Status: Pending
Subject:
  Common Name: system:node:ocp4-lk6b4-worker1.ocp4.example.org
  Serial Number:
  Organization: system:nodes
Events: <none>

5. If the CSR information is correct, approve the request:

```bash
$ oc adm certificate approve csr-m724n
```

6. Wait for the installation process to finish:

```bash
$ openshift-install wait-for install-complete --dir $ASSETS_DIR --log-level debug
```
When the installation completes, the command line displays the URL of the OpenShift Container Platform web console and the administrator user name and password.

13.3.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

13.4. INSTALLING A CLUSTER ON RHV IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.7, you can install a customized OpenShift Container Platform cluster on Red Hat Virtualization (RHV) in a restricted network by creating an internal mirror of the installation release content.

13.4.1. Prerequisites

The following items are required to install an OpenShift Container Platform cluster on a RHV environment.

- You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on RHV.
- You are familiar with the OpenShift Container Platform installation and update processes.
- Create a registry on your mirror host and obtain the imageContentSources data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

13.4.2. About installations in restricted networks
In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

13.4.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an *Unable to retrieve available updates* error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

13.4.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access **Quay.io** to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

13.4.4. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.7 cluster, the RHV environment must meet the following requirements.
Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

Requirements

- The RHV version is 4.4.
- The RHV environment has one data center whose state is Up.
- The RHV data center contains an RHV cluster.
- The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
  - Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
  - 112 GiB RAM or more, including:
    - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
    - 16 GiB or more for each of the three control plane machines which provide the control plane.
    - 16 GiB or more for each of the three compute machines, which run the application workloads.
- The RHV storage domain must meet these etcd backend performance requirements.
- In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.
- To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.
- The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.
A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:

- DiskOperator
- DiskCreator
- UserTemplateBasedVm
- TemplateOwner
- TemplateCreator
- ClusterAdmin on the target cluster

**WARNING**
Apply the principle of least privilege: Avoid using an administrator account with SuperUser privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary ovirt-config.yaml file that might be compromised.

### 13.4.5. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

**IMPORTANT**
These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

**Procedure**

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.7.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
c. Click the name of that data center.

d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.

e. Record the Domain Name for use later on.

f. Confirm Free Space has at least 230 GiB.

g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.

h. In the data center details, click the Clusters tab.

i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.

a. In the RHV Administration Portal, click Compute > Clusters.

b. Click the cluster where you plan to install OpenShift Container Platform.

c. In the cluster details, click the Hosts tab.

d. Inspect the hosts and confirm they have a combined total of at least 28 Logical CPU Cores available exclusively for the OpenShift Container Platform cluster.

e. Record the number of available Logical CPU Cores for use later on.

f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.

g. Confirm that, all together, the hosts have 112 GiB of Max free Memory for scheduling new virtual machines distributed to meet the requirements for each of the following OpenShift Container Platform machines:

- 16 GiB required for the bootstrap machine
- 16 GiB required for each of the three control plane machines
- 16 GiB for each of the three compute machines

h. Record the amount of Max free Memory for scheduling new virtual machines for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

```
$ curl -k -u <username>@<profile>:<password> \
https://<engine-fqdn>/ovirt-engine/api
```

For <username>, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For <profile>, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the Profile dropdown list. For <password>, specify the password for that user.
For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

For example:

```bash
$ curl -k -u ocpadmin@internal:pw123 \https://rhv-env.virtlab.example.com/ovirt-engine/api
```

### 13.4.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

#### Firewall

Configure your firewall so your cluster has access to required sites.

See also:

- [Red Hat Virtualization Manager firewall requirements](#)
- [Host firewall requirements](#)

#### DNS

Configure infrastructure-provided DNS to allow the correct resolution of the main components and services. If you use only one load balancer, these DNS records can point to the same IP address.

- Create DNS records for `api.<cluster_name>.<base_domain>` (internal and external resolution) and `api-int.<cluster_name>.<base_domain>` (internal resolution) that point to the load balancer for the control plane machines.

- Create a DNS record for `*.apps.<cluster_name>.<base_domain>` that points to the load balancer for the Ingress router. For example, ports 443 and 80 of the compute machines.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>N/A</td>
<td>Network reachability tests</td>
</tr>
</tbody>
</table>
### Table 13.12. All machines to control plane

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6443</td>
<td>Kubernetes API</td>
</tr>
</tbody>
</table>

### Table 13.13. Control plane machines to control plane machines

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

**Network topology requirements**  
The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

**Load balancers**  
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 13.14. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**

   Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.
   
   - A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

   Configure the following ports on both the front and back of the load balancers:

   **Table 13.15. Application Ingress load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### NTP configuration

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

### 13.4.7. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;..&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
### Component | Record | Description
--- | --- | ---
| api-int.<cluster_name>.<base_domain>. | Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster. |  

**IMPORTANT**
The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

### Routes
<table>
<thead>
<tr>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

### Bootstrap
<table>
<thead>
<tr>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

### Master hosts
<table>
<thead>
<tr>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

### Worker hosts
<table>
<thead>
<tr>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

### TIP
You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

#### Example 13.1. Sample DNS zone database
```ini
$TTL 1W
@ IN SOA ns1.example.com. root (  
```
The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 13.2. Sample DNS zone database for reverse records

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
;
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
;
; The api identifies the IP of your load balancer.
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5
;
; The wildcard also identifies the load balancer.
*.apps.ocp4 IN A 192.168.1.5
;
; Create an entry for the bootstrap host.
bootstrap.ocp4 IN A 192.168.1.96
;
; Create entries for the master hosts.
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
master2.ocp4 IN A 192.168.1.99
;
; Create entries for the worker hosts.
worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.17
;
;EOF
```
13.4.8. Setting up the installation machine

To run the binary `openshift-install` installation program and Ansible scripts, set up the RHV Manager or an Red Hat Enterprise Linux (RHEL) computer with network access to the RHV environment and the REST API on the Manager.

Procedure

1. Update or install Python3 and Ansible. For example:

   ```
   # dnf update python3 ansible
   ``

2. Install the `python3-ovirt-engine-sdk4` package to get the Python Software Development Kit.

3. Install the `ovirt.image-template` Ansible role. On the RHV Manager and other Red Hat Enterprise Linux (RHEL) machines, this role is distributed as the `ovirt-ansible-image-template` package. For example, enter:

   ```
   # dnf install ovirt-ansible-image-template
   ``

4. Install the `ovirt.vm-infra` Ansible role. On the RHV Manager and other RHEL machines, this role is distributed as the `ovirt-ansible-vm-infra` package.

   ```
   # dnf install ovirt-ansible-vm-infra
   ``

5. Create an environment variable and assign an absolute or relative path to it. For example, enter:

   ```
   $ export ASSETS_DIR=./wrk
   ```

   **NOTE**

   The installation program uses this variable to create a directory where it saves important installation-related files. Later, the installation process reuses this variable to locate those asset files. Avoid deleting this assets directory; it is required for uninstalling the cluster.

13.4.9. Setting up the CA certificate for RHV

Download the CA certificate from the Red Hat Virtualization (RHV) Manager and set it up on the installation machine.
You can download the certificate from a webpage on the RHV Manager or by using a `curl` command. Later, you provide the certificate to the installation program.

Procedure

1. Use either of these two methods to download the CA certificate:
   - Go to the Manager’s webpage, `https://<engine-fqdn>/ovirt-engine/`. Then, under Downloads, click the CA Certificate link.
   - Run the following command:
     
     ```bash
     ```

     For `<engine-fqdn>`, specify the fully qualified domain name of the RHV Manager, such as `rhv-env.virtlab.example.com`.

2. Configure the CA file to grant rootless user access to the Manager. Set the CA file permissions to have an octal value of `0644` (symbolic value: `-rw-r--r--`):

   ```bash
   $ sudo chmod 0644 /tmp/ca.pem
   ```

3. For Linux, copy the CA certificate to the directory for server certificates. Use `-p` to preserve the permissions:

   ```bash
   $ sudo cp -p /tmp/ca.pem /etc/pki/ca-trust/source/anchors/ca.pem
   ```

4. Add the certificate to the certificate manager for your operating system:

   - For macOS, double-click the certificate file and use the Keychain Access utility to add the file to the System keychain.
   - For Linux, update the CA trust:

     ```bash
     $ sudo update-ca-trust
     ```

   NOTE

   If you use your own certificate authority, make sure the system trusts it.

Additional resources

- To learn more, see Authentication and Security in the RHV documentation.

13.4.10. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.
NOTE

In a production environment, you require disaster recovery and debugging.

IMPORTANT

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   ```
   NOTE
   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.
   ```

2. Start the `ssh-agent` process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   Example output

   ```
   Agent pid 31874
   ```

   ```
   NOTE
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.
   ```

3. Add your SSH private key to the `ssh-agent`:

   ```
   $ ssh-add <path>/<file_name> 1
   ```
Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

13.4.11. Downloading the Ansible playbooks

Download the Ansible playbooks for installing OpenShift Container Platform version 4.7 on RHV.

Procedure

- On your installation machine, run the following commands:

  $ mkdir playbooks

  $ cd playbooks

  grep 'download_url.*.yml' |
  awk '{ print $2 }' | sed -r 's/"|,//g' |
  xargs -n 1 curl -O

Next steps

- After you download these Ansible playbooks, you must also create the environment variable for the assets directory and customize the `inventory.yml` file before you create an installation configuration file by running the installation program.

13.4.12. The inventory.yml file

You use the `inventory.yml` file to define and create elements of the OpenShift Container Platform cluster you are installing. This includes elements such as the Red Hat Enterprise Linux CoreOS (RHCOS) image, virtual machine templates, bootstrap machine, control plane nodes, and worker nodes. You also use `inventory.yml` to destroy the cluster.

The following `inventory.yml` example shows you the parameters and their default values. The quantities and numbers in these default values meet the requirements for running a production OpenShift Container Platform cluster in a RHV environment.

Example inventory.yml file

```yaml
---
all:
  vars:
```

1887
ovirt_cluster: "Default"
ocp:
  assets_dir: "{{ lookup('env', 'ASSETS_DIR') }}"
  ovirt_config_path: "{{ lookup('env', 'HOME') }}/.ovirt/ovirt-config.yaml"

### IMPORTANT

Enter values for parameters whose descriptions begin with "Enter." Otherwise, you can use the default value or replace it with a new value.

**General section**

- **ovirt_cluster**: Enter the name of an existing RHV cluster in which to install the OpenShift Container Platform cluster.

- **ocp.assets_dir**: The path of a directory the `openshift-install` installation program creates to store the files that it generates.

- **ocp.ovirt_config_path**: The path of the `ovirt-config.yaml` file the installation program generates, for example, `~/wrk/install-config.yaml`. This file contains the credentials required to interact with the REST API of the Manager.

**Red Hat Enterprise Linux CoreOS (RHCOS) section**

- **image_url**: Enter the URL of the RHCOS image you specified for download.
- `local_cmp_image_path`: The path of a local download directory for the compressed RHCOS image.
- `local_image_path`: The path of a local directory for the extracted RHCOS image.

Profiles section

This section consists of two profiles:

- `control_plane`: The profile of the bootstrap and control plane nodes.
- `compute`: The profile of workers nodes in the compute plane.

These profiles have the following parameters. The default values of the parameters meet the minimum requirements for running a production cluster. You can increase or customize these values to meet your workload requirements.

- `cluster`: The value gets the cluster name from `ovirt_cluster` in the General Section.
- `memory`: The amount of memory, in GB, for the virtual machine.
- `sockets`: The number of sockets for the virtual machine.
- `cores`: The number of cores for the virtual machine.
- `template`: The name of the virtual machine template. If plan to install multiple clusters, and these clusters use templates that contain different specifications, prepend the template name with the ID of the cluster.
- `operating_system`: The type of guest operating system in the virtual machine. With oVirt/RHV version 4.4, this value must be `rhcos_x64` so the value of Ignition script can be passed to the VM.
- `type`: Enter `server` as the type of the virtual machine.

**IMPORTANT**

You must change the value of the `type` parameter from `high_performance` to `server`.

- `disks`: The disk specifications. The `control_plane` and `compute` nodes can have different storage domains.
- `size`: The minimum disk size.
- `name`: Enter the name of a disk connected to the target cluster in RHV.
- `interface`: Enter the interface type of the disk you specified.
- `storage_domain`: Enter the storage domain of the disk you specified.
- `nics`: Enter the `name` and `network` the virtual machines use. You can also specify the virtual network interface profile. By default, NICs obtain their MAC addresses from the oVirt/RHV MAC pool.

Virtual machines section
CHAPTER 13. INSTALLING ON RHV

This final section, vms, defines the virtual machines you plan to create and deploy in the cluster. By
default, it provides the minimum number of control plane and worker nodes for a production
environment.
vms contains three required elements:
name: The name of the virtual machine. In this case, metadata.infraID prepends the virtual
machine name with the infrastructure ID from the metadata.yml file.
ocp_type: The role of the virtual machine in the OCP cluster. Possible values are bootstrap,
master, worker.
profile: The name of the profile from which each virtual machine inherits specifications. Possible
values in this example are control_plane or compute.
You can override the value a virtual machine inherits from its profile. To do this, you add the
name of the profile attribute to the virtual machine in inventory.yml and assign it an overriding
value. To see an example of this, examine the name: "{{ metadata.infraID }}-bootstrap" virtual
machine in the preceding inventory.yml example: It has a type attribute whose value, server,
overrides the value of the type attribute this virtual machine would otherwise inherit from the
control_plane profile.

Metadata variables
For virtual machines, metadata.infraID prepends the name of the virtual machine with the infrastructure
ID from the metadata.json file you create when you build the Ignition files.
The playbooks use the following code to read infraID from the specific file located in the
ocp.assets_dir.
--- name: include metadata.json vars
include_vars:
file: "{{ ocp.assets_dir }}/metadata.json"
name: metadata
...

13.4.13. Specifying the RHCOS image settings
Update the Red Hat Enterprise Linux CoreOS (RHCOS) image settings of the inventory.yml file. Later,
when you run this file one of the playbooks, it downloads a compressed Red Hat Enterprise Linux
CoreOS (RHCOS) image from the image_url URL to the local_cmp_image_path directory. The
playbook then uncompresses the image to the local_image_path directory and uses it to create
oVirt/RHV templates.
Procedure
1. Locate the RHCOS image download page for the version of OpenShift Container Platform you
are installing, such as Index of /pub/openshift-v4/dependencies/rhcos/latest/latest .
2. From that download page, copy the URL of an OpenStack qcow2 image, such as
3. Edit the inventory.yml playbook you downloaded earlier. In it, paste the URL as the value for
image_url. For example:

1891


Creating the install config file

You create an installation configuration file by running the installation program, `openshift-install`, and responding to its prompts with information you specified or gathered earlier.

When you finish responding to the prompts, the installation program creates an initial version of the `install-config.yaml` file in the assets directory you specified earlier, for example, `/wrk/install-config.yaml`

The installation program also creates a file, `$HOME/.ovirt/ovirt-config.yaml`, that contains all the connection parameters that are required to reach the Manager and use its REST API.

**NOTE:** The installation process does not use values you supply for some parameters, such as Internal API virtual IP and Ingress virtual IP, because you have already configured them in your infrastructure DNS.

It also uses the values you supply for parameters in `inventory.yml`, like the ones for oVirt cluster, oVirt storage, and oVirt network. And uses a script to remove or replace these same values from `install-config.yaml` with the previously mentioned virtual IPs.

**Procedure**

1. Run the installation program:

   ```bash
   $ openshift-install create install-config --dir $ASSETS_DIR
   ```

2. Respond to the installation program’s prompts with information about your system.

   **Example output**

   ```bash
   ? SSH Public Key /home/user/.ssh/id_dsa.pub
   ? Platform <ovirt>
   ? Enter ovirt-engine username <ocpadmin@internal>
   ? Enter password <******>
   ? oVirt cluster <cluster>
   ? oVirt storage <storage>
   ? oVirt network <net>
   ? Internal API virtual IP <172.16.0.252>
   ? Ingress virtual IP <172.16.0.251>
   ? Base Domain <example.org>
   ? Cluster Name <ocp4>
   ? Pull Secret [? for help] <*******>
   ```

   ```bash
   ? SSH Public Key /home/user/.ssh/id_dsa.pub
   ? Platform <ovirt>
   ? Enter ovirt-engine username <ocpadmin@internal>
   ? Enter password <******>
   ? oVirt cluster <cluster>
   ```
For **Internal API virtual IP** and **Ingress virtual IP**, supply the IP addresses you specified when you configured the DNS service.

Together, the values you enter for the **oVirt cluster** and **Base Domain** prompts form the FQDN portion of URLs for the REST API and any applications you create, such as [https://api.ocp4.example.org:6443/](https://api.ocp4.example.org:6443/) and [https://console-openshift-console.apps.ocp4.example.org](https://console-openshift-console.apps.ocp4.example.org).

You can get the pull secret from the Red Hat OpenShift Cluster Manager.

### 13.4.15. Sample install-config.yaml file for IBM Z

### 13.4.16. Sample install-config.yaml file for RHV

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:  
  - hyperthreading: Enabled
    name: worker
    replicas: 0
  controlPlane:  
    hyperthreading: Enabled
    name: master
    replicas: 3
metadata:  
  name: test
networking:  
  clusterNetwork:  
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  networkType: OpenShiftSDN
  serviceNetwork:  
    - 172.30.0.0/16
platform:  
  none: {}
fips: false
pullSecret: '{"auths": ...}'
sshKey: 'ssh-ed25519 AAAA...'
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
2. For **Internal API virtual IP** and **Ingress virtual IP**, supply the IP addresses you specified when you configured the DNS service.
The **controlPlane** section is a single mapping, but the **compute** section is a sequence of

Whether to enable or disable simultaneous multithreading (SMT), or **hyperthreading**. By default, SMT is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**
Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

**IMPORTANT**
If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml**, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set the value of the **replicas** parameter to **0**. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

**NOTE**
Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 \(2^{32} - 23\) - 2) pod IPs addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z infrastructure. RHV infrastructure.
13.4.16.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of
them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   ...
   
   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4 If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy readinessEndpoints field.
2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 13.4.17. Customizing install-config.yaml

Here, you use three Python scripts to override some of the installation program’s default behaviors:

- By default, the installation program uses the machine API to create nodes. To override this default behavior, you set the number of compute nodes to zero replicas. Later, you use Ansible playbooks to create the compute nodes.

- By default, the installation program sets the IP range of the machine network for nodes. To override this default behavior, you set the IP range to match your infrastructure.

- By default, the installation program sets the platform to `ovirt`. However, installing a cluster on user-provisioned infrastructure is more similar to installing a cluster on bare metal. Therefore, you delete the `ovirt` platform section from `install-config.yaml` and change the platform to `none`. Instead, you use `inventory.yml` to specify all of the required settings.

**NOTE**

These snippets work with Python 3 and Python 2.

#### Procedure

1. Set the number of compute nodes to zero replicas:

   ```bash
   $ python3 -c "import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["compute"][0]["replicas"] = 0
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))"
   ```

2. Set the IP range of the machine network. For example, to set the range to `172.16.0.0/16`, enter:

   ```bash
   $ python3 -c "import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["networking"]["machineNetwork"][0]["cidr"] = "172.16.0.0/16"
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))"
   ```

3. Remove the `ovirt` section and change the platform to `none`:

   ```bash
   $ python3 -c "import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["platform"]["name"] = "none"
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))"
   ```
13.4.18. Generate manifest files

Use the installation program to generate a set of manifest files in the assets directory.

The command to generate the manifest files displays a warning message before it consumes the install-config.yaml file.

If you plan to reuse the install-config.yaml file, create a backup copy of it before you back it up before you generate the manifest files.

Procedure

1. Optional: Create a backup copy of the install-config.yaml file:

   $ cp install-config.yaml install-config.yaml.backup

2. Generate a set of manifests in your assets directory:

   $ openshift-install create manifests --dir $ASSETS_DIR

   This command displays the following messages.

Example output

INFO Consuming Install Config from target directory
WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings

The command generates the following manifest files:
Example output

```
$ tree

    │         └── 99_openshift-machineconfig_99-worker-ssh.yaml
    └── openshift-install-manifests.yaml
```

Next steps

- Make control plane nodes non-schedulable.

**13.4.19. Making control-plane nodes non-schedulable**

Because you are manually creating and deploying the control plane machines, you must configure a manifest file to make the control plane nodes non-schedulable.

**Procedure**

1. To make the control plane nodes non-schedulable, enter:

```
$ python3 -c 'import os, yaml
path = "%s/manifests/cluster-scheduler-02-config.yaml" % os.environ["ASSETS_DIR"]'
```
To build the Ignition files from the manifest files you just generated and modified, you run the installation program. This action creates a Red Hat Enterprise Linux CoreOS (RHCOS) machine, initramfs, which fetches the Ignition files and performs the configurations needed to create a node.

In addition to the Ignition files, the installation program generates the following:

- An auth directory that contains the admin credentials for connecting to the cluster with the `oc` and `kubectl` utilities.
- A metadata.json file that contains information such as the OpenShift Container Platform cluster name, cluster ID, and infrastructure ID for the current installation.

The Ansible playbooks for this installation process use the value of `infraID` as a prefix for the virtual machines they create. This prevents naming conflicts when there are multiple installations in the same oVirt/RHV cluster.

**NOTE**

Certificates in Ignition configuration files expire after 24 hours. Complete the cluster installation and keep the cluster running in a non-degraded state for 24 hours so that the first certificate rotation can finish.

**Procedure**

1. To build the Ignition files, enter:

```
$ openshift-install create ignition-configs --dir $ASSETS_DIR
```

**Example output**

```
$ tree
.
    wrk
      ├── auth
      |   ├── kubeadmin-password
      |   └── kubeconfig
      └── bootstrap.ign
          └── master.ign
              └── metadata.json
                  └── worker.ign
```

**13.4.21. Creating templates and virtual machines**

After confirming the variables in the inventory.yml, you run the first Ansible provisioning playbook, create-templates-and-vms.yml.

This playbook uses the connection parameters for the RHV Manager from $HOME/.ovirt/ovirt-config.yaml and reads metadata.json in the assets directory.
If a local Red Hat Enterprise Linux CoreOS (RHCOS) image is not already present, the playbook downloads one from the URL you specified for `image_url` in `inventory.yml`. It extracts the image and uploads it to RHV to create templates.

The playbook creates a template based on the `control_plane` and `compute` profiles in the `inventory.yml` file. If these profiles have different names, it creates two templates.

When the playbook finishes, the virtual machines it creates are stopped. You can get information from them to help configure other infrastructure elements. For example, you can get the virtual machines’ MAC addresses to configure DHCP to assign permanent IP addresses to the virtual machines.

**Procedure**

1. In `inventory.yml`, under the `control_plane` and `compute` variables, change both instances of `type: high_performance` to `type: server`.

2. Optional: If you plan to perform multiple installations to the same cluster, create different templates for each OCP installation. In the `inventory.yml` file, prepend the value of `template` with `infraID`. For example:

   ```
   control_plane:
     cluster: "{{ ovirt_cluster }}"
     memory: 16GiB
     sockets: 4
     cores: 1
     template: "{{ metadata.infraID }}-rhcos_tpl"
     operating_system: "rhcos_x64"
   ... 
   ```

3. Create the templates and virtual machines:

   ```
   $ ansible-playbook -i inventory.yml create-templates-and-vms.yml
   ```

**13.4.22. Creating the bootstrap machine**

You create a bootstrap machine by running the `bootstrap.yml` playbook. This playbook starts the bootstrap virtual machine, and passes it the `bootstrap.ign` Ignition file from the assets directory. The bootstrap node configures itself so it can serve Ignition files to the control plane nodes.

To monitor the bootstrap process, you use the console in the RHV Administration Portal or connect to the virtual machine by using SSH.

**Procedure**

1. Create the bootstrap machine:

   ```
   $ ansible-playbook -i inventory.yml bootstrap.yml
   ```

2. Connect to the bootstrap machine using a console in the Administration Portal or SSH. Replace `<bootstrap_ip>` with the bootstrap node IP address. To use SSH, enter:

   ```
   $ ssh core@<bootstrap.ip>
   ```
3. Collect `bootkube.service` journald unit logs for the release image service from the bootstrap node:

```
$ journalctl -b -f -u release-image.service -u bootkube.service
```

**NOTE**

The `bootkube.service` log on the bootstrap node outputs etcd connection refused errors, indicating that the bootstrap server is unable to connect to etcd on control plane nodes (also known as the master nodes). After etcd has started on each control plane node and the nodes have joined the cluster, the errors should stop.

### 13.4.23. Creating the control plane nodes

You create the control plane nodes by running the `masters.yml` playbook. This playbook passes the `master.ign` Ignition file to each of the virtual machines. The Ignition file contains a directive for the control plane node to get the Ignition from a URL such as `https://api-int.ocp4.example.org:22623/config/master`. The port number in this URL is managed by the load balancer, and is accessible only inside the cluster.

**Procedure**

1. Create the control plane nodes:

   ```
   $ ansible-playbook -i inventory.yml masters.yml
   ```

2. While the playbook creates your control plane, monitor the bootstrapping process:

   ```
   $ openshift-install wait-for bootstrap-complete --dir $ASSETS_DIR
   ```

**Example output**

```
INFO API v1.18.3+b74c5ed up
INFO Waiting up to 40m0s for bootstrapping to complete...
```

3. When all the pods on the control plane nodes and etcd are up and running, the installation program displays the following output.

**Example output**

```
INFO It is now safe to remove the bootstrap resources
```

### 13.4.24. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```
   $ export KUBECONFIG=$ASSETS_DIR/auth/kubeconfig
   ```
The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```
   $ oc get nodes
   ```

3. View your cluster’s version:

   ```
   $ oc get clusterversion
   ```

4. View your Operators’ status:

   ```
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:

   ```
   $ oc get pods -A
   ```

**13.4.25. Removing the bootstrap machine**

After the `wait-for` command shows that the bootstrap process is complete, you must remove the bootstrap virtual machine to free up compute, memory, and storage resources. Also, remove settings for the bootstrap machine from the load balancer directives.

**Procedure**

1. To remove the bootstrap machine from the cluster, enter:

   ```
   $ ansible-playbook -i inventory.yml retire-bootstrap.yml
   ```

2. Remove settings for the bootstrap machine from the load balancer directives.

**13.4.26. Creating the worker nodes and completing the installation**

Creating worker nodes is similar to creating control plane nodes. However, worker nodes workers do not automatically join the cluster. To add them to the cluster, you review and approve the workers’ pending CSRs (Certificate Signing Requests).

After approving the first requests, you continue approving CSR until all of the worker nodes are approved. When you complete this process, the worker nodes become `Ready` and can have pods scheduled to run on them.

Finally, monitor the command line to see when the installation process completes.

**Procedure**

1. Create the worker nodes:

   ```
   $ ansible-playbook -i inventory.yml workers.yml
   ```

2. To list all of the CSRs, enter:
Eventually, this command displays one CSR per node. For example:

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-2lnxd</td>
<td>63m</td>

</tr>
</tbody>
</table>

3. To filter the list and see only pending CSRs, enter:

```bash
$ watch "oc get csr -A | grep pending -i"
```

This command refreshes the output every two seconds and displays only pending CSRs. For example:

**Example output**

Every 2.0s: oc get csr -A | grep pending -i

csr-m724n 10m kubernetes.io/kube-apiserver-client-kubelet system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
csr-wcbrf 11m kubernetes.io/kube-apiserver-client-kubelet system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending

4. Inspect each pending request. For example:

**Example output**

```bash
$ oc describe csr csr-m724n
```

**Example output**

Name: csr-m724n
Labels: <none>
5. If the CSR information is correct, approve the request:

```bash
$ oc adm certificate approve csr-m724n
```

6. Wait for the installation process to finish:

```bash
$ openshift-install wait-for install-complete --dir $ASSETS_DIR --log-level debug
```

When the installation completes, the command line displays the URL of the OpenShift Container Platform web console and the administrator user name and password.

### 13.4.27. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

### 13.4.28. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '[["op": "add", "path": "/spec/disableAllDefaultSources", "value": true]]'
  ```
13.5. UNINSTALLING A CLUSTER ON RHV

You can remove an OpenShift Container Platform cluster from Red Hat Virtualization (RHV).

13.5.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**Note**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

**Prerequisites**

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

**Procedure**

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```
   $ ./openshift-install destroy cluster --log-level info
   ```

   **Note**

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

13.5.2. Removing a cluster that uses user-provisioned infrastructure

When you are finished using the cluster, you can remove a cluster that uses user-provisioned infrastructure from your cloud.
Prerequisites

- Have the original playbook files, assets directory and files, and $ASSETS_DIR environment variable that you used to you install the cluster. Typically, you can achieve this by using the same computer you used when you installed the cluster.

Procedure

1. To remove the cluster, enter:

   ```bash
   $ ansible-playbook -i inventory.yml
   retire-bootstrap.yml
   retire-masters.yml
   retire-workers.yml
   ```

2. Remove any configurations you added to DNS, load balancers, and any other infrastructure for this cluster.
CHAPTER 14. INSTALLING ON VSPHERE

14.1. INSTALLING A CLUSTER ON VSPHERE

In OpenShift Container Platform version 4.7, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure.

NOTE
OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

14.1.1. Prerequisites

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

- Review details about the OpenShift Container Platform installation and update processes.

- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

NOTE
Be sure to also review this site list if you are configuring a proxy.

14.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

14.1.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 14.1. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.
Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

14.1.4. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

**Table 14.2. Ports used for all-machine to all-machine communications**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### 14.1.5. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 14.1. Roles and privileges required for installation**

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere object for role</td>

</tr>
</tbody>
</table>
vSphere object for role | When required | Required privileges
--- | --- | ---
| | | 

Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 14.2. Required permissions and propagation settings

<table>
<thead>
<tr>

<td>Existing folder</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see *vSphere Permissions and User Management Tasks* in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

If you intend on using vMotion in your vSphere environment, consider the following before installing a OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported. To help ensure the uptime of your compute and control plane nodes, it is recommended that you follow the VMware best practices for vMotion. It is also recommended to use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for **vMotion networking requirements** and **VM anti-affinity rules**.

- If you are using vSphere volumes in your pods, migrating a VM across datastores either manually
or through Storage vMotion causes, invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.

- Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

### Cluster resources

When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

### Cluster limits

Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

### Networking requirements

You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

### Required IP Addresses

An installer-provisioned vSphere installation requires two static IP addresses:
The **API** address is used to access the cluster API.

The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 14.5. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

14.1.6. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  # Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
   ```

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/<file_name>  # Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

14.1.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

14.1.8. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.
Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click **Download trusted root CA certificates** in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

```
certs
├── lin
│   ├── 108f4d17.0
│   └── 108f4d17.r1
│       ├── 7e757f6a.0
│       └── 8e4f8471.0
|       └── 8e4f8471.r0
├── mac
│   ├── 108f4d17.0
│   └── 108f4d17.r1
│       ├── 7e757f6a.0
│       └── 8e4f8471.0
|       └── 8e4f8471.r0
└── win
    ├── 108f4d17.0.crt
    └── 108f4d17.r1.crt
```

3 directories, 15 files

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
# update-ca-trust extract
```

### 14.1.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \       
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   Provide values at the prompts:

   a. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   b. Select `vsphere` as the platform to target.

   c. Specify the name of your vCenter instance.

   d. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

      The installation program connects to your vCenter instance.

   e. Select the datacenter in your vCenter instance to connect to.

   f. Select the default vCenter datastore to use.

      **NOTE**

      Datastore and cluster names cannot exceed 60 characters; therefore, ensure the combined string length does not exceed the 60 character limit.

   g. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.
h. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

i. Enter the virtual IP address that you configured for control plane API access.

j. Enter the virtual IP address that you configured for cluster ingress.

k. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

l. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

NOTE
Datastore and cluster names cannot exceed 60 characters; therefore, ensure the combined string length does not exceed the 60 character limit.

m. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

NOTE
The cluster access and credential information also outputs to <installation_directory>/openshift_install.log when an installation succeeds.
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kublet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

14.1.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of `oc`.

14.1.10.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   ```
   $ tar xzvf <file>
   ```

5. Place the `oc` binary in a directory that is on your `PATH`.
   To check your `PATH`, execute the following command:

   ```
   $ echo $PATH
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 14.1.10.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.7 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 14.1.10.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.7 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
14.1.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**
- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   
   Example output
   system:admin
   ``

14.1.12. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

14.1.12.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as `Removed`. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from `Removed` to `Managed`.

**NOTE**

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."
14.1.12.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

14.1.12.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have “100Gi” capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

**NOTE**

When using shared storage, review your security settings to prevent outside access.
2. Verify that you do not have a registry pod:

   $ oc get pod -n openshift-image-registry -l docker-registry=default

   **Example output**

   No resources found in openshift-image-registry namespace

   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   **Example output**

   ```yaml
   storage:
   pvc:
     claim: 1
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   $ oc get clusteroperator image-registry

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td>14.1.12.2.2. Configuring block registry storage for VMware vSphere</td>
</tr>
</tbody>
</table>

14.12.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.
1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1. A unique name that represents the **PersistentVolumeClaim** object.
   2. The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
   3. The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
   4. The size of the persistent volume claim.

   b. Create the **PersistentVolumeClaim** object from the file:

   ```
   $ oc create -f pvc.yaml -n openshift-image-registry
   ```

3. Edit the registry configuration so that it references the correct PVC:

   ```
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

   **Example output**

   ```yaml
   storage:
   pvc:
     claim: 1
   ```

   1. Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.
For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 14.1.13. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 14.1.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 14.1.15. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

### 14.2. INSTALLING A CLUSTER ON VSPHERE WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.7, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure. To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster.
NOTE
OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

14.2.1. Prerequisites

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

- Review details about the OpenShift Container Platform installation and update processes.

- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

NOTE
Be sure to also review this site list if you are configuring a proxy.

14.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT
If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

14.2.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.
Table 14.6. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware's NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**IMPORTANT**

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

14.2.4. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

Table 14.7. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>

</tr>
</tbody>
</table>

14.2.5. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

Required vCenter account privileges
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.
If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

Example 14.3. Roles and privileges required for installation

<table>
<thead>
<tr>

</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 14.4. Required permissions and propagation settings

</tbody>
</table>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](https://www.vmware.com/support/pubs/perm.html) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

If you intend on using vMotion in your vSphere environment, consider the following before installing a OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

  To help ensure the uptime of your compute and control plane nodes, it is recommended that you follow the VMware best practices for vMotion. It is also recommended to use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for [vMotion networking requirements](https://www.vmware.com/support/pubs/netw.html) and [VM anti-affinity rules](https://www.vmware.com/support/pubs/aff.html).
If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes, invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.

Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

NOTE

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:

- The API address is used to access the cluster API.
- The Ingress address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

14.2.6. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N " " -f <path>/<file_name>
   ```

   1. Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**
   
   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. Start the `ssh-agent` process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**
   
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

   ```
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   1. Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

   **Next steps**
• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

14.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

• You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

14.2.8. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.
Procedure

1. From the vCenter home page, download the vCenter's root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   └── lin
       ├── 108f4d17.0
       │    ├── 108f4d17.r1
       │    ├── 7e757f6a.0
       │    └── 8e4f8471.0
       │         └── 8e4f8471.r0
       └── mac
           ├── 108f4d17.0
           │    ├── 108f4d17.r1
           │    ├── 7e757f6a.0
           │    └── 8e4f8471.0
           │         └── 8e4f8471.r0
           └── win
               ├── 108f4d17.0.crt
               ├── 108f4d17.r1.crl
               ├── 7e757f6a.0.crt
               └── 8e4f8471.0.crt
                   └── 8e4f8471.r0.crl
   3 directories, 15 files
   ```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

14.2.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

Procedure
1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `vsphere` as the platform to target.

   iii. Specify the name of your vCenter instance.

   iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

      The installation program connects to your vCenter instance.

   v. Select the datacenter in your vCenter instance to connect to.

   vi. Select the default vCenter datastore to use.

   vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

   viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

   ix. Enter the virtual IP address that you configured for control plane API access.

   x. Enter the virtual IP address that you configured for cluster ingress.
xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

**IMPORTANT**

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 14.2.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster's platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the install-config.yaml file.

**IMPORTANT**

The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 14.2.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiUrl</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters and hyphens (-), such as <code>dev</code>.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{   &quot;auths&quot;:{   &quot;cloud.openshift.com&quot;:{     &quot;auth&quot;:&quot;b3Blb=&quot;,     &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;   },   &quot;quay.io&quot;:{     &quot;auth&quot;:&quot;b3Blb=&quot;,     &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;   }   } }</td>
</tr>
</tbody>
</table>
14.2.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 14.12. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the networking object after installation.</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>The default value is 23.</td>
<td></td>
</tr>
</tbody>
</table>
### networking.serviceNetwork

The IP address block for services. The default value is `172.30.0.0/16`.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

An array with an IP address block in CIDR format. For example:

```yaml
networking:
  serviceNetwork:
    - 172.30.0.0/16
```

### networking.machineNetwork

The IP address blocks for machines.

If you specify multiple IP address blocks, the blocks must not overlap.

If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network.

An array of objects. For example:

```yaml
networking:
  machineNetwork:
    - cidr: 10.0.0.0/16
```

### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

An IP network block in CIDR notation. For example, `10.0.0.0/16`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 14.2.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or <em>hyperthreading</em>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td><code>Enabled</code> or <code>Disabled</code></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><code>worker</code></td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <em>MachinePool</em> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
</tbody>
</table>
### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. The default value is <strong>External</strong>. Setting this field to <strong>Internal</strong> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example:</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <strong>ssh-agent</strong> process uses.</td>
<td></td>
</tr>
</tbody>
</table>

**14.2.9.1.4. Additional VMware vSphere configuration parameters**

Additional VMware vSphere configuration parameters are described in the following table:

**Table 14.14. Additional VMware vSphere cluster parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.vCenter</td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.username</td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.password</td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.datacenter</td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.defaultDatastore</td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.folder</td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, /&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;.</td>
</tr>
<tr>
<td>platform.vsphere.network</td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.cluster</td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.apiVIP</td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.ingressVIP</td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
</tbody>
</table>

14.2.9.15. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 14.15. Optional VMware vSphere machine pool parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <code>https://mirror.openshift.com/images/rhcos-&lt;version&gt;-vmware.&lt;architecture&gt;.ova</code>.</td>
</tr>
<tr>
<td>platform.vsphere.osDisk.diskSizeGB</td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.cpus</td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.coresPerSocket</td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is <code>platform.vsphere.cpus/platform.vsphere.coresPerSocket</code>. The default value is 1.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.memoryMB</td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

14.2.9.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: - hyperthreading: Enabled
  name: worker
  replicas: 3
  platform:
    vsphere:
      cpus: 2
      coresPerSocket: 2
      memoryMB: 8192
      osDisk:
        diskSizeGB: 120
    controlPlane: hyperthreading: Enabled
      name: master
      replicas: 3
      platform:
        vsphere: cpus: 4
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

14.2.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.
Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  \1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> \2
     noProxy: example.com \3
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA_CERT>
   -----END CERTIFICATE-----  \4
   ...
   ```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter's IP address and the IP range that you use for its machines.
   4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the Proxy object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

14.2.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   ...  
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"  
   INFO Time elapsed: 36m22s

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.
NOTE

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kublet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

14.2.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of `oc`.

14.2.11.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   ```bash
   $ tar xzvf <file>
   ```

5. Place the `oc` binary in a directory that is on your PATH. To check your PATH, execute the following command:

   ```bash
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

   ```bash
   $ oc <command>
   ```

14.2.11.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   ```cmd
   path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

   ```cmd
   oc <command>
   ```

14.2.11.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.
   To check your **PATH**, open a terminal and execute the following command:

   ```bash
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the **oc** command:

   ```bash
   $ oc <command>
   ```

### 14.2.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **NOTE**

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 14.2.13. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

#### 14.2.13.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.
NOTE

The Prometheus console provides an **ImageRegistryRemoved** alert, for example:

"Image Registry has been removed. **ImageStreamTags**, **BuildConfigs** and **DeploymentConfigs** which reference **ImageStreamTags** may not work as expected. Please configure storage and update the config to **Managed** state by editing configs.imageregistry.operator.openshift.io."

14.2.13.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

14.2.13.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.
Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim: [1]
   
   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   
   Example output
   
<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

14.2.13.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Recreate rollout strategy.
**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
   namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   **1** A unique name that represents the **PersistentVolumeClaim** object.

   **2** The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.

   **3** The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.

   **4** The size of the persistent volume claim.

   b. Create the **PersistentVolumeClaim** object from the file:

   ```
   $ oc create -f pvc.yaml -n openshift-image-registry
   ```

3. Edit the registry configuration so that it references the correct PVC:

   ```
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

**Example output**
Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 14.2.14. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See [Snapshot Limitations](#) for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 14.2.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

### 14.2.16. Next steps

- [Customize your cluster](#).
- [Opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).
Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

14.3. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.7, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

14.3.1. Prerequisites

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide `ReadWriteMany` access modes.
- Review details about the OpenShift Container Platform installation and update processes.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, confirm with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

14.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

14.3.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 14.16. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.
IMPORTANT

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

14.3.4. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

Table 14.17. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>N/A</td>
<td>Network reachability tests</td>

</tbody>
</table>

14.3.5. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

Required vCenter account privileges

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

Example 14.5. Roles and privileges required for installation

<table>
<thead>
<tr>
<th>vSphere object for role</th>

</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

**Example 14.6. Required permissions and propagation settings**

<table>
<thead>
<tr>
<th>vSphere object for role</th>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see **vSphere Permissions and User Management Tasks** in the vSphere documentation.

**Using OpenShift Container Platform with vMotion**

If you intend on using vMotion in your vSphere environment, consider the following before installing a OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

To help ensure the uptime of your compute and control plane nodes, it is recommended that you follow the VMware best practices for vMotion. It is also recommended to use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for **vMotion networking requirements** and **VM anti-affinity rules**.

- If you are using vSphere volumes in your pods, migrating a VM across datastores either manually
or through Storage vMotion causes, invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.

- Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**Cluster resources**
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**
An installer-provisioned vSphere installation requires two static IP addresses:
The **API** address is used to access the cluster API.

The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

**Table 14.20. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td><code>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**14.3.6. Generating an SSH private key and adding it to the agent**

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your **ssh-agent** and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "\n   -f <path>/<file_name>
   ```

   1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. Start the `ssh-agent` process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

   ```bash
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (computer_name)

   1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**
• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

14.3.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

• You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

14.3.8. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.
Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click **Download trusted root CA certificates** in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   └── lin
       ├── 108f4d17.0
       │    └── 7e757f6a.0
       │         └── 8e4f8471.0
       │              └── 8e4f8471.r0
       └── 108f4d17.r1
          └── 7e757f6a.0
             └── 8e4f8471.0
                └── 8e4f8471.r0
   ├── mac
   │    └── 108f4d17.0
   │         └── 7e757f6a.0
   │              └── 8e4f8471.0
   │                   └── 8e4f8471.r0
   └── win
       ├── 108f4d17.0.crt
       ├── 108f4d17.r1.crt
       ├──── 7e757f6a.0.crt
       │       └── 8e4f8471.0.crt
       │              └── 8e4f8471.r0.crt
   3 directories, 15 files
   ```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

### 14.3.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

**Procedure**
1. Create the **install-config.yaml** file.
   
a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory> 1
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select **vsphere** as the platform to target.

   iii. Specify the name of your vCenter instance.

   iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

   The installation program connects to your vCenter instance.

   v. Select the datacenter in your vCenter instance to connect to.

   vi. Select the default vCenter datastore to use.

   vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

   viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

   ix. Enter the virtual IP address that you configured for control plane API access.

   x. Enter the virtual IP address that you configured for cluster ingress.
xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 14.3.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 14.3.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 14.21. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters and hyphens (-), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auths&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;cloud.openshift.com&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>},</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;quay.io&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>
14.3.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 14.22. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>

<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>individual node. For example, if hostPrefix is</td>
<td>The default value is 23.</td>
</tr>
<tr>
<td></td>
<td>set to 23 then each node is assigned a /23</td>
<td></td>
</tr>
</tbody>
</table>
|                            | subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>networking: serviceNetwork: - 172.30.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>networking: machineNetwork: - cidr: 10.0.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</td>
</tr>
</tbody>
</table>

### 14.3.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 14.23. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <strong>compute</strong>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <strong>controlPlane.platform</strong> parameter value.</td>
<td><strong>aws</strong>, <strong>azure</strong>, <strong>gcp</strong>, <strong>openstack</strong>, <strong>ovirt</strong>, <strong>vsphere</strong>, or <strong>{}</strong></td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is <strong>3</strong>.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <strong>MachinePool</strong> objects. For details, see the following “Machine-pool” table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. IMPORTANT If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>

</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td>If the value of the field is set to <strong>Internal</strong>, the cluster will become non-functional. For more information, refer to BZ#1953035.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example:</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <strong>ssh-agent</strong> process uses.</td>
</tr>
</tbody>
</table>

### 14.3.9.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

**Table 14.24. Additional VMware vSphere cluster parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.password</code></td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.datacenter</code></td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.defaultDatastore</code></td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.folder</code></td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, <code>/&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;</code></td>
</tr>
<tr>
<td><code>platform.vsphere.network</code></td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.cluster</code></td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.apiVIP</code></td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td><code>platform.vsphere.ingressVIP</code></td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
</tbody>
</table>

### 14.3.9.15. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 14.25. Optional VMware vSphere machine pool parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.clustersOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td>platform.vsphere.osDisk.diskSizeGB</td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.cpus</td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.coresPerSocket</td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is platform.vsphere.cpus/platform.vsphere.coresPerSocket. The default value is 1.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.memoryMB</td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

### 14.3.9.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 3
    platform:
      vsphere:
        cpus: 2
        coresPerSocket: 2
        memoryMB: 8192
        osDisk:
          diskSizeGB: 120
    controlPlane:
      hyperthreading: Enabled
      name: master
      replicas: 3
      platform:
        vsphere:
          cpus: 4
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.
The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

14.3.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
noProxy: example.com
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its...
machines.

4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster` Proxy object is still created, but it will have a nil `spec`.

NOTE
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

14.3.10. Network configuration phases

When specifying a cluster configuration prior to installation, there are several phases in the installation procedures when you can modify the network configuration:

Phase 1
After entering the `openshift-install create install-config` command. In the `install-config.yaml` file, you can customize the following network-related fields:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`
  For more information on these fields, refer to "Installation configuration parameters".

NOTE
Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

Phase 2
After entering the `openshift-install create manifests` command. If you must specify advanced network configuration, during this phase you can define a customized Cluster Network Operator manifest with only the fields you want to modify.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

### 14.3.11. Specifying advanced network configuration

You can use advanced configuration customization to integrate your cluster into your existing network environment by specifying additional configuration for your cluster network provider. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

#### Prerequisites

- Create the `install-config.yaml` file and complete any modifications to it.

#### Procedure

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`

   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   EOF
   ```

   where:

   `<installation_directory>`

   Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and specify the advanced network configuration for your cluster, such as in the following examples:
Specify a different VXLAN port for the OpenShift SDN network provider

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    openshiftSDNConfig:
      vxlanPort: 4800
```

Enable IPsec for the OVN-Kubernetes network provider

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    ovnKubernetesConfig:
      ipsecConfig: {}
```

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

### 14.3.12. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**
  - IP address pools from which pod IP addresses are allocated.

- **serviceNetwork**
  - IP address pool for services.

- **defaultNetwork.type**
  - Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

### 14.3.12.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code></td>
<td><code>operator.openshift.io/v1</code></td>
</tr>
<tr>
<td><code>kind</code></td>
<td><code>Network</code></td>
</tr>
<tr>
<td><code>metadata.name</code></td>
<td><code>cluster</code></td>
</tr>
<tr>
<td><code>spec.defaultNetwork</code></td>
<td></td>
</tr>
<tr>
<td><code>openshiftSDNConfig.vxlanPort</code></td>
<td><code>4800</code></td>
</tr>
<tr>
<td><code>ovnKubernetesConfig.ipsecConfig</code></td>
<td><code>{}</code></td>
</tr>
<tr>
<td>Field</td>
<td>Type</td>
</tr>
<tr>
<td>------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>metadata.name</td>
<td>string</td>
</tr>
</tbody>
</table>
| spec.clusterNetwork         | array  | A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

    spec:
    - clusterNetwork:
      - cidr: 10.128.0.0/19
      - hostPrefix: 23
      - cidr: 10.128.32.0/19
      - hostPrefix: 23

    This value is ready-only and specified in the `install-config.yaml` file. |
| spec.serviceNetwork         | array  | A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

    spec:
    serviceNetwork:
    - 172.30.0.0/14

    This value is ready-only and specified in the `install-config.yaml` file. |
| spec.defaultNetwork         | object | Configures the Container Network Interface (CNI) cluster network provider for the cluster network. |
| spec.kubeProxy Config       | object | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect. |

**defaultNetwork object configuration**

The values for the `defaultNetwork` object are defined in the following table:

### Table 14.27. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

1992
Either **OpenShiftSDN** or **OVNKubernetes**. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.

**NOTE**

OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>type</strong></td>
<td>string</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>openshiftSDNConfig</strong></td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>
<tr>
<td><strong>ovnKubernetesConfig</strong></td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

**Configuration for the OpenShift SDN CNI cluster network provider**

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 14.28. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>mode</strong></td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. </tr>
</tbody>
</table>

**Example OVN-Kubernetes configuration**

defaultNetwork:
type: OVNKubernetes
ovnKubernetesConfig:
  mtu: 1400
genevePort: 6081
ipsecConfig: {}  

**kubeProxyConfig object configuration**
The values for the `kubeProxyConfig` object are defined in the following table:

---

**Table 14.30. kubeProxyConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

---

1995
### Field: `iptablesSyncPeriod`  
**Type:** string  
**Description:** The refresh period for `iptables` rules. The default value is 30s. Valid suffixes include `s`, `m`, and `h` and are described in the Go `time` package documentation.

**NOTE**
Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the `iptablesSyncPeriod` parameter is no longer necessary.

### Field: `proxyArguments.iptables-min-sync-period`
**Type:** array  
**Description:** The minimum duration before refreshing `iptables` rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include `s`, `m`, and `h` and are described in the Go `time` package. The default value is:

```
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period:
      - 0s
```

#### 14.3.13. Deploying the cluster
You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**
You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**
1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \  
  --log-level=info
```
For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover `kubelet` certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### 14.3.14. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

14.3.14.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

14.3.14.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.7 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```bash
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```bash
$ oc <command>
```

**14.3.15. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

1. Export the kubeadmin credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```
14.3.16. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

14.3.16.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

14.3.16.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

14.3.16.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.
OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim: 1
   ```
Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

```
$ oc get clusteroperator image-registry
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

### 14.3.16.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":{"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
   namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
       storage: 100Gi
   ```

1. A unique name that represents the PersistentVolumeClaim object.
The namespace for the PersistentVolumeClaim object, which is openshift-image-registry.

The access mode of the persistent volume claim. With ReadWriteOnce, the volume can be mounted with read and write permissions by a single node.

The size of the persistent volume claim.

b. Create the PersistentVolumeClaim object from the file:

```bash
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```bash
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
  pvc:
    claim: 1
```

Creating a custom PVC allows you to leave the claim field blank for the default automatic creation of an image-registry-storage PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 14.3.17. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 14.3.18. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

14.3.19. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

14.4. INSTALLING A CLUSTER ON VSPHERE WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.7, you can install a cluster on VMware vSphere infrastructure that you provision.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

14.4.1. Prerequisites

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- Review details about the OpenShift Container Platform installation and update processes.
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 14.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access [Quay.io](#) to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 14.4.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

<table>
<thead>
<tr>
<th>Table 14.31. Minimum supported vSphere version for VMware components</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Component</strong></td>
</tr>
<tr>
<td>Hypervisor</td>
</tr>
</tbody>
</table>
### Component

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**IMPORTANT**

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

### 14.4.4. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

#### 14.4.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.

**NOTE**

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

---

2006
To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

All virtual machines must reside in the same datastore and in the same folder as the installer.

14.4.4.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

14.4.4.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

14.4.4.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Table 14.32. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

14.4.4.5. Certificate signing requests management
Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 14.4.5. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

#### Prerequisites

- Review the [OpenShift Container Platform 4.x Tested Integrations](#) page before you create the supporting infrastructure for your cluster.

#### Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

#### 14.4.5.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in **initramfs** during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

</tbody>
</table>

Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

- A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 14.36. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**. Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

**Table 14.37. Application Ingress load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**Ethernet adaptor hardware address requirements**

When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:

- 00:05:69:00:00:00 to 00:05:69:FF:FF
- 00:0c:29:00:00:00 to 00:0c:29:FF:FF
- 00:1c:14:00:00:00 to 00:1c:14:FF:FF
- 00:50:56:00:00:00 to 00:50:56:FF:FF

If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

**Additional resources**

- Configuring chrony time service

**14.4.5.2. User-provisioned DNS requirements**

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-
provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 14.38. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>IMPORTANT</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.
The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

**Example 14.7. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root (  
2019070700 ; serial  
3H ; refresh (3 hours)  
30M ; retry (30 minutes)  
2W ; expiry (2 weeks)  
1W ) ; minimum (1 week)  
IN NS ns1.example.com.
IN MX 10 smtp.example.com.

ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5

; The api identifies the IP of your load balancer.
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5

; The wildcard also identifies the load balancer.
*.apps.ocp4 IN A 192.168.1.5

; Create an entry for the bootstrap host.
bootstrap.ocp4 IN A 192.168.1.96

; Create entries for the master hosts.
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
master2.ocp4 IN A 192.168.1.99

; Create entries for the worker hosts.
worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.7
}
```

The following example BIND zone file shows sample PTR records for reverse name resolution.

**Example 14.8. Sample DNS zone database for reverse records**

```
$TTL 1W
@ IN SOA ns1.example.com. root (  
2019070700 ; serial  
3H ; refresh (3 hours)  
30M ; retry (30 minutes)  
2W ; expiry (2 weeks)  
1W ) ; minimum (1 week)  
IN NS ns1.example.com.
```

2013
14.4.6. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ``

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

```bash
$ ssh-add <path>/<file_name>  
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

14.4.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar xvf openshift-install-linux.tar.gz
   $ mkdir <installation_directory>
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 14.4.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

14.4.8.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    controlPlane:
      hyperthreading: Enabled
      name: master
      replicas: 3

metadata:
  name: test

platform:
  vsphere:
    vcenter: your.vcenter.server
    username: username
    password: password
    datacenter: datacenter
    defaultDatastore: datastore
    folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>"

fips: false
pullSecret: "{"auths": {...}}"
sshKey: 'ssh-ed25519 AAAAA...'
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

The password associated with the vSphere user.

The vSphere datacenter.

The default vSphere datastore to use.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, /<datacenter_name>/vm/<folder_name>/<subfolder_name>. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this parameter.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

16 The pull secret that you obtained from OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

17 The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

14.4.8.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  
     noProxy: example.com
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ```
1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**
The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

**14.4.9. Creating the Kubernetes manifest and Ignition config files**

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.
IMPORTANT
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

NOTE
The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites
- You obtained the OpenShift Container Platform installation program.
- You created the install-config.yaml installation configuration file.

Procedure
1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory> 1
   ```

   For `<installation_directory>`, specify the installation directory that contains the install-config.yaml file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.

   - You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

   **WARNING**
   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │       └── kubectlconfig
   │           └── bootstrap.ign
   │           └── master.ign
   │                   └── metadata.json
   │                   └── worker.ign
   ```

14.4.10. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**
To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

### 14.4.11. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

Before you install a cluster that contains user-provisioned infrastructure on VMware vSphere, you must create RHCOS machines on vSphere hosts for it to use.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a **vSphere cluster**.

**Procedure**

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

```json
{
    "ignition": {
        "config": {
            "merge": [
                {
                    "source": "<bootstrap_ignition_config_url>",
                    "verification": {}
                }
            ],
            "timeouts": {},
            "version": "3.2.0"
        },
        "networkd": {},
        "passwd": {}
    }
}
```
1. Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```bash
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**

   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the **VMs and Templates** view.
   b. Right-click the name of your datacenter.
c. Click New Folder → New VM and Template Folder.

d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the install-config.yaml file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

**NOTE**

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.

b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.

c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.

d. On the Select a compute resource tab, click the name of your vSphere cluster.

e. On the Select storage tab, configure the storage options for your VM.

   - Select Thin Provision or Thick Provision, based on your storage preferences.

   - Select the datastore that you specified in your install-config.yaml file.

f. On the Select network tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the Customize template tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. After the template deploys, deploy a VM for a machine in the cluster.

a. Right-click the template name and click Clone → Clone to Virtual Machine.

b. On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as control-plane-0 or compute-1.

c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.
d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

e. Optional: On the **Select storage** tab, customize the storage options.

f. On the **Select clone options**, select **Customize this virtual machine's hardware**.

g. On the **Customize hardware** tab, click **VM Options → Advanced**.

- Optional: Override default DHCP networking in vSphere. To enable static IP networking:

  i. Set your static IP configuration:

     ```
     $ export IPCFG="ip=<ip>::<gateway>::<netmask>:
     <hostname>:<iface>::none
     nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]
     
     Example command
     $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0::none
     nameserver=8.8.8.8"
     
     ii. Set the **guestinfo.afterburn.initrd.network-kargs** property before booting a VM from an OVA in vSphere:

     ```

     ```
     $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-
     kargs=${IPCFG}"```

- Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list, select **High**. Ensure that your VM's CPU and memory reservation have the following values:

  - Memory reservation value must be equal to its configured memory size.
  - CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

- Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:

  - **guestinfo.ignition.config.data**: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
  - **disk.EnableUUID**: Specify **TRUE**.

h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

9. Create the rest of the machines for your cluster by following the preceding steps for each machine.
IMPORTANT

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

14.4.12. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

You can create more compute machines for your cluster that uses user-provisioned infrastructure on VMware vSphere.

Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

Procedure

1. After the template deploys, deploy a VM for a machine in the cluster.
   a. Right-click the template’s name and click **Clone → Clone to Virtual Machine**
   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.
   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
   e. Optional: On the **Select storage** tab, customize the storage options.
   f. On the **Select clone options**, select **Customize this virtual machine’s hardware**
   g. On the **Customize hardware** tab, click **VM Options → Advanced**.
      - From the **Latency Sensitivity** list, select **High**.
      - Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
        - `guestinfo.ignition.config.data`: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
        - `guestinfo.ignition.config.data.encoding`: Specify **base64**.
        - `disk.EnableUUID`: Specify **TRUE**.
   h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under **Add network adapter** if there are multiple networks available.
   i. Complete the configuration and power on the VM.
2. Continue to create more compute machines for your cluster.

14.4.13. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- **Create separate partitions:** For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

**IMPORTANT**

Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retain existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

### Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- **/var/lib/containers:** Holds container-related content that can grow as more images and containers are added to a system.

- **/var/lib/etcd:** Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- **/var:** Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

#### Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```
2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

```bash
$ openshift-install create manifests --dir $HOME/clusterconfig
? SSH Public Key ...
$ ls $HOME/clusterconfig/openshift/
 99_kubeadmin-password-secret.yaml
 99_openshift-cluster-api_master-machines-0.yaml
 99_openshift-cluster-api_master-machines-1.yaml
 99_openshift-cluster-api_master-machines-2.yaml
...```

3. Create a `MachineConfig` object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
        - device: /dev/<device_name> 1
        partitions:
          - label: var
            startMiB: <partition_start_offset> 2
            sizeMiB: <partition_size> 3
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
      systemd:
        units:
          - name: var.mount 4
            enabled: true
            contents: |
            [Unit]
            Before=local-fs.target
            [Mount]
            What=/dev/disk/by-partlabel/var
            Where=/var
            Options=defaults,prjquota 5
            [Install]
            WantedBy=local-fs.target
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is
The size of the data partition in mebibytes.

The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-lib-containers.mount`.

The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth  bootstrap.ign  master.ign  metadata.json  worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 14.4.14. Updating the bootloader using `bootupd`

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

#### Manual install method

You can manually install `bootupd` by using the `bootctl` command-line tool.

1. Inspect the system status:

```
# bootupctl status
```

**Example output**

```
Component EFI
  Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
  Update: At latest version
```
2. RHCOS images created without bootupd installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

**Machine config method**

Another way to enable bootupd is by providing a machine config.

- Provide a machine config file with the enabled systemd unit, as shown in the following example:

```
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update

        [Install]
        WantedBy=multi-user.target
```

**14.4.15. Installing the OpenShift CLI by downloading the binary**

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.
14.4.15.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

14.4.15.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
C:\> oc <command>
```

14.4.15.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.
Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

14.4.16. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify warn, debug, or error instead of info.

Example output

   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.20.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point.
You can also remove or reformat the machine itself.

### 14.4.17. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   ```
   (1)
   ```

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 14.4.18. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.
Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

   $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machineApprover if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}{{end}}| xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.
To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 14.4.19. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>SINCE</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>authentication</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>
Configure the Operators that are not available.

14.4.19.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

14.4.19.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

### 14.4.19.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have “100Gi” capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**
NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   **Example output**

   ```yaml
   storage:
   pvc:
     claim: 1
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the *clusteroperator* status:

   $ oc get clusteroperator image-registry

   **Example output**

   ```
   NAME             VERSION   AVAILABLE  PROGRESSING  DEGRADED   SINCE       MESSAGE
   image-registry   4.7       True       False        False      6h50m
   ```

14.4.19.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir":{}}}}'
  ```

**WARNING**

Configure this option for only non-production clusters.
If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 14.4.19.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the *Recreate* rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the *Recreate* rollout strategy and runs with only 1 replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
   
   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   **1** A unique name that represents the `PersistentVolumeClaim` object.
   **2** The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.
   **3** The access mode of the persistent volume claim. With ReadWriteOnce, the volume can be mounted with read and write permissions by a single node.
   **4** The size of the persistent volume claim.
b. Create the `PersistentVolumeClaim` object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
pvc:
  claim: 1
```

Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 14.4.20. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h56m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h39m</td>
</tr>
<tr>
<td>console</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h59m</td>
</tr>
<tr>
<td>csi-snapshot-controller</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h12m</td>
</tr>
<tr>
<td>dns</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h15m</td>
</tr>
<tr>
<td>etcd</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>image-registry</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h59m</td>
</tr>
<tr>
<td>ingress</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h30m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
2. Confirm that the Kubernetes API server is communicating with the pods.
   
a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>api-server-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 3m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>api-server-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>api-server-z25h4</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 2m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0 5m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace>  
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.

   a. All the worker nodes are restarted. To monitor the process, enter the following command:

   ```
   $ oc get nodes -w
   ```

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

   You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

**14.4.21. Backing up VMware vSphere volumes**

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach
and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 14.4.22. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service.

### 14.4.23. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

### 14.5. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.7, you can install a cluster on VMware vSphere infrastructure that you provision with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

You must set most of the network configuration parameters during installation, and you can modify only kubeProxy configuration parameters in a running cluster.
NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

14.5.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. Verify that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you must configure it to access Red Hat Insights.

14.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

14.5.3. VMware vSphere infrastructure requirements
You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

### Table 14.39. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.

**IMPORTANT**

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in [BZ#1935539](#).

### 14.5.4. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

#### 14.5.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
• Three control plane, or master, machines
• At least two compute machines, which are also known as worker machines.

**NOTE**

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

**IMPORTANT**

All virtual machines must reside in the same datastore and in the same folder as the installer.

### 14.5.4.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in *initramfs* during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

### 14.5.4.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

### 14.5.4.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

**Table 14.40. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Machine</td>
<td>Operating System</td>
<td>vCPU</td>
<td>Virtual RAM</td>
<td>Storage</td>
<td>IOPS</td>
</tr>
<tr>
<td>-------------</td>
<td>------------------</td>
<td>------</td>
<td>-------------</td>
<td>---------</td>
<td>------</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

### 14.5.4.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 14.5.5. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

**Prerequisites**

- Review the [OpenShift Container Platform 4.x Tested Integrations](#) page before you create the supporting infrastructure for your cluster.

**Procedure**

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

### 14.5.5.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in **initramfs** during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.
The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

Table 14.41. All machines to all machines

</tbody>
</table>

Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.
IMPORTANT

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   
   Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 14.44. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.
2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>x</td>
<td>x</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>x</td>
<td>x</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**Ethernet adaptor hardware address requirements**

When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:

- 00:05:69:00:00:00 to 00:05:69:FF:FF:FF
- 00:0c:29:00:00:00 to 00:0c:29:FF:FF:FF
- 00:1c:14:00:00:00 to 00:1c:14:FF:FF:FF
- 00:50:56:00:00:00 to 00:50:56:FF:FF:FF

If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.
14.5.5.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 14.46. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. IMPORTANT The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td><code>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td><code>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>
MASTER

hosts

<master><n>.<cluster_name>.<base_domain>.

DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.

WORKER

hosts

<worker><n>.<cluster_name>.<base_domain>.

Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

TIP

You can use the nslookup <hostname> command to verify name resolution. You can use the dig -x <ip_address> command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

Example 14.9. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
; ;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
; helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
; ; The api identifies the IP of your load balancer.
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5
; ; The wildcard also identifies the load balancer.
*.apps.ocp4 IN A 192.168.1.5
; ; Create an entry for the bootstrap host.
bootstrap.ocp4 IN A 192.168.1.96
; ; Create entries for the master hosts.
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
```
The following example BIND zone file shows sample PTR records for reverse name resolution.

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 
  2019070700 ; serial  
  3H ; refresh (3 hours)  
  30M ; retry (30 minutes)  
  2W ; expiry (2 weeks)  
  1W ) ; minimum (1 week)  
IN NS ns1.example.com.  
;  
; The syntax is "last octet" and the host must have an FQDN  
; with a trailing dot.  
97 IN PTR master0.ocp4.example.com.  
98 IN PTR master1.ocp4.example.com.  
99 IN PTR master2.ocp4.example.com.  
;  
96 IN PTR bootstrap.ocp4.example.com.  
;  
5 IN PTR api.ocp4.example.com.  
5 IN PTR api-int.ocp4.example.com.  
;  
11 IN PTR worker0.ocp4.example.com.  
7 IN PTR worker1.ocp4.example.com.  
;  
;EOF
```

**Example 14.10. Sample DNS zone database for reverse records**

14.5.6. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "\n   -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Next steps**
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

14.5.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   `$ tar xvf openshift-install-linux.tar.gz`

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

14.5.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.
Prerequisites

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**
   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**
   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**
   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

14.5.8.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
platform:
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

The password associated with the vSphere user.

The vSphere datacenter.

The default vSphere datastore to use.
Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example,

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret that you obtained from OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

### 14.5.8.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   ```
proxy:
httpProxy: http://<username>:<pswd>@<ip>:<port> ①
httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
noProxy: example.com ③
additionalTrustBundle: |

-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
...

① A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

② A proxy URL to use for creating HTTPS connections outside the cluster.

③ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

④ If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

14.5.9. Network configuration phases

When specifying a cluster configuration prior to installation, there are several phases in the installation procedures when you can modify the network configuration:

Phase 1

After entering the openshift-install create install-config command. In the install-config.yaml file, you can customize the following network-related fields:
Phase 2

After entering the `openshift-install create manifests` command. If you must specify advanced network configuration, during this phase you can define a customized Cluster Network Operator manifest with only the fields you want to modify.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

14.5.10. Specifying advanced network configuration

You can use advanced configuration customization to integrate your cluster into your existing network environment by specifying additional configuration for your cluster network provider. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

**Prerequisites**

- Create the `install-config.yaml` file and complete any modifications to it.
- Create the Ignition config files for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`
   
   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.
2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

```yaml
$ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
EOF
```

where:

```
<installation_directory>
```

Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and specify the advanced network configuration for your cluster, such as in the following examples:

**Specify a different VXLAN port for the OpenShift SDN network provider**

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  openshiftSDNConfig:
    vxlanPort: 4800
```

**Enable IPsec for the OVN-Kubernetes network provider**

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  ovnKubernetesConfig:
    ipsecConfig: {}
```

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

6. Remove the Kubernetes manifest files that define the control plane machines and compute `machineSets`:

```bash
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.
• You can preserve the MachineSet files to create compute machines by using the machine API, but you must update references to them to match your environment.

14.5.11. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**
  - IP address pools from which pod IP addresses are allocated.

- **serviceNetwork**
  - IP address pool for services.

- **defaultNetwork.type**
  - Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

14.5.11.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 14.47. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>metadata.name</code></td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td><code>spec.clusterNetwork</code></td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
</tbody>
</table>

```
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

This value is ready-only and specified in the `install-config.yaml` file.
A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

```
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

This value is ready-only and specified in the `install-config.yaml` file.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec.serviceNetwork</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the Container Network Interface (CNI) cluster network provider for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>

### defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either <a href="https://docs.openshift.com/container-platform/4.11/admin-guide/cluster-administration/networking-configuration.html#openshiftsdn">OpenShiftSDN</a> or <a href="https://docs.openshift.com/container-platform/4.11/admin-guide/cluster-administration/networking-configuration.html#ovnkubernetes">OVNKubernetes</a>. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

**NOTE**

OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

### Configuration for the OpenShift SDN CNI cluster network provider
The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 14.49. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is <strong>4789</strong>. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>

**Example OpenShift SDN configuration**

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```
Configuration for the OVN-Kubernetes CNI cluster network provider
The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 14.50. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

Example OVN-Kubernetes configuration

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
```

kubeProxyConfig object configuration
The values for the kubeProxyConfig object are defined in the following table:

Table 14.51. kubeProxyConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### iptablesSyncPeriod

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for <code>iptables</code> rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
</tbody>
</table>

**NOTE**

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the `iptablesSyncPeriod` parameter is no longer necessary.

### proxyArguments.iptables-min-sync-period

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing <code>iptables</code> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</td>
</tr>
</tbody>
</table>

    ```
    kubeProxyConfig:
    proxyArguments:
      iptables-min-sync-period:
        - 0s
    ```

14.5.12. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

- Obtain the Ignition config files:

```
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

If you created an `install-config.yaml` file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

The following files are generated in the directory:

```
├── auth
 │   ├── kubeadmin-password
 │   └── kubeconfig
 ├── bootstrap.ign
 ├── master.ign
 └── metadata.json
 └── worker.ign
```

14.5.13. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

- You generated the Ignition config files for your cluster.

- You installed the `jq` package.

Procedure
To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json  
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

---

**Example output**

```
openshift-vw9j6  
```

The output of this command is your cluster name and a random string.

---

### 14.5.14. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

Before you install a cluster that contains user-provisioned infrastructure on VMware vSphere, you must create RHCOS machines on vSphere hosts for it to use.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

**Procedure**

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

```json
{
  "ignition": {
    "config": {
      "merge": [
        {
          "source": "<bootstrap_ignition_config_url>",  
          "verification": {}
        }
      ],
      "timeouts": {},
      "version": "3.2.0"
    },
    "networkd": {},
    "passwd": {}
  }
}
```
1 Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the **VMs and Templates** view.
   b. Right-click the name of your datacenter.
c. Click **New Folder → New VM and Template Folder**.

d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

**NOTE**

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

a. From the **Hosts and Clusters** tab, right-click your cluster name and select **Deploy OVF Template**.

b. On the **Select an OVF** tab, specify the name of the RHCOS OVA file that you downloaded.

c. On the **Select a name and folder** tab, set a **Virtual machine name** for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.

d. On the **Select a compute resource** tab, click the name of your vSphere cluster.

e. On the **Select storage** tab, configure the storage options for your VM.

   - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.

   - Select the datastore that you specified in your `install-config.yaml` file.

f. On the **Select network** tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. After the template deploys, deploy a VM for a machine in the cluster.

a. Right-click the template name and click **Clone → Clone to Virtual Machine**

b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as `control-plane-0` or `compute-1`.

c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

e. Optional: On the **Select storage** tab, customize the storage options.

f. On the **Select clone options**, select **Customize this virtual machine’s hardware**.

g. On the **Customize hardware** tab, click **VM Options → Advanced**.
   
   - Optional: Override default DHCP networking in vSphere. To enable static IP networking:
     
     i. Set your static IP configuration:
        
        ```bash
        $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
        nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
        
        **Example command**
        ```bash
        $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
        nameserver=8.8.8.8"
        
        ii. Set the **guestinfo.afterburn.initrd.network-kargs** property before booting a VM from an OVA in vSphere:
        ```bash
        $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
        ```

   - Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list, select **High**. Ensure that your VM’s CPU and memory reservation have the following values:
     
     - Memory reservation value must be equal to its configured memory size.
     - CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

   - Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
     
     - **guestinfo.ignition.config.data**: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
     
     - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
     
     - **disk.EnableUUID**: Specify **TRUE**.

h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

   i. Complete the configuration and power on the VM.

9. Create the rest of the machines for your cluster by following the preceding steps for each machine.
IMPORTANT

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

14.5.15. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

You can create more compute machines for your cluster that uses user-provisioned infrastructure on VMware vSphere.

Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

Procedure

1. After the template deploys, deploy a VM for a machine in the cluster.
   a. Right-click the template’s name and click Clone → Clone to Virtual Machine
   b. On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as compute-1.
   c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.
   d. On the Select a compute resource tab, select the name of a host in your datacenter.
   e. Optional: On the Select storage tab, customize the storage options.
   f. On the Select clone options, select Customize this virtual machine’s hardware
   g. On the Customize hardware tab, click VM Options → Advanced.
      - From the Latency Sensitivity list, select High.
      - Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:
        - guestinfo.ignition.config.data: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
        - guestinfo.ignition.config.data.encoding: Specify base64.
        - disk.EnableUUID: Specify TRUE.
   h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under Add network adapter if there are multiple networks available.
   i. Complete the configuration and power on the VM.
2. Continue to create more compute machines for your cluster.

**14.5.16. Disk partitioning**

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- **Create separate partitions**: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, a separate partition, but not both.

  **IMPORTANT**

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retain existing partitions**: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

### Creating a separate `/var` partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.

- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```
2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
? SSH Public Key ...
$ ls $HOME/clusterconfig/openshift/
  99_kubeadmin-password-secret.yaml
  99_openshift-cluster-api_master-machines-0.yaml
  99_openshift-cluster-api_master-machines-1.yaml
  99_openshift-cluster-api_master-machines-2.yaml
  ...
```

3. Create a `MachineConfig` object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
        - device: /dev/<device_name> ①
        partitions:
          - label: var
            startMiB: <partition_start_offset> ②
            sizeMiB: <partition_size> ③
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
  systemd:
    units:
      - name: var.mount ④
        enabled: true
        contents: |
          [Unit]
          Before=local-fs.target
          [Mount]
          What=/dev/disk/by-partlabel/var
          Where=/var
          Options=defaults,prjquota ⑤
          [Install]
          WantedBy=local-fs.target
```

① The storage device name of the disk that you want to partition.

② When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is
3. The size of the data partition in mebibytes.

4. The name of the mount unit must match the directory specified in the Where= directive. For example, for a filesystem mounted on /var/lib/containers, the unit must be named var-lib-containers.mount.

5. The priquota mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

14.5.17. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use bootupd only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install bootupd by using the bootctl command-line tool.

1. Inspect the system status:

```bash
# bootupctl status
```

Example output

```
Component EFI
Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
Update: At latest version
```
2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

**Machine config method**

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

```
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes

        [Install]
        WantedBy=multi-user.target
```

### 14.5.18. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
• You used the Ignition config files to create RHCOS machines for your cluster.
• Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   
   ```
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

   - INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   - INFO API v1.20.0 up
   - INFO Waiting up to 30m0s for bootstrapping to complete...
   - INFO It is now safe to remove the bootstrap resources

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point.
   You can also remove or reformat the machine itself.

14.5.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

• You deployed an OpenShift Container Platform cluster.
• You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```shell
$ oc whoami
```

Example output

```
system:admin
```

14.5.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

```shell
$ oc get nodes
```

Example output

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  63m  v1.20.0
master-1  Ready     master  63m  v1.20.0
master-2  Ready     master  64m  v1.20.0
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```shell
$ oc get csr
```

Example output

```
NAME        AGE   REQUESTOR                                   CONDITION
csr-mddf5   20m   system:node:master-01.example.com   Approved,Issued
csr-z5rln   16m   system:node:worker-21.example.com   Approved,Issued
```
3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

1. `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td></td>
</tr>
</tbody>
</table>
If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:
  
  ```
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
  ```

After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

### 14.5.20.1. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

### Prerequisites

- Your control plane has initialized.

### Procedure
Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>

</tbody>
</table>

Configure the Operators that are not available.

### 14.5.20.2. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.
NOTE

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

14.5.20.3. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

14.5.20.3.1. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ``

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
   namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
   ```
A unique name that represents the **PersistentVolumeClaim** object.

2. The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.

3. The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.

4. The size of the persistent volume claim.

---

b. Create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
  pvc:
    claim: 1
```

1. Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 14.5.21. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```
   $ watch -n5 oc get clusteroperators
   ```

**Example output**
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

---

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   $ oc get pods --all-namespaces

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running 9m</td>
</tr>
<tr>
<td></td>
<td>Running 1 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 3m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 1m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 2m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 0 5m</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   $ oc logs <pod_name> -n <namespace>

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.
All the worker nodes are restarted. To monitor the process, enter the following command:

```
$ oc get nodes -w
```

**NOTE**

If you have additional machine types such as infrastructure nodes, repeat the process for these types.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

### 14.5.22. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 14.5.23. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager**.

After you confirm that your **OpenShift Cluster Manager** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 14.5.24. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

14.6. INSTALLING A CLUSTER ON VSPHERE IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.7, you can install a cluster on VMware vSphere infrastructure in a restricted network by creating an internal mirror of the installation release content.

NOTE
OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

14.6.1. Prerequisites

- Create a registry on your mirror host and obtain the imageContentSources data for your version of OpenShift Container Platform.

IMPORTANT
Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide the ReadWriteMany access mode.

- Review details about the OpenShift Container Platform installation and update processes.

- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

- If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.

NOTE
If you are configuring a proxy, be sure to also review this site list.

14.6.2. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require
internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

14.6.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

14.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access **Quay.io** to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

14.6.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 14.52. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OpenShift Container Platform Installing</td>
<td>6.0</td>

<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**IMPORTANT**

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

### 14.6.5. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

**Table 14.53. Ports used for all-machine to all-machine communications**
### Table 14.54. Ports used for all-machine to control plane communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

### 14.6.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

### Example 14.11. Roles and privileges required for installation

<table>
<thead>
<tr>

</tbody>
</table>

For more information about creating an account with only the required privileges, see **vSphere Permissions and User Management Tasks** in the vSphere documentation.

**Using OpenShift Container Platform with vMotion**

If you intend on using vMotion in your vSphere environment, consider the following before installing a OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.
  
To help ensure the uptime of your compute and control plane nodes, it is recommended that you follow the VMware best practices for vMotion. It is also recommended to use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for **vMotion networking requirements** and **VM anti-affinity rules**.
If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes, invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.

Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**Cluster resources**

When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**

Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**

You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. The VM in your restricted network must have access to vCenter so that it can provision and manage nodes, persistent volume claims (PVCs), and other resources. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.
Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:

- The API address is used to access the cluster API.
- The Ingress address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

DNS records
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 14.56. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

14.6.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**
In a production environment, you require disaster recovery and debugging.

**IMPORTANT**
Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "\n   -f <path>/<file_name>
   ```

   1. Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the `ssh-agent` process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

   ```
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   1. Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 14.6.8. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

#### Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click **Download trusted root CA certificates** in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
     └── lin
       ├── 108f4d17.0
       │    ├── 108f4d17.r1
       │    ├── 7e757f6a.0
       │    ├── 8e4f8471.0
       │    └── 8e4f8471.r0
       └── mac
         ├── 108f4d17.0
         │    ├── 108f4d17.r1
         │    ├── 7e757f6a.0
         │    └── 8e4f8471.0
         └── win
             ├── 108f4d17.0.crt
             └── 108f4d17.r1.crl
   3 directories, 15 files
   ```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

### 14.6.9. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network VMware vSphere environment.
Prerequisites

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

Procedure

2. Under Version, select the most recent release of OpenShift Container Platform 4.7 for RHEL 8.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - vSphere image.

4. Upload the image you downloaded to a location that is accessible from the bastion server.

   The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

14.6.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the `imageContentSources` values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.

- Obtain service principal permissions at the subscription level.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select vsphere as the platform to target.

iii. Specify the name of your vCenter instance.

iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

The installation program connects to your vCenter instance.

v. Select the datacenter in your vCenter instance to connect to.

vi. Select the default vCenter datastore to use.

vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the install-config.yaml file, set the value of platform.vsphere.clusterOSImage to the image location or name. For example:

```yaml
platform:
  vsphere:
```
3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: "{"auths":{"<mirror_host_name>:5000": {"auth": "<credentials>"}},"email": "you@example.com"}}"
   ``

   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

   b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
     -----END CERTIFICATE-----
   ``

   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

   c. Add the image content resources, which look like this excerpt:

   ```yaml
   imageContentSources:
   - mirrors:
     - `<mirror_host_name>:5000`/<repo_name>/release
       source: quay.example.com/openshift-release-dev/ocp-release
     - mirrors:
       - `<mirror_host_name>:5000`/<repo_name>/release
         source: registry.example.com/ocp/release
   ``

   To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.

5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

## 14.6.10.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe
your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 14.6.10.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code></td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td><code>baseDomain</code></td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td><code>metadata</code></td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td><code>metadata.name</code></td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>, <code>{{.baseDomain}}</code>.</td>
<td>String of lowercase letters and hyphens (-), such as dev.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere**. For additional information about platform,<platform> parameters, consult the table for your specific platform that follows.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <strong>aws, baremetal, azure, openstack, ovirt, vsphere</strong>. For additional information about platform,&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td><code>{  &quot;auths&quot;:{    &quot;cloud.openshift.com&quot;:{      &quot;auth&quot;:&quot;b3Blb=&quot;,      &quot;email&quot;:&quot;you@example.com&quot;    },    &quot;quay.io&quot;:{      &quot;auth&quot;:&quot;b3Blb=&quot;,      &quot;email&quot;:&quot;you@example.com&quot;    }} }</code></td>
</tr>
</tbody>
</table>

### 14.6.10.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 14.58. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>

<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
networking.machineNetwork

The IP address blocks for machines.
If you specify multiple IP address blocks, the blocks must not overlap.
If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.

networking.machineNetwork.cidr

Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

NOTE
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

14.6.10.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 14.59. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or <code>hyperthreading</code>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. The default value is <strong>External</strong>. Setting this field to <strong>Internal</strong> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example:</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <strong>ssh-agent</strong> process uses.</td>
<td></td>
</tr>
</tbody>
</table>
## 14.6.10.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

### Table 14.60. Additional VMware vSphere cluster parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform vsphere.password</code></td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform vsphere.datacenter</code></td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform vsphere.defaultDatastore</code></td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform vsphere.folder</code></td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, <code>/&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;</code>.</td>
</tr>
<tr>
<td><code>platform vsphere.network</code></td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform vsphere.cluster</code></td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform vsphere.apiVIP</code></td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td><code>platform vsphere.ingressVIP</code></td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
</tbody>
</table>
14.6.10.1.5. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 14.61. Optional VMware vSphere machine pool parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.clusterOSImage</code></td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-%3Cversion%3E-vmware.%3Carchitecture%3E.ova">https://mirror.openshift.com/images/rhcos-&lt;version&gt;-vmware.&lt;architecture&gt;.ova</a></td>
</tr>
<tr>
<td><code>platform.vsphere.osDisk.diskSizeGB</code></td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.cpus</code></td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.coresPerSocket</code></td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is <code>platform.vsphere.cpus/platform.vsphere.coresPerSocket</code>. The default value is 1</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.memoryMB</code></td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

14.6.10.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 2
  - hyperthreading: Enabled
name: worker
replicas: 3
platform:
  vsphere: 4
    cpus: 2
coresPerSocket: 2
memoryMB: 8192
osDisk:
  diskSizeGB: 120
controlPlane: 5
  hyperthreading: Enabled
```

1 2 3 4 5 6
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

---

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2.5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

3.6 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.
IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

The location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that is accessible from the bastion server.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

14.6.10.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure
1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
noProxy: example.com ³
additionalTrustBundle: ⁴
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
```

¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
² A proxy URL to use for creating HTTPS connections outside the cluster.
³ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.
⁴ If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RH COS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RH COS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

14.6.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
   ```

   1 For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   ...

   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s

   +

   NOTE

   The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

+ 

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

14.6.12. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of `oc`.

14.6.12.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   ```
   $ tar xvzf <file>
   ```

5. Place the `oc` binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 14.6.12.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.7 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your **PATH**.
   
   To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 14.6.12.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.7 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your **PATH**.
   
   To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
14.6.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **TIP**
   
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

14.6.14. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

  **TIP**
  
  Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

14.6.15. Creating registry storage
After you install the cluster, you must create storage for the Registry Operator.

### 14.6.15.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.

**NOTE**

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

"Image Registry has been removed. `ImageStreamTags`, `BuildConfigs` and `DeploymentConfigs` which reference `ImageStreamTags` may not work as expected. Please configure storage and update the config to **Managed** state by editing `configs.imageregistry.operator.openshift.io`.

### 14.6.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

#### 14.6.15.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.
IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   
   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

   2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**

   No resources found in openshift-image-registry namespace

   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

   **Example output**

   ```
   storage:
   pvc:
   claim: 1
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   ```
14.6.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

14.6.17. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.

14.7. INSTALLING A CLUSTER ON VSPHERE IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.7, you can install a cluster on VMware vSphere infrastructure that you provision in a restricted network.

NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

14.7.1. Prerequisites

- Create a registry on your mirror host and obtain the imageContentSources data for your version of OpenShift Container Platform.
IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- Provision persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

- Review details about the OpenShift Container Platform installation and update processes.

- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

- If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

14.7.2. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

14.7.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

14.7.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

14.7.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 14.62. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>
If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

IMPORTANT

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

14.7.5. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

14.7.5.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.

NOTE

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.
The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

**IMPORTANT**

All virtual machines must reside in the same datastore and in the same folder as the installer.

14.7.5.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

14.7.5.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

14.7.5.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

14.7.5.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using
kubelet credentials because it cannot confirm that the correct machine issued the request. You must
determine and implement a method of verifying the validity of the kubelet serving certificate requests
and approving them.

14.7.6. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure,
you must create the underlying infrastructure.

Prerequisites

- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the
  supporting infrastructure for your cluster.

Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

14.7.6.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot
to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection
to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API
servers and worker nodes are in different zones, you can configure a default DNS search zone to allow
the API server to resolve the node names. Another supported approach is to always refer to hosts by
their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to
communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

<table>
<thead>
<tr>
<th>Protocol</th>

Kubernetes node port

All machines to control plane

Kubernetes API

Control plane machines to control plane machines

etcd server and peer ports

Network topology requirements

The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 14.67. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer** Provide an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

**Table 14.68. Application Ingress load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**
If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**
A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**Ethernet adaptor hardware address requirements**
When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:

- 00:05:69:00:00:00 to 00:05:69:FF:FF
- 00:0c:29:00:00:00 to 00:0c:29:FF:FF
- 00:1c:14:00:00:00 to 00:1c:14:FF:FF
- 00:50:56:00:00:00 to 00:50:56:FF:FF

If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

**NTP configuration**
OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

**Additional resources**
- [Configuring chrony time service](#)

**14.7.6.2. User-provisioned DNS requirements**
DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-
provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

Table 14.69. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.
The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

Example 14.13. Sample DNS zone database

```dns
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.

ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5
*.apps.ocp4 IN A 192.168.1.5
bootstrap.ocp4 IN A 192.168.1.96
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
master2.ocp4 IN A 192.168.1.99
worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.17

; EOF
```

The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 14.14. Sample DNS zone database for reverse records

```dns
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks)
```
14.7.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user's `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' \
   -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```text
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   ```text
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   **1** Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

14.7.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

- Obtain the imageContentSources section from the output of the command to mirror the repository.

- Obtain the contents of the certificate for your mirror registry.
Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

**IMPORTANT**

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

**NOTE**

You must name this configuration file `install-config.yaml`.

- Unless you use a registry that RHCOS trusts by default, such as `docker.io`, you must provide the contents of the certificate for your mirror repository in the `additionalTrustBundle` section. In most cases, you must provide the certificate for your mirror.

- You must include the `imageContentSources` section from the output of the command to mirror the repository.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

14.7.8.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.
The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

The password associated with the vSphere user.

The vSphere datacenter.

The default vSphere datastore to use.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, /<datacenter_name>/vm/<folder_name>/<subfolder_name>. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this parameter.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

For <local_registry>, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example registry.example.com or registry.example.com:5000. For <credentials>, specify the base64-encoded user name and password for your mirror registry.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the imageContentSources section from the output of the command to mirror the repository.

14.7.8.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.
Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
     ...
   ...
   
   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for your machines.
   4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

Only the Proxy object named cluster is supported, and no additional proxies can be created.

14.7.9. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the install-config.yaml installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```
1. For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-* .yaml
   openshift/99_openshift-cluster-api_worker-machineset-* .yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.

   - You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

   **WARNING**
   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

   **IMPORTANT**
   When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory> 1
   ```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:
14.7.10. Configuring chrony time service

You must set the time server and related settings used by the chrony time service (chronyd) by modifying the contents of the `chrony.conf` file and passing those contents to your nodes as a machine config.

Procedure

1. Create the contents of the `chrony.conf` file and encode it as base64. For example:

   ```
   $ cat << EOF | base64
   pool 0.rhel.pool.ntp.org iburst
   driftfile /var/lib/chrony/drift
   makestep 1.0 3
   rtt-sync
   logdir /var/log/chrony
   EOF
   
   Specify any valid, reachable time source, such as the one provided by your DHCP server.
   ```

2. Create the `MachineConfig` object file, replacing the base64 string with the one you just created. This example adds the file to `master` nodes. You can change it to `worker` or make an additional `MachineConfig` for the `worker` role. Create `MachineConfig` files for each type of machine that your cluster uses:

   ```
   $ cat << EOF > ./99-masters-chrony-configuration.yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     labels:
     - machineconfiguration.openshift.io/role: master
   name: 99-masters-chrony-configuration
   spec:
     config:
       ignition:
         config: {}
       security:
         tls: {}
   EOF
   ```
Specify an octal value mode for the `mode` field in the machine config file. After creating the file and applying the changes, the `mode` is converted to a decimal value. You can check the YAML file with the command `oc get mc <mc-name> -o yaml`.

3. Make a backup copy of the configuration files.

4. Apply the configurations in one of two ways:
   - If the cluster is not up yet, after you generate manifest files, add this file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.
   - If the cluster is already running, apply the file:

     ```bash
     $ oc apply -f ./99-masters-chrony-configuration.yaml
     ```

14.7.11. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  ```bash
  $ jq -r .infraID <installation_directory>/metadata.json
  ```
1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

14.7.12. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

Before you install a cluster that contains user-provisioned infrastructure on VMware vSphere, you must create RHCOS machines on vSphere hosts for it to use.

Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

Procedure

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

```json
{
   "ignition": {
      "config": {
         "merge": [
            {
               "source": "<bootstrap_ignition_config_url>",
               "verification": {}
            }
         ],
         "timeouts": {},
         "version": "3.2.0"
      },
      "networkd": {},
      "passwd": {},
      "storage": {},
      "systemd": {}
   }
}
```

Specify the URL of the bootstrap Ignition config file that you hosted.
When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the **VMs and Templates** view.
   b. Right-click the name of your datacenter.
   c. Click **New Folder** → **New VM and Template Folder**
   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.
7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

**NOTE**

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

- a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.
- b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.
- c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.
- d. On the Select a compute resource tab, click the name of your vSphere cluster.
- e. On the Select storage tab, configure the storage options for your VM.
  - Select Thin Provision or Thick Provision, based on your storage preferences.
  - Select the datastore that you specified in your install-config.yaml file.
- f. On the Select network tab, specify the network that you configured for the cluster, if available.
- g. When creating the OVF template, do not specify values on the Customize template tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. After the template deploys, deploy a VM for a machine in the cluster.

- a. Right-click the template name and click Clone → Clone to Virtual Machine
- b. On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as control-plane-0 or compute-1.
- c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.
- d. On the Select a compute resource tab, select the name of a host in your datacenter.
- e. Optional: On the Select storage tab, customize the storage options.
- f. On the Select clone options, select Customize this virtual machine’s hardware.
- g. On the Customize hardware tab, click VM Options → Advanced.
Optional: Override default DHCP networking in vSphere. To enable static IP networking:

i. Set your static IP configuration:

```
$ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
```

Example command

```
$ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
nameserver=8.8.8.8"
```

ii. Set the guestinfo.afterburn.initrd.network-kargs property before booting a VM from an OVA in vSphere:

```
$ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
```

Optional: In the event of cluster performance issues, from the Latency Sensitivity list, select High. Ensure that your VM's CPU and memory reservation have the following values:

- Memory reservation value must be equal to its configured memory size.
- CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:

- guestinfo.ignition.config.data: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
- guestinfo.ignition.config.data.encoding: Specify base64.
- disk.EnableUUID: Specify TRUE.

h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

9. Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.
14.7.13. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

You can create more compute machines for your cluster that uses user-provisioned infrastructure on VMware vSphere.

Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

Procedure

1. After the template deploys, deploy a VM for a machine in the cluster.
   a. Right-click the template’s name and click Clone → Clone to Virtual Machine
   b. On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as compute-1.
   c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.
   d. On the Select a compute resource tab, select the name of a host in your datacenter.
   e. Optional: On the Select storage tab, customize the storage options.
   f. On the Select clone options, select Customize this virtual machine’s hardware.
   g. On the Customize hardware tab, click VM Options → Advanced.
      - From the Latency Sensitivity list, select High.
      - Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:
         - guestinfo.ignition.config.data: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
         - guestinfo.ignition.config.data.encoding: Specify base64.
         - disk.EnableUUID: Specify TRUE.
   h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under Add network adapter if there are multiple networks available.
   i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- **Create separate partitions**: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, a separate partition, but not both.

<table>
<thead>
<tr>
<th>IMPORTANT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.</td>
</tr>
</tbody>
</table>

- **Retain existing partitions**: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

Creating a separate `/var` partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.

- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:
Create a **MachineConfig** object and add it to a file in the openshift directory. For example, name the file **98-var-partition.yaml**, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
        - device: /dev/<device_name> 1
        partitions:
          - label: var
            startMiB: <partition_start_offset> 2
            sizeMiB: <partition_size> 3
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
  systemd:
    units:
      - name: var.mount 4
        enabled: true
        contents:
          [Unit]
          Before=local-fs.target
          [Mount]
          What=/dev/disk/by-partlabel/var
          Where=/var
          Options=defaults,prjquota 5
          [Install]
          WantedBy=local-fs.target
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future
reinstalls of RHCOS might overwrite the beginning of the data partition.

3. The size of the data partition in mebibytes.

4. The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-lib-containers.mount`.

5. The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 14.7.15. Updating the bootloader using `bootupd`

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

**Manual install method**

You can manually install `bootupd` by using the `bootctl` command-line tool.

1. Inspect the system status:

```bash
# bootupctl status
```

**Example output**
Component EFI
Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
Update: At latest version

2. RHCOS images created without bootupd installed on them require an explicit adoption phase. If the system status is Adoptable, perform the adoption:

    # bootupctl adopt-and-update

**Example output**

    Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:

    # bootupctl update

**Example output**

    Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

**Machine config method**

Another way to enable bootupd is by providing a machine config.

- Provide a machine config file with the enabled systemd unit, as shown in the following example:

**Example output**

```
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes

        [Install]
        WantedBy=multi-user.target
```

**14.7.16. Creating the cluster**

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.
Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.

Procedure

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \
   --log-level=info
```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.20.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.

14.7.17. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:
1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

### 14.7.18. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

   Example output
3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the `machine-approver` if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name> 1
  
  1  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name> 1
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

   ```
   $ oc get nodes
   ```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

14.7.19. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.
Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>

2. Configure the Operators that are not available.

### 14.7.19.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.
Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

### 14.7.19.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

#### 14.7.19.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have "100Gi" capacity.
**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   ```
14.7.19.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  {"storage":{"emptyDir":{}}}}'
  ```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

14.7.19.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

  ```
  $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
  {"rolloutStrategy":"Recreate","replicas":1}}'
  ```
2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage  
     namespace: openshift-image-registry
   spec:
     accessModes:
       - ReadWriteOnce 
     resources:
       requests:
         storage: 100Gi
   
   1. A unique name that represents the **PersistentVolumeClaim** object.
   2. The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
   3. The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
   4. The size of the persistent volume claim.

   b. Create the **PersistentVolumeClaim** object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   
   Example output
   
   ```yaml
   storage:
     pvc:
       claim: 1
   
   1. Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

   3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   
   Example output
   
   ```yaml
   storage:
     pvc:
       claim: 1
   
   1. Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

   For instructions about configuring registry storage so that it references the correct PVC, see *Configuring the registry for vSphere*.

### 14.7.20. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.
Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

<table>

</tr>
<tr>
<td>storage</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h30m</td>
</tr>
</tbody>
</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td>Running 1</td>
<td></td>
<td>9m</td>
<td></td>

</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td>Running 0</td>
<td></td>
<td>5m</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace>
   ```

1 Specify the pod name and namespace, as shown in the output of the previous command.
If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.

   a. All the worker nodes are restarted. To monitor the process, enter the following command:

   ```sh
   $ oc get nodes -w
   ```

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

4. Register your cluster on the Cluster registration page.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

### 14.7.21. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 14.7.22. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**
14.7.23. Next steps

- Customize your cluster.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

14.8. UNINSTALLING A CLUSTER ON VSPHERE THAT USES INSTALLER-PROVISIONED INFRASTRUCTURE

You can remove a cluster that you deployed in your VMware vSphere instance by using installer-provisioned infrastructure.

**NOTE**

When you run the `openshift-install destroy cluster` command to uninstall OpenShift Container Platform, vSphere volumes are not automatically deleted. The cluster administrator must manually find the vSphere volumes and delete them.

14.8.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

**Prerequisites**

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

**Procedure**

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```bash
   $ ./openshift-install destroy cluster
   --dir <installation_directory> --log-level info
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
To view different details, specify `warn`, `debug`, or `error` instead of `info`.

NOTE

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

14.9. USING THE VSPHERE PROBLEM DETECTOR OPERATOR

14.9.1. About the vSphere Problem Detector Operator

The vSphere Problem Detector Operator checks clusters that are deployed on vSphere for common installation and misconfiguration issues that are related to storage.

The Operator runs in the `openshift-cluster-storage-operator` namespace and is started by the Cluster Storage Operator when the Cluster Storage Operator detects that the cluster is deployed on vSphere. The vSphere Problem Detector Operator communicates with the vSphere vCenter Server to determine the virtual machines in the cluster, the default datastore, and other information about the vSphere vCenter Server configuration. The Operator uses the credentials from the Cloud Credential Operator to connect to vSphere.

The Operator runs the checks according to the following schedule:

- The checks run every 8 hours.
- If any check fails, the Operator runs the checks again in intervals of 1 minute, 2 minutes, 4, 8, and so on. The Operator doubles the interval up to a maximum interval of 8 hours.
- When all checks pass, the schedule returns to an 8 hour interval.

The Operator increases the frequency of the checks after a failure so that the Operator can report success quickly after the failure condition is remedied. You can run the Operator manually for immediate troubleshooting information.

14.9.2. Running the vSphere Problem Detector Operator checks

You can override the schedule for running the vSphere Problem Detector Operator checks and run the checks immediately.

The vSphere Problem Detector Operator automatically runs the checks every 8 hours. However, when the Operator starts, it runs the checks immediately. The Operator is started by the Cluster Storage Operator when the Cluster Storage Operator starts and determines that the cluster is running on vSphere. To run the checks immediately, you can scale the vSphere Problem Detector Operator to 0 and back to 1 so that it restarts the vSphere Problem Detector Operator.

**Prerequisites**

- Access to the cluster as a user with the `cluster-admin` role.
Procedure

1. Scale the Operator to 0:

   $ oc scale deployment/vsphere-problem-detector-operator --replicas=0 \
   -n openshift-cluster-storage-operator

   If the deployment does not scale to zero immediately, you can run the following command to wait for the pods to exit:

   $ oc wait pods -l name=vsphere-problem-detector-operator \
   --for=delete --timeout=5m -n openshift-cluster-storage-operator

2. Scale the Operator back to 1:

   $ oc scale deployment/vsphere-problem-detector-operator --replicas=1 \
   -n openshift-cluster-storage-operator

3. Delete the old leader lock to speed up the new leader election for the Cluster Storage Operator:

   $ oc delete -n openshift-cluster-storage-operator \
   cm vsphere-problem-detector-lock

Verification

- View the events or logs that are generated by the vSphere Problem Detector Operator. Confirm that the events or logs have recent timestamps.

14.9.3. Viewing the events from the vSphere Problem Detector Operator

After the vSphere Problem Detector Operator runs and performs the configuration checks, it creates events that can be viewed from the command line or from the OpenShift Container Platform web console.

Procedure

- To view the events by using the command line, run the following command:

  $ oc get event -n openshift-cluster-storage-operator \
  --sort-by={.metadata.creationTimestamp}

Example output

16m Normal Started pod/vsphere-problem-detector-operator-xxxxx Started container vsphere-problem-detector
16m Normal Created pod/vsphere-problem-detector-operator-xxxxx Created container vsphere-problem-detector
16m Normal LeaderElection configmap/vsphere-problem-detector-lock vsphere-problem-detector-operator-xxxxx became leader

- To view the events by using the OpenShift Container Platform web console, navigate to Home → Events and select openshift-cluster-storage-operator from the Project menu.
14.9.4. Viewing the logs from the vSphere Problem Detector Operator

After the vSphere Problem Detector Operator runs and performs the configuration checks, it creates log records that can be viewed from the command line or from the OpenShift Container Platform web console.

**Procedure**

- To view the logs by using the command line, run the following command:

  ```
  $ oc logs deployment/vsphere-problem-detector-operator
  -n openshift-cluster-storage-operator
  ```

**Example output**

```
I0108 08:32:28.445696       1 operator.go:209] ClusterInfo passed
I0108 08:32:28.451029       1 datastore.go:57] CheckStorageClasses checked 1 storage classes, 0 problems found
I0108 08:32:28.451047       1 operator.go:209] CheckStorageClasses passed
I0108 08:32:28.480648       1 operator.go:271] CheckNodeDiskUUID:<host_name> passed
I0108 08:32:28.480685       1 operator.go:271] CheckNodeProviderID:<host_name> passed
```

- To view the Operator logs with the OpenShift Container Platform web console, perform the following steps:

  a. Navigate to **Workloads → Pods**.

  b. Select **openshift-cluster-storage-operator** from the **Projects** menu.

  c. Click the link for the **vsphere-problem-detector-operator** pod.

  d. Click the **Logs** tab on the **Pod details** page to view the logs.

14.9.5. Configuration checks run by the vSphere Problem Detector Operator

The following tables identify the configuration checks that the vSphere Problem Detector Operator runs. Some checks verify the configuration of the cluster. Other checks verify the configuration of each node in the cluster.

**Table 14.70. Cluster configuration checks**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[List of tables]</td>
<td>[List of descriptions]</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| CheckDefaultDatastore   | Verifies that the default datastore name in the vSphere configuration is short enough for use with dynamic provisioning.  
If this check fails, you can expect the following:  
- **systemd** logs errors to the journal such as **Failed to set up mount unit: Invalid argument**.  
- **systemd** does not unmount volumes if the virtual machine is shut down or rebooted without draining all the pods from the node.  
If this check fails, reconfigure vSphere with a shorter name for the default datastore. |
| CheckFolderPermissions  | Verifies the permission to list volumes in the default datastore. This permission is required to create volumes. The Operator verifies the permission by listing the / and /kubevols directories. The root directory must exist. It is acceptable if the /kubevols directory does not exist when the check runs. The /kubevols directory is created when the datastore is used with dynamic provisioning if the directory does not already exist.  
If this check fails, review the required permissions for the vCenter account that was specified during the OpenShift Container Platform installation. |
| CheckStorageClasses     | Verifies the following:  
- The fully qualified path to each persistent volume that is provisioned by this storage class is less than 255 characters.  
- If a storage class uses a storage policy, the storage class must use one policy only and that policy must be defined.  
| CheckTaskPermissions     | Verifies the permission to list recent tasks and datastores.                                                                                                                                                                                                                                                                                                                                                                    |
| ClusterInfo             | Collects the cluster version and UUID from vSphere vCenter.                                                                                                                                                                                                                                                                                                                                                                       |

**Table 14.71. Node configuration checks**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| CheckNodeDiskUUID  | Verifies that all the vSphere virtual machines are configured with **disk.enableUUID=TRUE**.  
If this check fails, see the How to check 'disk.EnableUUID' parameter from VM in vSphere Red Hat Knowledgebase solution.                                                                                     |
### Name | Description
---|---
**CheckNodeProviderID** | Verifies that all nodes are configured with the **ProviderID** from vSphere vCenter. This check fails when the output from the following command does not include a provider ID for each node.

```
$ oc get nodes -o custom-columns=NAME:.metadata.name,PROVIDER_ID:.spec.providerID,UUID:.status.nodeInfo.systemUUID
```

If this check fails, refer to the vSphere product documentation for information about setting the provider ID for each node in the cluster.

**CollectNodeESXiVersion** | Reports the version of the ESXi hosts that run nodes.

**CollectNodeHWVersion** | Reports the virtual machine hardware version for a node.

### 14.9.6. About the storage class configuration check

The names for persistent volumes that use vSphere storage are related to the datastore name and cluster ID.

When a persistent volume is created, **systemd** creates a mount unit for the persistent volume. The **systemd** process has a 255 character limit for the length of the fully qualified path to the VDMK file that is used for the persistent volume.

The fully qualified path is based on the naming conventions for **systemd** and vSphere. The naming conventions use the following pattern:

```
/var/lib/kubelet/plugins/kubernetes.io/vsphere-volume-mounts/[/<datastore>] 00000000-0000-0000-0000-000000000000/<cluster_id>-dynamic-pvc-00000000-0000-0000-0000-000000000000.vmdk
```

- The naming conventions require 205 characters of the 255 character limit.
- The datastore name and the cluster ID are determined from the deployment.
- The datastore name and cluster ID are substituted into the preceding pattern. Then the path is processed with the **systemd-escape** command to escape special characters. For example, a hyphen character uses four characters after it is escaped. The escaped value is `\x2d`.
- After processing with **systemd-escape** to ensure that **systemd** can access the fully qualified path to the VDMK file, the length of the path must be less than 255 characters.

### 14.9.7. Metrics for the vSphere Problem Detector Operator

The vSphere Problem Detector Operator exposes the following metrics for use by the OpenShift Container Platform monitoring stack.
### Table 14.72. Metrics exposed by the vSphere Problem Detector Operator

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vsphere_cluster_check_total</td>
<td>Cumulative number of cluster-level checks that the vSphere Problem Detector Operator performed. This count includes both successes and failures.</td>
</tr>
<tr>
<td>vsphere_cluster_check_errors</td>
<td>Number of failed cluster-level checks that the vSphere Problem Detector Operator performed. For example, a value of 1 indicates that one cluster-level check failed.</td>
</tr>
<tr>
<td>vsphere_esxi_version_total</td>
<td>Number of ESXi hosts with a specific version. Be aware that if a host runs more than one node, the host is counted only once.</td>
</tr>
<tr>
<td>vsphere_node_check_total</td>
<td>Cumulative number of node-level checks that the vSphere Problem Detector Operator performed. This count includes both successes and failures.</td>
</tr>
<tr>
<td>vsphere_node_check_errors</td>
<td>Number of failed node-level checks that the vSphere Problem Detector Operator performed. For example, a value of 1 indicates that one node-level check failed.</td>
</tr>
<tr>
<td>vsphere_node_hw_version_total</td>
<td>Number of vSphere nodes with a specific hardware version.</td>
</tr>
<tr>
<td>vsphere_vcenter_info</td>
<td>Information about the vSphere vCenter Server.</td>
</tr>
</tbody>
</table>

### 14.9.8. Additional resources

- Monitoring overview
CHAPTER 15. INSTALLING ON VMC

15.1. INSTALLING A CLUSTER ON VMC

In OpenShift Container Platform version 4.7, you can install a cluster on VMware vSphere by deploying it to VMware Cloud (VMC) on AWS.

Once you have configured your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

15.1.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Allocate two IP addresses, outside the DHCP range, and configure them with reverse DNS records.
  - A DNS record for `api.<cluster_name>.<base_domain>` pointing to the allocated IP address.
  - A DNS record for `*.apps.<cluster_name>.<base_domain>` pointing to the allocated IP address.

- Configure the following firewall rules:
- An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the Internet. This is used by nodes and applications to download container images.

- An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.

- An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  
  - The OpenShift Container Platform cluster name, such as vmc-prod-1.
  
  - The base DNS name, such as companyname.com.

  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to 10.128.0.0/14 and 172.30.0.0/16, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.

  - The following vCenter information:
    - vCenter hostname, username, and password
    - Datacenter name, such as SDDC-Datacenter
    - Cluster name, such as Cluster-1
    - Network name
    - Datastore name, such as WorkloadDatastore

  
  **NOTE**
  
  It is recommended to move your vSphere cluster to the VMC **Compute-ResourcePool** resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.

  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have Internet connectivity and the ability to upload an OVA to the ESXi hosts.

  - Download and install the OpenShift CLI tools to the bastion host.
    - The `openshift-install` installation program
    - The OpenShift CLI (`oc`) tool
NOTE

You cannot use the VMware NSX Container Plugin for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

15.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

15.1.2. vSphere prerequisites

- Provision block registry storage. For more information on persistent storage, see Understanding persistent storage.

- Review details about the OpenShift Container Platform installation and update processes.

- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

  NOTE

  Be sure to also review this site list if you are configuring a proxy.

15.1.3. Internet access for OpenShift Container Platform
In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access **Quay.io** to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

15.1.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 15.1. Minimum supported vSphere version for VMware components**

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See **Edit Time Configuration for a Host** in the VMware documentation.
IMPORTANT

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

15.1.5. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

Table 15.2. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>

15.1.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 15.1. Roles and privileges required for installation**

<table>
<thead>
<tr>
<th>vSphere object for role</th>

</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 15.2. Required permissions and propagation settings

<table>
<thead>
<tr>
<th>vSphere object for role</th>

</tbody>
</table>

For more information about creating an account with only the required privileges, see **vSphere Permissions and User Management Tasks** in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

If you intend on using vMotion in your vSphere environment, consider the following before installing a OpenShift Container Platform cluster.

- **OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.**

  To help ensure the uptime of your compute and control plane nodes, it is recommended that you follow the VMware best practices for vMotion. It is also recommended to use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for **vMotion networking requirements** and **VM anti-affinity rules**.

- **If you are using vSphere volumes in your pods, migrating a VM across datastores either manually**
or through Storage vMotion causes, invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.

- Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:
- The API address is used to access the cluster API.
- The Ingress address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

15.1.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" \
   -f <path>/<file_name>  # Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
   ```

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/<file_name>  # Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (computer_name)

   Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.1.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.1.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.
Procedure

1. From the vCenter home page, download the vCenter's root CA certificates. Click **Download trusted root CA certificates** in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   ├── lin
   │   ├── 108f4d17.0
   │   ├── 108f4d17.r1
   │   ├── 7e757f6a.0
   │   └── 8e4f8471.0
   │       └── 8e4f8471.r0
   ├── mac
   │   ├── 108f4d17.0
   │   ├── 108f4d17.r1
   │   ├── 7e757f6a.0
   │   └── 8e4f8471.0
   │       └── 8e4f8471.r0
   └── win
      ├── 108f4d17.0.crt
      ├── 108f4d17.r1.crl
      ├── 7e757f6a.0.crt
      └── 8e4f8471.0.crt
          └── 8e4f8471.r0.crl
   ```

   3 directories, 15 files

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

15.1.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

Provide values at the prompts:

a. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

b. Select `vsphere` as the platform to target.

c. Specify the name of your vCenter instance.

d. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.
   The installation program connects to your vCenter instance.

e. Select the datacenter in your vCenter instance to connect to.

f. Select the default vCenter datastore to use.

   **NOTE**

   Datastore and cluster names cannot exceed 60 characters; therefore, ensure the combined string length does not exceed the 60 character limit.
g. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

h. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

i. Enter the virtual IP address that you configured for control plane API access.

j. Enter the virtual IP address that you configured for cluster ingress.

k. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

l. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

**NOTE**

Datastore and cluster names cannot exceed 60 characters; therefore, ensure the combined string length does not exceed the 60 character limit.

m. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

**IMPORTANT**

Use the `openshift-install` command from the bastion hosted in the VMC environment.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.
15.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

15.11.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.
4. Unpack the archive:
   ```bash
   $ tar xvzf <file>
   ```
5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:
   ```bash
   $ echo $PATH
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 15.1.11.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your **PATH**.

   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 15.1.11.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your **PATH**.

   To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
15.1.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ``

   Example output

   ```
   system:admin
   ```

15.1.13. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

15.1.13.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as `Removed`. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from `Removed` to `Managed`.

**NOTE**

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

"Image Registry has been removed. `ImageStreamTags`, `BuildConfigs` and `DeploymentConfigs` which reference `ImageStreamTags` may not work as expected. Please configure storage and update the config to `Managed` state by editing configs.imageregistry.operator.openshift.io."

CHAPTER 15. INSTALLING ON VMC
15.1.13.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

15.1.13.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

**NOTE**

When using shared storage, review your security settings to prevent outside access.
2. Verify that you do not have a registry pod:

```bash
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

**Example output**

No resources found in openshift-image-registry namespace

**NOTE**

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```bash
$ oc edit configs.imageregistry.operator.openshift.io
```

**Example output**

```
storage:
pvc:
  claim: 1
```

1. Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

```bash
$ oc get clusteroperator image-registry
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

**15.1.13.2.2. Configuring block registry storage for VMware vSphere**

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.
1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only **1** replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy": "Recreate","replicas":1}}'
   
   2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   
   1. A unique name that represents the **PersistentVolumeClaim** object.
   2. The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
   3. The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
   4. The size of the persistent volume claim.

   b. Create the **PersistentVolumeClaim** object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   
   3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   
   **Example output**

   ```yaml
   storage:
   pvc:
     claim: 1
   
   1. Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

2194
For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

15.1.14. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

15.1.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

15.1.16. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

15.2. INSTALLING A CLUSTER ON VMC WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.7, you can install a cluster on your VMware vSphere instance using installer-provisioned infrastructure by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in
the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

To customize the OpenShift Container Platform installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

**NOTE**
OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

### 15.2.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Allocate two IP addresses, outside the DHCP range, and configure them with reverse DNS records.
  - A DNS record for `api.<cluster_name>.<base_domain>` pointing to the allocated IP address.
  - A DNS record for `*.apps.<cluster_name>.<base_domain>` pointing to the allocated IP address.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the Internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with
You must have the following information to deploy OpenShift Container Platform:

- The OpenShift Container Platform cluster name, such as vmc-prod-1.
- The base DNS name, such as companyname.com.
- If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to 10.128.0.0/14 and 172.30.0.0/16, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
- The following vCenter information:
  - vCenter hostname, username, and password
  - Datacenter name, such as SDDC-Datacenter
  - Cluster name, such as Cluster-1
  - Network name
  - Datastore name, such as WorkloadDatastore

**NOTE**
It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have Internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The openshift-install installation program
    - The OpenShift CLI (oc) tool

**NOTE**
You cannot use the VMware NSX Container Plugin for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

**15.2.1.1. VMC Sizer tool**
VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

### 15.2.2. vSphere prerequisites

- Provision block registry storage. For more information on persistent storage, see Understanding persistent storage.
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 15.2.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 15.2.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

#### Table 15.6. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**IMPORTANT**

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

### 15.2.5. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.
### Table 15.7. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>N/A</td>

<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

### 15.2.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

### Example 15.3. Roles and privileges required for installation

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere Port Group</td>
<td>Always</td>
<td>Network.Assign</td>
</tr>
<tr>
<td>vSphere object for role</td>
<td>When required</td>
<td>Required privileges</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Add ExistingDisk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Add NewDisk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Add RemoveDevice</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.AdvancedConfig</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Annotation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.CPU Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Disk Extend</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Disk Lease</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config&gt;Edit Device</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Memory</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.RemoveDisk</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Rename</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.RestGuestInfo</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Resource</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.Setting</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.UpgradeVirtualHardware</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Interact.GuestControl</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Interact.PowerOff</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Interact.PowerOn</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Interact.Reset</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Inventory.Create</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Inventory.CreateFromExisting</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Inventory.Delete</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Provisioning.Clone</td>
</tr>
<tr>
<td>vSphere object for role</td>
<td>When required</td>
<td>Required privileges</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>----------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

**Example 15.4. Required permissions and propagation settings**

<table>
<thead>
<tr>
<th>vSphere object</th>
<th>Folder type</th>
<th>Propagate to children</th>
<th>Permissions required</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere vCenter</td>
<td>Always</td>
<td>False</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>vSphere vCenter</td>
<td>Existing folder</td>
<td>False</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>Datacenter</td>
<td>Installation program</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td></td>
<td>creates the folder</td>
<td></td>
<td></td>
</tr>
<tr>
<td>vSphere vCenter</td>
<td>Always</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>Cluster</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>vSphere vCenter</td>

<tr>
<td>vSphere Switch</td>
<td>Always</td>
<td>False</td>
<td><strong>ReadOnly</strong> permission</td>
</tr>
<tr>
<td>vSphere Port Group</td>
<td>Always</td>
<td>False</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>vSphere vCenter</td>
<td>Existing folder</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>Virtual Machine Folder</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see vSphere Permissions and User Management Tasks in the vSphere documentation.

**Using OpenShift Container Platform with vMotion**

If you intend on using vMotion in your vSphere environment, consider the following before installing a OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.
  
  To help ensure the uptime of your compute and control plane nodes, it is recommended that you follow the VMware best practices for vMotion. It is also recommended to use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for vMotion networking requirements and VM anti-affinity rules.
• If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes, invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.

• Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

• 1 Folder
• 1 Tag category
• 1 Tag
• Virtual machines:
• 1 template
• 1 temporary bootstrap node
• 3 control plane nodes
• 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

NOTE
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

### DNS records

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**15.2.7. Generating an SSH private key and adding it to the agent**

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ``

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/<file_name>  
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps
• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.2.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

• You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.2.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.
Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The \(<vCenter>/certs/download.zip\) file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   ├── lin
   │   ├── 108f4d17.0
   │   ├── 108f4d17.r1
   │   ├── 7e757f6a.0
   │   └── 8e4f8471.0
   │       └── 8e4f8471.r0
   ├── mac
   │   ├── 108f4d17.0
   │   ├── 108f4d17.r1
   │   ├── 7e757f6a.0
   │   └── 8e4f8471.0
   │       └── 8e4f8471.r0
   └── win
       ├── 108f4d17.0.crt
       ├── 108f4d17.r1.crt
       ├── 7e757f6a.0.crt
       └── 8e4f8471.0.crt
           └── 8e4f8471.r0.crt
   3 directories, 15 files
   ```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

15.2.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

Procedure
1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory>
```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `vsphere` as the platform to target.

   iii. Specify the name of your vCenter instance.

   iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

   The installation program connects to your vCenter instance.

   v. Select the datacenter in your vCenter instance to connect to.

   vi. Select the default vCenter datastore to use.

   vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

   viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

   ix. Enter the virtual IP address that you configured for control plane API access.

   x. Enter the virtual IP address that you configured for cluster ingress.
xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**
   
The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 15.2.10.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 15.2.10.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 15.11. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code></td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters and hyphens (-), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{</td>
</tr>
<tr>

<td></td>
<td>&quot;auths&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;cloud.openshift.com&quot;:{</td>
</tr>
</tbody>
</table>
|               |                                                                                                                                             |         "auth":"b3Blb=",
|               |                                                                                                                                             |         "email":"you@example.com"                                   |
|               |                                                                                                                                             |     },                                                            |
|               |                                                                                                                                             |     "quay.io":{                                                      |
|               |                                                                                                                                             |         "auth":"b3Blb=",
|               |                                                                                                                                             |         "email":"you@example.com"                                   |
|               |                                                                                                                                             |   }                                                               |
|               |                                                                                                                                             | }                                                                    |
15.2.10.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 15.12. Network parameters

<table>

<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute.hyperthreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><strong>compute.name</strong></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><code>worker</code></td>
</tr>
<tr>
<td><strong>compute.platform</strong></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td><strong>compute.replicas</strong></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><strong>controlPlane</strong></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. The default value is External. Setting this field to Internal is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</td>
</tr>
</tbody>
</table>

### IMPORTANT
If the value of the field is set to Internal, the cluster will become non-functional. For more information, refer to BZ#1953035.

#### 15.2.10.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Table 15.14. Additional VMware vSphere cluster parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>platform.vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
</tr>
<tr>
<td><code>platform.vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
</tr>
<tr>
<td><code>platform.vsphere.password</code></td>
<td>The password for the vCenter user name.</td>
</tr>
<tr>
<td><code>platform.vsphere.datacenter</code></td>
<td>The name of the datacenter to use in the vCenter instance.</td>
</tr>
<tr>
<td><code>platform.vsphere.defaultDatastore</code></td>
<td>The name of the default datastore to use for provisioning volumes.</td>
</tr>
<tr>
<td><code>platform.vsphere.folder</code></td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
</tr>
<tr>
<td><code>platform.vsphere.network</code></td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
</tr>
<tr>
<td><code>platform.vsphere.cluster</code></td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
</tr>
<tr>
<td><code>platform.vsphere.apiVIP</code></td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
</tr>
<tr>
<td><code>platform.vsphere.ingressVIP</code></td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
</tr>
</tbody>
</table>

15.2.10.15. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 15.15. Optional VMware vSphere machine pool parameters
### Parameter | Description | Values
--- | --- | ---
`platform.vsphere.clusterOSImage` | The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network. | An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, https://mirror.openshift.com/images/rhcos-<version>-vmware.<architecture>.ova.

`platform.vsphere.osDisk.diskSizeGB` | The size of the disk in gigabytes. | Integer

`platform.vsphere.cpus` | The total number of virtual processor cores to assign a virtual machine. | Integer

`platform.vsphere.coresPerSocket` | The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is `platform.vsphere.cpus / platform.vsphere.coresPerSocket`. The default value is 1 | Integer

`platform.vsphere.memoryMB` | The size of a virtual machine’s memory in megabytes. | Integer

### 15.2.10.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 2
  - hyperthreading: Enabled
    name: worker
    replicas: 3
    platform:
      vsphere: 4
      cpus: 2
      coresPerSocket: 2
      memoryMB: 8192
      osDisk:
        diskSizeGB: 120
    controlPlane: 5
    hyperthreading: Enabled
    name: master
    replicas: 3
    platform:
      vsphere: 7
      cpus: 4
```
coresPerSocket: 2
memoryMB: 16384
osDisk:
diskSizeGB: 120
metadata:
name: cluster
platform:
vsphere:
vcenter: your.vcenter.server
username: username
password: password
datacenter: datacenter
defaultDatastore: datastore
folder: folder
network: VM_Network
cluster: vsphere_cluster_name
apiVIP: api_vip
ingressVIP: ingress_vip
fips: false
pullSecret: '{"auths": ...}'
sshKey: 'ssh-ed25519 AAAA...

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, -, and the first line of the `controlPlane` section must not. Only one control plane pool is used.

3. Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

   **IMPORTANT**

   If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

4. Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

5. The cluster name that you specified in your DNS records.

6. The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

### 15.2.10.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.
Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (`169.254.169.254`).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
     httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
     noProxy: example.com ³
   additionalTrustBundle: | ⁴
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
     ...
   
   ¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   ² A proxy URL to use for creating HTTPS connections outside the cluster.
   ³ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.
   ⁴ If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
NOTE
The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

15.2.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites
- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
   ```

   1 For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   IMPORTANT
   Use the `openshift-install` command from the bastion hosted in the VMC environment.
NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### 15.2.12. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

15.2.12.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

15.2.12.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.

   To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:
15.2.12.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.7 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your PATH. To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

15.2.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```
15.2.14. Creating registry storage

After you install the cluster, you must create storage for the Registry Operator.

15.2.14.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

15.2.14.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

15.2.14.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.
IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim:
   ```
1. Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage PVC**.

4. Check the **clusteroperator** status:

   ```
   $ oc get clusteroperator image-registry
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

15.2.14.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1 A unique name that represents the **PersistentVolumeClaim** object.
The namespace for the PersistentVolumeClaim object, which is openshift-image-registry.

The access mode of the persistent volume claim. With ReadWriteOnce, the volume can be mounted with read and write permissions by a single node.

The size of the persistent volume claim.

b. Create the PersistentVolumeClaim object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

Example output

```
storage:
  pvc:
    claim: 
```

Creating a custom PVC allows you to leave the claim field blank for the default automatic creation of an image-registry-storage PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

15.2.15. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

15.2.16. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**
- See About remote health monitoring for more information about the Telemetry service

**15.2.17. Next steps**
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

**15.3. INSTALLING A CLUSTER ON VMC WITH NETWORK CUSTOMIZATIONS**

In OpenShift Container Platform version 4.7, you can install a cluster on your VMware vSphere instance using installer-provisioned infrastructure with customized network configuration options by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

By customizing your OpenShift Container Platform network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing VXLAN configurations. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster. You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

**15.3.1. Setting up VMC for vSphere**

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.
You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Allocate two IP addresses, outside the DHCP range, and configure them with reverse DNS records.
  - A DNS record for api.<cluster_name>.<base_domain> pointing to the allocated IP address.
  - A DNS record for *.apps.<cluster_name>.<base_domain> pointing to the allocated IP address.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the Internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as vmc-prod-1.
  - The base DNS name, such as companyname.com.
  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to 10.128.0.0/14 and 172.30.0.0/16, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
  - The following vCenter information:
    - vCenter hostname, username, and password
    - Datacenter name, such as SDDC-Datacenter
- Cluster name, such as Cluster-1
- Network name
- Datastore name, such as WorkloadDatastore

**NOTE**

It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have Internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The openshift-install installation program
    - The OpenShift CLI (oc) tool

**NOTE**

You cannot use the VMware NSX Container Plugin for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

### 15.3.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
- vRAM
- Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

15.3.2. vSphere prerequisites

- Provision block registry storage. For more information on persistent storage, see Understanding persistent storage.
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

**NOTE**
Be sure to also review this site list if you are configuring a proxy.

15.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**
If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

15.3.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

<table>
<thead>
<tr>
<th>Table 15.16. Minimum supported vSphere version for VMware components</th>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
</table>

## Component Minimum supported versions Description

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
<td></td>
</tr>
<tr>
<td>Storage with in-tree drivers vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
<td></td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.

**IMPORTANT**

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in [BZ#1935539](#).

### 15.3.5. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

**Table 15.17. Ports used for all-machine to all-machine communications**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>

<td>Host level services, including the node exporter on ports 9100-9101 and the Cluster Version Operator on port 9099.</td>
</tr>
<tr>
<td></td>
<td>10250-10259</td>
<td>The default ports that Kubernetes reserves</td>
</tr>
</tbody>
</table>
15.3.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

Required vCenter account privileges
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

</tbody>
</table>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

**Using OpenShift Container Platform with vMotion**

If you intend on using vMotion in your vSphere environment, consider the following before installing a OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.
  To help ensure the uptime of your compute and control plane nodes, it is recommended that you follow the VMware best practices for vMotion. It is also recommended to use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for [vMotion networking requirements](#) and [VM anti-affinity rules](#).
• If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes, invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.

• Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

• 1 Folder
• 1 Tag category
• 1 Tag

• Virtual machines:
  • 1 template
  • 1 temporary bootstrap node
  • 3 control plane nodes
  • 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

NOTE
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:

- The API address is used to access the cluster API.
- The Ingress address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

**Table 15.20. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**15.3.7. Generating an SSH private key and adding it to the agent**

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user's ~/.ssh/authorized_keys list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ``

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**
   
   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ``

   **Example output**

   ```bash
   Agent pid 31874
   ``

   **NOTE**
   
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/<file_name>
   ``

   **Example output**

   ```bash
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ``

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   **Next steps**
• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.3.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

• You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.3.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.
**Procedure**

1. From the vCenter home page, download the vCenter’s root CA certificates. Click **Download trusted root CA certificates** in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   ├── lin
   │   ├── 108f4d17.0
   │   ├── 108f4d17.r1
   │   ├── 7e757f6a.0
   │   └── 8e4f8471.0
   │       └── 8e4f8471.r0
   │
   │   └── mac
   │       ├── 108f4d17.0
   │       ├── 108f4d17.r1
   │       └── 7e757f6a.0
   │           └── 8e4f8471.0
   │               └── 8e4f8471.r0
   ├── win
   │   ├── 108f4d17.0.crt
   │   ├── 108f4d17.r1.crt
   │   └── 7e757f6a.0.crt
   │       └── 8e4f8471.0.crt
   │           └── 8e4f8471.r0.crt
   ├── 3 directories, 15 files
   ```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

**15.3.10. Creating the installation configuration file**

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

**Procedure**
1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `vsphere` as the platform to target.

      iii. Specify the name of your vCenter instance.

      iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

      The installation program connects to your vCenter instance.

      v. Select the datacenter in your vCenter instance to connect to.

      vi. Select the default vCenter datastore to use.

      vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

      viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

      ix. Enter the virtual IP address that you configured for control plane API access.

      x. Enter the virtual IP address that you configured for cluster ingress.
xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

**IMPORTANT**

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

15.3.10.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the install-config.yaml file.

**IMPORTANT**

The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.3.10.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 15.21. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters and hyphens (-), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td></td>
</tr>
</tbody>
</table>

```json
{
   "auths":{
      "cloud.openshift.com":{
         "auth":"b3Blb=",
         "email":"you@example.com"
      },
      "quay.io":{
         "auth":"b3Blb=",
         "email":"you@example.com"
      }
   }
}
```
### 15.3.10.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 15.22. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong> You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking.network.Type</td>
<td>The cluster network provider</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td></td>
<td>Container Network Interface (CNI) plug-in to install.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
</tbody>
</table>
### networking.serviceNetwork

The IP address block for services. The default value is `172.30.0.0/16`.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

An array with an IP address block in CIDR format. For example:

```
networking:
  serviceNetwork:
    - 172.30.0.0/16
```

### networking.machineNetwork

The IP address blocks for machines.

If you specify multiple IP address blocks, the blocks must not overlap.

If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network.

An array of objects. For example:

```
networking:
  machineNetwork:
    - cidr: 10.0.0.0/16
```

### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

An IP network block in CIDR notation. For example, `10.0.0.0/16`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 15.3.10.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 15.23. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><strong>aws</strong>, <strong>azure</strong>, <strong>gcp</strong>, <strong>openstack</strong>, <strong>ovirt</strong>, <strong>vsphere</strong>, or <code>{}</code></td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <strong>MachinePool</strong> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <em>hyperthreading</em>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td><code>master</code></td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is <code>3</code>, which is the default value.</td>
</tr>
</tbody>
</table>
### credentialsMode

The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the *Cloud Credential Operator* entry in the *Cluster Operators reference* content.

### fips

Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. The default value is <strong>External</strong>. Setting this field to <strong>Internal</strong> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example:</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <strong>ssh-agent</strong> process uses.</td>
<td></td>
</tr>
</tbody>
</table>

15.3.10.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

Table 15.24. Additional VMware vSphere cluster parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.vCenter</td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.username</td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.password</td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.datacenter</td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.defaultDatastore</td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.folder</td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>/&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;.</td>
</tr>
<tr>
<td>platform.vsphere.network</td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.cluster</td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.apiVIP</td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.ingressVIP</td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
</tbody>
</table>
### Parameter | Description | Values
--- | --- | ---
**platform.vsphere.clusterOSImage** | The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network. | An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, https://mirror.openshift.com/images/rhcos-<version>-vmware.<architecture>.ova. |
**platform.vsphere.osDisk.diskSizeGB** | The size of the disk in gigabytes. | Integer |
**platform.vsphere.cpus** | The total number of virtual processor cores to assign a virtual machine. | Integer |
**platform.vsphere.coresPerSocket** | The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is **platform.vsphere.cpus/platform.vsphere.coresPerSocket**. The default value is 1 | Integer |
**platform.vsphere.memoryMB** | The size of a virtual machine’s memory in megabytes. | Integer |

#### 15.3.10.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 2
- hyperthreading: Enabled
  name: worker
  replicas: 3
  platform:
    vsphere: 4
    cpus: 2
    coresPerSocket: 2
    memoryMB: 8192
    osDisk:
      diskSizeGB: 120
  controlPlane: 5
  hyperthreading: Enabled
  name: master
  replicas: 3
  platform:
    vsphere: 7
    cpus: 4
```

2256
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.
The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

15.3.10.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
   noProxy: example.com
   additionalTrustBundle:
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   ...
   ```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its
If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster` `Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 15.3.11. Network configuration phases

When specifying a cluster configuration prior to installation, there are several phases in the installation procedures when you can modify the network configuration:

**Phase 1**

After entering the `openshift-install create install-config` command. In the `install-config.yaml` file, you can customize the following network-related fields:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`

For more information on these fields, refer to "Installation configuration parameters".

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

**Phase 2**
After entering the `openshift-install create manifests` command. If you must specify advanced network configuration, during this phase you can define a customized Cluster Network Operator manifest with only the fields you want to modify.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

### 15.3.12. Specifying advanced network configuration

You can use advanced configuration customization to integrate your cluster into your existing network environment by specifying additional configuration for your cluster network provider. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

**Prerequisites**

- Create the `install-config.yaml` file and complete any modifications to it.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ``

   where:

   `<installation_directory>`
   
   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   EOF
   ``

   where:

   `<installation_directory>`
   
   Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and specify the advanced network configuration for your cluster, such as in the following examples:
Specify a different VXLAN port for the OpenShift SDN network provider

```yaml
apiVersion: operator.openshift.io/v1
class: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  openshiftSDNConfig:
    vxlanPort: 4800
```

Enable IPsec for the OVN-Kubernetes network provider

```yaml
apiVersion: operator.openshift.io/v1
class: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  ovnKubernetesConfig:
    ipsecConfig: {}
```

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

### 15.3.13. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**
  - IP address pools from which pod IP addresses are allocated.

- **serviceNetwork**
  - IP address pool for services.

- **defaultNetwork.type**
  - Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

#### 15.3.13.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<p>| Table 15.26. Cluster Network Operator configuration object |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This value is ready-only and specified in the <code>install-config.yaml</code> file.</td>
</tr>
<tr>
<td>spec.serviceNetwork</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This value is ready-only and specified in the <code>install-config.yaml</code> file.</td>
</tr>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the Container Network Interface (CNI) cluster network provider for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>

defaultNetwork object configuration
The values for the defaultNetwork object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td></td>
<td>---------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.

**NOTE**
OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

Configuration for the OpenShift SDN CNI cluster network provider
The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 15.28. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy. The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

**Example OpenShift SDN configuration**

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

**Configuration for the OVN-Kubernetes CNI cluster network provider**

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

**Table 15.29. ovnKubernetesConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultNetwork:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>type: OpenShiftSDN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshiftSDNConfig:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mode: NetworkPolicy</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mtu: 1450</td>
<td></td>
<td></td>
</tr>
<tr>
<td>vxlanPort: 4789</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

This value cannot be changed after cluster installation.

genevePort integer

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

ipsecConfig object

Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.

Example OVN-Kubernetes configuration

defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}

kubeProxyConfig object configuration

The values for the kubeProxyConfig object are defined in the following table:

Table 15.30. kubeProxyConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400. This value cannot be changed after cluster installation.</td>
</tr>
<tr>

<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
### Field Description

**iptablesSyncPeriod**

String

The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.

**NOTE**

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.

**proxyArguments.iptables-min-sync-period**

Array

The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:

```
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period:
      - 0s
```

### 15.3.14. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:
For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**IMPORTANT**

Use the `openshift-install` command from the bastion hosted in the VMC environment.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

**Example output**

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
15.3.15. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

15.3.15.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xzvf <file>

5. Place the oc binary in a directory that is on your PATH.
   
   To check your PATH, execute the following command:

   $ echo $PATH
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 15.3.15.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.7 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`.
   
   To check your `PATH`, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

   After you install the OpenShift CLI, it is available using the `oc` command:

   
   ```
   C:\> oc <command>
   ```

### 15.3.15.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.7 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your `PATH`.
   
   To check your `PATH`, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the `oc` command:

   
   ```
   $ oc <command>
   ```
15.3.16. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   Example output

   system:admin

15.3.17. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

15.3.17.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as `Removed`. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from `Removed` to `Managed`.

**NOTE**

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."
15.3.17.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

15.3.17.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

**NOTE**

When using shared storage, review your security settings to prevent outside access.
2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   NOTE
   
   If you do have a registry pod in your output, you do not need to continue with this procedure.
   
3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim: 1

   Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   ```
   $ oc get clusteroperator image-registry
   
   Example output
   
   NAME       VERSION         AVAILABLE PROGRESSING DEGRADED  SINCE      MESSAGE
   image-registry  4.7       True     False     False     6h50m     OpenShift Container Platform 4.7 Installing

15.3.17.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Replicate rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.
1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only 1 replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
{"rolloutStrategy":"Recreate","replicas":1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   A unique name that represents the `PersistentVolumeClaim` object.

   The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.

   The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.

   The size of the persistent volume claim.

   b. Create the `PersistentVolumeClaim` object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

   Example output

   ```yaml
   storage:
   pvc:
     claim: 1
   ```

   Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.
For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

15.3.18. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

15.3.19. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

15.3.20. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

15.4. INSTALLING A CLUSTER ON VMC IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.7, you can install a cluster on VMware vSphere infrastructure in a restricted network by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in
the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

NOTE
OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

15.4.1. Setting up VMC for vSphere
You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Allocate two IP addresses, outside the DHCP range, and configure them with reverse DNS records.
  - A DNS record for `api.<cluster_name>.<base_domain>` pointing to the allocated IP address.
  - A DNS record for `*.apps.<cluster_name>.<base_domain>` pointing to the allocated IP address.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as `vmc-prod-1`. 
The base DNS name, such as `companyname.com`.

If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to `10.128.0.0/14` and `172.30.0.0/16`, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.

The following vCenter information:
- vCenter hostname, username, and password
- Datacenter name, such as `SDDC-Datacenter`
- Cluster name, such as `Cluster-1`
- Network name
- Datastore name, such as `WorkloadDatastore`

**NOTE**

It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have Internet connectivity and the ability to upload an OVA to the ESXi hosts.

- Download and install the OpenShift CLI tools to the bastion host.
  - The `openshift-install` installation program
  - The OpenShift CLI (`oc`) tool

**NOTE**

You cannot use the VMware NSX Container Plugin for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

### 15.4.1.1 VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.
To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

15.4.2. vSphere prerequisites

- Create a registry on your mirror host and obtain the imageContentSources data for your version of OpenShift Container Platform.

  IMPORTANT

  Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- Provision block registry storage. For more information on persistent storage, see Understanding persistent storage.

- Review details about the OpenShift Container Platform installation and update processes.

- If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.

  NOTE

  If you are configuring a proxy, be sure to also review this site list.

15.4.3. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the
OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

15.4.3.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

15.4.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

15.4.5. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 15.31. Minimum supported vSphere version for VMware components**

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OpenShift Container Platform 4.7 Installing</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

### IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](VMware documentation) in the VMware documentation.

### IMPORTANT

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in [BZ#1935539](BZ#1935539).

#### 15.4.6. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

**Table 15.32. Ports used for all-machine to all-machine communications**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>

15.4.7. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder
to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

### Example 15.7. Roles and privileges required for installation

<table>
<thead>
<tr>
<th>vSphere object for role</th>

</tr>
<tr>
<td>vSphere object for role</td>
<td>When required</td>
<td>Required privileges</td>
</tr>
<tr>
<td>-------------------------</td>
<td>--------------</td>
<td>-------------------</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 15.8. Required permissions and propagation settings

<table>
<thead>
<tr>
<th>vSphere object</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see **vSphere Permissions and User Management Tasks** in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

If you intend on using vMotion in your vSphere environment, consider the following before installing a OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.
  
  To help ensure the uptime of your compute and control plane nodes, it is recommended that you follow the VMware best practices for vMotion. It is also recommended to use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for **vMotion networking requirements** and **VM anti-affinity rules**.
If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes, invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.

Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. The VM in your restricted network must have access to vCenter so that it can provision and manage nodes, persistent volume claims (PVCs), and other resources. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

NOTE
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.
**Required IP Addresses**
An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.  

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td><code>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**15.4.8. Generating an SSH private key and adding it to the agent**

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.
You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N " \n   -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 15.4.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

**Procedure**

1. From the vCenter home page, download the vCenter’s root CA certificates. Click **Download trusted root CA certificates** in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

```
certs
  └── lin
      ├── 108f4d17.0
      │    ├── 108f4d17.r1
      │    └── 7e757f6a.0
      │    └── 8e4f8471.0
      │    └── 8e4f8471.r0
      └── mac
          ├── 108f4d17.0
          │    ├── 108f4d17.r1
          │    └── 7e757f6a.0
          │    └── 8e4f8471.0
          │    └── 8e4f8471.r0
          └── win
              ├── 108f4d17.0.crt
              │    └── 108f4d17.r1.crt
              │    └── 7e757f6a.0.crt
              │    └── 8e4f8471.0.crt
              │    └── 8e4f8471.r0.crt
              3 directories, 15 files
```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
# update-ca-trust extract
```

### 15.4.10. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network VMware vSphere environment.
Prerequisites

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

Procedure

2. Under Version, select the most recent release of OpenShift Container Platform 4.7 for RHEL 8.

   IMPORTANT

   The RH COS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RH COS) - vSphere image.

4. Upload the image you downloaded to a location that is accessible from the bastion server.

The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

15.4.11. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the imageContentSources values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

- Retrieve a Red Hat Enterprise Linux CoreOS (RH COS) image and upload it to an accessible location.

- Obtain service principal permissions at the subscription level.

Procedure

1. Create the install-config.yaml file.

   a. Change to the directory that contains the installation program and run the following command:

      ```
      $ ./openshift-install create install-config --dir <installation_directory>
      ```

      For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   ii. Select vsphere as the platform to target.

   iii. Specify the name of your vCenter instance.

   iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster. The installation program connects to your vCenter instance.

   v. Select the datacenter in your vCenter instance to connect to.

   vi. Select the default vCenter datastore to use.

   vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

   viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

   ix. Enter the virtual IP address that you configured for control plane API access.

   x. Enter the virtual IP address that you configured for cluster ingress.

   xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

   xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

   xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the `install-config.yaml` file, set the value of `platform.vsphere.clusterOSImage` to the image location or name. For example:

   ```yaml
   platform:
     vsphere:
   ```
3. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: {"auths":{"<mirror_host_name>:5000": {"auth": "<credentials>"},"email": "you@example.com"}}
   ```

   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

   b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
     -----END CERTIFICATE-----
   ```

   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

   c. Add the image content resources, which look like this excerpt:

   ```yaml
   imageContentSources:
   - mirrors:
     - <mirror_host_name>:5000/<repo_name>/release
       source: quay.example.com/openshift-release-dev/ocp-release
     - mirrors:
     - <mirror_host_name>:5000/<repo_name>/release
       source: registry.example.com/ocp/release
   ```

   To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

15.4.11.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe
your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 15.4.11.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code></td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td><code>baseDomain</code></td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td><code>metadata</code></td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td><code>metadata.name</code></td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters and hyphens (–), such as <code>dev</code>.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere.** For additional information about `platform.<platform>` parameters, consult the table for your specific platform that follows.

### 15.4.11.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 15.37. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NOTE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the <strong>networking</strong> object after installation.</td>
</tr>
<tr>
<td>networking.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <strong>networking.clusterNetwork</strong>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>An IPv4 network.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <strong>hostPrefix</strong> is set to 23 then each node is assigned a /23 subnet out of the given <strong>cidr</strong>. A <strong>hostPrefix</strong> value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
</tbody>
</table>
### networking.machineNetwork

The IP address blocks for machines.

- If you specify multiple IP address blocks, the blocks must not overlap.
- If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network.

**Values**

- An array of objects. For example:
  ```json
  networking:
    machineNetwork:
      - cidr: 10.0.0.0/16
  ```

### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

**Values**

- An IP network block in CIDR notation.
- For example, `10.0.0.0/16`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

#### 15.4.11.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

### Table 15.38. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute.hyperthreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td><strong>compute.name</strong></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><code>worker</code></td>
</tr>
<tr>
<td><strong>compute.platform</strong></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td><strong>compute.replicas</strong></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to <code>2</code>. The default value is <code>3</code>.</td>
</tr>
<tr>
<td><strong>controlPlane</strong></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
| controlPlane.hypertreading| Whether to enable or disable simultaneous multithreading, or **hypertreading**, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.  

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. | Enabled or Disabled |
<p>| controlPlane.name         | Required if you use <code>controlPlane</code>. The name of the machine pool.                                                                                                                                         | master                  |
| controlPlane.platform     | Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.                                 | <code>aws, azure, gcp, openstack, ovirt, vsphere, or {}</code> |
| controlPlane.replicas     | The number of control plane machines to provision.                                                                                                                                                         | The only supported value is 3, which is the default value. |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Cluster Operators reference content.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. The default value is <strong>External</strong>. Setting this field to <strong>Internal</strong> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](https://bz.redhat.com/bugzilla/show_bug.cgi?id=1953035).
### 15.4.11.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.password</code></td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.datacenter</code></td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.defaultDatastore</code></td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.folder</code></td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, <code>/&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;</code></td>
</tr>
<tr>
<td><code>platform.vsphere.network</code></td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.cluster</code></td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.apiVIP</code></td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example <code>128.0.0.1</code>.</td>
</tr>
<tr>
<td><code>platform.vsphere.ingressVIP</code></td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example <code>128.0.0.1</code>.</td>
</tr>
</tbody>
</table>
15.4.11.1.5. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 15.40. Optional VMware vSphere machine pool parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td>platform.vsphere.osDisk.diskSizeGB</td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.cpus</td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.coresPerSocket</td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is platform.vsphere.cpus/platform.vsphere.coresPerSocket. The default value is 1</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.memoryMB</td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

15.4.11.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 3
    platform:
      vsphere:
        cpus: 2
        coresPerSocket: 2
        memoryMB: 8192
        osDisk:
          diskSizeGB: 120
        controlPlane:
          hyperthreading: Enabled
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or `hyperthreading`. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.
IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

The location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that is accessible from the bastion server.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

15.4.11.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure
1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
noProxy: example.com ③
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
... ④
```

① A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

② A proxy URL to use for creating HTTPS connections outside the cluster.

③ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

④ If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**
The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

15.4.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
IMPORTANT

You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info

   1 For <installation_directory>, specify the location of your customized ./install-config.yaml file.

   2 To view different installation details, specify warn, debug, or error instead of info.

IMPORTANT

Use the openshift-install command from the bastion hosted in the VMC environment.

NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

Example output

...  
INFO Install complete!  
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'  
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com  
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-yyBZj-Wt5AL"  
INFO Time elapsed: 36m22s
NOTE

The cluster access and credential information also outputs to
<installation_directory>/.openshift_install.log when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

15.4.13. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

15.4.13.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>
5. Place the `oc` binary in a directory that is on your `PATH`. To check your `PATH`, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 15.4.13.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the `Version` drop-down menu.

3. Click `Download Now` next to the [OpenShift v4.7 Windows Client](https://customer.redhat.com/downloads) entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your `PATH`. To check your `PATH`, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 15.4.13.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the `Version` drop-down menu.

3. Click `Download Now` next to the [OpenShift v4.7 MacOSX Client](https://customer.redhat.com/downloads) entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your `PATH`. To check your `PATH`, open a terminal and execute the following command:

```
$ echo $PATH
```

```
After you install the OpenShift CLI, it is available using the `oc` command:

$ oc <command>

15.4.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami

   **Example output**

   system:admin

15.4.15. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
15.4.16. Creating registry storage

After you install the cluster, you must create storage for the Registry Operator.

15.4.16.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

15.4.16.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

15.4.16.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.
IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   Example output
   No resources found in openshift-image-registry namespace
   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.
   ```

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   Example output
   ```

   ```
   storage:
pvc:
   claim: 1
   ```
1. Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage PVC**.

4. Check the **clusteroperator** status:

   ```bash
   $ oc get clusteroperator image-registry
   ```

   **Example output**

<table>

15.4.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager**.

After you confirm that your **OpenShift Cluster Manager** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, **use subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

15.4.18. Next steps

- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the **must-gather** tool.
- Learn how to [use Operator Lifecycle Manager (OLM) on restricted networks](#).
- If necessary, you can [opt out of remote health reporting](#).
- Set up your registry and configure registry storage.

15.5. INSTALLING A CLUSTER ON VMC WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.7, you can install a cluster on VMware vSphere infrastructure that you provision by deploying it to **VMware Cloud (VMC) on AWS**.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.
NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

15.5.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the Internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as vmc-prod-1.
  - The base DNS name, such as companyname.com.
  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to 10.128.0.0/14 and 172.30.0.0/16, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
  - The following vCenter information:
- vCenter hostname, username, and password
- Datacenter name, such as SDDC-Datacenter
- Cluster name, such as Cluster-1
- Network name
- Datastore name, such as WorkloadDatastore

**NOTE**

It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have Internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The openshift-install installation program
    - The OpenShift CLI (oc) tool

**NOTE**

You cannot use the VMware NSX Container Plugin for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

### 15.5.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
Storage requirements

- vCPUs
- vRAM
- Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

15.5.2. vSphere prerequisites

- Provision block registry storage. For more information on persistent storage, see Understanding persistent storage.
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

15.5.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

15.5.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 15.41. Minimum supported vSphere version for VMware components
<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**IMPORTANT**

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

### 15.5.5. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

#### 15.5.5.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.

**NOTE**

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

15.5.5.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

15.5.5.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

15.5.5.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

Table 15.42. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

15.5.5.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using...
kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

15.5.6. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

Prerequisites

- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the supporting infrastructure for your cluster.

Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

15.5.6.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

</tr>
</tbody>
</table>

Network topology requirements

The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
• Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

• A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 15.46. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>

| 22623| Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. | X        |          | Machine config server        |

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer.** Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

• Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

• A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

**Table 15.47. Application Ingress load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

### 15.5.6.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

**Table 15.48. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.

**IMPORTANT**
The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Routes</strong></td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td><strong>Bootstrap</strong></td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td><strong>Master hosts</strong></td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td><strong>Worker hosts</strong></td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**TIP**
You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

**Example 15.9. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 
```
The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 15.10. Sample DNS zone database for reverse records

```

worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.7
;
;EOF
```

The following example BIND zone file shows sample PTR records for reverse name resolution.
15.5.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" \
   -f <path>/<file_name> 1
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.
2. Start the `ssh-agent` process as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

**15.5.8. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.
The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 15.5.9. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.
NOTE

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

15.5.9.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - name: worker
    replicas: 0
    controlPlane:
      hyperthreading: Enabled
      name: master
      replicas: 3
      metadata:
        name: test
    platform:
      vsphere:
        vcenter: your.vcenter.server
        username: username
        password: password
        datacenter: datacenter
        defaultDatastore: datastore
        folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>"
      fips: false
      pullSecret: '{"auths": ...}'
      sshKey: 'ssh-ed25519 AAAA...'
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3. Whether to enable or disable simultaneous multithreading, or `hyperthreading`. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous
multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

4. You must set the value of the `replicas` parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

7. The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8. The cluster name that you specified in your DNS records.

9. The fully-qualified hostname or IP address of the vCenter server.

10. The name of the user for accessing the server. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

11. The password associated with the vSphere user.

12. The vSphere datacenter.

13. The default vSphere datastore to use.

14. Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, `/<datacenter_name>/vm/<folder_name>/<subfolder_name>`. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this parameter.

15. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

16. The pull secret that you obtained from OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

17. The public portion of the default SSH key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).
15.5.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
     noProxy: example.com
     additionalTrustBundle: |
       -----BEGIN CERTIFICATE-----
       <MY_TRUSTED_CA_CERT>
       -----END CERTIFICATE-----
       ...
   
   1  A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2  A proxy URL to use for creating HTTPS connections outside the cluster.
   3  A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.
   4  If provided, the installation program generates a config map that is named `user-ca-bundle`
The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

### 15.5.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

#### IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

#### NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory>
```
1. For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   
   Because you create and manage these resources yourself, you do not have to initialize them. • You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

   **WARNING**
   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

   +

   **IMPORTANT**
   When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory> 1
   
   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:
15.5.11. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware Cloud on AWS. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**

To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

15.5.12. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

Before you install a cluster that contains user-provisioned infrastructure on VMware vSphere, you must create RHCOS machines on vSphere hosts for it to use.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.
Procedure

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

   ```
   
   "ignition": {
   "config": {
   "merge": [
   
   "source": `<bootstrap_ignition_config_url>`,
   "verification": {}
   
   ],
   "timeout": {},
   "version": "3.2.0"
   },
   "networkd": {},
   "passwd": {},
   "storage": {},
   "systemd": {}
   }
   
   ```

   1. Specify the URL of the bootstrap Ignition config file that you hosted.

   When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:

   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```
IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format rhcos-vmware.<architecture>.ova.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the VMs and Templates view.
   b. Right-click the name of your datacenter.
   c. Click New Folder → New VM and Template Folder.
   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the install-config.yaml file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

NOTE

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

   a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.
   b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.
   c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.
   d. On the Select a compute resource tab, click the name of your vSphere cluster.
   e. On the Select storage tab, configure the storage options for your VM.
      - Select Thin Provision or Thick Provision, based on your storage preferences.
- Select the datastore that you specified in your `install-config.yaml` file.

f. On the **Select network** tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RH COS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. After the template deploys, deploy a VM for a machine in the cluster.

   a. Right-click the template name and click **Clone → Clone to Virtual Machine**

   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as `control-plane-0` or `compute-1`.

   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

   e. Optional: On the **Select storage** tab, customize the storage options.

   f. On the **Select clone options**, select **Customize this virtual machine's hardware**

   g. On the **Customize hardware** tab, click **VM Options → Advanced**.

   - Optional: Override default DHCP networking in vSphere. To enable static IP networking:

     i. Set your static IP configuration:

     ```
     $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
     nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
     ```

     **Example command**

     ```
     $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
     nameserver=8.8.8.8"
     ```

     ii. Set the `guestinfo.afterburn.initrd.network-kargs` property before booting a VM from an OVA in vSphere:

     ```
     $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
     ```

   - Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list, select **High**. Ensure that your VM's CPU and memory reservation have the following values:
- Memory reservation value must be equal to its configured memory size.
- CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

- Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
  
  - guestinfo.ignition.config.data: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  
  - guestinfo.ignition.config.data.encoding: Specify **base64**.
  
  - disk.EnableUUID: Specify **TRUE**.

h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

9. Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

**15.5.13. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere**

You can create more compute machines for your cluster that uses user-provisioned infrastructure on VMware vSphere.

**Prerequisites**

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

**Procedure**

1. After the template deploys, deploy a VM for a machine in the cluster.
   
a. Right-click the template’s name and click **Clone → Clone to Virtual Machine**
   
b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.
   
c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
   
d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
e. Optional: On the **Select storage** tab, customize the storage options.

f. On the **Select clone options**, select **Customize this virtual machine’s hardware**.

g. On the **Customize hardware** tab, click **VM Options → Advanced**.

   - From the **Latency Sensitivity** list, select **High**.
   - Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
     - `guestinfo.ignition.config.data`: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
     - `guestinfo.ignition.config.data.encoding`: Specify **base64**.
     - `disk.EnableUUID`: Specify **TRUE**.

h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under **Add network adapter** if there are multiple networks available.

i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

### 15.5.14. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- **Create separate partitions**: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, a separate partition, but not both.

  **IMPORTANT**

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

  - **Retain existing partitions**: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

**Creating a separate `/var` partition**

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.
OpenShift Container Platform supports the addition of a single partition to attach storage to either the 
/var partition or a subdirectory of /var. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   ```bash
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a MachineConfig object and add it to a file in the openshift directory. For example, name the file **98-var-partition.yaml**, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

   ```yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
   name: 98-var-partition
   spec:
     config:
       ignition:
         version: 3.2.0
       storage:
         disks:
   ```
- device: /dev/<device_name>  
  partitions:
  - label: var
    startMiB: <partition_start_offset>  
    sizeMiB: <partition_size>  
  filesystems:
    - device: /dev/disk/by-partlabel/var
      path: /var
      format: xfs
  systemd:
    units:
      - name: var.mount  
        enabled: true
        contents: |
        [Unit]
        Before=local-fs.target
        [Mount]
        What=/dev/disk/by-partlabel/var
        Where=/var
        Options=defaults,prjquota
        [Install]
        WantedBy=local-fs.target

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
4. The name of the mount unit must match the directory specified in the Where= directive. For example, for a filesystem mounted on /var/lib/containers, the unit must be named var-lib-containers.mount.
5. The prjquota mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

2338
Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

15.5.15. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use bootupd only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install bootupd by using the bootctl command-line tool.

1. Inspect the system status:

   ```bash
   # bootupctl status
   ``

   **Example output**

   ```
   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version
   ```

2. RHCOS images created without bootupd installed on them require an explicit adoption phase. If the system status is Adoptable, perform the adoption:

   ```bash
   # bootupctl adopt-and-update
   ``

   **Example output**

   ```
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```bash
   # bootupctl update
   ``

   **Example output**

   ```
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

Machine config method

Another way to enable bootupd is by providing a machine config.
• Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

**Example output**

```yaml
variant: rhcos
version: 1.1.0
systemd:
    units:
        - name: custom-bootupd-auto.service
          enabled: true
          contents: |
            [Unit]
            Description=Bootupd automatic update

            [Service]
            ExecStart=/usr/bin/bootupctl update
            RemainAfterExit=yes

            [Install]
            WantedBy=multi-user.target
```

### 15.5.16. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of **oc**.

#### 15.5.16.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:

   ```bash
   $ tar xzvf <file>
   ```

5. Place the **oc** binary in a directory that is on your **PATH**.

   To check your **PATH**, execute the following command:

   ```bash
   $ echo $PATH
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 15.5.16.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the [OpenShift v4.7 Windows Client](https://www.redhat.com/en) entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your PATH.

   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 15.5.16.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the [OpenShift v4.7 MacOSX Client](https://www.redhat.com/en) entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.

   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
15.5.17. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   Example output

   ```
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.20.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.

15.5.18. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites
You deployed an OpenShift Container Platform cluster.

You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   
   example output
   
   system:admin
   
15.5.19. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   
   Example output
   
   NAME    STATUS   ROLES      AGE     VERSION
   master-0 Ready master 63m    v1.20.0
   master-1 Ready master 63m    v1.20.0
   master-2 Ready master 64m    v1.20.0
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.
2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' xargs --no-run-if-empty oc adm certificate approve
  ```

**NOTE**

Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME        AGE     REQUESTOR                                             CONDITION  
csr-bfd72   5m26s   system:node:ip-10-0-50-126.us-east-2.compute.internal Pending  
csr-c57lv   5m26s   system:node:ip-10-0-95-157.us-east-2.compute.internal Pending  
... 
```

5. If the remaining CSRs are not approved, and are in the *Pending* status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>  
  
  1  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the *Ready* status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION  
master-0  Ready     master  73m  v1.20.0  
master-1  Ready     master  73m  v1.20.0  
master-2  Ready     master  74m  v1.20.0  
worker-0  Ready     worker  11m  v1.20.0  
worker-1  Ready     worker  11m  v1.20.0  
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the *Ready* status.

**Additional information**

- For more information on CSRs, see *Certificate Signing Requests*. 

15.5.20. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>

</tbody>
</table>

2. Configure the Operators that are not available.

15.5.20.1. Image registry removed during installation
On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

15.5.20.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

15.5.20.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

IMPORTANT

OpenShift Container Platform supportsReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have "100Gi" capacity.
IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry.cluster` resource.

   **NOTE**
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
     claim: 1
   
   **NOTE**
   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```bash
   $ oc get clusteroperator image-registry
   ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

### 15.5.20.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {
  "storage": {
    "emptyDir": {}}}}'
  ```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 15.5.20.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {
    "rolloutStrategy": "Recreate",
    "replicas": 1}}'
   ```
2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1. A unique name that represents the PersistentVolumeClaim object.
   2. The namespace for the PersistentVolumeClaim object, which is `openshift-image-registry`.
   3. The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.
   4. The size of the persistent volume claim.

   b. Create the PersistentVolumeClaim object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

   **Example output**

   ```yaml
   storage:
   pvc:
   claim: 1
   ```

   1. Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

**15.5.21. Completing installation on user-provisioned infrastructure**

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.
Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>

</tr>
</tbody>
</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td></td>
</tr>
<tr>
<td>Running 1 9m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td>3m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>

<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td></td>
</tr>
<tr>
<td>Running 0 5m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.
If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.

   a. All the worker nodes are restarted. To monitor the process, enter the following command:

   $ oc get nodes -w

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

### 15.5.22. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 15.5.23. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

* See About remote health monitoring for more information about the Telemetry service
15.5.24. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

15.6. INSTALLING A CLUSTER ON VMC WITH USER-PROVISIONED INFRASTRUCTURE AND NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.7, you can install a cluster on your VMware vSphere instance using infrastructure you provision with customized network configuration options by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing VXLAN configurations. You must set most of the network configuration parameters during installation, and you can modify only kubeProxy configuration parameters in a running cluster.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

15.6.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:
• Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

• Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the Internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

• You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as `vmc-prod-1`.
  - The base DNS name, such as `companyname.com`.
  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to `10.128.0.0/14` and `172.30.0.0/16`, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
  - The following vCenter information:
    - vCenter hostname, username, and password
    - Datacenter name, such as `SDDC-Datacenter`
    - Cluster name, such as `Cluster-1`
    - Network name
    - Datastore name, such as `WorkloadDatastore`

  **NOTE**
  It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

• A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have Internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The `openshift-install` installation program
    - The OpenShift CLI (`oc`) tool
NOTE

You cannot use the VMware NSX Container Plugin for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

15.6.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

15.6.2. vSphere prerequisites

- Provision block registry storage. For more information on persistent storage, see Understanding persistent storage.
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to access Red Hat Insights.

15.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:
• Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

**15.6.4. VMware vSphere infrastructure requirements**

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 15.49. Minimum supported vSphere version for VMware components**

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.
IMPORTANT

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

15.6.5. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

15.6.5.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.

NOTE

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

15.6.5.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

15.6.5.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

15.6.5.4. Minimum resource requirements
Each cluster machine must meet the following minimum requirements:

### Table 15.50. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

#### 15.6.5.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

#### 15.6.6. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

**Prerequisites**

- Review the [OpenShift Container Platform 4.x Tested Integrations](#) page before you create the supporting infrastructure for your cluster.

**Procedure**

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

#### 15.6.6.1. Networking requirements for user-provisioned infrastructure
All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

### Table 15.51. All machines to all machines

<table>

</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6443</td>
<td>Kubernetes API</td>
</tr>
</tbody>
</table>

### Table 15.53. Control plane machines to control plane machines
### Network topology requirements

The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Load balancers

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 15.54. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application Ingress load balancer: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

Table 15.55. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

TIP

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

NTP configuration

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

15.6.6.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records
are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
TIP

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

Example 15.11. Sample DNS zone database

```
$TTL 1W

worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.7
; ;EOF
```

The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 15.12. Sample DNS zone database for reverse records
15.6.7. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" \
   -f <path>/<file_name>
   ```
Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the **ssh-agent** process as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**15.6.8. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space
Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   $ mkdir <installation_directory>
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 15.6.9. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

15.6.9.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
platform:
  vsphere:
    vcenter: your.vcenter.server
    username: username
    password: password
    datacenter: datacenter
    defaultDatastore: datastore
    folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>"
fips: false
pullSecret: '{"auths": ...}'
sshKey: 'ssh-ed25519 AAAA...'
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

The password associated with the vSphere user.

The vSphere datacenter.

The default vSphere datastore to use.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, `<datacenter_name>/vm/<folder_name>/<subfolder_name>`. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this parameter.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

16 The pull secret that you obtained from OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

17 The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

15.6.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
  additionalTrustBundle: |4
  -----BEGIN CERTIFICATE-----
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

15.6.10. Specifying advanced network configuration

You can use advanced configuration customization to integrate your cluster into your existing network environment by specifying additional configuration for your cluster network provider. You can specify advanced network configuration only before you install the cluster.

IMPORTANT
Modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites
- Create the `install-config.yaml` file and complete any modifications to it.
- Create the Ignition config files for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ``

   where:

   `<installation_directory>`
   
   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   EOF
   
   where:

   `<installation_directory>`
   
   Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and specify the advanced network configuration for your cluster, such as in the following examples:

   **Specify a different VXLAN port for the OpenShift SDN network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       openshiftSDNConfig:
         vxlanPort: 4800
   
   **Enable IPsec for the OVN-Kubernetes network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

6. Remove the Kubernetes manifest files that define the control plane machines and compute machineSets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the MachineSet files to create compute machines by using the machine API, but you must update references to them to match your environment.

### 15.6.11. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`
  IP address pools from which pod IP addresses are allocated.

- `serviceNetwork`
  IP address pool for services.

- `defaultNetwork.type`
  Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

#### 15.6.11.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>metadata.name</code></td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
</tbody>
</table>
spec.clusterNetwork
array
A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

```
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

This value is ready-only and specified in the `install-config.yaml` file.

spec.serviceNetwork
array
A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

```
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

This value is ready-only and specified in the `install-config.yaml` file.

spec.defaultNetwork
object
Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

spec.kubeProxy
object
The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration
The values for the `defaultNetwork` object are defined in the following table:

Table 15.58. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cidr</td>
<td>string</td>
<td>Specifies the IP address range for the default network.</td>
</tr>
<tr>
<td>hostPrefix</td>
<td>integer</td>
<td>Specifies the subnet prefix length for the default network.</td>
</tr>
</tbody>
</table>

OpenShift Container Platform 4.7 Installing
Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.

**NOTE**

OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>openshiftSDNConfig</th>
<th>object</th>
<th>This object is only valid for the OpenShift SDN cluster network provider.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 15.59. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy. The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

```yaml
defaultNetwork:
type: OpenShiftSDN
openshiftSDNConfig:
  mode: NetworkPolicy
  mtu: 1450
  vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 15.60. ovnKubernetesConfig object
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

This value cannot be changed after cluster installation.

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.

Example OVN-Kubernetes configuration

```
defaultNetwork:
  type: OVNKubernetes
ovnKubernetesConfig:
  mtu: 1400
genevePort: 6081
ipsecConfig: {}
```

kubeProxyConfig object configuration

The values for the `kubeProxyConfig` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 15.61. `kubeProxyConfig` object
### iptablesSyncPeriod

The refresh period for *iptables* rules. The default value is **30s**. Valid suffixes include **s**, **m**, and **h** and are described in the Go *time* package documentation.

**NOTE**

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the `iptablesSyncPeriod` parameter is no longer necessary.

### proxyArguments.iptables-min-sync-period

The minimum duration before refreshing *iptables* rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include **s**, **m**, and **h** and are described in the Go *time* package. The default value is:

```
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period:
      - 0s
```

### 15.6.12. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

Procedure

- Obtain the Ignition config files:

  ```
  $ ./openshift-install create ignition-configs --dir <installation_directory>
  ```

  For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

  **IMPORTANT**

  If you created an `install-config.yaml` file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

  The following files are generated in the directory:

  ```
  ├── auth
  │   └── kubeadmin-password
  │       └── kubeconfig
  ├── bootstrap.ign
  ├── master.ign
  ├── metadata.json
  └── worker.ign
  ```

15.6.13. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware Cloud on AWS. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

Procedure
To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```bash
$ jq -r .infraID <installation_directory>/metadata.json
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

**15.6.14. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere**

Before you install a cluster that contains user-provisioned infrastructure on VMware vSphere, you must create RHCOS machines on vSphere hosts for it to use.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

**Procedure**

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

```json
{
  "ignition": {
    "config": {
      "merge": {
        "source": "<bootstrap_ignition_config_url>",
        "verification": {}
      }
    },
    "timeouts": {},
    "version": "3.2.0"
  },
  "networkd": {},
  "passwd": {}
}
```
Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
   * `<installation_directory>/master.ign`
   * `<installation_directory>/worker.ign`
   * `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the **VMs and Templates** view.
   b. Right-click the name of your datacenter.
c. Click **New Folder → New VM and Template Folder**.

d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

   **NOTE**
   
   In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

   a. From the **Hosts and Clusters** tab, right-click your cluster name and select **Deploy OVF Template**.

   b. On the **Select an OVF** tab, specify the name of the RHCOS OVA file that you downloaded.

   c. On the **Select a name and folder** tab, set a **Virtual machine name** for your template, such as `Template-RHCOS`. Click the name of your vSphere cluster and select the folder you created in the previous step.

   d. On the **Select a compute resource** tab, click the name of your vSphere cluster.

   e. On the **Select storage** tab, configure the storage options for your VM.

      - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.

      - Select the datastore that you specified in your `install-config.yaml` file.

   f. On the **Select network** tab, specify the network that you configured for the cluster, if available.

   g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

   **IMPORTANT**
   
   Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. After the template deploys, deploy a VM for a machine in the cluster.

   a. Right-click the template name and click **Clone → Clone to Virtual Machine**

   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as `control-plane-0` or `compute-1`.

   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

e. Optional: On the **Select storage** tab, customize the storage options.

f. On the **Select clone options** tab, select **Customize this virtual machine’s hardware**.

g. On the **Customize hardware** tab, click **VM Options → Advanced**.

   - Optional: Override default DHCP networking in vSphere. To enable static IP networking:

     i. Set your static IP configuration:

        ```
        $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
        nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]
        
        Example command
        $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
        nameserver=8.8.8.8"
        
        ii. Set the **guestinfo.afterburn.initrd.network-kargs** property before booting a VM from an OVA in vSphere:

        $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
        
        - Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list, select **High**. Ensure that your VM’s CPU and memory reservation have the following values:

            - Memory reservation value must be equal to its configured memory size.

            - CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

        - Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:

            - **guestinfo.ignition.config.data**: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.

            - **guestinfo.ignition.config.data.encoding**: Specify **base64**.

            - **disk.EnableUUID**: Specify **TRUE**.

h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

   i. Complete the configuration and power on the VM.

9. Create the rest of the machines for your cluster by following the preceding steps for each machine.
15.6.15. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

You can create more compute machines for your cluster that uses user-provisioned infrastructure on VMware vSphere.

Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

Procedure

1. After the template deploys, deploy a VM for a machine in the cluster.
   a. Right-click the template’s name and click **Clone → Clone to Virtual Machine**
   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.
   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
   e. Optional: On the **Select storage** tab, customize the storage options.
   f. On the **Select clone options**, select **Customize this virtual machine’s hardware**
   g. On the **Customize hardware** tab, click **VM Options → Advanced**.
      - From the **Latency Sensitivity** list, select **High**.
      - Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
        - **guestinfo.ignition.config.data**: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
        - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
        - **disk.EnableUUID**: Specify **TRUE**.
   h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under **Add network adapter** if there are multiple networks available.
   i. Complete the configuration and power on the VM.
2. Continue to create more compute machines for your cluster.

15.6.16. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

  IMPORTANT
  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   $ mkdir $HOME/clusterconfig
2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

```bash
$ openshift-install create manifests --dir $HOME/clusterconfig
? SSH Public Key ...
$ ls $HOME/clusterconfig/openshift/
 99_kubeadmin-password-secret.yaml
 99_openshift-cluster-api_master-machines-0.yaml
 99_openshift-cluster-api_master-machines-1.yaml
 99_openshift-cluster-api_master-machines-2.yaml
...
```

3. Create a `MachineConfig` object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
        - device: /dev/<device_name>  # 1
        partitions:
          - label: var
            startMiB: <partition_start_offset>  # 2
            sizeMiB: <partition_size>  # 3
        filesystems:
          - device: /dev/disk/by-partlabel/var
            path: /var
            format: xfs
  systemd:
    units:
      - name: var.mount  # 4
        enabled: true
        contents: |
          [Unit]
          Before=local-fs.target
          [Mount]
          What=/dev/disk/by-partlabel/var
          Where=/var
          Options=defaults,prjquota  # 5
          [Install]
          WantedBy=local-fs.target
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is
3. The size of the data partition in mebibytes.

4. The name of the mount unit must match the directory specified in the Where= directive. For example, for a filesystem mounted on /var/lib/containers, the unit must be named var-lib-containers.mount.

5. The priquota mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

15.6.17. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use bootupd only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install bootupd by using the bootctl command-line tool.

1. Inspect the system status:

   ```bash
   # bootupctl status
   ```

   Example output

   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version
2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

**Machine config method**

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

```
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update
        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes
        [Install]
        WantedBy=multi-user.target
```

**15.6.18. Creating the cluster**

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
You used the Ignition config files to create RHCOS machines for your cluster.

Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.20.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**
   
   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.

15.6.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   Example output
   system:admin
   ```

### 15.6.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   Example output
   
<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>
   
   The output lists all of the machines that you created.

   **NOTE**
   
   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   Example output
   
<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved, Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved, Issued</td>
</tr>
</tbody>
</table>
3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name> 1
  
  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' xargs --no-run-if-empty oc adm certificate approve
  
  Some Operators might not become available until some CSRs are approved.
  ```

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  ```bash
  $ oc get csr
  
  Example output
  ```

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td></td>
</tr>
</tbody>
</table>
OpenShift Container Platform 4.7 Installing

Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
6. After all client and server CSRs have been approved, the machines have the Ready status.
Verify this by running the following command:
$ oc get nodes

Example output
NAME
master-0
master-1
master-2
worker-0
worker-1

STATUS ROLES AGE VERSION
Ready master 73m v1.20.0
Ready master 73m v1.20.0
Ready master 74m v1.20.0
Ready worker 11m v1.20.0
Ready worker 11m v1.20.0

NOTE
It can take a few minutes after approval of the server CSRs for the machines to
transition to the Ready status.
Additional information
For more information on CSRs, see Certificate Signing Requests .

15.6.21. Initial Operator configuration
After the control plane initializes, you must immediately configure some Operators so that they all
become available.
Prerequisites
Your control plane has initialized.
Procedure

2392


1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

   **Example output**

</table>

2. Configure the Operators that are not available.

15.6.21.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.
NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

15.6.21.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

15.6.21.2.1. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Recreate rollout strategy.

IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the Recreate rollout strategy and runs with only 1 replica:

\$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{{"spec":
   "rolloutStrategy":"Recreate","replicas":1}}'

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

```yaml
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: image-registry-storage
  namespace: openshift-image-registry
spec:
  accessModes:
  - ReadWriteOnce
```
A unique name that represents the `PersistentVolumeClaim` object.

2. The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.

3. The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.

4. The size of the persistent volume claim.

b. Create the `PersistentVolumeClaim` object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
pvc:
  claim:
```

Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 15.6.22. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

**Example output**
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

   ```
   NAMESPACE                         NAME                                            READY   STATUS
   RESTARTS   AGE
   openshift-apiserver-operator      openshift-apiserver-operator-85cb746d55-zqhs8   1/1     Running     1/1 Running     9m
   openshift-apiserver               apiserver-67b9g                                 1/1     Running     0
   3m
   openshift-apiserver               apiserver-ljcmx                                 1/1     Running     0
   1m
   openshift-apiserver               apiserver-z25h4                                 1/1     Running     0
   2m
   openshift-authentication-operator  authentication-operator-69d5d8bf84-vh2n8        1/1     Running     0
   5m
   ...                                
   ```

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```bash
   $ oc logs <pod_name> -n <namespace>  
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation configuration* documentation for more information.
a. All the worker nodes are restarted. To monitor the process, enter the following command:

   $ oc get nodes -w

   **NOTE**

   If you have additional machine types such as infrastructure nodes, repeat the process for these types.

You can add extra compute machines after the cluster installation is completed by following [Adding compute machines to vSphere](#).

### 15.6.23. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See [Snapshot Limitations](#) for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 15.6.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#). After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service.

### 15.6.25. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).
Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

15.7. INSTALLING A CLUSTER ON VMC IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.7, you can install a cluster on VMware vSphere infrastructure that you provision in a restricted network by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

15.7.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.
You must have the following information to deploy OpenShift Container Platform:

- The OpenShift Container Platform cluster name, such as `vmc-prod-1`.
- The base DNS name, such as `companyname.com`.
- If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to `10.128.0.0/14` and `172.30.0.0/16`, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
- The following vCenter information:
  - vCenter hostname, username, and password
  - Datacenter name, such as `SDDC-Datacenter`
  - Cluster name, such as `Cluster-1`
  - Network name
  - Datastore name, such as `WorkloadDatastore`

**NOTE**

It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have Internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The `openshift-install` installation program
    - The OpenShift CLI (`oc`) tool

**NOTE**

You cannot use the VMware NSX Container Plugin for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

### 15.7.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi
hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the **VMC on AWS Sizer**. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

### 15.7.2. vSphere prerequisites

- **Create a registry on your mirror host** and obtain the **imageContentSources** data for your version of OpenShift Container Platform.

  **IMPORTANT**
  
  Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- Provision **block registry storage**. For more information on persistent storage, see **Understanding persistent storage**.

- Review details about the **OpenShift Container Platform installation and update** processes.

- If you use a firewall and plan to use telemetry, you must **configure the firewall to allow the sites** that your cluster requires access to.

  **NOTE**
  
  Be sure to also review this site list if you are configuring a proxy.

### 15.7.3. About installations in restricted networks

In OpenShift Container Platform 4.7, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require
internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

15.7.3.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an **Unable to retrieve available updates** error.

- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

15.7.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access [OpenShift Cluster Manager](https://openshift.redhat.com) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access [Quay.io](https://quay.io) to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

15.7.5. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.
Table 15.62. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**IMPORTANT**

Virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. This is a known issue that is being addressed in BZ#1935539.

15.7.6. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

15.7.6.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.

**NOTE**

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

15.7.6.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

15.7.6.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

15.7.6.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

15.7.6.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using
kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

15.7.7. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

Prerequisites

- Review the OpenShift Container Platform 4.x Tested Integrations page before you create the supporting infrastructure for your cluster.

Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

15.7.7.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

</tr>
</tbody>
</table>

Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

IMPORTANT
OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. API load balancer: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 15.67. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer** Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

**Table 15.68. Application Ingress load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

**15.7.7.2. User-provisioned DNS requirements**

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the install-config.yaml file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>..

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

### Componenent Record Description

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

**Example 15.13. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root ( |
The following example BIND zone file shows sample PTR records for reverse name resolution.

```
15.7.8. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an
SSH key to both your `ssh-agent` and the installation program. You can use this key to access the
bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE
In a production environment, you require disaster recovery and debugging.

IMPORTANT
Do not skip this procedure in production environments where disaster recovery and
debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the
key is added to the `core` user’s `~/.ssh/authorized_keys` list.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your
computer, create one. For example, on a computer that uses a Linux operating system, run the
following command:

```
$ ssh-keygen -t ed25519 -N "" \\
   -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an
existing key pair, ensure your public key is in the your `~/.ssh` directory.

Running this command generates an SSH key that does not require a password in the location
that you specified.

NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS
Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead,
create a key that uses the `rsa` or `ecdsa` algorithm.
2. Start the **ssh-agent** process as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

### 15.7.9. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.
- Obtain the `imageContentSources` section from the output of the command to mirror the repository.
- Obtain the contents of the certificate for your mirror registry.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```
You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

**NOTE**

You must name this configuration file `install-config.yaml`.

- Unless you use a registry that RHCOS trusts by default, such as `docker.io`, you must provide the contents of the certificate for your mirror repository in the `additionalTrustBundle` section. In most cases, you must provide the certificate for your mirror.

- You must include the `imageContentSources` section from the output of the command to mirror the repository.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

### 15.7.9.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
platform:
  vsphere:
    vcenter: your.vcenter.server
    username: username
    password: password
datacenter: datacenter
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

The password associated with the vSphere user.
The vSphere datacenter.

The default vSphere datastore to use.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, 
/\<datacenter_name>/vm/\<folder_name>/\<subfolder_name>. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this parameter.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

The public portion of the default SSH key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the **imageContentSources** section from the output of the command to mirror the repository.

15.7.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

**Prerequisites**

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to
bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations. You must include vCenter's IP address and the IP range that you use for its machines.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the **Proxy** object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy `readinessEndpoints` field.
2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 15.7.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the `client image mirror`. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.
2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

```bash
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be scheduleable.

**+**

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to **false**.

   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```bash
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

```bash
├── auth
│   ├── kubeadmin-password
│   └── kubectl
└── bootstrap.ign
```
### 15.7.11. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware Cloud on AWS. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**

To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```bash
$ jq -r .infraID <installation_directory>/metadata.json
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```bash
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

### 15.7.12. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

Before you install a cluster that contains user-provisioned infrastructure on VMware vSphere, you must create RHCOS machines on vSphere hosts for it to use.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

**Procedure**
1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

   ```json
   {
     "ignition": {
       "config": {
         "merge": [
           {
             "source": "<bootstrap_ignition_config_url>",
             "verification": {}
           }
         ],
         "timeouts": {},
         "version": "3.2.0"
       },
       "networkd": {},
       "passwd": {},
       "storage": {},
       "systemd": {}
     }
   }
   ```

   1 Specify the URL of the bootstrap Ignition config file that you hosted.

   When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:

   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM.

   For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```bash
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```
IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the VMs and Templates view.
   b. Right-click the name of your datacenter.
   c. Click New Folder → New VM and Template Folder.
   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

NOTE

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

   a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.
   b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.
   c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.
   d. On the Select a compute resource tab, click the name of your vSphere cluster.
   e. On the Select storage tab, configure the storage options for your VM.
      - Select Thin Provision or Thick Provision, based on your storage preferences.
- Select the datastore that you specified in your `install-config.yaml` file.

f. On the **Select network** tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RH COS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. After the template deploys, deploy a VM for a machine in the cluster.

a. Right-click the template name and click **Clone → Clone to Virtual Machine**

b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as `control-plane-0` or `compute-1`.

c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

e. Optional: On the **Select storage** tab, customize the storage options.

f. On the **Select clone options**, select **Customize this virtual machine’s hardware**

g. On the **Customize hardware** tab, click **VM Options → Advanced**.

- Optional: Override default DHCP networking in vSphere. To enable static IP networking:

  i. Set your static IP configuration:

     ```
     $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
     nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
     ```

     **Example command**

     ```
     $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
     nameserver=8.8.8.8"
     ```

  ii. Set the `guestinfo.afterburn.initrd.network-kargs` property before booting a VM from an OVA in vSphere:

     ```
     $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-
     kargs=${IPCFG}"
     ```

- Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list, select **High**. Ensure that your VM’s CPU and memory reservation have the following values:
- Memory reservation value must be equal to its configured memory size.
- CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

- Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:
  - guestinfo.ignition.config.data: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - guestinfo.ignition.config.data.encoding: Specify base64.
  - disk.EnableUUID: Specify TRUE.

h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

9. Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

15.7.13. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

You can create more compute machines for your cluster that uses user-provisioned infrastructure on VMware vSphere.

**Prerequisites**

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

**Procedure**

1. After the template deploys, deploy a VM for a machine in the cluster.
   - Right-click the template’s name and click Clone → Clone to Virtual Machine
   - On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as compute-1.
   - On the Select a name and folder tab, select the name of the folder that you created for the cluster.
   - On the Select a compute resource tab, select the name of a host in your datacenter.
e. Optional: On the Select storage tab, customize the storage options.

f. On the Select clone options, select Customize this virtual machine’s hardware.

g. On the Customize hardware tab, click VM Options → Advanced.
   - From the Latency Sensitivity list, select High.
   - Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:
     - guestinfo.ignition.config.data: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
     - guestinfo.ignition.config.data.encoding: Specify base64.
     - disk.EnableUUID: Specify TRUE.

h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under Add network adapter if there are multiple networks available.

i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

15.7.14. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

  IMPORTANT

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.
OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

### Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

   ```bash
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ... 
   $ ls $HOME/clusterconfig/openshift/  
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a `MachineConfig` object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

   ```yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
   name: 98-var-partition
   spec:
     config:
       ignition:
         version: 3.2.0
     storage:
       disks:
   ```
The storage device name of the disk that you want to partition.

When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

The size of the data partition in mebibytes.

The name of the mount unit must match the directory specified in the Where= directive. For example, for a filesystem mounted on /var/lib/containers, the unit must be named var-lib-containers.mount.

The prjquota mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth  bootstrap.ign  master.ign  metadata.json  worker.ign
```
Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

15.7.15. Updating the bootloader using bootupd

To update the bootloader by using **bootupd**, you must either install **bootupd** on RHCOS machines manually or provide a machine config with the enabled **systemd** unit. Unlike **grubby** or other bootloader tools, **bootupd** does not manage kernel space configuration such as passing kernel arguments.

After you have installed **bootupd**, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

**Manual install method**

You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:

   ```bash
   # bootupctl status
   ``

   **Example output**

   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version

2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

   ```bash
   # bootupctl adopt-and-update
   ``

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```bash
   # bootupctl update
   ``

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

**Machine config method**

Another way to enable **bootupd** is by providing a machine config.
• Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

**Example output**

```yaml
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes

        [Install]
        WantedBy=multi-user.target
```

### 15.7.16. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.

**Procedure**

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Example output**

```text
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.20.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```
The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.

15.7.17. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   `system:admin`

15.7.18. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**
1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  63m  v1.20.0
master-1  Ready     master  63m  v1.20.0
master-2  Ready     master  64m  v1.20.0
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME        AGE   REQUESTOR                                   CONDITION
csr-mddf5   20m   system:node:master-01.example.com   Approved,Issued
csr-z5rln   16m   system:node:worker-21.example.com   Approved,Issued
```

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine approver** if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name> ①
  ① <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```bash
$ oc get csr
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the `Pending` status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name> ①
  ① <csr_name> is the name of a CSR from the list of current CSRs.
  ```
OpenShift Container Platform 4.7 Installing

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
6. After all client and server CSRs have been approved, the machines have the Ready status.
Verify this by running the following command:
$ oc get nodes

Example output
NAME
master-0
master-1
master-2
worker-0
worker-1

STATUS ROLES AGE VERSION
Ready master 73m v1.20.0
Ready master 73m v1.20.0
Ready master 74m v1.20.0
Ready worker 11m v1.20.0
Ready worker 11m v1.20.0

NOTE
It can take a few minutes after approval of the server CSRs for the machines to
transition to the Ready status.
Additional information
For more information on CSRs, see Certificate Signing Requests .

15.7.19. Initial Operator configuration
After the control plane initializes, you must immediately configure some Operators so that they all
become available.
Prerequisites
Your control plane has initialized.
Procedure
1. Watch the cluster components come online:
$ watch -n5 oc get clusteroperators

Example output
NAME
SINCE
authentication
baremetal
cloud-credential
cluster-autoscaler
config-operator

2432

VERSION AVAILABLE PROGRESSING DEGRADED

6h39m


2. Configure the Operators that are not available.

## 15.7.19.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

### Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json
  -p '[$("op": "add", "path": "/spec/disableAllDefaultSources", "value": true)]'
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

## 15.7.19.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the *Recreate* rollout strategy during upgrades.

### 15.7.19.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports *ReadWriteOnce* access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, *ReadWriteMany* access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```
Example output

No resources found in openshift-image-registry namespace

NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   Example output

   storage:
   pvc:
   claim:

   Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

   Example output

   NAME             VERSION                              AVAILABLE   PROGRESSING   DEGRADED   SINCE   MESSAGE
   image-registry   4.7                                  True        False         False      6h50m

15.7.19.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  {"storage":{"emptyDir":{}}}'}
WARNING
Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

15.7.19.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only 1 replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": "rolloutStrategy":"Recreate","replicas":1}'}
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   ① A unique name that represents the `PersistentVolumeClaim` object.
The namespace for the PersistentVolumeClaim object, which is openshift-image-registry.

The access mode of the persistent volume claim. With ReadWriteOnce, the volume can be mounted with read and write permissions by a single node.

The size of the persistent volume claim.

b. Create the PersistentVolumeClaim object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

Example output

```yaml
storage:
  pvc:
    claim: 1
```

Creating a custom PVC allows you to leave the claim field blank for the default automatic creation of an image-registry-storage PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring registry storage for VMware vSphere.

15.7.20. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h56m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.7.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>Running</td>
<td></td>
<td>1</td>
<td>9m</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>3m</td>
<td></td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>1m</td>
<td></td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>2m</td>
<td></td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td></td>
</tr>
<tr>
<td>Running</td>
<td></td>
<td>0</td>
<td>5m</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace>
   ```

   **Specify the pod name and namespace, as shown in the output of the previous command.**

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.
a. All the worker nodes are restarted. To monitor the process, enter the following command:

```
$ oc get nodes -w
```

**NOTE**

If you have additional machine types such as infrastructure nodes, repeat the process for these types.

4. Register your cluster on the [Cluster registration](#) page.

You can add extra compute machines after the cluster installation is completed by following [Adding compute machines to vSphere](#).

### 15.7.21. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See [Snapshot Limitations](#) for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 15.7.22. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use [subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

### 15.7.23. Next steps

- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the [must-gather](#) tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

### 15.8. UNINSTALLING A CLUSTER ON VMC

You can remove a cluster installed on VMware vSphere infrastructure that you deployed to VMware Cloud (VMC) on AWS by using installer-provisioned infrastructure.

#### 15.8.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

**Prerequisites**

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

**Procedure**

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```bash
   $ ./openshift-install destroy cluster --dir <installation_directory> --log-level info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2. To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.
CHAPTER 16. INSTALLING ON ANY PLATFORM

16.1. INSTALLING A CLUSTER ON ANY PLATFORM

In OpenShift Container Platform version 4.7, you can install a cluster on any infrastructure that you provision, including virtualization and cloud environments.

IMPORTANT
Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you attempt to install an OpenShift Container Platform cluster in virtualized or cloud environments.

16.1.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

NOTE
Be sure to also review this site list if you are configuring a proxy.

16.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.7, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT
If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

16.1.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

16.1.3.1. Required machines
The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines.

**NOTE**

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

### 16.1.3.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. The machines are configured with static IP addresses. No DHCP server is required. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server.

### 16.1.3.3. IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

### 16.1.3.4. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

**Table 16.1. Minimum resource requirements**

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>---------</td>
<td>------------------</td>
<td>---------</td>
<td>-------------</td>
<td>---------</td>
<td>------</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

### 16.1.3.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 16.1.4. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

#### Prerequisites

- Review the [OpenShift Container Platform 4.x Tested Integrations](#) page before you create the supporting infrastructure for your cluster.

#### Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Provision the required load balancers.
4. Configure the ports for your machines.
5. Configure DNS.

#### 16.1.4.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

Ensure that the machines have persistent IP addresses and host names.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API
servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

### Table 16.2. All machines to all machines

**Network topology requirements**

The infrastructure that you provision for your cluster must meet the following network topology requirements.
IMPORTANT

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 16.5. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.
2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Table 16.6. Application Ingress load balancer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td>443</td>
</tr>
<tr>
<td>80</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

**Additional resources**

- [Configuring chrony time service](#)

**16.1.4.2. User-provisioned DNS requirements**

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is
the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>..<base_domain>`.

Table 16.7. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td><code>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add a wildcard DNS A/AAAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td><code>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td><code>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td><code>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.
The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

Example 16.1. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
;
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
;
; The api identifies the IP of your load balancer.
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5
;
; The wildcard also identifies the load balancer.
*.apps.ocp4 IN A 192.168.1.5
;
; Create an entry for the bootstrap host.
bootstrap.ocp4 IN A 192.168.1.96
;
; Create entries for the master hosts.
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
master2.ocp4 IN A 192.168.1.99
;
; Create entries for the worker hosts.
worker0.ocp4 IN A 192.168.1.11
worker1.ocp4 IN A 192.168.1.17
;
;EOF
```

The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 16.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks)
```
16.1.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

**IMPORTANT**

Do not skip this procedure in production environments where disaster recovery and debugging is required.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" \
   -f <path>/<file_name>  
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   $ eval "$(ssh-agent -s)"

   Example output

   Agent pid 31874

   NOTE

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

16.1.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

16.1.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.7. Download and install the new version of oc.

16.1.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Linux Client entry and save the file.

4. Unpack the archive:
$ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

$ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

16.1.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

C:\> path

After you install the OpenShift CLI, it is available using the oc command:

C:\> oc <command>

16.1.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.7 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

$ echo $PATH

$ oc <command>
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ echo $PATH
```

$ oc <command>

# 16.1.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

**IMPORTANT**

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

**NOTE**

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

# 16.1.8.1. Sample install-config.yaml file for IBM Z

# 16.1.8.2. Sample install-config.yaml file for other platforms

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the hyperthreading parameter has no effect.

**IMPORTANT**

If you disable hyperthreading, whether in the BIOS or in the install-config.yaml, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.
The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \((2^{32} - 23) - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to `none`. You cannot provide additional platform configuration variables for IBM Z infrastructure.

WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to `none`, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

16.1.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE
The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
   ```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

16.1.9. Configuring a three-node cluster

You can optionally install and run three-node clusters in OpenShift Container Platform with no workers. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for development, production, and testing.

Procedure

- Edit the install-config.yaml file to set the number of compute replicas, which are also known as worker replicas, to 0, as shown in the following compute stanza:
16.10.1. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.
WARNING
If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

IMPORTANT
When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>  
   ```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │       └── kubecfg
   │       └── bootstrap.ign
   │   ├── master.ign
   │   └── metadata.json
   │   └── worker.ign
   ```

16.1.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.
To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

**NOTE**

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments:** You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the `APPEND` parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special `coreos.inst.*` arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- **Ignition configs:** OpenShift Container Platform Ignition config files (*.ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the `coreos-installer` to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- **coreos-installer:** You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the `coreos-installer` command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

**NOTE**

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

### 16.1.11.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image

Before you install a cluster on infrastructure that you provision, you must create RHCOS machines for it to use. You can use an ISO image to create the machines.

**Prerequisites**

- Obtain the Ignition config files for your cluster.
Have access to an HTTP server that can be accessed from your computer, and from the machines that you create.

Procedure

1. Upload the control plane, compute, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

   ISO file names resemble the following example:

   `rhcos-<version>-live.<architecture>.iso`

3. Use the ISO to start the RHCOS installation. Use one of the following installation options:

   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection via a LOM interface.

4. Boot the ISO image. You can interrupt the installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command instead of adding kernel arguments. If you run the live installer without options or interruption, the installer boots up to a shell prompt on the live system, ready for you to install RHCOS to disk.

5. Review the Advanced RHCOS installation reference section for different ways of configuring features, such as networking and disk partitions, before running the `coreos-installer`.

6. Run the `coreos-installer` command. At a minimum, you must identify the Ignition config file location for your node type, and the location of the disk you are installing to. Here is an example:

   `$ sudo coreos-installer install
    --ignition-url=https://host/worker.ign /dev/sda`

7. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

8. Continue to create the other machines for your cluster.
IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

16.1.11.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting

Before you install a cluster that uses manually-provisioned RHCOS nodes, such as bare metal, you must create RHCOS machines for it to use. You can use PXE or iPXE booting to create the machines.

Prerequisites

- Obtain the Ignition config files for your cluster.
- Configure suitable PXE or iPXE infrastructure.
- Have access to an HTTP server that you can access from your computer.

Procedure

1. Upload the master, worker, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS kernel, initramfs and rootfs files from the RHCOS image mirror page.

IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described below for this procedure. RHCOS qcow2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: rhcos-<version>-live-kernel-<architecture>
- initramfs: rhcos-<version>-live-initramfs.<architecture>.img
- rootfs: rhcos-<version>-live-rootfs.<architecture>.img

3. Upload the additional files that are required for your booting method:

- For traditional PXE, upload the kernel and initramfs files to your TFTP server and the rootfs file to your HTTP server.
For iPXE, upload the kernel, initramfs, and rootfs files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

4. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

5. Configure PXE or iPXE installation for the RHCOS images.

Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot

KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
<architecture>.img coreos.live.roots_url=http://<HTTP_server>/rhcos-<version>-live-
rootsfs.<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
```

1. Specify the location of the live kernel file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the initramfs file, the `coreos.live.roots_url` parameter value is the location of the rootfs file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the `APPEND` line to configure networking or other boot options.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=ttv0` `console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?.

- For iPXE:

```
kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
```
<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign

initrd --name main http://<HTTP_server>/rhcos<version>-live-initramfs.
<architecture>.img

1 Specify locations of the RHCOS files that you uploaded to your HTTP server. The kernel parameter value is the location of the kernel file, the initrd=main argument is needed for booting on UEFI systems, the coreos.live.rootfs_url parameter value is the location of the rootfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file.

2 If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3 Specify the location of the initramfs file that you uploaded to your HTTP server.

NOTE
This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more console= arguments to the kernel line. For example, add console=tty0 console=ttyS0 to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?

6. If you use PXE UEFI, perform the following actions:

   a. Provide the shimx64.efi and grubx64.efi EFI binaries and the grub.cfg file that are required for booting the system.

      • Extract the necessary EFI binaries by mounting the RHCOS ISO to your host and then mounting the images/efiboot.img file to your host:

        $ mkdir -p /mnt/iso

        $ mkdir -p /mnt/efiboot

        $ mount -o loop rhcos-installer.x86_64.iso /mnt/iso

        $ mount -o loop,ro /mnt/iso/images/efiboot.img /mnt/efiboot

      • From the efiboot.img mount point, copy the EFI/redhat/shimx64.efi and EFI/redhat/grubx64.efi files to your TFTP server:

        $ cp /mnt/efiboot/EFI/redhat/shimx64.efi .

        $ cp /mnt/efiboot/EFI/redhat/grubx64.efi .

        $ umount /mnt/efiboot
Copy the `EFI/redhat/grub.cfg` file that is included in the RHCOS ISO to your TFTP server.

b. Edit the `grub.cfg` file to include arguments similar to the following:

```bash
menuentry 'Install Red Hat Enterprise Linux CoreOS' --class fedora --class gnu-linux --class gnu --class os {
  linuxefi rhcos-<version>-live-kernel-<architecture> coreos.inst.install_dev=/dev/sda
  <architecture>.img coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  initrdefi rhcos-<version>-live-initramfs.<architecture>.img
}
```

where:

- `rhcos-<version>-live-kernel-<architecture>`
  - Specifies the kernel file that you uploaded to your TFTP server.

  - Specifies the location of the live rootfs image that you uploaded to your HTTP server.

- `http://<HTTP_server>/bootstrap.ign`
  - Specifies the location of the bootstrap Ignition config file that you uploaded to your HTTP server.

- `rhcos-<version>-live-initramfs.<architecture>.img`
  - Specifies the location of the initramfs file that you uploaded to your TFTP server.

**NOTE**

For more information on how to configure a PXE server for UEFI boot, see the Red Hat Knowledgebase article: [How to configure/setup a PXE server for UEFI boot for Red Hat Enterprise Linux?](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/7/html-single/creating_a_red_hat_enterprise_linux_coreos_cluster/chapter-16).

7. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

### 16.1.11.3. Advanced Red Hat Enterprise Linux CoreOS (RHCOS) installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

16.1.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

Procedure

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

   ```
   $ coreos-installer install --copy-network \
      --ignition-url=http://host/worker.ign /dev/sda
   ```

   **IMPORTANT**

   The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

16.1.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.
However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- **Create separate partitions:** For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, a separate partition, but not both.

  **IMPORTANT**

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retain existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

### 16.1.11.3.2.1. Creating a separate `/var` partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- **/var/lib/containers:** Holds container-related content that can grow as more images and containers are added to a system.

- **/var/lib/etcd:** Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- **/var:** Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

### Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

   ```
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   ```
Create a MachineConfig object and add it to a file in the openshift directory. For example, name the file 98-var-partition.yaml, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
        - device: /dev/<device_name>
      partitions:
        - label: var
          startMiB: <partition_start_offset>
          sizeMiB: <partition_size>
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
  systemd:
    units:
      - name: var.mount
        enabled: true
        contents: |
          [Unit]
          Before=local-fs.target
          [Mount]
          What=/dev/disk/by-partlabel/var
          Where=/var
          Options=defaults,prjquota
          [Install]
          WantedBy=local-fs.target
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
4. The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-

5. The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the ISO or PXE manual installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

16.1.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command line that causes the installer to maintain one or more existing partitions. For a PXE installation, you can **APPEND coreos.inst.*** options to preserve partitions.

Saved partitions might be partitions from an existing OpenShift Container Platform system that has data partitions that you want to keep. Here are a few tips:

- If you save existing partitions, and those partitions do not leave enough space for RHCOS, installation will fail without damaging the saved partitions.
- Identify the disk partitions you want to keep either by partition label or by number.

**For an ISO installation**

This example preserves any partition in which the partition label begins with `data` (`data*`):

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partlabel 'data*' /dev/sda
```

The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partindex 5- /dev/sda
```
In the previous examples where partition saving is used, coreos-installer recreates the partition immediately.

**For a PXE installation**

This `APPEND` option preserves any partition in which the partition label begins with ‘data’ (`data*`):

```
coreos.inst.save_partlabel=data*
```

This `APPEND` option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This `APPEND` option preserves partition 6:

```
coreos.inst.save_partindex=6
```

---

**16.1.11.3.3. Identifying Ignition configs**

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config**: Every manual RHCOS installation needs to pass one of the Ignition config files generated by openshift-installer, such as bootstrap.ign, master.ign and worker.ign, to carry out the installation.

  IMPORTANT

  It is not recommended to modify these files.

  For PXE installations, you pass the Ignition configs on the `APPEND` line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the coreos-installer command line with the `--ignition-url=` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config**: This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be performed once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

  For PXE or ISO boots, you can create the Ignition config and `APPEND` the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` `ignition.platform.id=metal` or the `ignition.config.url` option will be ignored.

---

**16.1.11.3.3.1. Embedding an Ignition config in the RHCOS ISO**

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

**Procedure**

1. Download the coreos-installer binary from the following image mirror page: https://mirror.openshift.com/pub/openshift-v4/clients/coreos-installer/latest/.
2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as `/mnt`:

```
# cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
# chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
```

3. Run the following command to embed the Ignition config into the ISO:

```
# ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign \  
   /mnt/rhcos-<version>-live.x86_64.iso
```

You can now use that ISO to install RHCOS using the specified live install Ignition config.

**IMPORTANT**

Using `coreos-installer iso ignition embed` to embed a file generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

```
# ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
```

```
# diff -s bootstrap.ign mybootstrap.ign
```

**Example output**

Files bootstrap.ign and mybootstrap.ign are identical

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

```
# ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
```

You can now embed another Ignition config into the ISO or use the ISO in its pristine state.

### 16.1.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

**Routing and bonding options at RHCOS boot prompt**

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node’s networking. If no networking arguments are used, the installation defaults to using DHCP.

**IMPORTANT**

When adding networking arguments, you must also add the `rd.neednet=1` kernel argument.
The following table describes how to use `ip=`, `nameserver=`, and `bond=` kernel arguments for live ISO installs.

**NOTE**
Ordering is important when adding kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

**Routing and bonding options for ISO**

The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

<table>
<thead>
<tr>

<tr>
<td>Optional: You can configure routes to additional networks by setting an <code>rd.route=</code> value. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</td>
<td>To configure the default gateway: <code>ip=:10.10.10.254:::</code> To configure the route for the additional network: <code>rd.route=20.20.20.0/24:20.20.20.254:enp2s0</code></td>
</tr>
<tr>
<td>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used.</td>
<td><code>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code> <code>ip=:core0.example.com:enp2s0:none</code></td>
</tr>
</tbody>
</table>
You can combine DHCP and static IP configurations on systems with multiple network interfaces.

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can provide multiple DNS servers by adding a nameserver= entry for each server.</td>
</tr>
<tr>
<td>Optional: You can configure VLANs on individual interfaces by using the vlan= parameter.</td>
</tr>
</tbody>
</table>

### Examples

| ip=enp1s0:dhcp  
| ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none |

Optional: Bonding multiple network interfaces to a single interface is supported using the bond= option. In these two examples:

- The syntax for configuring a bonded interface is:
  
  bond=name[:network_interfaces] [:options]

- `name` is the bonding device name (bond0), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and `options` is a comma-separated list of bonding options. Enter modinfo bonding to see available options.

- When you create a bonded interface using bond=, you must specify how the IP address is assigned and other information for the bonded interface.

### Examples

| nameserver=1.1.1.1  
| nameserver=8.8.8.8 |

To configure a VLAN on a network interface and use a static IP address:

| ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none  
| vlan=enp2s0.100:enp2s0 |

To configure a VLAN on a network interface and to use DHCP:

| ip=enp2s0.100:dhcp  
<p>| vlan=enp2s0.100:enp2s0 |</p>
<table>
<thead>
<tr>

</tr>
<tr>
<td>The syntax for configuring a team interface is: <strong>team</strong>=<strong>name[::network_interfaces]</strong> name is the team device name (<strong>team0</strong>) and network_interfaces represents a comma-separated list of physical (ethernet) interfaces (<strong>em1, em2</strong>).</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this [Red Hat Knowledgebase Article](#).

### 16.1.11.4. Updating the bootloader using bootupd

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.
Manual install method

You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:

   ```
   # bootupctl status
   ``

   **Example output**

   ```
   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version
   ```

2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

   ```
   # bootupctl adopt-and-update
   ``

   **Example output**

   ```
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```
   # bootupctl update
   ``

   **Example output**

   ```
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

Machine config method

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

   **Example output**

   ```
   variant: rhcos
   version: 1.1.0
   systemd:
   units:
   - name: custom-bootupd-auto.service
     enabled: true
     contents:
     [Unit]
     Description=Bootupd automatic update
     [Service]
     ExecStart=/usr/bin/bootupctl update
     RemainAfterExit=yes
   ```
16.1.12. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Create the required infrastructure for the cluster.
- You obtained the installation program and generated the Ignition config files for your cluster.
- You used the Ignition config files to create RHCOS machines for your cluster.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 
   --log-level=info
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.20.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the machine itself.

16.1.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the
correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ``

   Example output

   ```
   system:admin
   ```

16.1.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ``

   Example output

   ```
   NAME     STATUS   ROLES   AGE   VERSION
   master-0 Ready master 63m  v1.20.0
   master-1 Ready master 63m  v1.20.0
   master-2 Ready master 64m  v1.20.0
   ``

   The output lists all of the machines that you created.
1. The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved, Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved, Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   ```
   NOTE
   ```

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

   ```
   NOTE
   ```

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

   - To approve them individually, run the following command for each valid CSR:

     ```
     $ oc adm certificate approve <csr_name> 1
     ```

     1. `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:
Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```bash
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>
NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

16.1.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>

</table>
2. Configure the Operators that are not available.

16.1.15.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

16.1.15.2. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as `Removed`. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from `Removed` to `Managed`.

NOTE

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

"Image Registry has been removed. `ImageStreamTags`, `BuildConfigs` and `DeploymentConfigs` which reference `ImageStreamTags` may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

16.1.15.3. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

16.1.15.3.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on IBM Z.
- Persistent storage provisioned for your cluster.

**IMPORTANT**

OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   Example output
   No resources found in openshift-image-registry namespace
   
   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:
Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

```bash
$ oc get clusteroperator image-registry
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```bash
$ oc edit configs.imageregistry/operator.openshift.io
```

Then, change the line

```json
managementState: Removed
```

to

```json
managementState: Managed
```

16.1.15.3.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

```bash
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir":{}}}}'
```
WARNING
Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 16.1.15.3.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1})'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

### 16.1.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:
$ watch -n5 oc get clusteroperators

Example output

<table>

</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

$ ./openshift-install --dir <installation_directory> wait-for install-complete

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   
a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

   ```
   NAMESPACE                         NAME                                            READY   STATUS
   RESTARTS   AGE
   openshift-apiserver-operator     openshift-apiserver-operator-85cb746d55-zqhs8   1/1     Running     1          9m
   openshift-apiserver               apiserver-67b9g                                 1/1     Running     0          3m
   openshift-apiserver               apiserver-ljcmx                                 1/1     Running     0          1m
   openshift-apiserver               apiserver-z25h4                                 1/1     Running     0          2m
   openshift-authentication-operator authentication-operator-69d5d8bf84-vh2n8        1/1     Running     0          5m
   ...  
   ```

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace>  
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation configuration documentation for more information.
a. All the worker nodes are restarted. To monitor the process, enter the following command:

```
$ oc get nodes -w
```

**NOTE**

If you have additional machine types such as infrastructure nodes, repeat the process for these types.

16.1.17. **Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.7, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager**.

After you confirm that your **OpenShift Cluster Manager** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, **use subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See **About remote health monitoring** for more information about the Telemetry service

16.1.18. **Next steps**

- **Customize your cluster**.
- If necessary, you can **opt out of remote health reporting**.
- **Set up your registry and configure registry storage**.

OpenShift Container Platform 4.7 Installing

2488
CHAPTER 17. INSTALLATION CONFIGURATION

17.1. CUSTOMIZING NODES

Although directly making changes to OpenShift Container Platform nodes is discouraged, there are times when it is necessary to implement a required low-level security, redundancy, networking, or performance feature. Direct changes to OpenShift Container Platform nodes can be done by:

- Creating machine configs that are included in manifest files to start up a cluster during openshift-install.
- Creating machine configs that are passed to running OpenShift Container Platform nodes via the Machine Config Operator.
- Creating an Ignition config that is passed to coreos-installer when installing bare-metal nodes.

The following sections describe features that you might want to configure on your nodes in this way.

17.1.1. Adding day-1 kernel arguments

Although it is often preferable to modify kernel arguments as a day-2 activity, you might want to add kernel arguments to all master or worker nodes during initial cluster installation. Here are some reasons you might want to add kernel arguments during cluster installation so they take effect before the systems first boot up:

- You want to disable a feature, such as SELinux, so it has no impact on the systems when they first come up.

**WARNING**

Disabling SELinux on RHCOS is not supported.

- You need to do some low-level network configuration before the systems start.

To add kernel arguments to master or worker nodes, you can create a MachineConfig object and inject that object into the set of manifest files used by Ignition during cluster setup.

For a listing of arguments you can pass to a RHEL 8 kernel at boot time, see Kernel.org kernel parameters. It is best to only add kernel arguments with this procedure if they are needed to complete the initial OpenShift Container Platform installation.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   ./openshift-install create manifests --dir <installation_directory>
   ```
2. Decide if you want to add kernel arguments to worker or control plane nodes (also known as the master nodes).

3. In the openshift directory, create a file (for example, 99-openshift-machineconfig-master-kargs.yaml) to define a MachineConfig object to add the kernel settings. This example adds a loglevel=7 kernel argument to control plane nodes:

```
$ cat << EOF > 99-openshift-machineconfig-master-kargs.yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: master
  name: 99-openshift-machineconfig-master-kargs
spec:
  kernelArguments:
  - loglevel=7
EOF
```

You can change master to worker to add kernel arguments to worker nodes instead. Create a separate YAML file to add to both master and worker nodes.

You can now continue on to create the cluster.

17.1.2. Adding kernel modules to nodes

For most common hardware, the Linux kernel includes the device driver modules needed to use that hardware when the computer starts up. For some hardware, however, modules are not available in Linux. Therefore, you must find a way to provide those modules to each host computer. This procedure describes how to do that for nodes in an OpenShift Container Platform cluster.

When a kernel module is first deployed by following these instructions, the module is made available for the current kernel. If a new kernel is installed, the kmods-via-containers software will rebuild and deploy the module so a compatible version of that module is available with the new kernel.

The way that this feature is able to keep the module up to date on each node is by:

- Adding a systemd service to each node that starts at boot time to detect if a new kernel has been installed and
- If a new kernel is detected, the service rebuilds the module and installs it to the kernel

For information on the software needed for this procedure, see the kmods-via-containers github site.

A few important issues to keep in mind:

- This procedure is Technology Preview.
- Software tools and examples are not yet available in official RPM form and can only be obtained for now from unofficial github.com sites noted in the procedure.
- Third-party kernel modules you might add through these procedures are not supported by Red Hat.
- In this procedure, the software needed to build your kernel modules is deployed in a RHEL 8 container. Keep in mind that modules are rebuilt automatically on each node when that node
gets a new kernel. For that reason, each node needs access to a **yum** repository that contains the kernel and related packages needed to rebuild the module. That content is best provided with a valid RHEL subscription.

17.1.2.1. Building and testing the kernel module container

Before deploying kernel modules to your OpenShift Container Platform cluster, you can test the process on a separate RHEL system. Gather the kernel module’s source code, the KVC framework, and the kmod-via-containers software. Then build and test the module. To do that on a RHEL 8 system, do the following:

**Procedure**

1. Register a RHEL 8 system:
   ```bash
   # subscription-manager register
   ```

2. Attach a subscription to the RHEL 8 system:
   ```bash
   # subscription-manager attach --auto
   ```

3. Install software that is required to build the software and container:
   ```bash
   # yum install podman make git -y
   ```

4. Clone the **kmod-via-containers** repository:
   a. Create a folder for the repository:
      ```bash
      $ mkdir kmods; cd kmods
      ```
   b. Clone the repository:
      ```bash
      $ git clone https://github.com/kmods-via-containers/kmods-via-containers
      ```

5. Install a KVC framework instance on your RHEL 8 build host to test the module. This adds a **kmods-via-container** systemd service and loads it:
   a. Change to the **kmod-via-containers** directory:
      ```bash
      $ cd kmods-via-containers/
      ```
   b. Install the KVC framework instance:
      ```bash
      $ sudo make install
      ```
   c. Reload the systemd manager configuration:
      ```bash
      $ sudo systemctl daemon-reload
      ```

6. Get the kernel module source code. The source code might be used to build a third-party module that you do not have control over, but is supplied by others. You will need content similar to the content shown in the **kvc-simple-kmod** example that can be cloned to your
system as follows:

```bash
$ cd .. ; git clone https://github.com/kmods-via-containers/kvc-simple-kmod
```

7. Edit the configuration file, `simple-kmod.conf` file, in this example, and change the name of the Dockerfile to `Dockerfile.rhel`:

   a. Change to the `kvc-simple-kmod` directory:

```bash
$ cd kvc-simple-kmod
```

   b. Rename the Dockerfile:

```bash
$ cat simple-kmod.conf
```

Example Dockerfile

```bash
KMOD_CONTAINER_BUILD_CONTEXT="https://github.com/kmods-via-containers/kvc-simple-kmod.git"
KMOD_CONTAINER_BUILD_FILE=Dockerfile.rhel
KMOD_SOFTWARE_VERSION=dd1a7d4
KMOD_NAMES="simple-kmod simple-procfs-kmod"
```

8. Create an instance of `kmods-via-containers@.service` for your kernel module, `simple-kmod` in this example:

```bash
$ sudo make install
```

9. Enable the `kmods-via-containers@.service` instance:

```bash
$ sudo kmods-via-containers build simple-kmod $(uname -r)
```

10. Enable and start the systemd service:

```bash
$ sudo systemctl enable kmods-via-containers@simple-kmod.service --now
```

   a. Review the service status:

```bash
$ sudo systemctl status kmods-via-containers@simple-kmod.service
```

Example output

```bash
● kmods-via-containers@simple-kmod.service - Kmods Via Containers - simple-kmod
   Loaded: loaded (/etc/systemd/system/kmods-via-containers@.service; enabled; vendor preset: disabled)
   Active: active (exited) since Sun 2020-01-12 23:49:49 EST; 5s ago...
```

11. To confirm that the kernel modules are loaded, use the `lsmod` command to list the modules:

```bash
$ lsmod | grep simple_
```

Example output
12. Optional. Use other methods to check that the simple-kmod example is working:

- Look for a "Hello world" message in the kernel ring buffer with dmesg:

  ```
  $ dmesg | grep 'Hello world'
  
  Example output
  [ 6420.761332] Hello world from simple_kmod.
  ```

- Check the value of simple-procfs-kmod in /proc:

  ```
  $ sudo cat /proc/simple-procfs-kmod
  
  Example output
  simple-procfs-kmod number = 0
  ```

- Run the spkut command to get more information from the module:

  ```
  $ sudo spkut 44
  
  Example output
  KVC: wrapper simple-kmod for 4.18.0-147.3.1.el8_1.x86_64
  Running userspace wrapper using the kernel module container...
  + podman run -i --rm --privileged
  simple-kmod-dd1a7d4:4.18.0-147.3.1.el8_1.x86_64 spkut 44
  simple-procfs-kmod number = 0
  simple-procfs-kmod number = 44
  ```

Going forward, when the system boots this service will check if a new kernel is running. If there is a new kernel, the service builds a new version of the kernel module and then loads it. If the module is already built, it will just load it.

### 17.1.2.2. Provisioning a kernel module to OpenShift Container Platform

Depending on whether or not you must have the kernel module in place when OpenShift Container Platform cluster first boots, you can set up the kernel modules to be deployed in one of two ways:

- **Provision kernel modules at cluster install time (day-1)** You can create the content as a MachineConfig object and provide it to openshift-install by including it with a set of manifest files.

- **Provision kernel modules via Machine Config Operator (day-2)** If you can wait until the cluster is up and running to add your kernel module, you can deploy the kernel module software via the Machine Config Operator (MCO).
In either case, each node needs to be able to get the kernel packages and related software packages at the time that a new kernel is detected. There are a few ways you can set up each node to be able to obtain that content.

- Provide RHEL entitlements to each node.
- Get RHEL entitlements from an existing RHEL host, from the `/etc/pki/entitlement` directory and copy them to the same location as the other files you provide when you build your Ignition config.
- Inside the Dockerfile, add pointers to a `yum` repository containing the kernel and other packages. This must include new kernel packages as they are needed to match newly installed kernels.

### 17.1.2.2.1. Provision kernel modules via a MachineConfig object

By packaging kernel module software with a MachineConfig object, you can deliver that software to worker or master nodes at installation time or via the Machine Config Operator.

First create a base Ignition config that you would like to use. At installation time, the Ignition config will contain the ssh public key to add to the `authorized_keys` file for the `core` user on the cluster. To add the MachineConfig object later via the MCO instead, the SSH public key is not required. For both type, the example simple-kmod service creates a systemd unit file, which requires a `kmods-via-containers@simple-kmod.service`.

**NOTE**

The systemd unit is a workaround for an upstream bug and makes sure that the `kmods-via-containers@simple-kmod.service` gets started on boot:

1. Register a RHEL 8 system:
   ```bash
   # subscription-manager register
   ```
2. Attach a subscription to the RHEL 8 system:
   ```bash
   # subscription-manager attach --auto
   ```
3. Install software needed to build the software:
   ```bash
   # yum install podman make git -y
   ```
4. Create an Ignition config file that creates a systemd unit file:
   a. Create a directory to host the Ignition config file:
      ```bash
      $ mkdir kmods; cd kmods
      ```
   b. Create the Ignition config file that creates a systemd unit file:
      ```bash
      $ cat <<EOF > ./baseconfig.ign
      {
        "ignition": { "version": "3.2.0" },
        "passwd": {
          
      ```
"users": [  
  {  
    "name": "core",  
    "groups": ["sudo"],  
    "sshAuthorizedKeys": [  
      "ssh-rsa AAAA"  
    ]  
  }  
],  
"systemd": {  
  "units": [  
    {  
      "name": "require-kvc-simple-kmod.service",  
      "enabled": true,  
      "contents": "[Unit]
Requires=kmods-via-containers@simple-kmod.service
[Service]
Type=oneshot
ExecStart=/usr/bin/true

[Install]
WantedBy=multi-user.target"
    ]  
  }  
},
EOF

NOTE

You must add your public SSH key to the baseconfig.ign file to use the file during openshift-install. The public SSH key is not needed if you create the MachineConfig object using the MCO.

5. Create a base MCO YAML snippet that uses the following configuration:

```
$ cat <<EOF > mc-base.yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 10-kvc-simple-kmod
spec:
  config:
EOF
```

NOTE

The mc-base.yaml is set to deploy the kernel module on worker nodes. To deploy on master nodes, change the role from worker to master. To do both, you could repeat the whole procedure using different file names for the two types of deployments.

6. Get the kmods-via-containers software:

   a. Clone the kmods-via-containers repository:

      ```
      $ git clone https://github.com/kmods-via-containers/kmods-via-containers
      ```
b. Clone the `kvc-simple-kmod` repository:

```
$ git clone https://github.com/kmods-via-containers/kvc-simple-kmod
```

7. Get your module software. In this example, `kvc-simple-kmod` is used:

8. Create a fakeroot directory and populate it with files that you want to deliver via Ignition, using the repositories cloned earlier:

   a. Create the directory:

   ```
   $ FAKEROOT=$(mktemp -d)
   ```

   b. Change to the `kmod-via-containers` directory:

   ```
   $ cd kmods-via-containers
   ```

   c. Install the KVC framework instance:

   ```
   $ make install DESTDIR=${FAKEROOT}/usr/local CONFDIR=${FAKEROOT}/etc/
   ```

   d. Change to the `kvc-simple-kmod` directory:

   ```
   $ cd ../kvc-simple-kmod
   ```

   e. Create the instance:

   ```
   $ make install DESTDIR=${FAKEROOT}/usr/local CONFDIR=${FAKEROOT}/etc/
   ```

9. Get a tool called `filetranspiler` and dependent software:

```
$ cd .. ; sudo yum install -y python3
    git clone https://github.com/ashcrow/filetranspiler.git
```

10. Generate a final machine config YAML (`mc.yaml`) and have it include the base Ignition config, base machine config, and the fakeroot directory with files you would like to deliver:

```
$ ./filetranspiler/filetranspile -i ./baseconfig.ign \
   -f ${FAKEROOT} --format=yaml --dereference-symlinks \
   | sed 's/^/     /' | (cat mc-base.yaml -) > 99-simple-kmod.yaml
```

11. If the cluster is not up yet, generate manifest files and add this file to the `openshift` directory. If the cluster is already running, apply the file as follows:

```
$ oc create -f 99-simple-kmod.yaml
```

   Your nodes will start the `kmods-via-containers@simple-kmod.service` service and the kernel modules will be loaded.

12. To confirm that the kernel modules are loaded, you can log in to a node (using `oc debug node/<openshift-node>`, then `chroot /host`). To list the modules, use the `lsmod` command:

```
$ lsmod | grep simple_
```
17.1.3. Encrypting disks during installation

You can enable encryption for the boot disks on the control plane and compute nodes at installation time. OpenShift Container Platform supports the Trusted Platform Module (TPM) v2 and Tang encryption modes.

- **TPM v2:** This is the preferred mode. TPM v2 stores passphrases in a secure cryptoprocessor contained within a server. You can use this mode to prevent the boot disk data on a cluster node from being decrypted if the disk is removed from the server.

- **Tang:** Tang and Clevis are server and client components that enable network-bound disk encryption (NBDE). You can bind the boot disk data on your cluster nodes to a Tang server. This prevents the data from being decrypted unless the nodes are on a secure network where the Tang server can be accessed. Clevis is an automated decryption framework that is used to implement the decryption on the client side.

**IMPORTANT**

The use of Tang encryption mode to encrypt your disks is only supported for bare metal and vSphere installations on user-provisioned infrastructure.

When the TPM v2 or Tang encryption modes are enabled, the RHCOS boot disks are encrypted using the LUKS2 format.

This feature:

- Is available for installer-provisioned infrastructure and user-provisioned infrastructure deployments
- Is supported on Red Hat Enterprise Linux CoreOS (RHCOS) systems only
- Sets up disk encryption during the manifest installation phase so all data written to disk, from first boot forward, is encrypted
- Requires no user intervention for providing passphrases
- Uses AES-256-CBC encryption

Follow one of the two procedures to enable disk encryption for the nodes in your cluster.

17.1.3.1. Enabling TPM v2 disk encryption

Use the following procedure to enable TPM v2 mode disk encryption during an OpenShift Container Platform installation.
**NOTE**

On previous versions of RHCOS, disk encryption was configured by specifying `/etc/clevis.json` in the Ignition config. That file is not supported in clusters created with OpenShift Container Platform 4.7 or above, and the LUKS device should be configured directly via the Ignition `luks` section.

**Prerequisites**

- You have downloaded the OpenShift Container Platform installation program on your installation node.

**Procedure**

1. Check to see if TPM v2 encryption needs to be enabled in the BIOS on each node. This is required on most Dell systems. Check the manual for your computer.

2. On your installation node, change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory> ①
   
   Replace `<installation_directory>` with the path to the directory that you want to store the installation files in.
   
3. Create machine config files to encrypt the boot disks for the control plane or compute nodes using the TPM v2 encryption mode.

   **IMPORTANT**

   If you are also configuring boot disk mirroring on the affected nodes, skip this step. You will configure disk encryption when configuring boot disk mirroring.

   - To configure encryption on the control plane nodes, save the following machine config sample to a file in the `<installation_directory>/openshift` directory. For example, name the file `99-openshift-master-tpmv2-encryption.yaml`:

     ```yaml
     apiVersion: machineconfiguration.openshift.io/v1
     kind: MachineConfig
     metadata:
       name: master-tpm
     labels:
       machineconfiguration.openshift.io/role: master
     spec:
       config:
         ignition:
           version: 3.2.0
         storage:
           luks:
             - name: root
               device: /dev/disk/by-partlabel/root
               clevis:
                 tpm2: true ①
               options: [--cipher, aes-cbc-essiv:sha256]
     ```
Set this attribute to **true** to use a Trusted Platform Module (TPM) secure cryptoprocessor to encrypt the root file system.

To configure encryption on the compute nodes, save the following machine config sample to a file in the `<installation_directory>/openshift` directory. For example, name the file `99-openshift-worker-tpmv2-encryption.yaml`:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  name: worker-tpm
  labels:
    machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      luks:
        - name: root
          device: /dev/disk/by-partlabel/root
          clevis:
            tpm2: true
          options: [--cipher, aes-cbc-essiv:sha256]
          wipeVolume: true
        filesystems:
          - device: /dev/mapper/root
            format: xfs
            wipeFilesystem: true
            label: root
```

Set this attribute to **true** to use a Trusted Platform Module (TPM) secure cryptoprocessor to encrypt the root file system.

4. Create a backup copy of the YAML files. The original YAML files are consumed when you create the Ignition config files.

5. Continue with the remainder of the OpenShift Container Platform deployment.

**IMPORTANT**

If you configure additional data partitions, they will not be encrypted unless encryption is explicitly requested.

17.1.3.2. Enabling Tang disk encryption
Use the following procedure to enable Tang mode disk encryption during an OpenShift Container Platform installation.

**NOTE**
On previous versions of RHCOS, disk encryption was configured by specifying `/etc/clevis.json` in the Ignition config. That file is not supported in clusters created with OpenShift Container Platform 4.7 or above, and the LUKS device should be configured directly via the Ignition `luks` section.

**Prerequisites**
- You have downloaded the OpenShift Container Platform installation program on your installation node.
- You have access to a Red Hat Enterprise Linux (RHEL) 8 machine that can be used to generate a thumbprint of the Tang exchange key.

**Procedure**

1. Set up a Tang server or access an existing one. See [Network-bound disk encryption](#) for instructions.

2. Add kernel arguments to configure networking when you do the Red Hat Enterprise Linux CoreOS (RHCOS) installations for your cluster. For example, to configure DHCP networking, identify `ip=dhcp`, or set static networking when you add parameters to the kernel command line. For both DHCP and static networking, you also must provide the `rd.neednet=1` kernel argument.

   **IMPORTANT**
   Skipping this step causes the second boot to fail.

4. Install the `clevis` package on a RHEL 8 machine, if it is not already installed:

   ```
   $ sudo yum install clevis
   ```

5. On the RHEL 8 machine, run the following command to generate a thumbprint of the exchange key. Replace `http://tang.example.com:7500` with the URL of your Tang server:

   ```
   $ clevis-encrypt-tang '{"url":"http://tang.example.com:7500"}' < /dev/null > /dev/null
   ```

   In this example, `tangd.socket` is listening on port **7500** on the Tang server.

**NOTE**
The `clevis-encrypt-tang` command is used in this step only to generate a thumbprint of the exchange key. No data is being passed to the command for encryption at this point, so `/dev/null` is provided as an input instead of plain text. The encrypted output is also sent to `/dev/null`, because it is not required for this procedure.
Example output

The advertisement contains the following signing keys:

PLjNyRdGw03zlRoGjQYMahSZGu9

1  The thumbprint of the exchange key.

When the Do you wish to trust these keys? [ynYN] prompt displays, type Y.

NOTE

RHEL 8 provides Clevis version 15, which uses the SHA-1 hash algorithm to generate thumbprints. Some other distributions provide Clevis version 17 or later, which use the SHA-256 hash algorithm for thumbprints. You must use a Clevis version that uses SHA-1 to create the thumbprint, to prevent Clevis binding issues when you install Red Hat Enterprise Linux CoreOS (RHCOS) on your OpenShift Container Platform cluster nodes.

6. If you have not yet generated the Kubernetes manifests, change to the directory that contains the installation program on your installation node and create them:

   $ ./openshift-install create manifests --dir <installation_directory>

   Replace <installation_directory> with the path to the directory that you want to store the installation files in.

7. Create machine config files to encrypt the boot disks for the control plane or compute nodes using the Tang encryption mode.

   IMPORTANT

   If you are also configuring boot disk mirroring on the affected nodes, record the exchange key thumbprint for later use, and skip this step. You will configure disk encryption when configuring boot disk mirroring.

   • To configure encryption on the control plane nodes, save the following machine config sample to a file in the <installation_directory>/openshift directory. For example, name the file 99-openshift-master-tang-encryption.yaml:

   ```yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     name: master-tang
   labels:
     machineconfiguration.openshift.io/role: master
   spec:
     config:
       ignition:
         version: 3.2.0
     storage:
       luks:
   ```
Specify the URL of a Tang server. In this example, `tangd.socket` is listening on port 7500 on the Tang server.

Specify the exchange key thumbprint, which was generated in a preceding step.

Add the `rd.neednet=1` kernel argument to bring the network up in the initramfs. This argument is required.

- To configure encryption on the compute nodes, save the following machine config sample to a file in the `<installation_directory>/openshift` directory. For example, name the file `99-openshift-worker-tang-encryption.yaml`:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  name: worker-tang
  labels:
    machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      luks:
        - name: root
          device: /dev/disk/by-partlabel/root
clevis:
  tang:
    - url: http://tang.example.com:7500
      thumbprint: PLjNyRdGw03zlIRoGjQYMahrSZGu9
    options: [--cipher, aes-cbc-essiv:sha256]
wipeVolume: true
  filesystems:
    - device: /dev/mapper/root
      format: xfs
      wipeFileSystem: true
      label: root
    kernelArguments:
      - rd.neednet=1
```

1 Specify the URL of a Tang server. In this example, `tangd.socket` is listening on port 7500 on the Tang server.

2 Specify the exchange key thumbprint, which was generated in a preceding step.

3 Add the `rd.neednet=1` kernel argument to bring the network up in the initramfs. This argument is required.

2502
Specify the URL of a Tang server. In this example, `tangd.socket` is listening on port \texttt{7500} on the Tang server.

Specify the exchange key thumbprint, which was generated in a preceding step.

Add the \texttt{rd.neednet=1} kernel argument to bring the network up in the initramfs. This argument is required.

8. Create a backup copy of the YAML files. The original YAML files are consumed when you create the Ignition config files.

9. Continue with the remainder of the OpenShift Container Platform installation.

\textbf{IMPORTANT}

If you configure additional data partitions, they will not be encrypted unless encryption is explicitly requested.

17.1.4. Mirroring disks during installation

During OpenShift Container Platform installation on control plane and compute nodes, you can enable mirroring of the boot disk to two or more redundant storage devices. A node continues to function after storage device failure as long as one device remains available.

Mirroring does not support replacement of a failed disk. To restore the mirror to a pristine, non-degraded state, reprovision the node.

\textbf{IMPORTANT}

Mirroring is available only for user-provisioned infrastructure deployments on Red Hat Enterprise Linux CoreOS (RHCOS) systems. Mirroring support is available on x86_64 nodes booted with BIOS or UEFI and on ppc64le nodes.

**Procedure**

To enable boot disk mirroring during OpenShift Container Platform deployment:

1. Follow the bare metal install procedure up to the point where you created Ignition configs for your installation.
   For example, you should have entered the following command:

   \$ openshift-install create ignition-configs --dir $HOME/clusterconfig

2. Verify that the Ignition config files were created:

   \$ ls $HOME/clusterconfig/

\textbf{Example output}
3. Create a RHCOS Config (RCC) with a reference to your master.ign or worker.ign config, depending on the type of node you are configuring. The RCC must specify the devices to be used for boot disk mirroring. If you want LUKS encryption on the mirrored root filesystem, you must configure it in this RCC.

The following RCC example demonstrates how to create $HOME/clusterconfig/worker-raid.rcc:

### RCC example

```yaml
variant: rhcos
version: 0.1.0

ignition:
  config:
    merge:
      - local: worker.ign

boot_device:
  mirror:
    devices:
      - /dev/sda
      - /dev/sdb
    luks:
      tpm2:
        true
      tang:
        url: http://tang.example.com:7500
        thumbprint: <tang_thumbprint>
    storage:
      luks:
        - name: root
          options: [--cipher, aes-cbc-essiv:sha256]
```

1. Use the name of the Ignition config for your node type.
2. List all disk devices that should be included in the boot disk mirror, including the disk that RHCOS will be installed onto.
3. Include this section if you want to encrypt the root filesystem. See "Encrypting disks during installation" for more details.
4. Include this field if you want to use a Trusted Platform Module (TPM) to encrypt the root filesystem. See "Enabling TPM v2 disk encryption" for more details.
5. Include this section if you want to use a Tang server. To obtain the server URL and thumbprint, follow the instructions in "Enabling Tang disk encryption".
6. Include this section if you want to encrypt the root filesystem.

4. Run the Fedora CoreOS Config Transpiler (FCCT) tool to merge your RCC, such as worker-raid.rcc, with the Ignition config specified in the RCC that you created in the previous step:

```
$ podman run --pull=always --rm --volume $HOME/clusterconfig:/pwd --workdir /pwd \
  quay.io/coreos/fcct:release --files-dir . worker-raid.rcc --output worker-raid.ign
```
This command produces a combined Ignition config in $HOME/clusterconfig/worker-raid.ign.

5. Continue with the remainder of the OpenShift Container Platform deployment, using the combined Ignition config to provision nodes.

17.1.4.1. Configuring a RAID-enabled data volume

You can enable software RAID partitioning to provide an external data volume.

Procedure

- Create a machine config in the <installation_directory>/openshift directory that configures a data volume by using software RAID. In this example, it is called raid1-alt-storage.yaml:

Sample RAID 1 on secondary disks configuration file

```yaml
apiVersion: machineconfiguration.openshift.io/v1
class: MachineConf
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: raid1-alt-storage
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
      - device: /dev/sdc
        partitions:
        - label: data-1
          wipeTable: true
        - device: /dev/sdd
          partitions:
          - label: data-2
            wipeTable: true
      filesystems:
      - device: /dev/md/md-data
        format: xfs
        path: /var/lib/containers
        wipeFilesystem: true
      raid:
      - devices:
        - /dev/disk/by-partlabel/data-1
        - /dev/disk/by-partlabel/data-2
        level: raid1
        name: md-data
      systemd:
        units:
        - contents: |
          [Unit]
          Before=local-fs.target
          Requires=systemd-fsck@dev-md-md\x2ddata.service
          After=systemd-fsck@dev-md-md\x2ddata.service
```
If you choose a different mount point, you must update the unit name to correspond to your mount point. Otherwise the unit will not activate. You can generate a matching unit name with `echo $(systemd-escape -p $mountpoint).mount` where `$mountpoint` is your chosen mount point.

### 17.1.5. Configuring chrony time service

You can set the time server and related settings used by the chrony time service (chronyd) by modifying the contents of the `chrony.conf` file and passing those contents to your nodes as a machine config.

**Procedure**

1. Create the contents of the `chrony.conf` file and encode it as base64. For example:

   ```bash
   $ cat << EOF | base64
   pool 0.rhel.pool.ntp.org iburst
   driftfile /var/lib/chrony/drift
   makestep 1.0 3
   rtsync
   logdir /var/log/chrony
   EOF
   ```

   1 Specify any valid, reachable time source, such as the one provided by your DHCP server. Alternately, you can specify any of the following NTP servers: 1.rhel.pool.ntp.org, 2.rhel.pool.ntp.org, or 3.rhel.pool.ntp.org.

2. Create the `MachineConfig` object file, replacing the base64 string with the one you just created. This example adds the file to `master` nodes. You can change it to `worker` or make an additional MachineConfig for the `worker` role. Create MachineConfig files for each type of machine that your cluster uses:

   ```yaml
   $ cat << EOF > ./99-masters-chrony-configuration.yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   ```
Specify an octal value mode for the `mode` field in the machine config file. After creating the file and applying the changes, the `mode` is converted to a decimal value. You can check the YAML file with the command `oc get mc <mc-name> -o yaml`.

3. Make a backup copy of the configuration files.

4. Apply the configurations in one of two ways:
   - If the cluster is not up yet, after you generate manifest files, add this file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.
   - If the cluster is already running, apply the file:

     ```bash
     $ oc apply -f ./99-masters-chrony-configuration.yaml
     ```

17.1.6. Additional resources

- See [Support for FIPS cryptography](#) for information on FIPS support.

17.2. CONFIGURING YOUR FIREWALL

If you use a firewall, you must configure it so that OpenShift Container Platform can access the sites that it requires to function. You must always grant access to some sites, and you grant access to more if you use Red Hat Insights, the Telemetry service, a cloud to host your cluster, and certain build strategies.
17.2.1. Configuring your firewall for OpenShift Container Platform

Before you install OpenShift Container Platform, you must configure your firewall to grant access to the sites that OpenShift Container Platform requires.

There are no special configuration considerations for services running on only controller nodes versus worker nodes.

Procedure

1. Allowlist the following registry URLs:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>registry.redhat.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn.quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn01.quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn02.quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn03.quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>sso.redhat.com</td>
<td>443, 80</td>
<td>The <a href="https://console.redhat.com/openshift">https://console.redhat.com/openshift</a> site uses authentication from sso.redhat.com</td>
</tr>
</tbody>
</table>

You can use the wildcard *.quay.io instead of cdn0[1-3].quay.io in your allowlist. When you add a site, such as quay.io, to your allowlist, do not add a wildcard entry, such as *.quay.io, to your denylist. In most cases, image registries use a content delivery network (CDN) to serve images. If a firewall blocks access, then image downloads are denied when the initial download request is redirected to a hostname such as cdn01.quay.io.

2. Allowlist any site that provides resources for a language or framework that your builds require.

3. If you do not disable Telemetry, you must grant access to the following URLs to access Red Hat Insights:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>cert-api.access.redhat.com</td>
<td>443, 80</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>api.access.redhat.com</td>
<td>443, 80</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>infogw.api.openshift.com</td>
<td>443, 80</td>
<td>Required for Telemetry</td>
</tr>
</tbody>
</table>
4. If you use Amazon Web Services (AWS), Microsoft Azure, or Google Cloud Platform (GCP) to host your cluster, you must grant access to the URLs that provide the cloud provider API and DNS for that cloud:

<table>
<thead>
<tr>
<th>Cloud</th>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS</td>
<td>*.amazonaws.com</td>
<td>443, 80</td>
<td>Required to access AWS services and resources. Review the AWS Service</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Endpoints in the AWS documentation to determine the exact endpoints to</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>allow for the regions that you use.</td>
</tr>
<tr>
<td>GCP</td>
<td>*.googleapis.com</td>
<td>443, 80</td>
<td>Required to access GCP services and resources. Review Cloud Endpoints</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>in the GCP documentation to determine the endpoints to allow for your</td>
</tr>
<tr>
<td></td>
<td>accounts.google.com</td>
<td>443, 80</td>
<td>APIs.</td>
</tr>
<tr>
<td>Azure</td>
<td>management.azure.com</td>
<td>443, 80</td>
<td>Required to access Azure services and resources. Review the Azure REST</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>API reference in the Azure documentation to determine the endpoints to</td>
</tr>
<tr>
<td></td>
<td>*.blob.core.windows.net</td>
<td>443, 80</td>
<td>allow for your APIs.</td>
</tr>
<tr>
<td></td>
<td>login.microsoftonline.com</td>
<td>443, 80</td>
<td>Required to access Azure services and resources. Review the Azure REST</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>API reference in the Azure documentation to determine the endpoints to</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>allow for your APIs.</td>
</tr>
</tbody>
</table>

5. Allowlist the following URLs:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>console.redhat.com/api/ingress</td>
<td>443, 80</td>
<td>Required for Telemetry and for insights-operator</td>
</tr>
<tr>
<td>URL</td>
<td>Port</td>
<td>Function</td>
</tr>
<tr>
<td>------------------------------------------</td>
<td>------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mirror.openshift.com</td>
<td>443, 80</td>
<td>Required to access mirrored installation content and images. This site is also a source of release image signatures, although the Cluster Version Operator needs only a single functioning source.</td>
</tr>
<tr>
<td>storage.googleapis.com/openshift-release</td>
<td>443, 80</td>
<td>A source of release image signatures, although the Cluster Version Operator needs only a single functioning source.</td>
</tr>
<tr>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>443, 80</td>
<td>Required to access the default cluster routes unless you set an ingress wildcard during installation.</td>
</tr>
<tr>
<td>quayio-production-s3.s3.amazonaws.com</td>
<td>443, 80</td>
<td>Required to access Quay image content in AWS.</td>
</tr>
<tr>
<td>api.openshift.com</td>
<td>443, 80</td>
<td>Required both for your cluster token and to check if updates are available for the cluster.</td>
</tr>
<tr>
<td>rhcos-redirector.apps.art.xq1c.p1.openshiftapps.com, rhcos.mirror.openshift.com</td>
<td>443, 80</td>
<td>Required to download Red Hat Enterprise Linux CoreOS (RHCOS) images.</td>
</tr>
<tr>
<td>console.redhat.com/openshift</td>
<td>443, 80</td>
<td>Required for your cluster token.</td>
</tr>
<tr>
<td>registry.access.redhat.com</td>
<td>443, 80</td>
<td>Required for odo CLI.</td>
</tr>
</tbody>
</table>

Operators require route access to perform health checks. Specifically, the authentication and web console Operators connect to two routes to verify that the routes work. If you are the cluster administrator and do not want to allow `*.apps.<cluster_name>.<base_domain>`, then
allow these routes:

- `oauth-openshift.apps.<cluster_name>.<base_domain>`
- `console-openshift-console.apps.<cluster_name>.<base_domain>`, or the hostname that is specified in the `spec.route.hostname` field of the `consoles.operator/cluster` object if the field is not empty.

6. Allowlist the following URLs for optional third-party content:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>registry.connect.redhat.com</code></td>
<td>443, 80</td>
<td>Required for all third-party images and certified operators.</td>
</tr>
<tr>
<td><code>rhc4tp-prod-z8cxf-image-registry-us-east-1-evenkyleffocxqvofrk.s3.dualstack.us-east-1.amazonaws.com</code></td>
<td>443, 80</td>
<td>Provides access to container images hosted on <code>registry.connect.redhat.com</code></td>
</tr>
<tr>
<td><code>oso-rhc4tp-docker-registry.s3-us-west-2.amazonaws.com</code></td>
<td>443, 80</td>
<td>Required for Sonatype Nexus, F5 Big IP operators.</td>
</tr>
</tbody>
</table>

7. If you use a default Red Hat Network Time Protocol (NTP) server allow the following URLs:

- `1.rhel.pool.ntp.org`
- `2.rhel.pool.ntp.org`
- `3.rhel.pool.ntp.org`

**NOTE**

If you do not use a default Red Hat NTP server, verify the NTP server for your platform and allow it in your firewall.
CHAPTER 18. VALIDATING AN INSTALLATION

You can check the status of an OpenShift Container Platform cluster after an installation by following the procedures in this document.

18.1. REVIEWING THE INSTALLATION LOG

You can review a summary of an installation in the OpenShift Container Platform installation log. If an installation succeeds, the information required to access the cluster is included in the log.

Prerequisites

- You have access to the installation host.

Procedure

- Review the `{/.openshift_install.log` log file in the installation directory on your installation host:

  ```
  $ cat <install_dir>/.openshift_install.log
  ...
  time="2020-12-03T09:50:47Z" level=info msg="Install complete!"
  time="2020-12-03T09:50:47Z" level=info msg="To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'"
  time="2020-12-03T09:50:47Z" level=info msg="Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com"
  time="2020-12-03T09:50:47Z" level=info msg="Login to the console with user: "kubeadmin", and password: "6zYlx-ckbW3-4d2Ne-lWvDF"
  time="2020-12-03T09:50:47Z" level=debug msg="Time elapsed per stage:"
  time="2020-12-03T09:50:47Z" level=debug msg="  Infrastructure: 6m45s"
  time="2020-12-03T09:50:47Z" level=debug msg="  Bootstrap Complete: 11m30s"
  time="2020-12-03T09:50:47Z" level=debug msg="  Bootstrap Destroy: 1m5s"
  time="2020-12-03T09:50:47Z" level=debug msg="  Cluster Operators: 17m31s"
  time="2020-12-03T09:50:47Z" level=info msg="Time elapsed: 37m26s"
  ...
  ```

Example output

Cluster credentials are included at the end of the log if the installation is successful, as outlined in the following example:

```
... time="2020-12-03T09:50:47Z" level=info msg="Install complete!"
 time="2020-12-03T09:50:47Z" level=info msg="To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'"
 time="2020-12-03T09:50:47Z" level=info msg="Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com"
 time="2020-12-03T09:50:47Z" level=info msg="Login to the console with user: "kubeadmin", and password: "6zYlx-ckbW3-4d2Ne-lWvDF"
 time="2020-12-03T09:50:47Z" level=debug msg="Time elapsed per stage:"
 time="2020-12-03T09:50:47Z" level=debug msg="  Infrastructure: 6m45s"
 time="2020-12-03T09:50:47Z" level=debug msg="  Bootstrap Complete: 11m30s"
 time="2020-12-03T09:50:47Z" level=debug msg="  Bootstrap Destroy: 1m5s"
 time="2020-12-03T09:50:47Z" level=debug msg="  Cluster Operators: 17m31s"
 time="2020-12-03T09:50:47Z" level=info msg="Time elapsed: 37m26s"
...```

18.2. VIEWING THE IMAGE PULL SOURCE

For clusters with unrestricted network connectivity, you can view the source of your pulled images by using a command on a node, such as `crictl images`.

However, for disconnected installations, to view the source of pulled images, you must review the CRI-O logs to locate the `Trying to access` log entry, as shown in the following procedure. Other methods to view the image pull source, such as the `crictl images` command, show the non-mirrored image name, even though the image is pulled from the mirrored location.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
Procedure

- Review the CRI-O logs for a master or worker node:

  $ oc adm node-logs <node_name> -u crio

Example output

The **Trying to access** log entry indicates where the image is being pulled from.

```
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1366]: time="2021-08-05 10:33:21.594930907Z" level=info msg="Pulling image: quay.io/openshift-release-dev/ocp-release:4.8.4-ppc64le" id=abcd713b-d0e1-4844-ac1c-474c5b60c07c name=/runtime.v1alpha2.ImageService/PullImage
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1484]: time="2021-03-17 02:52:50.194341109Z" level=info msg="Trying to access "li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec98b00628970e974284b6d9a6a086cb9a7a6c31"
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1484]: time="2021-03-17 02:52:50.226788351Z" level=info msg="Trying to access "li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec98b00628970e974284b6d9a6a086cb9a7a6c31"
```

The log might show the image pull source twice, as shown in the preceding example.

If your **ImageContentSourcePolicy** object lists multiple mirrors, OpenShift Container Platform attempts to pull the images in the order listed in the configuration, for example:

```
Trying to access "li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec98b00628970e974284b6d9a6a086cb9a7a6c31"
```

18.3. GETTING CLUSTER VERSION, STATUS, AND UPDATE DETAILS

You can view the cluster version and status by running the **oc get clusterversion** command. If the status shows that the installation is still progressing, you can review the status of the Operators for more information.

You can also list the current update channel and review the available cluster updates.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have installed the OpenShift CLI (**oc**).

Procedure

1. Obtain the cluster version and overall status:

   ```
OpenShift Container Platform 4.7 Installing

$ oc get clusterversion

Example output
NAME
VERSION AVAILABLE PROGRESSING SINCE STATUS
version 4.6.4 True
False
6m25s Cluster version is 4.6.4
The example output indicates that the cluster has been installed successfully.
2. If the cluster status indicates that the installation is still progressing, you can obtain more
detailed progress information by checking the status of the Operators:
$ oc get clusteroperators.config.openshift.io
3. View a detailed summary of cluster specifications, update availability, and update history:
$ oc describe clusterversion
4. List the current update channel:
$ oc get clusterversion -o jsonpath='{.items[0].spec}{"\n"}'

Example output
{"channel":"stable-4.6","clusterID":"245539c1-72a3-41aa-9cec-72ed8cf25c5c"}
5. Review the available cluster updates:
$ oc adm upgrade

Example output
Cluster version is 4.6.4
Updates:
VERSION IMAGE
4.6.6 quay.io/openshift-release-dev/ocprelease@sha256:c7e8f18e8116356701bd23ae3a23fb9892dd5ea66c8300662ef30563d7104f3
9
Additional resources
See Querying Operator status after installation for more information about querying Operator
status if your installation is still progressing.
See Troubleshooting Operator issues for information about investigating issues with Operators.
See Updating a cluster for more information on updating your cluster.
See OpenShift Container Platform upgrade channels and releases for an overview about
upgrade release channels.

18.4. QUERYING THE STATUS OF THE CLUSTER NODES BY USING THE CLI

You can verify the status of the cluster nodes after an installation.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. List the status of the cluster nodes. Verify that the output lists all of the expected control plane and compute nodes and that each node has a `Ready` status:

   ```
   $ oc get nodes
   NAME                          STATUS   ROLES    AGE   VERSION
   compute-1.example.com         Ready    worker   33m   v1.19.0+9f84db3
   control-plane-1.example.com   Ready    master   41m   v1.19.0+9f84db3
   control-plane-2.example.com   Ready    master   45m   v1.19.0+9f84db3
   compute-2.example.com         Ready    worker   38m   v1.19.0+9f84db3
   compute-3.example.com         Ready    worker   33m   v1.19.0+9f84db3
   control-plane-3.example.com   Ready    master   41m   v1.19.0+9f84db3
   ```

2. Review CPU and memory resource availability for each cluster node:

   ```
   $ oc adm top nodes
   NAME                          CPU(cores)   CPU%   MEMORY(bytes)   MEMORY%
   compute-1.example.com         128m         8%     1132Mi          16%
   control-plane-1.example.com   801m         22%    3471Mi          23%
   control-plane-2.example.com   1718m        49%    6085Mi          40%
   compute-2.example.com         935m         62%    5178Mi          75%
   compute-3.example.com         111m         7%     1131Mi          16%
   control-plane-3.example.com   942m         26%    4100Mi          27%
   ```

Additional resources

- See `Verifying node health` for more details about reviewing node health and investigating node issues.

18.5. REVIEWING THE CLUSTER STATUS FROM THE OPENSHIFT CONTAINER PLATFORM WEB CONSOLE

You can review the following information in the `Overview` page in the OpenShift Container Platform web console:
- The general status of your cluster
- The status of the control plane, cluster Operators, and storage
- CPU, memory, file system, network transfer, and pod availability
- The API address of the cluster, the cluster ID, and the name of the provider
- Cluster version information
- Cluster update status, including details of the current update channel and available updates
- A cluster inventory detailing node, pod, storage class, and persistent volume claim (PVC) information
- A list of ongoing cluster activities and recent events

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.

Procedure

1. In the Administrator perspective, navigate to Home → Overview.

18.6. REVIEWING THE CLUSTER STATUS FROM RED HAT OPENSHEFT CLUSTER MANAGER

You can review detailed information about the status of your cluster in the OpenShift Cluster Manager.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.

Procedure

1. In the Administrator perspective, navigate to Home → Overview → Details → OpenShift Cluster Manager to open the Overview page for the cluster in OpenShift Cluster Manager.

   **NOTE**

   Alternatively, you can navigate to OpenShift Cluster Manager directly and select your cluster ID from the list of available clusters.

2. In the Overview page, review the following information about your cluster:
   - vCPU and memory availability and resource usage
   - The cluster ID, status, type, location, and the provider name
   - Node counts by node type
   - Cluster version details, the creation date of the cluster, and the name of the cluster owner
   - The life cycle support status of the cluster
• Subscription information, including the service level agreement (SLA) status, the subscription unit type, the production status of the cluster, the subscription obligation, and the service level

• A cluster history

3. Navigate to the **Monitoring** page to review the following information:

• A list of any issues that have been detected

• A list of alerts that are firing

• The cluster Operator status and version

• Cluster resource usage

4. Navigate to the **Insights** page to review the following information provided by Red Hat Insights:

• Potential issues that your cluster might be exposed to, categorized by risk level

• Health-check status by category

Additional resources

• See **Using Insights to identify issues with your cluster** for more information about reviewing potential issues with your cluster.

### 18.7. CHECKING CLUSTER RESOURCE AVAILABILITY AND UTILIZATION

OpenShift Container Platform provides a comprehensive set of monitoring dashboards that help you understand the state of cluster components.

In the **Administrator** perspective, you can access dashboards for core OpenShift Container Platform components, including:

• etcd

• Kubernetes compute resources

• Kubernetes network resources

• Prometheus

• Dashboards relating to cluster and node performance
Figure 18.1. Example compute resources dashboard

<table>
<thead>
<tr>
<th>Dashboard</th>
<th>CPU Utilisation</th>
<th>CPU Requests Commitment</th>
<th>CPU Limits Commitment</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>24.38%</td>
<td>117.73%</td>
<td>66.00%</td>
</tr>
<tr>
<td>Memory Utilisation</td>
<td>20.74%</td>
<td>61.42%</td>
<td>24.00%</td>
</tr>
</tbody>
</table>

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.

Procedure

1. In the Administrator perspective in the OpenShift Container Platform web console, navigate to Monitoring → Dashboards.
2. Choose a dashboard in the Dashboard list. Some dashboards, such as the etcd dashboard, produce additional sub-menus when selected.
3. Optional: Select a time range for the graphs in the Time Range list.
4. Optional: Select a Refresh Interval
5. Hover over each of the graphs within a dashboard to display detailed information about specific items.

Additional resources

- See Monitoring overview for more information about the OpenShift Container Platform monitoring stack.

18.8. LISTING ALERTS THAT ARE FIRING

Alerts provide notifications when a set of defined conditions are true in an OpenShift Container Platform cluster. You can review the alerts that are firing in your cluster by using the Alerting UI in the OpenShift Container Platform web console.
Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.

Procedure

1. In the Administrator perspective, navigate to the Monitoring → Alerting → Alerts page.
2. Review the alerts that are firing, including their Severity, State, and Source.
3. Select an alert to view more detailed information in the Alert Details page.

Additional resources

- See Managing alerts for further details about alerting in OpenShift Container Platform.

18.9. NEXT STEPS

- See Troubleshooting installations if you experience issues when installing your cluster.
- After installing OpenShift Container Platform, you can further expand and customize your cluster.
CHAPTER 19. TROUBLESHOOTING INSTALLATION ISSUES

To assist in troubleshooting a failed OpenShift Container Platform installation, you can gather logs from the bootstrap and control plane, or master, machines. You can also get debug information from the installation program.

19.1. PREREQUISITES

- You attempted to install an OpenShift Container Platform cluster, and installation failed.

19.2. GATHERING LOGS FROM A FAILED INSTALLATION

If you gave an SSH key to your installation program, you can gather data about your failed installation.

NOTE

You use a different command to gather logs about an unsuccessful installation than to gather logs from a running cluster. If you must gather logs from a running cluster, use the `oc adm must-gather` command.

Prerequisites

- Your OpenShift Container Platform installation failed before the bootstrap process finished. The bootstrap node is running and accessible through SSH.

- The `ssh-agent` process is active on your computer, and you provided the same SSH key to both the `ssh-agent` process and the installation program.

- If you tried to install a cluster on infrastructure that you provisioned, you must have the fully qualified domain names of the bootstrap and control plane nodes (also known as the master nodes).

Procedure

1. Generate the commands that are required to obtain the installation logs from the bootstrap and control plane machines:

   - If you used installer-provisioned infrastructure, change to the directory that contains the installation program and run the following command:

     ```bash
     $ ./openshift-install gather bootstrap --dir <installation_directory>
     ```

       * `$ <installation_directory>` is the directory you specified when you ran `./openshift-install create cluster`. This directory contains the OpenShift Container Platform definition files that the installation program creates.

       For installer-provisioned infrastructure, the installation program stores information about the cluster, so you do not specify the hostnames or IP addresses.

   - If you used infrastructure that you provisioned yourself, change to the directory that contains the installation program and run the following command:

     ```bash
     $ ./openshift-install gather bootstrap --dir <installation_directory>
     ```
For **installation_directory**, specify the same directory you specified when you ran `./openshift-install create cluster`. This directory contains the OpenShift Container Platform definition files that the installation program creates.

**<bootstrap_address>** is the fully qualified domain name or IP address of the cluster's bootstrap machine.

For each control plane, or master, machine in your cluster, replace **<master_*_address>** with its fully qualified domain name or IP address.

**NOTE**

A default cluster contains three control plane machines. List all of your control plane machines as shown, no matter how many your cluster uses.

**Example output**

```
INFO Pulling debug logs from the bootstrap machine
INFO Bootstrap gather logs captured here "<installation_directory>/log-bundle-<timestamp>.tar.gz"
```

If you open a Red Hat support case about your installation failure, include the compressed logs in the case.

**19.3. MANUALLY GATHERING LOGS WITH SSH ACCESS TO YOUR HOST(S)**

Manually gather logs in situations where **must-gather** or automated collection methods do not work.

**IMPORTANT**

By default, SSH access to the OpenShift Container Platform nodes is disabled on the Red Hat OpenStack Platform (RHOSP) based installations.

**Prerequisites**

- You must have SSH access to your host(s).

**Procedure**

1. Collect the **bootkube.service** service logs from the bootstrap host using the **journalctl** command by running:

   ```
   $ journalctl -b -f -u bootkube.service
   ```
2. Collect the bootstrap host’s container logs using the podman logs. This is shown as a loop to get all of the container logs from the host:

   $ for pod in $(sudo podman ps -a -q); do sudo podman logs $pod; done

3. Alternatively, collect the host’s container logs using the `tail` command by running:

   # tail -f /var/lib/containers/storage/overlay-containers/*/userdata/ctr.log

4. Collect the `kubelet.service` and `crio.service` service logs from the master and worker hosts using the `journalctl` command by running:

   $ journalctl -b -f -u kubelet.service -u crio.service

5. Collect the master and worker host container logs using the `tail` command by running:

   $ sudo tail -f /var/log/containers/*

19.4. MANUALLY GATHERING LOGS WITHOUT SSH ACCESS TO YOUR HOST(S)

Manually gather logs in situations where `must-gather` or automated collection methods do not work.

If you do not have SSH access to your node, you can access the systems journal to investigate what is happening on your host.

Prerequisites

- Your OpenShift Container Platform installation must be complete.
- Your API service is still functional.
- You have system administrator privileges.

Procedure

1. Access `journald` unit logs under `/var/log` by running:

   $ oc adm node-logs --role=master -u kubelet

2. Access host file paths under `/var/log` by running:

   $ oc adm node-logs --role=master --path=openshift-apiserver

19.5. GETTING DEBUG INFORMATION FROM THE INSTALLATION PROGRAM

You can use any of the following actions to get debug information from the installation program.

- Look at debug messages from a past installation in the hidden `.openshift_install.log` file. For example, enter:
19.6. REINSTALLING THE OPENSHIFT CONTAINER PLATFORM CLUSTER

If you are unable to debug and resolve issues in the failed OpenShift Container Platform installation, consider installing a new OpenShift Container Platform cluster. Before starting the installation process again, you must complete thorough cleanup. For a user-provisioned infrastructure (UPI) installation, you must manually destroy the cluster and delete all associated resources. The following procedure is for an installer-provisioned infrastructure (IPI) installation.

Procedure

1. Destroy the cluster and remove all the resources associated with the cluster, including the hidden installer state files in the installation directory:

   $ ./openshift-install destroy cluster --dir <installation_directory>  

   <installation_directory> is the directory you specified when you ran ./openshift-install create cluster. This directory contains the OpenShift Container Platform definition files that the installation program creates.

2. Before reinstalling the cluster, delete the installation directory:

   $ rm -rf <installation_directory>

3. Follow the procedure for installing a new OpenShift Container Platform cluster.

Additional resources

- Installing an OpenShift Container Platform cluster
CHAPTER 20. SUPPORT FOR FIPS CRYPTOGRAPHY

You can install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture.

For the Red Hat Enterprise Linux CoreOS (RHCOS) machines in your cluster, this change is applied when the machines are deployed based on the status of an option in the install-config.yaml file, which governs the cluster options that a user can change during cluster deployment. With Red Hat Enterprise Linux (RHEL) machines, you must enable FIPS mode when you install the operating system on the machines that you plan to use as worker machines. These configuration methods ensure that your cluster meet the requirements of a FIPS compliance audit: only FIPS Validated / Modules in Process cryptography packages are enabled before the initial system boot.

Because FIPS must be enabled before the operating system that your cluster uses boots for the first time, you cannot enable FIPS after you deploy a cluster.

20.1. FIPS VALIDATION IN OPENSOURCE CONTAINER PLATFORM

OpenShift Container Platform uses certain FIPS Validated / Modules in Process modules within RHEL and RHCOS for the operating system components that it uses. See RHEL7 core crypto components. For example, when users SSH into OpenShift Container Platform clusters and containers, those connections are properly encrypted.

OpenShift Container Platform components are written in Go and built with Red Hat’s golang compiler. When you enable FIPS mode for your cluster, all OpenShift Container Platform components that require cryptographic signing call RHEL and RHCOS cryptographic libraries.

Table 20.1. FIPS mode attributes and limitations in OpenShift Container Platform 4.7

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIPS support in RHEL 7 operating systems.</td>
<td>The FIPS implementation does not offer a single function that both computes hash functions and validates the keys that are based on that hash. This limitation will continue to be evaluated and improved in future OpenShift Container Platform releases.</td>
</tr>
<tr>
<td>FIPS support in CRI-O runtimes.</td>
<td></td>
</tr>
<tr>
<td>FIPS support in OpenShift Container Platform services.</td>

<tr>
<td>Use of FIPS compatible golang compiler.</td>
<td>TLS FIPS support is not complete but is planned for future OpenShift Container Platform releases.</td>
</tr>
<tr>
<td>FIPS support across multiple architectures.</td>
<td>FIPS is currently only supported on OpenShift Container Platform deployments using the x86_64 architecture.</td>
</tr>
</tbody>
</table>

20.2. FIPS SUPPORT IN COMPONENTS THAT THE CLUSTER USES
Although the OpenShift Container Platform cluster itself uses FIPS Validated / Modules in Process modules, ensure that the systems that support your OpenShift Container Platform cluster use FIPS Validated / Modules in Process modules for cryptography.

### 20.2.1. etcd

To ensure that the secrets that are stored in etcd use FIPS Validated / Modules in Process encryption, boot the node in FIPS mode. After you install the cluster in FIPS mode, you can encrypt the etcd data by using the FIPS-approved aes cbc cryptographic algorithm.

### 20.2.2. Storage

For local storage, use RHEL-provided disk encryption or Container Native Storage that uses RHEL-provided disk encryption. By storing all data in volumes that use RHEL-provided disk encryption and enabling FIPS mode for your cluster, both data at rest and data in motion, or network data, are protected by FIPS Validated / Modules in Process encryption. You can configure your cluster to encrypt the root filesystem of each node, as described in Customizing nodes.

### 20.2.3. Runtimes

To ensure that containers know that they are running on a host that is using FIPS Validated / Modules in Process cryptography modules, use CRI-O to manage your runtimes. CRI-O supports FIPS mode, in that it configures the containers to know that they are running in FIPS mode.

### 20.3. INSTALLING A CLUSTER IN FIPS MODE

To install a cluster in FIPS mode, follow the instructions to install a customized cluster on your preferred infrastructure. Ensure that you set `fips: true` in the `install-config.yaml` file before you deploy your cluster.

- Amazon Web Services
- Microsoft Azure
- Bare metal
- Google Cloud Platform
- Red Hat OpenStack Platform (RHOSP)
- VMware vSphere

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

To apply AES CBC encryption to your etcd data store, follow the Encrypting etcd data process after you install your cluster.

If you add RHEL nodes to your cluster, ensure that you enable FIPS mode on the machines before their initial boot. See Adding RHEL compute machines to an OpenShift Container Platform cluster and Enabling FIPS Mode in the RHEL 7 documentation.
