</tr>
<tr>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
<td></td>
</tr>
<tr>
<td></td>
<td>hostPrefix: 23</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- cidr: fd01::/48</td>
<td></td>
</tr>
<tr>
<td></td>
<td>hostPrefix: 64</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. The prefix length for an IPv6 block is between 0 and 128. For example, 10.128.0.0/14 or fd01::/48.</td>
</tr>
<tr>
<td></td>
<td>If you use the OpenShift SDN network provider, specify an IPv4 network. If you use the OVN-Kubernetes network provider, you can specify IPv4 and IPv6 networks.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. For an IPv4 network the default value is 23. For an IPv6 network the default value is 64. The default value is also the minimum value for IPv6.</td>
</tr>
</tbody>
</table>
The IP address block for services. The default value is `172.30.0.0/16`.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

If you use the OVN-Kubernetes network provider, you can specify an IP address block for both of the IPv4 and IPv6 address families.

An array with an IP address block in CIDR format. For example:

```
networking:
  serviceNetwork:
  - 172.30.0.0/16
  - fd02::/112
```

The IP address blocks for machines.

If you specify multiple IP address blocks, the blocks must not overlap.

An array of objects. For example:

```
networking:
  machineNetwork:
  - cidr: 10.0.0.0/16
```

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

An IP network block in CIDR notation. For example, `10.0.0.0/16` or `fd00::/48`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 7.2.9.13. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 7.10. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>additionalTrustBundle</code></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
</tbody>
</table>
### compute

The configuration for the machines that comprise the compute nodes.

Array of `MachinePool` objects. For details, see the following "Machine-pool” table.

### compute.architecture

Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are `amd64` (the default).

String

### compute.hyperthreading

Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT** If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

**Enabled** or **Disabled**

### compute.name

Required if you use `compute`. The name of the machine pool.

`worker`

### compute.platform

Required if you use `compute`. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the `controlPlane.platform` parameter value.

`aws`, `azure`, `gcp`, `openstack`, `ovirt`, `vsphere`, or `{}`

### compute.replicas

The number of compute machines, which are also known as worker machines, to provision.

A positive integer greater than or equal to 2. The default value is 3.

### controlPlane

The configuration for the machines that comprise the control plane.

Array of `MachinePool` objects. For details, see the following "Machine-pool” table.
<table>

<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
</tbody>
</table>
### 7.2.9.2. Sample install-config.yaml file for bare metal

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
  name: worker
  replicas: 0 4
controlPlane: 5
  hyperthreading: Enabled 6
  name: master
  replicas: 3 7
metadata:
  name: test 8
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14 9
      hostPrefix: 23 10
  networkType: OpenShiftSDN
  serviceNetwork: 11
    - 172.30.0.0/16
platform:
  none: {} 12
fips: false 13
pullSecret: '{"auths": ...}' 14
sshKey: 'ssh-ed25519 AAAA...' 15
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to `Disabled`. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.
NOTE
Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

IMPORTANT
If you disable **hyperthreading**, whether in the BIOS or in the `install-config.yaml`, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE
If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to 23, then each node is assigned a /23 subnet out of the given **cidr**, which allows for 510 \(2^{(32 - 23)} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for your platform.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.
The pull secret that you obtained from the Red Hat OpenShift Cluster Manager site. This pull secret allows you to authenticate with the services that are provided by the included authorities.

The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

**Additional resources**

- See Load balancing requirements for user-provisioned infrastructure for more information on the API and application ingress load balancing requirements.

### 7.2.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**NOTE**

For bare metal installations, if you do not assign node IP addresses from the range that is specified in the `networking.machineNetwork[].cidr` field in the `install-config.yaml` file, you must include them in the `proxy.noProxy` field.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the...
nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
  noProxy: example.com  # 3
  additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
    ...
```

   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an `httpProxy` value.

   2 A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then `httpProxy` is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an `httpsProxy` value.

   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

   4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

   NOTE

   The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`. 

---

CHAPTER 7. INSTALLING ON BARE METAL

1079
NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

7.2.9.4. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing install-config.yaml file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your install-config.yaml file, as shown in the following compute stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

NOTE

You must set the value of the replicas parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the mastersSchedulable parameter in the <installation_directory>/manifests/cluster-scheduler-02-config.yml file is set to true. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.
7.2.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir=<installation_directory>
   ```

   **Example output**

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```
Because you create and manage the worker machines yourself, you do not need to initialize these machines.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
   name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
       id: mycluster-100419-private-zone
     publicZone: 2
       id: example.openshift.com
   status: {}
   
   Remove this section completely.
   
   If you do so, you must add ingress DNS records manually in a later step.
   
6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir=<installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.
Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the `<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

**Additional resources**

- See [Recovering from expired control plane certificates](#) for more information about recovering kubelet certificates.

### 7.2.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

**NOTE**

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments**: You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the `APPEND` parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special `coreos.inst.*` arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- **Ignition configs**: OpenShift Container Platform Ignition config files (`*.ign`) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system.
after completing installation. This special Ignition config is consumed by the `coreos-installer` to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- **coreos-installer**: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the `coreos-installer` command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

**NOTE**

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

### 7.2.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

**Procedure**

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your `bootstrap.ign` Ignition config file:

   ```bash
   $ sha512sum <installation_directory>/bootstrap.ign
   
   a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78dd10116e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
   
   installation_directory/bootstrap.ign
   
   Example output
   ```

   The digests are provided to the `coreos-installer` in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.
IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

$ curl -k http://<HTTP_server>/bootstrap.ign

Example output

Replace bootstrap.ign with master.ign or worker.ign in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

rhcos-<version>-live.<architecture>.iso

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:

- Burn the ISO image to a disk and boot it directly.
- Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the coreos-installer command as outlined in the following steps, instead of adding kernel arguments.
7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=SHA512-<digest>
```

1 You must run the `coreos-installer` command by using `sudo`, because the core user does not have the required root privileges to perform the installation.

2 The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.

The following example initializes a bootstrap node installation to the `/dev/sda` device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-
hash=SHA512-
a5a2d43879223273c9b60af66b44202a1d1248fe01cf156c46d4a79f552b6bad47bc8cc78dd01
6e80c59d2ea9e32ba53bc807afba581a059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

10. Continue to create the other machines for your cluster.

   IMPORTANT

   You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.
If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the core user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 7.2.11.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

**Procedure**

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ```

**Example output**

```
% Total  % Received % Xferd  Average Speed   Time    Time     Time  Current
```
Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS `kernel`, `initramfs` and `rootfs` files from the Product Downloads page on the Red Hat customer portal or the RHCOS image mirror page.

**IMPORTANT**
The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate `kernel`, `initramfs`, and `rootfs` artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the `rootfs`, `kernel`, and `initramfs` files to your HTTP server.

**IMPORTANT**
If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE or iPXE installation for the RHCOS images and begin the installation.

Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE:
  ```
  DEFAULT pxeboot
  TIMEOUT 20
  PROMPT 0
  LABEL pxeboot
  KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> 1
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign 2 3
  ```
1. Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the `initramfs` file, the `coreos.live.rootfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the **APPEND** line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see *How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?*.

- For iPXE:

  ```plaintext
  kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
<architecture>.img
boot
  ```

1. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **kernel** parameter value is the location of the **kernel** file, the **initrd=main** argument is needed for booting on UEFI systems, the **coreos.live.rootfs_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition_url** parameter value is the location of the bootstrap Ignition config file.

2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify the location of the **initramfs** file that you uploaded to your HTTP server.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the **kernel** line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see *How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?*.
7. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the core user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 7.2.11.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
- Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

#### 7.2.11.3.1. Using advanced networking options for PXE and ISO installations
Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

**Procedure**

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

   ```bash
   $ coreos-installer install --copy-network
   --ignition-url=http://host/worker.ign /dev/sda
   ```

   **IMPORTANT**

   The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

**Additional resources**

- See [Getting started with nmcli](https://doc.rhevm.org/rhevm/3.4/mgmt/admin-guide/1-cmdline/1-nmcli.html) and [Getting started with nmtui](https://doc.rhevm.org/rhevm/3.4/mgmt/admin-guide/1-cmdline/1-nmtui.html) in the RHEL 8 documentation for more information about the `nmcli` and `nmtui` tools.

### 7.2.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:
Creating separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting /var or a subdirectory of /var, such as /var/lib/etcd, on a separate partition, but not both.

**IMPORTANT**

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

Retaining existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

**WARNING**

The use of custom partitions could result in those partitions not being monitored by OpenShift Container Platform or alerted on. If you are overriding the default partitioning, see Understanding OpenShift File System Monitoring (eviction conditions) for more information about how OpenShift Container Platform monitors your host file systems.

### 7.2.11.3.2.1. Creating a separate /var partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var directory or a subdirectory of /var. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the /var directory or a subdirectory of /var also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate /var partition by adding a MachineConfig object that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

**Procedure**
1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ openshift-install create manifests --dir=<installation_directory>
```

2. Create a MachineConfig object and add it to a file in the `<installation_directory>/openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the compute nodes, and set the storage size as appropriate. This example mounts the /var directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
        - device: /dev/<device_name> ①
          partitions:
            - sizeMiB: <partition_size> ②
              startMiB: <partition_start_offset> ③
              label: var
      filesystems:
        - path: /var
device: /dev/disk/by-partlabel/var
      format: xfs
  systemd:
    units:
      - name: var.mount
        enabled: true
        contents:
          [Unit]
          Before=local-fs.target
          [Mount]
          Where=/var
          What=/dev/disk/by-partlabel/var
          [Install]
          WantedBy=local-fs.target
```

① The storage device name of the disk that you want to partition.
② The size of the data partition in mebibytes.
③ When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
NOTE

When creating a separate /var partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create the Ignition config files:

```bash
$ openshift-install create ignition-configs --dir=<installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

```
├── auth
│   ├── kubeadm-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

The files in the `<installation_directory>/manifest` and `<installation_directory>/openshift` directories are wrapped into the Ignition config files, including the file that contains the `98-var-partition` custom MachineConfig object.

Next steps

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

7.2.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add `coreos.inst.*` options to the APPEND parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

NOTE

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

Retaining existing partitions during an ISO installation

This example preserves any partition in which the partition label begins with `data` (`data*`):

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
   --save-partlabel 'data*' /dev/sda
```
The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \\
   --save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \\
   --save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

**Retaining existing partitions during a PXE installation**

This `APPEND` option preserves any partition in which the partition label begins with 'data' ('data*'):

```
coreos.inst.save_partlabel=data*
```

This `APPEND` option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This `APPEND` option preserves partition 6:

```
coreos.inst.save_partindex=6
```

**7.2.11.3.3. Identifying Ignition configs**

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config**: Every manual RHCOS installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.

  **IMPORTANT**

  It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

  For PXE installations, you pass the Ignition configs on the `APPEND` line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the `coreos-installer` command line with the `--ignition-url=` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config**: This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or
after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

For PXE or ISO boots, you can create the Ignition config and APPEND the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` or the `ignition.config.url` option will be ignored.

7.2.11.3.3.1. Embedding a live install Ignition config in the RHCOS ISO

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

**Procedure**

1. Download the `coreos-installer` binary from the following image mirror page: https://mirror.openshift.com/pub/openshift-v4/clients/coreos-installer/latest/.

2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as `/mnt`:

   ```bash
   # cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
   # chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
   ```

3. Run the following command to embed the Ignition config into the ISO:

   ```bash
   # ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign 
   /mnt/rhcos-<version>-live.x86_64.iso
   ```

   You can now use that ISO to install RHCOS using the specified live install Ignition config.

   **IMPORTANT**

   Using `coreos-installer iso ignition embed` to embed a file generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

   ```bash
   # ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
   # diff -s bootstrap.ign mybootstrap.ign
   ```

   **Example output**

   Files `bootstrap.ign` and `mybootstrap.ign` are identical

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

   ```bash
   # ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
   ```

   You can now embed another Ignition config into the ISO or use the ISO in its pristine state.
7.2.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the coreos-installer command.

7.2.11.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the dracut tool during system boot. For more information about the networking options supported by dracut, see the dracut.cmdline manual page.

**Table 7.12. Networking and bonding options for ISO installations**
<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=host_ip). If setting a static IP, you must then identify the DNS server IP address (nameserver=dns_ip) on each node. This example sets:</td>
<td></td>
</tr>
</tbody>
</table>
|  - The node’s IP address to 10.10.10.2  
|  - The gateway address to 10.10.10.254  
|  - The netmask to 255.255.255.0  
|  - The hostname to core0.example.com  
|  - The DNS server address to 4.4.4.41  
|  - The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically. | ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41 |

**NOTE**

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

| Specification multiple network interfaces by specifying multiple ip= entries. |  
| ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none  
| ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none |

Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.

| Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used. |

</tr>
</tbody>
</table>
### Description
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

### Examples
To configure the bonded interface with a VLAN and to use DHCP:
```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:
```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

#### 7.2.11.3.4.2. `coreos-installer` options for ISO installations

You can install RHCOS by running `coreos-installer install <options> <device>` at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the `coreos-installer` command.

| Table 7.13. `coreos-installer` subcommands, command-line options, and arguments |
|---------------------------------|--------------------------------|

#### `coreos-installer install` subcommand

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
</table>

```
$ coreos-installer install <options> <device>
```

Embed an Ignition config in an ISO image.

#### `coreos-installer install` subcommand options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>

- `-u, --image-url <url>` Specify the image URL manually.
- `-f, --image-file <path>` Specify a local image file manually. Used for debugging.
- `--ignition-file <path>` Embed an Ignition config from a file.
- `--ignition-url <URL>` Embed an Ignition config from a URL.
- `--ignition-hash <digest>` Digest type-value of the Ignition config.
<table>
<thead>
<tr>

7.2.11.3.4.3. coreos.inst boot options for ISO or PXE installations

You can automatically invoke coreos-installer options at boot time by passing coreos.inst boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the coreos.inst options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing TAB while the RHEL CoreOS (Live) menu option is highlighted.

- For PXE or iPXE installations, the coreos.inst options must be added to the APPEND line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer coreos.inst boot options for ISO and PXE installations.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>coreos.inst.image_url</td>
<td>Optional: Download and install the specified RHCOS image.</td>
</tr>
<tr>
<td></td>
<td>• This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>• While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>• If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>• Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.skip_reboot</td>
<td>Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td>coreos.inst.platform_id</td>
<td>Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: coreos.inst.platform_id=vmware.</td>
</tr>
<tr>
<td>ignition.config.url</td>
<td>Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how coreos-installer is invoked, or to run code before or after the installation. This is different from coreos.inst.ignition_url, which is the Ignition config for the installed system.</td>
</tr>
</tbody>
</table>

### 7.2.11.4. Enabling multipathing with kernel arguments on RHCOS

RHCOS supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability.

You can enable multipathing at installation time for nodes that were provisioned in OpenShift Container Platform 4.8 or later. While post-installation support is available by activating multipathing via the machine config, enabling multipathing during installation is recommended.
In setups where any I/O to non-optimized paths results in I/O system errors, you must enable multipathing at installation time.

**IMPORTANT**

On IBM Z and LinuxONE, you can enable multipathing only if you configured your cluster for it during installation. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process" in *Installing a cluster with z/VM on IBM Z and LinuxONE*.

The following procedure enables multipath at installation time and appends kernel arguments to the `coreos-installer install` command so that the installed system itself will use multipath beginning from the first boot.

**Prerequisites**

- You have a running OpenShift Container Platform cluster that uses version 4.8 or later.
- You are logged in to the cluster as a user with administrative privileges.

**Procedure**

1. To enable multipath and start the `multipath` daemon, run the following command:

   ```bash
   $ mpathconf --enable && systemctl start multipathd.service
   ```

   Optional: If booting the PXE or ISO, you can instead enable multipath by adding `rd.multipath=default` from the kernel command line.

2. Append the kernel arguments by invoking the `coreos-installer` program:

   - If there is only one multipath device connected to the machine, it should be available at path `/dev/mapper/mpatha`. For example:

     ```bash
     $ coreos-installer install /dev/mapper/mpatha
     --append-karg rd.multipath=default
     --append-karg root=/dev/disk/by-label/dm-mpath-root
     ```

     1 Indicates the path of the single multipathed device.

   - If there are multiple multipath devices connected to the machine, or to be more explicit, instead of using `/dev/mapper/mpatha`, it is recommended to use the World Wide Name (WWN) symlink available in `/dev/disk/by-id`. For example:

     ```bash
     $ coreos-installer install /dev/disk/by-id/wwn-<wwn_ID>
     --append-karg rd.multipath=default
     --append-karg root=/dev/disk/by-label/dm-mpath-root
     ```

     1 Indicates the WWN ID of the target multipathed device. For example, `0xx194e957fcedb4841`. 

---

This procedure may also be used when running `coreos-installer` from a bare-metal system.
This symlink can also be used as the `coreos.inst.install_dev` kernel argument when using special `coreos.inst.*` arguments to direct the live installer. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process".

3. Check that the kernel arguments worked by going to one of the worker nodes and listing the kernel command line arguments (in `/proc/cmdline` on the host):

   ```
   $ oc debug node/ip-10-0-141-105.ec2.internal
   
   Example output
   
   Starting pod/ip-10-0-141-105ec2internal-debug ...
   To use host binaries, run `chroot /host`
   
   sh-4.2# cat /host/proc/cmdline
   ...
   rd.multipath=default root=/dev/disk/by-label/dm-mpath-root
   ...
   
   sh-4.2# exit
   
   You should see the added kernel arguments.
   
   Additional resources
   
   - See [Installing RHCOS and starting the OpenShift Container Platform bootstrap process](#) for more information on using special `coreos.inst.*` arguments to direct the live installer.
   
   7.2.11.5. Updating the bootloader using `bootupd`

   To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

   After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

   **NOTE**

   It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

   **Manual install method**

   You can manually install `bootupd` by using the `bootctl` command-line tool.

   1. Inspect the system status:

      ```
      # bootupctl status
      
      Example output
      ```
2. RHCOS images created without `bootupd` installed on them require an explicit adoption phase. If the system status is `Adoptable`, perform the adoption:

```sh
# bootupctl adopt-and-update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```sh
# bootupctl update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

**Machine config method**

Another way to enable `bootupd` is by providing a machine config.

- Provide a machine config file with the enabled `systemd` unit, as shown in the following example:

**Example output**

```
variant: rhcos
version: 1.1.0
systemd:
units:
  - name: custom-bootupd-auto.service
    enabled: true
    contents:
      [Unit]
      Description=Bootupd automatic update
      
      [Service]
      ExecStart=/usr/bin/bootupctl update
      RemainAfterExit=yes
      
      [Install]
      WantedBy=multi-user.target
```

### 7.2.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.
Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```
   $ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \  
   --log-level=info
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.21.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

Additional resources

- See Monitoring installation progress for more information about monitoring the installation logs and retrieving diagnostic data if installation issues arise.

7.2.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.
Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadm` credentials:

   ```sh
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```sh
   $ oc whoami
   system:admin
   
   Example output
   
   system:admin
   ``

7.2.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```sh
   $ oc get nodes
   
   Example output
   
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.21.0
   master-1  Ready     master  63m  v1.21.0
   master-2  Ready     master  64m  v1.21.0
   worker-0  NotReady  worker  76s  v1.21.0
   worker-1  NotReady  worker  70s  v1.21.0
   
   The output lists all of the machines that you created.
NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>  
```

1
<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```bash
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```bash
$ oc adm certificate approve <csr_name>
```

<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>
It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 7.2.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>

2. Configure the Operators that are not available.

Additional resources

- See Gathering logs from a failed installation for details about gathering data in the event of a failed OpenShift Container Platform installation.

- See Troubleshooting Operator issues for steps to check Operator pod health across the cluster and gather Operator logs for diagnosis.

### 7.2.15.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

**NOTE**

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

### 7.2.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

#### 7.2.15.2.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.
Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   `$ oc get pod -n openshift-image-registry`

   **NOTE**

   If the storage type is `emptyDir`, the replica number cannot be greater than 1.

3. Check the registry configuration:

   `$ oc edit configs.imageregeristy.operator.openshift.io`

   **Example output**

   ```yaml
   storage:
   pvc:
   claim:
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   `$ oc get clusteroperator image-registry`
5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:
  
  $ oc edit configs.imageregistry/cluster

  Then, change the line

  managementState: Removed

  to

  managementState: Managed

7.2.15.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'

  **WARNING**
  
  Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found

  Wait a few minutes and run the command again.

7.2.15.2.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.
Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   
   $ watch -n5 oc get clusteroperators
   
   NAME                                       VERSION AVAILABLE   PROGRESSING   DEGRADED  SINCE
   authentication                             4.8.0   True        False         False      3h56m
   baremetal                                  4.8.0   True        False         False      29h
   cloud-credential                           4.8.0   True        False         False      29h

   etcd                                       4.8.0   True        False         False      29h
   image-registry                             4.8.0   True        False         False      3h59m
   ingress                                    4.8.0   True        False         False      4h30m
   insights                                   4.8.0   True        False         False      29h
   kube-apiserver                             4.8.0   True        False         False      29h
   kube-controller-manager                    4.8.0   True        False         False      29h
   kube-scheduler                             4.8.0   True        False         False      29h
   kube-storage-version-migrator              4.8.0   True        False         False      4h2m
   machine-api                                4.8.0   True        False         False      29h
   machine-approver                           4.8.0   True        False         False      6h34m
   machine-config                             4.8.0   True        False         False      3h56m
   marketplace                                4.8.0   True        False         False      4h2m
   
   2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

7.2.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   
   Example output
   ```
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

```
<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Running 1 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apisher-67b9g</td>
<td>1/1</td>
<td>Running 0 3m</td>
</tr>
</tbody>
</table>
b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

**NOTE**

When installing with multipath, it is strongly recommended to enable it at installation time, and not at a later time, which can cause problems.

See “Enabling multipathing with kernel arguments on RHCOS” in the *Installing on bare metal* documentation for more information.

### 7.2.17. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.

### 7.3. INSTALLING A USER-PROVISIONED BARE METAL CLUSTER WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform 4.8, you can install a cluster on bare metal infrastructure that you provision with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

When you customize OpenShift Container Platform networking, you must set most of the network configuration parameters during installation. You can modify only *kubeProxy* network configuration parameters in a running cluster.
7.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

7.3.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

Additional resources

- See [Installing a user-provisioned bare metal cluster on a restricted network](#) for more information about performing a restricted network installation on bare metal infrastructure that you provision.

7.3.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.
7.3.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

### Table 7.15. Default monitoring stack components

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**NOTE**

As an exception, you can run zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production. Running one compute machine is not supported.

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

**IMPORTANT**

If the `platform: none` field is defined in the `install-config.yaml` file, virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. For more information, see [BZ#1935539](#). Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

7.3.3.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:
<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS or RHEL 7.9</td>
<td>2</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

1. 1 vCPU is equivalent to 1 physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. As with all user-provisioned installations, if you choose to use RHEL 7 compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

### 7.3.3.3. Managing certificate signing requests

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

**Additional resources**

- See [Configuring a three-node cluster](#) for details about deploying three-node clusters in bare metal environments.
- See [Approving the certificate signing requests for your machines](#) for more information about approving cluster certificate signing requests after installation.

### 7.3.3.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

#### 7.3.3.4.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as `localhost` or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.
Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

### 7.3.3.4.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have Internet access to pull images for platform containers and provide telemetry data to Red Hat.

#### Table 7.16. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>N/A</td>
<td>Network reachability tests</td>

<td>30000-32767</td>
<td>Kubernetes node port</td>
</tr>
</tbody>
</table>

#### Table 7.17. Ports used for all-machine to control plane communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6443</td>
<td>Kubernetes API</td>
</tr>
</tbody>
</table>

#### Table 7.18. Ports used for control plane machine to control plane machine communications
### Additional resources
- Configuring chrony time service

#### 7.3.3.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

**Table 7.19. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Component</td>
<td>Record</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>api-int</td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
TIP
You can use the `dig` command to verify name and reverse name resolution. See the section on 
Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

7.3.3.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for 
deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant 
to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-
provisioned cluster.

```
Example 7.4. Sample DNS zone database

```

1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

**Example DNS PTR record configuration for a user-provisioned cluster**

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

**Example 7.5. Sample DNS zone database for reverse records**

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1;
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4;
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5;
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7;
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8;
;EOF
```
Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.

NOTE
A PTR record is not required for the OpenShift Container Platform application wildcard.

- Validating DNS resolution for user-provisioned infrastructure

7.3.3.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **NOTE**
   Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

**Table 7.20. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application ingress load balancer: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 7.21. Application ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>Port</td>
<td>Back-end machines (pool members)</td>
<td>Internal</td>
<td>External</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>---------------------------------</td>
<td>----------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 7.3.3.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**Example 7.6. Sample API and application ingress load balancer configuration**

```plaintext
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000

daemon
defaults
mode http
log global
option dontlognull
option http-server-close
option redispatch
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
timeout server 1m
```
In the example, the cluster name is **ocp4**.

Port **6443** handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port **22623** handles the machine config server traffic and points to the control plane machines.

Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller.
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports **6443, 22623, 443**, and **80** by running `netstat -nltupe` on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

### 7.3.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

**Prerequisites**

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.

- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

**Procedure**

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.

   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.
NOTE
If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines section for more information about static IP provisioning and advanced networking options.

c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

NOTE
If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

4. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
      See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.
NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

Additional resources

- Requirements for a cluster with user-provisioned infrastructure
- Installing RHCSOS and starting the OpenShift Container Platform bootstrap process
- Setting the cluster node hostnames through DHCP
- Advanced RHCSOS installation configuration
- Networking requirements for user-provisioned infrastructure
- User-provisioned DNS requirements
- Validating DNS resolution for user-provisioned infrastructure
- Load balancing requirements for user-provisioned infrastructure

7.3.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   Example output

   ```
   api.ocp4.example.com  0 IN A 192.168.1.5
   ```
b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

**Example output**

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

**Example output**

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.
2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

**Additional resources**

- User-provisioned DNS requirements
- Load balancing requirements for user-provisioned infrastructure

### 7.3.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.
If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      ```
      ```
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the **ssh-agent**:

   ```
   $ ssh-add <path>/<file_name> 1
   1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa
   ```

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

2. Set the **GOOGLE_APPLICATION_CREDENTIALS** environment variable to the full path to your service account private key file.

   ```
   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
   ```

3. Verify that the credentials were applied.

   ```
   $ gcloud auth list
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**Additional resources**

- [Verifying node health](#)

### 7.3.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```

5. From the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 7.3.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.8. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the **Command line interface** section, select **Linux** from the drop-down menu and click **Download command-line tools**.

4. Unpack the archive:

```bash
$ tar xvf <file>
```
5. Place the `oc` binary in a directory that is on your `PATH`. To check your `PATH`, execute the following command:

```
$ echo $PATH
```

After you install the CLI, it is available using the `oc` command:

```
$ oc <command>
```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the **Command line interface** section, select **Windows** from the drop-down menu and click **Download command-line tools**.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`. To check your `PATH`, open the command prompt and execute the following command:

```
C:> path
```

After you install the CLI, it is available using the `oc` command:

```
C:> oc <command>
```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the **Command line interface** section, select **MacOS** from the drop-down menu and click **Download command-line tools**.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your `PATH`. To check your `PATH`, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the CLI, it is available using the `oc` command:
7.3.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   $$\texttt{mkdir <installation_directory>}$$

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.  

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.
7.3.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

7.3.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Table 7.22. Required parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter</strong></td>
</tr>
<tr>
<td>apiVersion</td>
</tr>
<tr>
<td>baseDomain</td>
</tr>
<tr>
<td>metadata</td>
</tr>
<tr>
<td>metadata.name</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation:

- **aws**
- **baremetal**
- **azure**
- **openstack**
- **ovirt**
- **vsphere**

For additional information about platform.<platform> parameters, consult the table for your specific platform that follows.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform</strong></td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>pullSecret</strong></td>
<td>Get a pull secret from <a href="https://cloud.redhat.com/openshift/install/pull-secret">https://cloud.redhat.com/openshift/install/pull-secret</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td></td>
</tr>
</tbody>
</table>

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

7.3.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

If you use the OVN-Kubernetes cluster network provider, both IPv4 and IPv6 address families are supported.

If you use the OpenShift SDN cluster network provider, only the IPv4 address family is supported.

If you configure your cluster to use both IP address families, you must specify IPv4 and IPv6 addresses in the same order for all network configuration parameters. For example, in the following configuration IPv4 addresses are listed before IPv6 addresses.

```yaml
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
    - cidr: fd00:10:128::/56
      hostPrefix: 64
  serviceNetwork:
    - 172.30.0.0/16
    - fd00:172:16::/112
```
Table 7.23. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The default value is <strong>OpenShiftSDN</strong>.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>

</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td><code>hostPrefix</code> is set to <strong>23</strong> then each node is assigned a <strong>/23</strong> subnet out</td>
<td></td>
</tr>
<tr>
<td></td>
<td>of the given <code>cidr</code>. <strong>A hostPrefix</strong> value of <strong>23</strong> provides 510 (2^{(32 - 23) - 2}) pod IP addresses.</td>
<td>For an IPv4 network the default value is <strong>23</strong>. For an IPv6 network the default value is <strong>64</strong>. The default value is also the minimum value for IPv6.</td>
</tr>
</tbody>
</table>
### networking.serviceNetwork

The IP address block for services. The default value is **172.30.0.0/16**.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

If you use the OVN-Kubernetes network provider, you can specify an IP address block for both of the IPv4 and IPv6 address families.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <strong>172.30.0.0/16</strong>. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. If you use the OVN-Kubernetes network provider, you can specify an IP address block for both of the IPv4 and IPv6 address families.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - <strong>172.30.0.0/16</strong> - fd02::/112</td>
</tr>
</tbody>
</table>

### networking.machineNetwork

The IP address blocks for machines.

If you specify multiple IP address blocks, the blocks must not overlap.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: machineNetwork: - cidr: <strong>10.0.0.0/16</strong></td>
</tr>
</tbody>
</table>

### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is **10.0.0.0/16** for all platforms other than libvirt. For libvirt, the default value is **192.168.126.0/24**.

An IP network block in CIDR notation. For example, **10.0.0.0/16** or **fd00::/48**.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 7.3.9.13. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 7.24. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set publish to Internal. The default value is External.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

### 7.3.9.1.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

Table 7.25. Additional GCP parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.gcp.network</td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.gcp.type</td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td>platform.gcp.zones</td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as us-central1-a, in a YAML sequence.</td>
</tr>
<tr>
<td>platform.gcp.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.computeSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.name</td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.location</td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.name</td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>compute.platform.gc.p.osDisk.encryption.Key.kmsKey.location</code></td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>compute.platform.gc.p.osDisk.encryption.Key.kmsKey.projectId</code></td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

**7.3.9.2. Sample install-config.yaml file for bare metal**

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com 1
compute: 2
  - hyperthreading: Enabled 3
    name: worker
    replicas: 0 4
controlPlane: 5
  hyperthreading: Enabled 6
  name: master
  replicas: 3 7
metadata:
  name: test 8
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14 9
  hostPrefix: 23 10
  networkType: OpenShiftSDN
  serviceNetwork: 11
    - 172.30.0.0/16
platform:
  none: {} 12
fips: false 13
pullSecret: '{"auths": ...}' 14
sshKey: 'ssh-ed25519 AAAA...' 15
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
2. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation.
Only one control plane pool is used.

Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

**IMPORTANT**

If you disable **hyperthreading**, whether in the BIOS or in the `install-config.yaml`, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

**NOTE**

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a `/23` subnet out of the given **cidr**, which allows for 510 ($2^{32} - 23 - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for your platform.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

---

**CHAPTER 7. INSTALLING ON BARE METAL**

1151
IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret that you obtained from the Red Hat OpenShift Cluster Manager site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

Additional resources

- See Load balancing requirements for user-provisioned infrastructure for more information on the API and application ingress load balancing requirements.

7.3.10. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1

You can customize the following network-related fields in the install-config.yaml file before you create the manifest files:

- networking.networkType
- networking.clusterNetwork
- networking.serviceNetwork
- networking.machineNetwork

For more information on these fields, refer to Installation configuration parameters.

NOTE

Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

Phase 2

After creating the manifest files by running openshift-install create manifests, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.
You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

### 7.3.11. Specifying advanced network configuration

You can use advanced network configuration for your cluster network provider to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

**Prerequisites**

- You have created the `install-config.yaml` file and completed any modifications to it.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir=<installation_directory>  
   
   <installation_directory> specifies the name of the directory that contains the `install-config.yaml` file for your cluster.
   ```

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   ```

3. Specify the advanced network configuration for your cluster in the `cluster-network-03-config.yml` file, such as in the following examples:

   **Specify a different VXLAN port for the OpenShift SDN network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       openshiftSDNConfig:
         vxlanPort: 4800
   ```

   **Enable IPsec for the OVN-Kubernetes network provider**

   ```
7.3.12. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**: IP address pools from which pod IP addresses are allocated.
- **serviceNetwork**: IP address pool for services.
- **defaultNetwork.type**: Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

### 7.3.12.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
</tbody>
</table>

4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  ovnKubernetesConfig:
  ipsecConfig: {}
```

OpenShift Container Platform 4.8 Installing
**spec.clusterNetwork**
array
A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

```
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

**spec.serviceNetwork**
array
A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

```
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

**spec.defaultNetwork**
object
Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

**spec.kubeProxy Config**
object
The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

---

defaultNetwork object configuration
The values for the `defaultNetwork` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Either **OpenShiftSDN** or **OVNKubernetes**. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.

**NOTE**

OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

**openshiftSDNConfig** object

This object is only valid for the OpenShift SDN cluster network provider.

**ovnKubernetesConfig** object

This object is only valid for the OVN-Kubernetes cluster network provider.

Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 7.28. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 7.29. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

This value cannot be changed after cluster installation.

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.

Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

destination | string | One of the following additional audit log targets:
| | | libc
| | | The libc syslog() function of the journald process on the host.
| | | udp:<host>:<port>
| | | A syslog server. Replace <host>:<port> with the host and port of the syslog server.
| | | unix:<file>
| | | A Unix Domain Socket file specified by <file>.
| | | null
| | | Do not send the audit logs to any additional target.

syslogFacility | string | The syslog facility, such as kern, as defined by RFC5424. The default value is local0.

### Example OVN-Kubernetes configuration

defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}

### kubeProxyConfig object configuration

The values for the kubeProxyConfig object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
</tbody>
</table>

**NOTE**

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.
7.3.13. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

- Obtain the Ignition config files:

  ```
  $ ./openshift-install create ignition-configs --dir=<installation_directory>
  ```

  For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

If you created an `install-config.yaml` file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing <code>iptables</code> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>kubeProxyConfig:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>proxyArguments:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>iptables-min-sync-period:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>- 0s</code></td>
</tr>
</tbody>
</table>
The following files are generated in the directory:

- auth
  - kubeadmin-password
  - kubeconfig
- bootstrap.ign
- master.ign
- metadata.json
- worker.ign

7.3.14. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

**NOTE**

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments**: You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the `APPEND` parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special `coreos.inst.*` arguments to direct the installer, as well as standard boot arguments for turning standard kernel services on or off.

- **Ignition configs**: OpenShift Container Platform Ignition config files (*.ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the `coreos-installer` to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- **coreos-installer**: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run
the `coreos-installer` command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

### 7.3.14.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

#### Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your `bootstrap.ign` Ignition config file:

   ```bash
   $ sha512sum <installation_directory>/bootstrap.ign
   a5a2d438723273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf01166e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
   installation_directory/bootstrap.ign
   ```

   The digests are provided to the `coreos-installer` in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```bash
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ```
Example output

```
% Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
     0      0      0     0     0     0      0   --:--:--      2       0
0  0  0  0  0  0  0   0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0  0
{"ignition":
{"version":"3.2.0"},"passwd":{"users":[{"name":"core","sshAuthorizedKeys":["ssh-rsa...
```

Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

```
rhcos-<version>-live.<architecture>.iso
```

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:

- Burn the ISO image to a disk and boot it directly.
- Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

**NOTE**

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=SHA512-<digest> 1 2
```

**1** You must run the `coreos-installer` command by using `sudo`, because the `core` user does not have the required root privileges to perform the installation.

**2** The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.
is the Ignition config file SHA512 digest obtained in a preceding step.

NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running coreos-installer.

The following example initializes a bootstrap node installation to the /dev/sda device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

$ sudo coreos-installer install --ignition-url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=SHA512-a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf0116e80c59d2ea9e32ba53bc807afbc581aa059311def2c3e3b

8. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

10. Continue to create the other machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.
NOTE

RHCOS nodes do not include a default password for the `core` user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

7.3.14.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the `Advanced RHCOS installation configuration` section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ```

   **Example output**

   ```
   % Total    % Received % Xferd Average Speed   Time    Time     Time  Current
   Dload  Upload   Total   Spent    Left  Speed
   0 0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0["ignition":
   {
   "version":"3.2.0"},
   "passwd":{
   "users":{
   "name":"core",
   "sshAuthorizedKeys":[]
   }
   }
   ```
Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS `kernel`, `initramfs` and `rootfs` files from the Product Downloads page on the Red Hat customer portal or the RHCOS image mirror page.

**IMPORTANT**

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate `kernel`, `initramfs`, and `rootfs` artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>.img`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the `rootfs`, `kernel`, and `initramfs` files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE or iPXE installation for the RHCOS images and begin the installation. Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

   - **For PXE:**

```plaintext
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign

1 Specify the location of the live kernel file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2 If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.```
Specify the locations of the RHCOS files that you uploaded to your HTTP server. The initrd parameter value is the location of the initramfs file, the coreos.live.rootfs_url.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more console= arguments to the APPEND line. For example, add console=tty0 console=ttyS0 to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?

- For iPXE:

```
initrd --name main http://<HTTP_server>/rhcos-<version>-live-initramfs.<<architecture>.img
```

1. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The kernel parameter value is the location of the kernel file, the initrd=main argument is needed for booting on UEFI systems, the coreos.live.rootfs_url parameter value is the location of the rootfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file.

2. If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3. Specify the location of the initramfs file that you uploaded to your HTTP server.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more console= arguments to the kernel line. For example, add console=tty0 console=ttyS0 to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?

7. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.
8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the `core` user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 7.3.14.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
- Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

#### 7.3.14.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

**Procedure**

1. Boot the ISO installer.
2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.
3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

   ```bash
   $ coreos-installer install --copy-network \ 
   --ignition-url=http://host/worker.ign /dev/sda
   ``

   **IMPORTANT**

   The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

**Additional resources**

- See [Getting started with `nmcli`](link) and [Getting started with `nmtui`](link) in the RHEL 8 documentation for more information about the `nmcli` and `nmtui` tools.

### 7.3.14.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:

- Creating separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, on a separate partition, but not both.
IMPORTANT

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retaining existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

WARNING

The use of custom partitions could result in those partitions not being monitored by OpenShift Container Platform or alerted on. If you are overriding the default partitioning, see Understanding OpenShift File System Monitoring (eviction conditions) for more information about how OpenShift Container Platform monitors your host file systems.

7.3.14.3.2.1. Creating a separate /var partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var directory or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the /var directory or a subdirectory of /var also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate /var partition by adding a MachineConfig object that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

Procedure

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:
Create a MachineConfig object and add it to a file in the ./<installation_directory>/openshift directory. For example, name the file 98-var-partition.yaml, change the disk device name to the name of the storage device on the compute nodes, and set the storage size as appropriate. This example mounts the /var directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.2.0
  storage:
    disks:
      - device: /dev/<device_name>
        partitions:
          - sizeMiB: <partition_size>
            startMiB: <partition_start_offset>
            label: var
    filesystems:
      - path: /var
        device: /dev/disk/by-partlabel/var
        format: xfs
    systemd:
      units:
        - name: var.mount
          enabled: true
          contents: |
          [Unit]
          Before=local-fs.target
          [Mount]
          Where=/var
          What=/dev/disk/by-partlabel/var
          [Install]
          WantedBy=local-fs.target
```

1. The storage device name of the disk that you want to partition.
2. The size of the data partition in mebibytes.
3. When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
NOTE
When creating a separate /var partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create the Ignition config files:

```bash
$ openshift-install create ignition-configs --dir=<installation_directory>  
```

For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

```
├── auth
│   ├── kubedadmin-password
│   └── kubecfg
├── bootstrap.ign
├── master.ign
└── worker.ign
```

The files in the `<installation_directory>/manifest` and `<installation_directory>/openshift` directories are wrapped into the Ignition config files, including the file that contains the 98-var-partition custom MachineConfig object.

**Next steps**

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

7.3.14.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add `coreos.inst.*` options to the APPEND parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

NOTE
If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

**Retaining existing partitions during an ISO installation**

This example preserves any partition in which the partition label begins with data (data*):

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \  --save-partlabel 'data*' /dev/sda
```
The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign   --save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

### Retaining existing partitions during a PXE installation

This `APPEND` option preserves any partition in which the partition label begins with 'data' ('data*'):

```bash
coreos.inst.save_partlabel=data*
```

This `APPEND` option preserves partitions 5 and higher:

```bash
coreos.inst.save_partindex=5-
```

This `APPEND` option preserves partition 6:

```bash
coreos.inst.save_partindex=6
```

### 7.3.14.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config**: Every manual RHCOS installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.

  **IMPORTANT**

  It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

  For PXE installations, you pass the Ignition configs on the `APPEND` line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the `coreos-installer` command line with the `--ignition-url=` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config**: This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or
after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

For PXE or ISO boots, you can create the Ignition config and append the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot ignition.platform.id=metal` or the `ignition.config.url` option will be ignored.

### 7.3.14.3.3.1. Embedding a live install Ignition config in the RHCOS ISO

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

**Procedure**

1. Download the `coreos-installer` binary from the following image mirror page:

2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as `/mnt`:

   ```bash
   # cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
   # chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
   ```

3. Run the following command to embed the Ignition config into the ISO:

   ```bash
   # ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign \
   /mnt/rhcos-<version>-live.x86_64.iso
   ```

   You can now use that ISO to install RHCOS using the specified live install Ignition config.

   **IMPORTANT**

   Using `coreos-installer iso ignition embed` to embed a file generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign`, and `worker.ign`, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

   ```bash
   # ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
   # diff -s bootstrap.ign mybootstrap.ign
   ```

   **Example output**

   Files `bootstrap.ign` and `mybootstrap.ign` are identical

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

   ```bash
   # ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
   ```

   You can now embed another Ignition config into the ISO or use the ISO in its pristine state.
7.3.14.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

7.3.14.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

Table 7.32. Networking and bonding options for ISO installations
<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=&lt;host_ip&gt;). If setting a static IP, you must then identify the DNS server IP address (nameserver=&lt;dns_ip&gt;) on each node. This example sets:</td>
<td>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</td>
</tr>
<tr>
<td>- The node’s IP address to 10.10.10.2</td>
<td></td>
</tr>
<tr>
<td>- The gateway address to 10.10.10.254</td>
<td></td>
</tr>
<tr>
<td>- The netmask to 255.255.255.0</td>
<td></td>
</tr>
<tr>
<td>- The hostname to core0.example.com</td>
<td></td>
</tr>
<tr>
<td>- The DNS server address to 4.4.4.41</td>
<td></td>
</tr>
<tr>
<td>- The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically.</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Specify multiple network interfaces by specifying multiple ip= entries.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</td>
</tr>
<tr>
<td>ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</td>
</tr>
</tbody>
</table>

Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</td>
</tr>
<tr>
<td>ip=:::core0.example.com:enp2s0:none</td>
</tr>
</tbody>
</table>

You can combine DHCP and static IP configurations on systems with multiple network interfaces.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip=enp1s0:dhcp</td>
</tr>
<tr>
<td>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</td>
</tr>
</tbody>
</table>
Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

To configure a VLAN on a network interface and use a static IP address:

```text
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0
```

To configure a VLAN on a network interface and to use DHCP:

```text
ip==enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

You can provide multiple DNS servers by adding a `nameserver=` entry for each server.

```text
nameserver=1.1.1.1
nameserver=8.8.8.8
```

Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples:

- The syntax for configuring a bonded interface is: `bond=name[:network_interfaces][:options]`
  - `name` is the bonding device name (`bond0`), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.
  - When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.

To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:

```text
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp
```

To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```text
bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:nonen
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface with a VLAN and to use DHCP:

```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

### 7.3.14.3.4.2. coreos-installer options for ISO installations

You can install RHCOS by running `coreos-installer install <options> <device>` at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the `coreos-installer` command.

#### Table 7.33. `coreos-installer` subcommands, command-line options, and arguments

<table>
<thead>
<tr>
<th>coreos-installer install subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$ coreos-installer install &lt;options&gt; &lt;device&gt;</td>
<td>Embed an Ignition config in an ISO image.</td>
</tr>
</tbody>
</table>

#### coreos-installer install subcommand options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-u, --image-url &lt;url&gt;</td>
<td>Specify the image URL manually.</td>
</tr>
<tr>
<td>-f, --image-file &lt;path&gt;</td>
<td>Specify a local image file manually. Used for debugging.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>Embed an Ignition config from a file.</td>
</tr>
<tr>
<td>-l, --ignition-url &lt;URL&gt;</td>
<td>Embed an Ignition config from a URL.</td>
</tr>
<tr>
<td>--ignition-hash &lt;digest&gt;</td>
<td>Digest <code>type-value</code> of the Ignition config.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>&lt;device&gt;</td>
<td>The destination device.</td>
</tr>
</tbody>
</table>

coreos-installer ISO Ignition subcommands

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-p, --platform &lt;name&gt;</td>
<td>Override the Ignition platform ID for the installed system.</td>
</tr>
<tr>
<td>--append-karg &lt;arg&gt;...</td>
<td>Append a default kernel argument to the installed system.</td>
</tr>
<tr>
<td>--delete-karg &lt;arg&gt;...</td>
<td>Delete a default kernel argument from the installed system.</td>
</tr>
<tr>
<td>-n, --copy-network</td>
<td>Copy the network configuration from the install environment.</td>
</tr>
<tr>
<td></td>
<td>+ IMPORTANT</td>
</tr>
<tr>
<td></td>
<td>The --copy-network option only copies networking configuration found under /etc/NetworkManager/system-connections. In particular, it does not copy the system hostname.</td>
</tr>
<tr>
<td>--network-dir &lt;path&gt;</td>
<td>For use with -n. Default is /etc/NetworkManager/system-connections/.</td>
</tr>
<tr>
<td>--save-partlabel &lt;lx&gt;..</td>
<td>Save partitions with this label glob.</td>
</tr>
<tr>
<td>--save-partindex &lt;id&gt;...</td>
<td>Save partitions with this number or range.</td>
</tr>
<tr>
<td>--insecure</td>
<td>Skip signature verification.</td>
</tr>
<tr>
<td>--insecure-ignition</td>
<td>Allow Ignition URL without HTTPS or hash.</td>
</tr>
<tr>
<td>--architecture &lt;name&gt;</td>
<td>Target CPU architecture. Default is x86_64.</td>
</tr>
<tr>
<td>--preserve-on-error</td>
<td>Do not clear partition table on error.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

coreos-install install subcommand argument

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;device&gt;</td>
<td>The destination device.</td>
</tr>
</tbody>
</table>
$ coreos-installer iso ignition embed
<options> --ignition-file <file_path>
<ISO_image>

Embed an Ignition config in an ISO image.

coreos-installer iso ignition show <options>
<ISO_image>

Show the embedded Ignition config from an ISO image.

coreos-installer iso ignition remove
<options> <ISO_image>

Remove the embedded Ignition config from an ISO image.

coreos-installer ISO Ignition subcommand options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f, --force</td>
<td>Overwrite an existing Ignition config.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

coreos-installer PXE Ignition subcommands

coreos-installer pxe ignition wrap <options>

Wrap an Ignition config in an image.

coreos-installer pxe ignition unwrap
<options> <image_name>

Show the wrapped Ignition config in an image.

coreos-installer PXE Ignition subcommand options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>

<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>
7.3.14.3.4.3. coreos.inst boot options for ISO or PXE installations

You can automatically invoke `coreos-installer` options at boot time by passing `coreos.inst` boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the `coreos.inst` options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing TAB while the RHEL CoreOS (Live) menu option is highlighted.

- For PXE or iPXE installations, the `coreos.inst` options must be added to the APPEND line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer `coreos.inst` boot options for ISO and PXE installations.

Table 7.34. coreos.inst boot options

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **coreos.inst.image_url** | Optional: Download and install the specified RHCOS image.  
  - This argument should not be used in production environments and is intended for debugging purposes only.  
  - While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.  
  - If you are using `coreos.inst.image_url`, you must also use `coreos.inst.insecure`. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.  
  - Only HTTP and HTTPS protocols are supported. |
| **coreos.inst.skip_reboot** | Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only. |
| **coreos.inst.platform_id** | Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is `metal`. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example:  
  `coreos.inst.platform_id=vmware`. |
| **ignition.config.url**     | Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how `coreos-installer` is invoked, or to run code before or after the installation. This is different from `coreos.inst.ignition_url`, which is the Ignition config for the installed system. |

**7.3.14.4. Enabling multipathing with kernel arguments on RHCOS**

RHCOS supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability.

You can enable multipathing at installation time for nodes that were provisioned in OpenShift Container Platform 4.8 or later. While post-installation support is available by activating multipathing via the machine config, enabling multipathing during installation is recommended.
In setups where any I/O to non-optimized paths results in I/O system errors, you must enable multipathing at installation time.

**IMPORTANT**

On IBM Z and LinuxONE, you can enable multipathing only if you configured your cluster for it during installation. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process” in *Installing a cluster with z/VM on IBM Z and LinuxONE*.

The following procedure enables multipath at installation time and appends kernel arguments to the `coreos-installer install` command so that the installed system itself will use multipath beginning from the first boot.

**Prerequisites**

- You have a running OpenShift Container Platform cluster that uses version 4.8 or later.
- You are logged in to the cluster as a user with administrative privileges.

**Procedure**

1. To enable multipath and start the `multipath` daemon, run the following command:

   ```bash
   $ mpathconf --enable && systemctl start multipathd.service
   ```

   Optional: If booting the PXE or ISO, you can instead enable multipath by adding `rd.multipath=default` from the kernel command line.

2. Append the kernel arguments by invoking the `coreos-installer` program:

   - If there is only one multipath device connected to the machine, it should be available at path `/dev/mapper/mpatha`. For example:

     ```bash
     $ coreos-installer install /dev/mapper/mpatha
     --append-karg rd.multipath=default
     --append-karg root=/dev/disk/by-label/dm-mpath-root
     ```

     1 Indicates the path of the single multipathed device.

   - If there are multiple multipath devices connected to the machine, or to be more explicit, instead of using `/dev/mapper/mpatha`, it is recommended to use the World Wide Name (WWN) symlink available in `/dev/disk/by-id`. For example:

     ```bash
     $ coreos-installer install /dev/disk/by-id/wwn-<wwn_ID>
     --append-karg rd.multipath=default
     --append-karg root=/dev/disk/by-label/dm-mpath-root
     ```

     1 Indicates the WWN ID of the target multipathed device. For example, 0xx194e957fcedb4841.
This symlink can also be used as the `coreos.inst.Install_dev` kernel argument when using special `coreos.inst.*` arguments to direct the live installer. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process".

3. Check that the kernel arguments worked by going to one of the worker nodes and listing the kernel command line arguments (in `/proc/cmdline` on the host):

```bash
$ oc debug node/ip-10-0-141-105.ec2.internal
```

**Example output**

```
Starting pod/ip-10-0-141-105ec2internal-debug ...
To use host binaries, run `chroot /host`
sh-4.2# cat /host/proc/cmdline
...
rd.multipath=default root=/dev/disk/by-label/dm-mpath-root 
...
sh-4.2# exit
```

You should see the added kernel arguments.

### 7.3.14.5. Updating the bootloader using bootupd

To update the bootloader by using **bootupd**, you must either install **bootupd** on RHCOS machines manually or provide a machine config with the enabled **systemd** unit. Unlike **grubby** or other bootloader tools, **bootupd** does not manage kernel space configuration such as passing kernel arguments.

After you have installed **bootupd**, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

**Manual install method**

You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:

   ```bash
   # bootupctl status
   ```

   **Example output**

   ```
   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version
   ```

2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:
3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

Example output

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

### Machine config method

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

```
variant: rhcos
version: 1.1.0
systemd:
units:
  - name: custom-bootupd-auto.service
    enabled: true
    contents: |
      [Unit]
      Description=Bootupd automatic update

      [Service]
      ExecStart=/usr/bin/bootupctl update
      RemainAfterExit=yes

      [Install]
      WantedBy=multi-user.target
```

### 7.3.15. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RH COS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
You have obtained the installation program and generated the Ignition config files for your cluster.

You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

**Procedure**

1. **Monitor the bootstrap process:**

   ```
   $ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.21.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

**Additional resources**

- See [Monitoring installation progress](#) for more information about monitoring the installation logs and retrieving diagnostic data if installation issues arise.

**7.3.16. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   system:admin
   ``

**7.3.17. Approving the certificate signing requests for your machines**

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ``

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>NotReady</td>
<td>worker</td>
<td>76s</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>NotReady</td>
<td>worker</td>
<td>70s</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.
2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  ```

  <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:
NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

   $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     $ oc adm certificate approve <csr_name>  

     <csr_name> is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}} | xargs oc adm certificate approve

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

   $ oc get nodes

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>
NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

7.3.18. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

   Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
2. Configure the Operators that are not available.

**Additional resources**

- See [Gathering logs from a failed installation](#) for details about gathering data in the event of a failed OpenShift Container Platform installation.

- See [Troubleshooting Operator issues](#) for steps to check Operator pod health across the cluster and gather Operator logs for diagnosis.

### 7.3.18.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

**NOTE**

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

### 7.3.18.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

### 7.3.18.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the Recreate rollout strategy.
IMPORTANT

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

7.3.19. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h56m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h39m</td>
</tr>
<tr>
<td>console</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h59m</td>
</tr>
<tr>
<td>csi-snapshot-controller</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h12m</td>
</tr>
<tr>
<td>dns</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h15m</td>
</tr>
<tr>
<td>etcd</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>image-registry</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h59m</td>
</tr>
<tr>
<td>ingress</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h30m</td>
</tr>
<tr>
<td>insights</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>kube-apiserver</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>kube-controller-manager</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

```yaml
kube-scheduler  4.8.0   True   False   False   29h
kube-storage-version-migrator  4.8.0   True   False   False   4h2m
machine-api  4.8.0   True   False   False   29h
machine-approver  4.8.0   True   False   False   3h63m
machine-config  4.8.0   True   False   False   29h
marketplace  4.8.0   True   False   False   4h2m
monitoring  4.8.0   True   False   False   6h31m
network  4.8.0   True   False   False   29h
node-tuning  4.8.0   True   False   False   4h30m
openshift-apiserver  4.8.0   True   False   False   3h56m
openshift-controller-manager  4.8.0   True   False   False   4h36m
openshift-samples  4.8.0   True   False   False   4h30m
operator-lifecycle-manager  4.8.0   True   False   False   29h
operator-lifecycle-manager-catalog  4.8.0   True   False   False   29h
operator-lifecycle-manager-packageserver  4.8.0   True   False   False   3h59m
service-ca  4.8.0   True   False   False   29h
storage  4.8.0   True   False   False   4h30m
```
b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

**NOTE**

When installing with multipath, it is strongly recommended to enable it at installation time, and not at a later time, which can cause problems.

See "Enabling multipathing with kernel arguments on RHCOS" in the *Installing on bare metal* documentation for more information.

### 7.3.20. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.

### 7.4. INSTALLING A USER-PROVISIONED BARE METAL CLUSTER ON A RESTRICTED NETWORK

In OpenShift Container Platform 4.8, you can install a cluster on bare metal infrastructure that you provision in a restricted network.
Important

While you might be able to follow this procedure to deploy a cluster on virtualized or cloud environments, you must be aware of additional considerations for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you attempt to install an OpenShift Container Platform cluster in such an environment.

7.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You created a registry on your mirror host and obtained the imageContentSources data for your version of OpenShift Container Platform.

Important

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

Note

Be sure to also review this site list if you are configuring a proxy.

7.4.2. About installations in restricted networks

In OpenShift Container Platform 4.8, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.
Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

7.4.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

7.4.3. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to obtain the images that are necessary to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the **Red Hat OpenShift Cluster Manager (OCM)**.

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use **subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the **Red Hat OpenShift Cluster Manager** page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access **Quay.io** to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

7.4.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.
7.4.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 7.35. Default monitoring stack components

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**NOTE**

As an exception, you can run zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production. Running one compute machine is not supported.

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

**IMPORTANT**

If the `platform: none` field is defined in the `install-config.yaml` file, virtual machines (VMs) configured to use virtual hardware version 14 or greater might result in a failed installation. It is recommended to configure VMs with virtual hardware version 13. For more information, see BZ#1935539.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

7.4.4.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>

1. 1 vCPU is equivalent to 1 physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. As with all user-provisioned installations, if you choose to use RHEL 7 compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

### 7.4.4.3. Managing certificate signing requests

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

#### Additional resources

- See [Configuring a three-node cluster](#) for details about deploying three-node clusters in bare metal environments.
- See [Approving the certificate signing requests for your machines](#) for more information about approving cluster certificate signing requests after installation.

### 7.4.4.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

#### 7.4.4.4.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as `localhost` or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.
Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

### 7.4.4.4.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**Table 7.36. Ports used for all-machine to all-machine communications**

Additional resources
7.4.4.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the [DHCP recommendations for user-provisioned infrastructure](#) section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 7.39. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;..&lt;base_domain&gt;</code>.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Component</td>
<td>Record</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
<td></td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the **dig** command to verify name and reverse name resolution. See the section on **Validating DNS resolution for user-provisioned infrastructure** for detailed validation steps.
7.4.4.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is ocp4 and the base domain is example.com.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial

;EOF
```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API
load balancer.

2. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API
load balancer and is used for internal cluster communications.

3. Provides name resolution for the wildcard routes. The record refers to the IP address of the
application ingress load balancer. The application ingress load balancer targets the machines.
application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- Provides name resolution for the bootstrap machine.
- Provides name resolution for the control plane machines.
- Provides name resolution for the compute machines.

**Example DNS PTR record configuration for a user-provisioned cluster**

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

**Example 7.8. Sample DNS zone database for reverse records**

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

- Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

**Additional resources**

- Validating DNS resolution for user-provisioned infrastructure

### 7.4.4.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer** provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **NOTE**

   Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

**Table 7.40. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application ingress load balancer: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 7.41. Application ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

7.4.4.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 7.9. Sample API and application ingress load balancer configuration

```plaintext
global
  log          127.0.0.1 local2
  pidfile      /var/run/haproxy.pid
  maxconn      4000
defaults
  mode         http
  log          global
  option       dontlognull
  option       http-server-close
  option       redispatch
  retries      3
  timeout http-request 10s
  timeout queue  1m
  timeout connect 10s
  timeout client 1m
  timeout server 1m
  timeout http-keep-alive 10s
  timeout check  10s
  maxconn       3000
frontend stats
  bind *:1936
  mode         http
  log          global
  maxconn      10
  stats enable
```
In the example, the cluster name is **ocp4**.

**Port 6443** handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

**Port 22623** handles the machine config server traffic and points to the control plane machines.

**Port 443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**Port 80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.
TIP

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -nltupe on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running setsebool -P haproxy_connect_any=1.

7.4.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   NOTE

   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines section for more information about static IP provisioning and advanced networking options.
c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

**NOTE**

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.

4. Setup the required DNS infrastructure for your cluster.
   
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.

   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

   See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.
   
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.

   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

   See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

**NOTE**

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

**Additional resources**

- Requirements for a cluster with user-provisioned infrastructure
- Installing RHCOS and starting the OpenShift Container Platform bootstrap process
- Setting the cluster node hostnames through DHCP
7.4.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

      ```bash
      $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
      api.ocp4.example.com. 0 IN A 192.168.1.5
      ``

      Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

      ```bash
      $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
      api-int.ocp4.example.com. 0 IN A 192.168.1.5
      ```
c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com.
```
Provides the record name for the Kubernetes internal API.

Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

Additional resources

- User-provisioned DNS requirements
- Load balancing requirements for user-provisioned infrastructure

7.4.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
NOTE
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE
On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.
1. Add your SSH private key to the **ssh-agent**:

   ```sh
   $ ssh-add /path/to/your/key
   ```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`.

   **Example output**

   ```sh
   Identity added: /home/<you>/path/to/your/key (computer_name)
   ```

2. Set the **GOOGLE_APPLICATION_CREDENTIALS** environment variable to the full path to your service account private key file.

   ```sh
   $ export GOOGLE_APPLICATION_CREDENTIALS="/path/to/your/service_account_key.json"
   ```

3. Verify that the credentials were applied.

   ```sh
   $ gcloud auth list
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

**Additional resources**

- [Verifying node health](#)

### 7.4.8. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

- Obtain the **imageContentSources** section from the output of the command to mirror the repository.

- Obtain the contents of the certificate for your mirror registry.

**Procedure**

1. Create an installation directory to store your required installation assets in:
$ mkdir <installation_directory>

**IMPORTANT**

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

**NOTE**

You must name this configuration file `install-config.yaml`.

- **NOTE**
  
  Unless you use a registry that RHCOS trusts by default, such as `docker.io`, you must provide the contents of the certificate for your mirror repository in the `additionalTrustBundle` section. In most cases, you must provide the certificate for your mirror.

- You must include the `imageContentSources` section from the output of the command to mirror the repository.

**NOTE**

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

### 7.4.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.
IMPORTANT

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

7.4.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 7.42. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: `aws`, `baremetal`, `azure`, `openstack`, `ovirt`, `vsphere`. For additional information about platform.<platform> parameters, consult the table for your specific platform that follows.

### pullSecret

Get a pull secret from [https://cloud.redhat.com/openshift/install/pull-secret](https://cloud.redhat.com/openshift/install/pull-secret) to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

---

**7.4.8.1.2. Network configuration parameters**

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

If you use the OVN-Kubernetes cluster network provider, both IPv4 and IPv6 address families are supported.

If you use the OpenShift SDN cluster network provider, only the IPv4 address family is supported.

If you configure your cluster to use both IP address families, you must specify IPv4 and IPv6 addresses in the same order for all network configuration parameters. For example, in the following configuration IPv4 addresses are listed before IPv6 addresses.

```yaml
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
    - cidr: fd00:10:128::/56
      hostPrefix: 64
  serviceNetwork:
    - 172.30.0.0/16
    - fd00:172:16::/112
```

Table 7.43. Network parameters

---

---

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: fd01::/48</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 64</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. The prefix length for an IPv6 block is between 0 and 128. For example, 10.128.0.0/14 or fd01::/48.</td>
</tr>
<tr>
<td></td>
<td>If you use the OpenShift SDN network provider, specify an IPv4 network. If you use the OVN-Kubernetes network provider, you can specify IPv4 and IPv6 networks.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. For an IPv4 network the default value is 23. For an IPv6 network the default value is 64. The default value is also the minimum value for IPv6.</td>
</tr>
</tbody>
</table>
### networking.serviceNetwork
The IP address block for services. The default value is 172.30.0.0/16.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

If you use the OVN-Kubernetes network provider, you can specify an IP address block for both of the IPv4 and IPv6 address families.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking: serviceNetwork: - 172.30.0.0/16 - fd02::/112</td>
</tr>
</tbody>
</table>

### networking.machineNetwork
The IP address blocks for machines.

If you specify multiple IP address blocks, the blocks must not overlap.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>

### networking.machineNetwork.cidr
Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16 or fd00::/48.</td>
</tr>
</tbody>
</table>

**NOTE**
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

### 7.4.8.13. Optional configuration parameters
Optional installation configuration parameters are described in the following table:

**Table 7.44. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
</tbody>
</table>
### OpenShift Container Platform 4.8 Installing

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute.hyperthreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>

<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the <strong>x86_64</strong> architecture.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td><strong>Array of strings</strong></td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. To deploy a private cluster, which cannot be accessed from the internet, set <strong>publish</strong> to <strong>Internal</strong>. The default value is <strong>External</strong>.</td>
</tr>
</tbody>
</table>
**sshKey**

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
<key1>
<key2>
<key3>
```

### 7.4.8.1.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

**Table 7.45. Additional GCP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.gcp.network</code></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.gcp.type</code></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><code>platform.gcp.zones</code></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>platform.gcp.controlPlaneSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>platform.gcp.computeSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKeyName</code></td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</code></td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.location</code></td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</code></td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td><code>compute.platform.gcp.osDisk.encryptionKey.kmsKey.name</code></td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td><code>compute.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</code></td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><code>compute.platform.gcp.osDisk.encryptionKey.kmsKey.location</code></td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>compute.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</code></td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

7.4.8.2. Sample `install-config.yaml` file for bare metal

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not.

Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

**IMPORTANT**

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml**, ensure that your capacity planning accounts for the dramatically decreased machine performance.
You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{32 - 23} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to none. You cannot provide additional platform configuration variables for your platform.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

For <local_registry>, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, registry.example.com or registry.example.com:5000. For <credentials>, specify the base64-encoded user name and password for your mirror registry.

The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

Additional resources

- See Load balancing requirements for user-provisioned infrastructure for more information on the API and application ingress load balancing requirements.

### 7.4.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**NOTE**

For bare metal installations, if you do not assign node IP addresses from the range that is specified in the `networking.machineNetwork[].cidr` field in the `install-config.yaml` file, you must include them in the `proxy.noProxy` field.

**Prerequisites**

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpProxy value.

A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then httpProxy is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpsProxy value.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster–wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.
You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing `install-config.yaml` file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

  ```yaml
  compute:
  - name: worker
    platform: {}
    replicas: 0
  ```

  **NOTE**

  You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to true. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

### 7.4.9. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.
The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir=<installation_directory>
   ```

   **Example output**

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.
4. Check that the `mastersSchedulable` parameter in the
<installation_directory>/manifests/cluster-scheduler-02-config.yml Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the <installation_directory>/manifests/cluster-scheduler-02-config.yml file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the <installation_directory>/manifests/cluster-dns-02-config.yml DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
   name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone:  
       id: mycluster-100419-private-zone
     publicZone:  
       id: example.openshift.com
   status: {}
   ```

   **1 2** Remove this section completely.

   If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir=<installation_directory>  
   ```

   **1** For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the ./<installation_directory>/auth directory:
```
auth
  ├── kubeadmin-password
  │   └── kubeconfig
  │     └── bootstrap.ign
  │         └── master.ign
  │               └── metadata.json
  │                   └── worker.ign
  └── bootstrap.ign
  └── master.ign
  └── metadata.json
  └── worker.ign
```

**Additional resources**

- See [Recovering from expired control plane certificates](#) for more information about recovering kubelet certificates.

### 7.4.10. Configuring chrony time service

You must set the time server and related settings used by the chrony time service (*chrony*) by modifying the contents of the *chrony.conf* file and passing those contents to your nodes as a machine config.

**Procedure**

1. Create a Butane config including the contents of the *chrony.conf* file. For example, to configure chrony on worker nodes, create a *99-worker-chrony.bu* file.

   ```yaml
   variant: openshift
   version: 4.8.0
   metadata:
     name: 99-worker-chrony
     labels:
       machineconfiguration.openshift.io/role: worker
   storage:
     files:
       - path: /etc/chrony.conf
         mode: 0644
         overwrite: true
         contents:
           inline:
             pool 0.rhel.pool.ntp.org iburst
             driftfile /var/lib/chrony/drift
             makestep 1.0
             rtcmsg
             logdir /var/log/chrony
   ```

   **NOTE**

   See “Creating machine configs with Butane” for information about Butane.

   - On control plane nodes, substitute `master` for `worker` in both of these locations.
   - Specify any valid, reachable time source, such as the one provided by your DHCP server.

2. Use Butane to generate a *MachineConfig* object file, *99-worker-chrony.yaml*, containing the configuration to be delivered to the nodes:
Apply the configurations in one of two ways:

- If the cluster is not running yet, after you generate manifest files, add the `MachineConfig` object file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.

- If the cluster is already running, apply the file:

  ```
  $ oc apply -f ./99-worker-chrony.yaml
  ```

### 7.4.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

**NOTE**

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments:** You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the `APPEND` parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special `coreos.inst.*` arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- **Ignition configs:** OpenShift Container Platform Ignition config files (*.ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the `coreos-installer` to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- **coreos-installer:** You can boot the live ISO installer to a shell prompt, which allows you to

```bash
$ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
$ oc apply -f ./99-worker-chrony.yaml
```
prepare the permanent system in a variety of ways before first boot. In particular, you can run the `coreos-installer` command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

### 7.4.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

**Procedure**

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your `bootstrap.ign` Ignition config file:

   ```bash
   $ sha512sum <installation_directory>/bootstrap.ign
   a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf0116e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
   installation_directory/bootstrap.ign
   ```

   The digests are provided to the `coreos-installer` in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:
$ curl -k http://<HTTP_server>/bootstrap.ign

Example output

```
% Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
         0     0  0.00K      0           0            0           0              0    0
0  0  0  0  0  0  0  0  0  0  --:--:--  --:--:--  --:--:--  0
{"ignition":
{"version":"3.2.0"},
"passwd":{
"users":{
"name":"core","sshAuthorizedKeys":
["ssh-rsa...
```

Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

```
rhcos-<version>-live.<architecture>.iso
```

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:

- Burn the ISO image to a disk and boot it directly.
- Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

**NOTE**

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=SHA512=<digest>
```

You must run the `coreos-installer` command by using `sudo`, because the `core` user does not have the required root privileges to perform the installation.
The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node.

**NOTE**

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running `coreos-installer`.

The following example initializes a bootstrap node installation to the `/dev/sda` device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```bash
$ sudo coreos-installer install --ignition-url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=SHA512-a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf0116e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

10. Continue to create the other machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.
NOTE

RHCOS nodes do not include a default password for the core user. You can access the nodes by running ssh core@<node>.<cluster_name>.<base_domain> as a user with access to the SSH private key that is paired to the public key that you specified in your install_config.yaml file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

7.4.11.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   IMPORTANT
   
   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   `$ curl -k http://<HTTP_server>/bootstrap.ign`

   Example output

   ```
   % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
   Dload  Upload   Total   Spent    Left  Speed
   0      0      0     0    0     0     0 --:--:-- --:--:-- --:--:--    0"ignition":
   {"version":"3.2.0"},"passwd":{"users":{"name":"core","sshAuthorizedKeys":[]}"ssh-rsa..."`
Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS `kernel`, `initramfs` and `rootfs` files from the Product Downloads page on the Red Hat customer portal or the RHCOS image mirror page.

**IMPORTANT**

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate `kernel`, `initramfs`, and `rootfs` artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the `rootfs`, `kernel`, and `initramfs` files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE or iPXE installation for the RHCOS images and begin the installation.

Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- **For PXE:**

  ```
  DEFAULT pxeboot
  TIMEOUT 20
  PROMPT 0
  LABEL pxeboot
  
  KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> 1
  APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
  coreos.inst.install_dev=/dev/sda
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign 2 3
  ```

  1 Specify the location of the live `kernel` file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

  2 If you use multiple NICs, specify a single interface in the `ip` option. For example, to use
Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the `initramfs` file, the `coreos.live.rootfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=ttys0` or `console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?

- For iPXE:

```
<architecture>.img
<architecture>.img
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
```

1. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `kernel` parameter value is the location of the `kernel` file, the `initrd=main` argument is needed for booting on UEFI systems, the `coreos.live.rootfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.

2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify the location of the `initramfs` file that you uploaded to your HTTP server.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `kernel` line. For example, add `console=ttys0` or `console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.
8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the `core` user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 7.4.11.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
- Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

#### 7.4.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

**Procedure**

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

   ```bash
   $ coreos-installer install --copy-network \   --ignition-url=http://host/worker.ign /dev/sda
   ```

   **IMPORTANT**

   The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

**Additional resources**

- See *Getting started with nmcli* and *Getting started with nmtui* in the RHEL 8 documentation for more information about the `nmcli` and `nmtui` tools.

### 7.4.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:

- Creating separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, on a separate partition, but not both.
IMPORTANT

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retaining existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

WARNING

The use of custom partitions could result in those partitions not being monitored by OpenShift Container Platform or alerted on. If you are overriding the default partitioning, see Understanding OpenShift File System Monitoring (eviction conditions) for more information about how OpenShift Container Platform monitors your host file systems.

7.4.11.3.2.1. Creating a separate /var partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var directory or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the /var directory or a subdirectory of /var also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate /var partition by adding a MachineConfig object that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

Procedure

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:
2. Create a `MachineConfig` object and add it to a file in the `./<installation_directory>/openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the compute nodes, and set the storage size as appropriate. This example mounts the `/var` directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 98-var-partition
spec:
  config:
    version: 3.2.0
  storage:
    disks:
      - device: /dev/<device_name>
        partitions:
          - sizeMiB: <partition_size>
            startMiB: <partition_start_offset>
            label: var
  filesystems:
    - path: /var
      device: /dev/disk/by-partlabel/var
      format: xfs
  systemd:
    units:
      - name: var.mount
        enabled: true
        contents: |
          [Unit]
          Before=local-fs.target
          [Mount]
          Where=/var
          What=/dev/disk/by-partlabel/var
          [Install]
          WantedBy=local-fs.target
```

1. The storage device name of the disk that you want to partition.
2. The size of the data partition in mebibytes.
3. When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
NOTE

When creating a separate /var partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create the Ignition config files:

```bash
$ openshift-install create ignition-configs --dir=<installation_directory> ①

① For `<installation_directory>`, specify the same installation directory.
```

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

```
  ├── auth
  │    └── kubeadmin-password
  │         └── kubeconfig
  └── bootstrap.ign
    ├── master.ign
    └── worker.ign
```

The files in the `<installation_directory>/manifest` and `<installation_directory>/openshift` directories are wrapped into the Ignition config files, including the file that contains the `98-var-partition` custom MachineConfig object.

Next steps

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

7.4.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add `coreos.inst.*` options to the APPEND parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

NOTE

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

Retaining existing partitions during an ISO installation

This example preserves any partition in which the partition label begins with `data` (data*):

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign
   --save-partlabel 'data*' /dev/sda
```
The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign   --save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

Retaining existing partitions during a PXE installation

This **APPEND** option preserves any partition in which the partition label begins with 'data' ('data*'):

```bash
coreos.inst.save_partlabel=data*
```

This **APPEND** option preserves partitions 5 and higher:

```bash
coreos.inst.save_partindex=5-
```

This **APPEND** option preserves partition 6:

```bash
coreos.inst.save_partindex=6
```

7.4.11.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config**: Every manual RHCOS installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.

  **IMPORTANT**

  It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

  For PXE installations, you pass the Ignition configs on the **APPEND** line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the `coreos-installer` command line with the `--ignition-url=` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config**: This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or
after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

For PXE or ISO boots, you can create the Ignition config and **APPEND** the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` or the `ignition.config.url` option will be ignored.

### 7.4.11.3.3.1. Embedding a live install Ignition config in the RHCOS ISO

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

**Procedure**

1. Download the `coreos-installer` binary from the following image mirror page: https://mirror.openshift.com/pub/openshift-v4/clients/coreos-installer/latest/.

2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as `/mnt`:

   ```
   # cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
   # chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
   ```

3. Run the following command to embed the Ignition config into the ISO:

   ```
   # ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign 
   /mnt/rhcos-<version>-live.x86_64.iso
   ```

   You can now use that ISO to install RHCOS using the specified live install Ignition config.

   **IMPORTANT**

   Using `coreos-installer iso ignition embed` to embed a file generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

   ```
   # ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
   # diff -s bootstrap.ign mybootstrap.ign
   ```

   **Example output**

   Files `bootstrap.ign` and `mybootstrap.ign` are identical

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

   ```
   # ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
   ```

   You can now embed another Ignition config into the ISO or use the ISO in its pristine state.
7.4.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

7.4.11.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=.`

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

Table 7.46. Networking and bonding options for ISO installations
To configure an IP address, either use DHCP (ip= dhcp) or set an individual static IP address (ip= <host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver= <dns_ip>) on each node. This example sets:

- The node’s IP address to 10.10.10.2
- The gateway address to 10.10.10.254
- The netmask to 255.255.255.0
- The hostname to core0.example.com
- The DNS server address to 4.4.4.41
- The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically.

**NOTE**

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Specify multiple network interfaces by specifying multiple ip= entries.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</td>
</tr>
</tbody>
</table>

Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</td>
</tr>
<tr>
<td>ip=:::core0.example.com:enp2s0:none</td>
</tr>
</tbody>
</table>

You can combine DHCP and static IP configurations on systems with multiple network interfaces.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip=enp1s0:dhcp</td>
</tr>
<tr>
<td>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none</td>
</tr>
<tr>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
</tr>
<tr>
<td>Optional: You can configure VLANs on individual interfaces by using the <code>vlan=</code> parameter.</td>
</tr>
<tr>
<td>&gt; ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none</td>
</tr>
<tr>
<td>&gt; vlan=enp2s0.100:enp2s0</td>
</tr>
<tr>
<td>You can provide multiple DNS servers by adding a <code>nameserver=</code> entry for each server.</td>
</tr>
<tr>
<td>Optional: Bonding multiple network interfaces to a single interface is supported using the <code>bond=</code> option. In these two examples:</td>
</tr>
</tbody>
</table>
| > The syntax for configuring a bonded interface is: `bond=name[:network_interfaces][:options]`  
  
  name is the bonding device name (bond0), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.  
  
  > When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface. | To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example: |
| > bond=bond0:em1,em2:mode=active-backup  
  
  ip=bond0:dhcp |
| > To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example: |
| > bond=bond0:em1,em2:mode=active-backup  
  
  ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none |
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface with a VLAN and to use DHCP:
```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:
```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

---

### 7.4.11.3.4.2. coreos-installer options for ISO installations

You can install RHCOS by running `coreos-installer install <options> <device>` at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the `coreos-installer` command.

### Table 7.47. coreos-installer subcommands, command-line options, and arguments

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$ coreos-installer install &lt;options&gt; &lt;device&gt;</code></td>
<td>Embed an Ignition config in an ISO image.</td>
</tr>
</tbody>
</table>

#### coreos-installer install subcommand options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-u, --image-url &lt;url&gt;</code></td>
<td>Specify the image URL manually.</td>
</tr>
<tr>
<td><code>-f, --image-file &lt;path&gt;</code></td>
<td>Specify a local image file manually. Used for debugging.</td>
</tr>
<tr>
<td><code>-i, --ignition-file &lt;path&gt;</code></td>
<td>Embed an Ignition config from a file.</td>
</tr>
<tr>
<td><code>-l, --ignition-url &lt;URL&gt;</code></td>
<td>Embed an Ignition config from a URL.</td>
</tr>
<tr>
<td><code>--ignition-hash &lt;digest&gt;</code></td>
<td>Digest <code>type-value</code> of the Ignition config.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>&lt;device&gt;</td>
<td>The destination device.</td>
</tr>
</tbody>
</table>

## coreos-installer ISO Ignition subcommands

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
$ coreos-installer iso ignition embed <options> --ignition-file <file_path> <ISO_image>

Embed an Ignition config in an ISO image.

**coreos-installer iso ignition show <options> <ISO_image>**

Show the embedded Ignition config from an ISO image.

**coreos-installer iso ignition remove <options> <ISO_image>**

Remove the embedded Ignition config from an ISO image.

**coreos-installer ISO Ignition subcommand options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f, --force</td>
<td>Overwrite an existing Ignition config.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

**coreos-installer PXE Ignition subcommands**

**Subcommand**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
</table>

Note that not all of these options are accepted by all subcommands.

**coreos-installer pxe ignition wrap <options>**

Wrap an Ignition config in an image.

**coreos-installer pxe ignition unwrap <options> <image_name>**

Show the wrapped Ignition config in an image.

**coreos-installer PXE Ignition subcommand options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>
7.4.11.3.4.3. **coreos.inst boot options for ISO or PXE installations**

You can automatically invoke `coreos-installer` options at boot time by passing `coreos.inst` boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the `coreos.inst` options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing `TAB` while the RHEL CoreOS (Live) menu option is highlighted.

- For PXE or iPXE installations, the `coreos.inst` options must be added to the `APPEND` line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer `coreos.inst` boot options for ISO and PXE installations.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>coreos.inst.install_dev</code></td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as <code>/dev/sda</code>, although <code>sda</code> is allowed.</td>
</tr>
<tr>
<td><code>coreos.inst.ignition_url</code></td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td><code>coreos.inst.save_partlabel</code></td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Globs-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td><code>coreos.inst.save_partindex</code></td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges <code>m-n</code> are permitted, and either <code>m</code> or <code>n</code> can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td><code>coreos.inst.insecure</code></td>
<td>Optional: Permits the OS image that is specified by <code>coreos.inst.image_url</code> to be unsigned.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| `coreos.inst.image_url`       | Optional: Download and install the specified RHCOS image.  
  - This argument should not be used in production environments and is intended for debugging purposes only.  
  - While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.  
  - If you are using `coreos.inst.image_url`, you must also use `coreos.inst.insecure`. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.  
  - Only HTTP and HTTPS protocols are supported. |
| `coreos.inst.skip_reboot`     | Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only. |
| `coreos.inst.platform_id`     | Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is `metal`. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: `coreos.inst.platform_id=vmware`. |
| `ignition.config.url`         | Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how `coreos-installer` is invoked, or to run code before or after the installation. This is different from `coreos.inst.ignition_url`, which is the Ignition config for the installed system. |

### 7.4.11.4. Enabling multipathing with kernel arguments on RHCOS

RHCOS supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability.

You can enable multipathing at installation time for nodes that were provisioned in OpenShift Container Platform 4.8 or later. While post-installation support is available by activating multipathing via the machine config, enabling multipathing during installation is recommended.
In setups where any I/O to non-optimized paths results in I/O system errors, you must enable multipathing at installation time.

**IMPORTANT**

On IBM Z and LinuxONE, you can enable multipathing only if you configured your cluster for it during installation. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process" in *Installing a cluster with z/VM on IBM Z and LinuxONE*.

The following procedure enables multipath at installation time and appends kernel arguments to the `coreos-installer install` command so that the installed system itself will use multipath beginning from the first boot.

**Prerequisites**

- You have a running OpenShift Container Platform cluster that uses version 4.8 or later.
- You are logged in to the cluster as a user with administrative privileges.

**Procedure**

1. To enable multipath and start the `multipath` daemon, run the following command:

   ```bash
   $ mpathconf --enable && systemctl start multipathd.service
   ```

   Optional: If booting the PXE or ISO, you can instead enable multipath by adding `rd.multipath=default` from the kernel command line.

2. Append the kernel arguments by invoking the `coreos-installer` program:

   ```bash
   $ coreos-installer install /dev/mapper/mpatha \
   --append-karg rd.multipath=default \
   --append-karg root=/dev/disk/by-label/dm-mpath-root
   ```

   Indicates the path of the single multipathed device.

   ```bash
   $ coreos-installer install /dev/disk/by-id/wwn-<wwn_ID> \
   --append-karg rd.multipath=default \
   --append-karg root=/dev/disk/by-label/dm-mpath-root
   ```

   Indicates the WWN ID of the target multipathed device. For example, `0xx194e957fcedb4841`.

   ```bash
   $ mpathconf --enable && systemctl start multipathd.service
   ```

   ```bash
   $ coreos-installer install /dev/mapper/mpatha \
   --append-karg rd.multipath=default \
   --append-karg root=/dev/disk/by-label/dm-mpath-root
   ```

   Indicates the path of the single multipathed device.

   ```bash
   $ coreos-installer install /dev/disk/by-id/wwn-<wwn_ID> \
   --append-karg rd.multipath=default \
   --append-karg root=/dev/disk/by-label/dm-mpath-root
   ```

   Indicates the WWN ID of the target multipathed device. For example, `0xx194e957fcedb4841`. 

This chapter was also included in the `coreos-installer install` documentation at a later date.
This symlink can also be used as the `coreos.inst.install_dev` kernel argument when using special `coreos.inst.*` arguments to direct the live installer. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process".

3. Check that the kernel arguments worked by going to one of the worker nodes and listing the kernel command line arguments (in `/proc/cmdline` on the host):

```bash
$ oc debug node/ip-10-0-141-105.ec2.internal

Example output

Starting pod/ip-10-0-141-105ec2internal-debug ...
To use host binaries, run `chroot /host`
sh-4.2# cat /host/proc/cmdline
...  
rd.multipath=default root=/dev/disk/by-label/dm-mpath-root
...  
sh-4.2# exit
```

You should see the added kernel arguments.

7.4.11.5. Updating the bootloader using bootupd

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install `bootupd` by using the `bootctl` command-line tool.

1. Inspect the system status:

```bash
# bootupctl status

Example output

Component EFI
Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
Update: At latest version
```

2. RHCOS images created without `bootupd` installed on them require an explicit adoption phase. If the system status is Adoptable, perform the adoption:
CHAPTER 7. INSTALLING ON BARE METAL

# bootupctl adopt-and-update

Example output

Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:

# bootupctl update

Example output

Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

Machine config method

Another way to enable bootupd is by providing a machine config.

- Provide a machine config file with the enabled systemd unit, as shown in the following example:

Example output

variant: rhcos
version: 1.1.0
systemd:
units:
  - name: custom-bootupd-auto.service
    enabled: true
    contents: |
      [Unit]
      Description=Bootupd automatic update

      [Service]
      ExecStart=/usr/bin/bootupctl update
      RemainAfterExit=yes

      [Install]
      WantedBy=multi-user.target

7.4.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCSOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
• You have obtained the installation program and generated the Ignition config files for your cluster.

• You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

1. Monitor the bootstrap process:

   ```
   $ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ 
   --log-level=info
   ```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.21.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

Additional resources

• See Monitoring installation progress for more information about monitoring the installation logs and retrieving diagnostic data if installation issues arise.

7.4.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

• You deployed an OpenShift Container Platform cluster.

• You installed the `oc` CLI.
Procedure

1. Export the `kubeadmin` credentials:
   
   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:
   
   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

7.4.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:
   
   ```
   $ oc get nodes
   ```

   Example output

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.21.0
   master-1  Ready     master  63m  v1.21.0
   master-2  Ready     master  64m  v1.21.0
   worker-0  NotReady  worker  76s  v1.21.0
   worker-1  NotReady  worker  70s  v1.21.0
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:
Example output

```
NAME    AGE      REQUESTOR                        CONDITION
--- ----- -------- ------------------------------ ------
csr-8b2br 15m  system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
.....
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in `Pending` status, approve the CSRs for your cluster machines:

```
NOTE
Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the `machine-approver` if the Kubelet requests a new certificate with identical parameters.

NOTE
For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

1. `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```
Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     ```
     $ oc adm certificate approve <csr_name>  
     ```

     `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     ```
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
     ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

   ```
   $ oc get nodes
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.
Additional information

- For more information on CSRs, see Certificate Signing Requests.

7.4.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   
   ```bash
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>
<thead>
<tr>
<th>NAME</th>

2. Configure the Operators that are not available.

Additional resources

- See [Gathering logs from a failed installation](#) for details about gathering data in the event of a failed OpenShift Container Platform installation.

- See [Troubleshooting Operator issues](#) for steps to check Operator pod health across the cluster and gather Operator logs for diagnosis.

### 7.4.15.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json -p 
  \[\{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true\}\]
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

### 7.4.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

#### 7.4.15.2.1. Changing the image registry’s management state

To start the image registry, you must change the Image Registry Operator configuration’s `managementState` from Removed to Managed.

**Procedure**

- Change `managementState` Image Registry Operator configuration from Removed to Managed. For example:
7.4.15.2.2. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry
   ```

   **NOTE**

   If the storage type is emptyDIR, the replica number cannot be greater than 1.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

Example output
Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

   ```bash
   $ oc get clusteroperator image-registry
   ```

5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:
     ```bash
     $ oc edit configs.imageregistry/cluster
     ```
     Then, change the line
     ```json
     managementState: Removed
     ```
     to
     ```json
     managementState: Managed
     ```

7.4.15.2.3. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'
  ```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```bash
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.
7.4.15.2.4. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

7.4.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>SINCE</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>authentication</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>3h56m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>6h39m</td>
</tr>
<tr>
<td>console</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>3h59m</td>
</tr>
<tr>
<td>csi-snapshot-controller</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>4h12m</td>
</tr>
<tr>
<td>dns</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>4h15m</td>
</tr>
<tr>
<td>etcd</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>29h</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover `kubelet` certificates. See the documentation for Recovering from expired control plane certificates for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:
$ oc get pods --all-namespaces

Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
<td>9m</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
<td>5m</td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

$ oc logs <pod_name> -n <namespace> ①

① Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

NOTE

When installing with multipath, it is strongly recommended to enable it at installation time, and not at a later time, which can cause problems.

See “Enabling multipathing with kernel arguments on RHCOS” in the Installing on bare metal documentation for more information.

4. Register your cluster on the Cluster registration page.

7.4.17. Next steps

- Validating an installation.
- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.

- If necessary, you can opt out of remote health reporting.
CHAPTER 8. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL

8.1. OVERVIEW

Installer-provisioned installation provides support for installing OpenShift Container Platform on bare metal nodes. This guide provides a methodology to achieving a successful installation.

During installer-provisioned installation on bare metal, the installer on the bare metal node labeled as provisioner creates a bootstrap virtual machine (VM). The role of the bootstrap VM is to assist in the process of deploying an OpenShift Container Platform cluster. The bootstrap VM connects to the baremetal network and to the provisioning network, if present, via the network bridges.

When the installation of OpenShift control plane nodes is complete and fully operational, the installer destroys the bootstrap VM automatically and moves the virtual IP addresses (VIPs) to the control plane nodes.

8.2. PREREQUISITES

Installer-provisioned installation of OpenShift Container Platform requires:

1. One provisioner node with Red Hat Enterprise Linux (RHEL) 8.x installed.

2. Three control plane nodes.

3. Baseboard Management Controller (BMC) access to each node.

4. At least one network:
   a. One required routable network
b. One optional network for provisioning nodes; and,

c. One optional management network.

Before starting an installer-provisioned installation of OpenShift Container Platform, ensure the hardware environment meets the following requirements.

8.2.1. Node requirements

Installer-provisioned installation involves a number of hardware node requirements:

- **CPU architecture:** All nodes must use **x86_64** CPU architecture.

- **Similar nodes:** Red Hat recommends nodes have an identical configuration per role. That is, Red Hat recommends nodes be the same brand and model with the same CPU, memory, and storage configuration.

- **Baseboard Management Controller:** The **provisioner** node must be able to access the baseboard management controller (BMC) of each OpenShift Container Platform cluster node. You may use IPMI, Redfish, or a proprietary protocol.

- **Latest generation:** Nodes must be of the most recent generation. Installer-provisioned installation relies on BMC protocols, which must be compatible across nodes. Additionally, RHEL 8 ships with the most recent drivers for RAID controllers. Ensure that the nodes are recent enough to support RHEL 8 for the **provisioner** node and RHCOS 8 for the control plane and worker nodes.

- **Registry node:** (Optional) If setting up a disconnected mirrored registry, it is recommended the registry reside in its own node.

- **Provisioner node:** Installer-provisioned installation requires one **provisioner** node.

- **Control plane:** Installer-provisioned installation requires three control plane nodes for high availability.

- **Worker nodes:** While not required, a typical production cluster has one or more worker nodes. Smaller clusters are more resource efficient for administrators and developers during development, production, and testing.

- **Network interfaces:** Each node must have at least one 10GB network interface for the routable **baremetal** network. Each node must have one 10GB network interface for a **provisioning** network when using the **provisioning** network for deployment. Using the **provisioning** network is the default configuration. Network interface names must follow the same naming convention across all nodes. For example, the first NIC name on a node, such as **eth0** or **eno1**, must be the same name on all of the other nodes. The same principle applies to the remaining NICs on each node.

- **Unified Extensible Firmware Interface (UEFI):** Installer-provisioned installation requires UEFI boot on all OpenShift Container Platform nodes when using IPv6 addressing on the **provisioning** network. In addition, UEFI Device PXE Settings must be set to use the IPv6 protocol on the **provisioning** network NIC, but omitting the **provisioning** network removes this requirement.

- **Secure Boot:** Many production scenarios require nodes with Secure Boot enabled to verify the node only boots with trusted software, such as UEFI firmware drivers, EFI applications, and the operating system. You may deploy with Secure Boot manually or managed.
1. **Manually:** To deploy an OpenShift Container Platform cluster with Secure Boot manually, you must enable UEFI boot mode and Secure Boot on each control plane node and each worker node. Red Hat supports Secure Boot with manually enabled UEFI and Secure Boot only when installer-provisioned installations use Redfish virtual media. See “Configuring nodes for Secure Boot manually” in the “Configuring nodes” section for additional details.

2. **Managed:** To deploy an OpenShift Container Platform cluster with managed Secure Boot, you must set the `bootMode` value to `UEFISecureBoot` in the `install-config.yaml` file. Red Hat only supports installer-provisioned installation with managed Secure Boot on 10th generation HPE hardware and 13th generation Dell hardware running firmware version 2.75.75.75 or greater. Deploying with managed Secure Boot does not require Redfish virtual media. See “Configuring managed Secure Boot” in the “Setting up the environment for an OpenShift installation” section for details.

**NOTE**

Red Hat does not support Secure Boot with self-generated keys.

### 8.2.2. Firmware requirements for installing with virtual media

The installer for installer-provisioned OpenShift Container Platform clusters validates the hardware and firmware compatibility with Redfish virtual media. The following table lists supported firmware for installer-provisioned OpenShift Container Platform clusters deployed with Redfish virtual media.

**Table 8.1. Firmware compatibility for Redfish virtual media**

<table>
<thead>
<tr>
<th>Hardware</th>
<th>Model</th>
<th>Management</th>
<th>Firmware Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP</td>
<td>10th Generation</td>
<td>iLO5</td>
<td>N/A</td>
</tr>
<tr>
<td>HP</td>
<td>9th Generation</td>
<td>iLO4</td>
<td>N/A</td>
</tr>
<tr>
<td>Dell</td>
<td>14th Generation</td>
<td>iDRAC 9</td>
<td>v4.20.20.20 - 04.40.00.00</td>
</tr>
<tr>
<td>Dell</td>
<td>13th Generation</td>
<td>iDRAC 8</td>
<td>v2.75.75.75+</td>
</tr>
</tbody>
</table>

**NOTE**

Refer to the hardware documentation for the nodes or contact the hardware vendor for information on updating the firmware.

There are no known firmware limitations for HP servers.

For Dell servers, ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: **Configuration → Virtual Media → Attach Mode → AutoAttach**. With iDRAC 9 firmware version 04.40.00.00, the Virtual Console plug-in defaults to eHTML5, which causes problems with the `InsertVirtualMedia` workflow. Set the plug-in to HTML5 to avoid this issue. The menu path is: **Configuration → Virtual console → Plug-in Type → HTML5**.
The installer will not initiate installation on a node if the node firmware is below the foregoing versions when installing with virtual media.

8.2.3. Network requirements

Installer-provisioned installation of OpenShift Container Platform involves several network requirements. First, installer-provisioned installation involves an optional non-routable provisioning network for provisioning the operating system on each bare metal node. Second, installer-provisioned installation involves a routable baremetal network.

Configuring NICs

OpenShift Container Platform deploys with two networks:

- **provisioning**: The provisioning network is an optional non-routable network used for provisioning the underlying operating system on each node that is a part of the OpenShift Container Platform cluster. The network interface for the provisioning network on each cluster node must have the BIOS or UEFI configured to PXE boot. In OpenShift Container Platform 4.3, when deploying using the provisioning network, the first NIC on each node, such as eth0 or eno1, must interface with the provisioning network.

  In OpenShift Container Platform 4.4 and later releases, you can specify the provisioning network NIC with the provisioningNetworkInterface configuration setting.

- **baremetal**: The baremetal network is a routable network.

  In OpenShift Container Platform 4.3, when deploying using the provisioning network, the second NIC on each node, such as eth1 or eno2, must interface with the baremetal network.

  In OpenShift Container Platform 4.4 and later releases, you can use any NIC order to interface with the baremetal network, provided it is the same NIC order across worker and control plane nodes and not the NIC specified in the provisioningNetworkInterface configuration setting for the provisioning network.

**NOTE**

Use a compatible approach such that cluster nodes use the same NIC ordering on all cluster nodes. NICs must have heterogeneous hardware with the same NIC naming convention such as eth0 or eno1.

**IMPORTANT**

When using a VLAN, each NIC must be on a separate VLAN corresponding to the appropriate network.

Configuring the DNS server

Clients access the OpenShift Container Platform cluster nodes over the baremetal network. A network administrator must configure a subdomain or subzone where the canonical name extension is the cluster name.

```
<cluster-name>.<domain-name>
```

For example:
OpenShift Container Platform 4.8 and later releases include functionality that uses cluster membership information to generate A/AAAA records. This resolves the node names to their IP addresses. Once the nodes are registered with the API, the cluster can disperse node information without using CoreDNS-mDNS. This eliminates the network traffic associated with multicast DNS.

Dynamic Host Configuration Protocol (DHCP) requirements

By default, installer-provisioned installation deploys `ironic-dnsmasq` with DHCP enabled for the `provisioning` network. No other DHCP servers should be running on the `provisioning` network when the `provisioningNetwork` configuration setting is set to `managed`, which is the default value. If you have a DHCP server running on the `provisioning` network, you must set the `provisioningNetwork` configuration setting to `unmanaged` in the `install-config.yaml` file.

Network administrators must reserve IP addresses for each node in the OpenShift Container Platform cluster for the `baremetal` network on an external DHCP server.

**Reserving IP addresses for nodes with the DHCP server**

For the `baremetal` network, a network administrator must reserve a number of IP addresses, including:

1. Two virtual IP addresses.
   - One IP address for the API endpoint
   - One IP address for the wildcard ingress endpoint
2. One IP address for the provisioner node.
3. One IP address for each control plane (master) node.
4. One IP address for each worker node, if applicable.

**RESERVING IP ADDRESSES SO THEY BECOME STATIC IP ADDRESSES**

Some administrators prefer to use static IP addresses so that each node's IP address remains constant in the absence of a DHCP server. To use static IP addresses in the OpenShift Container Platform cluster, reserve the IP addresses with an infinite lease. During deployment, the installer will reconfigure the NICs from DHCP assigned addresses to static IP addresses. NICs with DHCP leases that are not infinite will remain configured to use DHCP.

**NETWORKING BETWEEN EXTERNAL LOAD BALANCERS AND CONTROL PLANE NODES**

External load balancing services and the control plane nodes must run on the same L2 network, and on the same VLAN when using VLANs to route traffic between the load balancing services and the control plane nodes.

The following table provides an exemplary embodiment of fully qualified domain names. The API and Nameserver addresses begin with canonical name extensions. The host names of the control plane and worker nodes are exemplary, so you can use any host naming convention you prefer.
### Network Time Protocol (NTP)

Each OpenShift Container Platform node in the cluster must have access to an NTP server. OpenShift Container Platform nodes use NTP to synchronize their clocks. For example, cluster nodes use SSL certificates that require validation, which might fail if the date and time between the nodes are not in sync.

**IMPORTANT**

Define a consistent clock date and time format in each cluster node’s BIOS settings, or installation might fail.

You may reconfigure the control plane nodes to act as NTP servers on disconnected clusters, and reconfigure worker nodes to retrieve time from the control plane nodes.

### State-driven network configuration requirements (Technology Preview)

OpenShift Container Platform supports additional post-installation state-driven network configuration on the secondary network interfaces of cluster nodes using `kubernetes-nmstate`. For example, system administrators might configure a secondary network interface on cluster nodes after installation for a storage network.

**NOTE**

Configuration must occur before scheduling pods.

State-driven network configuration requires installing `kubernetes-nmstate`, and also requires Network Manager running on the cluster nodes. See [OpenShift Virtualization > Kubernetes NMState (Tech Preview)] for additional details.
8.2.4. Configuring nodes

Configuring nodes when using the provisioning network

Each node in the cluster requires the following configuration for proper installation.

**WARNING**

A mismatch between nodes will cause an installation failure.

While the cluster nodes can contain more than two NICs, the installation process only focuses on the first two NICs:

<table>
<thead>
<tr>
<th>NIC</th>
<th>Network</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC1</td>
<td>provisioning</td>
<td>&lt;provisioning-vlan&gt;</td>
</tr>
<tr>
<td>NIC2</td>
<td>baremetal</td>
<td>&lt;baremetal-vlan&gt;</td>
</tr>
</tbody>
</table>

NIC1 is a non-routable network (provisioning) that is only used for the installation of the OpenShift Container Platform cluster.

The Red Hat Enterprise Linux (RHEL) 8.x installation process on the provisioner node might vary. To install Red Hat Enterprise Linux (RHEL) 8.x using a local Satellite server or a PXE server, PXE-enable NIC2.

<table>
<thead>
<tr>
<th>PXE</th>
<th>Boot order</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC1 PXE-enabled provisioning network</td>
<td>1</td>
</tr>
<tr>
<td>NIC2 baremetal network. PXE-enabled is optional.</td>
<td>2</td>
</tr>
</tbody>
</table>

**NOTE**

Ensure PXE is disabled on all other NICs.

Configure the control plane and worker nodes as follows:

<table>
<thead>
<tr>
<th>PXE</th>
<th>Boot order</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC1 PXE-enabled (provisioning network)</td>
<td>1</td>
</tr>
</tbody>
</table>

Configuring nodes without the provisioning network
The installation process requires one NIC:

<table>
<thead>
<tr>
<th>NIC</th>
<th>Network</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NICx</td>
<td>baremetal</td>
<td>&lt;baremetal-vlan&gt;</td>
</tr>
</tbody>
</table>

NICx is a routable network (baremetal) that is used for the installation of the OpenShift Container Platform cluster, and routable to the internet.

### Configuring nodes for Secure Boot manually

Secure Boot prevents a node from booting unless it verifies the node is using only trusted software, such as UEFI firmware drivers, EFI applications, and the operating system.

**NOTE**

Red Hat only supports manually configured Secure Boot when deploying with Redfish virtual media.

To enable Secure Boot manually, refer to the hardware guide for the node and execute the following:

1. Boot the node and enter the BIOS menu.
2. Set the node’s boot mode to UEFI Enabled.
3. Enable Secure Boot.

**IMPORTANT**

Red Hat does not support Secure Boot with self-generated keys.

### 8.2.5. Out-of-band management

Nodes will typically have an additional NIC used by the Baseboard Management Controllers (BMCs). These BMCs must be accessible from the **provisioner** node.

Each node must be accessible via out-of-band management. When using an out-of-band management network, the **provisioner** node requires access to the out-of-band management network for a successful OpenShift Container Platform 4 installation.

The out-of-band management setup is out of scope for this document. We recommend setting up a separate management network for out-of-band management. However, using the **provisioning** network or the **baremetal** network are valid options.

### 8.2.6. Required data for installation

Prior to the installation of the OpenShift Container Platform cluster, gather the following information from all cluster nodes:

- Out-of-band management IP
  - Examples
    - Dell (iDRAC) IP
HP (iLO) IP
Fujitsu (iRMC) IP

When using the provisioning network
- NIC1 (provisioning) MAC address
- NIC2 (baremetal) MAC address

When omitting the provisioning network
- NICx (baremetal) MAC address

8.2.7. Validation checklist for nodes

When using the provisioning network
- NIC1 VLAN is configured for the provisioning network. (optional)
- NIC1 is PXE-enabled on the provisioner, control plane (master), and worker nodes when using a provisioning network. (optional)
- NIC2 VLAN is configured for the baremetal network.
- PXE has been disabled on all other NICs.
- Control plane and worker nodes are configured.
- All nodes accessible via out-of-band management.
- A separate management network has been created. (optional)
- Required data for installation.

When omitting the provisioning network
- NICx VLAN is configured for the baremetal network.
- Control plane and worker nodes are configured.
- All nodes accessible via out-of-band management.
- A separate management network has been created. (optional)
- Required data for installation.

8.3. SETTING UP THE ENVIRONMENT FOR AN OPENSSHIFT INSTALLATION

8.3.1. Installing RHEL on the provisioner node

With the networking configuration complete, the next step is to install RHEL 8.x on the provisioner node. The installer uses the provisioner node as the orchestrator while installing the OpenShift Container
Platform cluster. For the purposes of this document, installing RHEL on the provisioner node is out of scope. However, options include but are not limited to using a RHEL Satellite server, PXE, or installation media.

8.3.2. Preparing the provisioner node for OpenShift Container Platform installation

Perform the following steps to prepare the environment.

Procedure

1. Log in to the provisioner node via `ssh`.

2. Create a non-root user (`kni`) and provide that user with `sudo` privileges:

   ```
   # useradd kni
   # passwd kni
   # echo "kni ALL=(root) NOPASSWD:ALL" | tee -a /etc/sudoers.d/kni
   # chmod 0440 /etc/sudoers.d/kni
   ```

3. Create an `ssh` key for the new user:

   ```
   # su - kni -c "ssh-keygen -t ed25519 -f /home/kni/.ssh/id_rsa -N ""
   ```

4. Log in as the new user on the provisioner node:

   ```
   # su - kni
   $'
   ```

5. Use Red Hat Subscription Manager to register the provisioner node:

   ```
   $ sudo subscription-manager register --username=<user> --password=<pass> --auto-attach
   $ sudo subscription-manager repos --enable=rhel-8-for-x86_64-appstream-rpms --enable=rhel-8-for-x86_64-baseos-rpms
   ```

   ![NOTE]

   For more information about Red Hat Subscription Manager, see Using and Configuring Red Hat Subscription Manager.

6. Install the following packages:

   ```
   $ sudo dnf install -y libvirt qemu-kvm mkisofs python3-devel jq ipmitool
   ```

7. Modify the user to add the `libvirt` group to the newly created user:

   ```
   $ sudo usermod --append --groups libvirt <user>
   ```

8. Restart `firewalld` and enable the `http` service:

   ```
   $ sudo systemctl start firewalld
   $ sudo firewall-cmd --zone=public --add-service=http --permanent
   $ sudo firewall-cmd --reload
   ```
9. Start and enable the **libvirtd** service:

   
   ```
   $ sudo systemctl enable libvirtd --now
   ```

10. Create the **default** storage pool and start it:

   ```
   $ sudo virsh pool-define-as --name default --type dir --target /var/lib/libvirt/images
   $ sudo virsh pool-start default
   $ sudo virsh pool-autostart default
   ```

11. Configure networking.

    **NOTE**

    You can also configure networking from the web console.

Export the **baremetal** network NIC name:

   ```
   $ export PUB_CONN=<baremetal_nic_name>
   ```

Configure the **baremetal** network:

   ```
   $ sudo nohup bash -c "
   nmcli con down "$PUB_CONN"
   nmcli con delete "$PUB_CONN"
   # RHEL 8.1 appends the word "System" in front of the connection, delete in case it exists
   nmcli con down "System $PUB_CONN"
   nmcli con delete "System $PUB_CONN"
   nmcli connection add ifname baremetal type bridge con-name baremetal
   nmcli con add type bridge-slave ifname "$PUB_CONN" master baremetal
   pkill dhclient;dhclient baremetal
   "
   ```

If you are deploying with a **provisioning** network, export the **provisioning** network NIC name:

   ```
   $ export PROV_CONN=<prov_nic_name>
   ```

If you are deploying with a **provisioning** network, configure the **provisioning** network:

   ```
   $ sudo nohup bash -c "
   nmcli con down "$PROV_CONN"
   nmcli con delete "$PROV_CONN"
   nmcli connection add ifname provisioning type bridge con-name provisioning
   nmcli con add type bridge-slave ifname "$PROV_CONN" master provisioning
   nmcli connection modify provisioning ipv6.addresses fd00:1101::1/64 ipv6.method manual
   nmcli con down provisioning
   nmcli con up provisioning
   "
   ```
NOTE

The **ssh** connection might disconnect after executing these steps.

The IPv6 address can be any address as long as it is not routable via the **baremetal** network.

Ensure that UEFI is enabled and UEFI PXE settings are set to the IPv6 protocol when using IPv6 addressing.

12. **ssh** back into the provisioner node (if required).
   
   ```bash
   # ssh kni@provisioner.<cluster-name>.<domain>
   ```

13. Verify the connection bridges have been properly created.
   
   ```bash
   $ sudo nmcli con show
   ```
   
<table>
<thead>
<tr>
<th>NAME</th>
<th>UUID</th>
<th>TYPE</th>
<th>DEVICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>baremetal</td>
<td>4d5133a5-8351-4bb9-bfd4-3af264801530</td>
<td>bridge</td>
<td>baremetal</td>
</tr>
<tr>
<td>provisioning</td>
<td>43942805-017f-4d7d-a2c2-7cb3324482ed</td>
<td>bridge</td>
<td>provisioning</td>
</tr>
<tr>
<td>virbr0</td>
<td>d9bca40f-eee1-410b-8879-a2d4bb0465e7</td>
<td>bridge</td>
<td>virbr0</td>
</tr>
<tr>
<td>bridge-slave-eno1</td>
<td>76a8ed50-c7e5-4999-b4f6-6d9014dd0812</td>
<td>ethernet</td>
<td>eno1</td>
</tr>
<tr>
<td>bridge-slave-eno2</td>
<td>f31c3353-54b7-48de-893a-02d2b34c4736</td>
<td>ethernet</td>
<td>eno2</td>
</tr>
</tbody>
</table>

14. Create a **pull-secret.txt** file.
   
   ```bash
   $ vim pull-secret.txt
   ```
   
   In a web browser, navigate to Install on Bare Metal with user-provisioned infrastructure, and scroll down to the Downloads section. Click Copy pull secret. Paste the contents into the **pull-secret.txt** file and save the contents in the **kni** user’s home directory.

### 8.3.3. Retrieving the OpenShift Container Platform installer

Use the **latest-4.x** version of the installer to deploy the latest generally available version of OpenShift Container Platform:

```bash
$ export VERSION=latest-4.8
export RELEASE_IMAGE=$(curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/release.txt | grep 'Pull From: quay.io' | awk -F ' ' '{print $3}')
```

### 8.3.4. Extracting the OpenShift Container Platform installer

After retrieving the installer, the next step is to extract it.

#### Procedure

1. Set the environment variables:

   ```bash
   $ export cmd=openshift-baremetal-install
   $ export pullsecret_file=~/pull-secret.txt
   $ export extract_dir=$(pwd)
   ```
2. Get the `oc` binary:

```
```

3. Extract the installer:

```
$ sudo cp oc /usr/local/bin
$ oc adm release extract --registry-config "${pullsecret_file}" --command=${cmd} --to "$extract_dir" ${RELEASE_IMAGE}
$ sudo cp openshift-baremetal-install /usr/local/bin
```

### 8.3.5. Creating an RHCOS images cache (optional)

To employ image caching, you must download two images: the Red Hat Enterprise Linux CoreOS (RHCOS) image used by the bootstrap VM and the RHCOS image used by the installer to provision the different nodes. Image caching is optional, but especially useful when running the installer on a network with limited bandwidth.

If you are running the installer on a network with limited bandwidth and the RHCOS images download takes more than 15 to 20 minutes, the installer will timeout. Caching images on a web server will help in such scenarios.

Install a container that contains the images.

**Procedure**

1. Install `podman`:

```
$ sudo dnf install -y podman
```

2. Open firewall port **8080** to be used for RHCOS image caching:

```
$ sudo firewall-cmd --add-port=8080/tcp --zone=public --permanent
$ sudo firewall-cmd --reload
```

3. Create a directory to store the `bootstraposimage` and `clusterosimage`:

```
$ mkdir /home/kni/rhcos_image_cache
```

4. Set the appropriate SELinux context for the newly created directory:

```
$ sudo semanage fcontext -a -t httpd_sys_content_t "/home/kni/rhcos_image_cache(/.*)?"
$ sudo restorecon -Rv rhcos_image_cache/
```

5. Get the commit ID from the installer:

```
$ export COMMIT_ID=$(/usr/local/bin/openshift-baremetal-install version | grep "^built from commit' | awk '{print $4}')
```
The ID determines which images the installer needs to download.

6. Get the URI for the RHCOS image that the installer will deploy on the nodes:

```bash
$ export RHCOS_OPENSTACK_URI=($(curl -s -S https://raw.githubusercontent.com/openshift/installer/${COMMIT_ID}/data/data/rhcos.json | jq .images.openstack.path | sed 's/\"//g')
```

7. Get the URI for the RHCOS image that the installer will deploy on the bootstrap VM:

```bash
$ export RHCOS_QEMU_URI=($(curl -s -S https://raw.githubusercontent.com/openshift/installer/${COMMIT_ID}/data/data/rhcos.json | jq .images.qemu.path | sed 's/\"//g')
```

8. Get the path where the images are published:

```bash
$ export RHCOS_PATH=($(curl -s -S https://raw.githubusercontent.com/openshift/installer/${COMMIT_ID}/data/data/rhcos.json | jq .baseURI | sed 's/\"//g')
```

9. Get the SHA hash for the RHCOS image that will be deployed on the bootstrap VM:

```bash
$ export RHCOS_QEMU_SHA_UNCOMPRESSED=($(curl -s -S https://raw.githubusercontent.com/openshift/installer/${COMMIT_ID}/data/data/rhcos.json | jq -r '.images.qemu["uncompressed-sha256"]')
```

10. Get the SHA hash for the RHCOS image that will be deployed on the nodes:

```bash
$ export RHCOS_OPENSTACK_SHA_COMPRESSED=($(curl -s -S https://raw.githubusercontent.com/openshift/installer/${COMMIT_ID}/data/data/rhcos.json | jq -r '.images.openstack.sha256')
```

11. Download the images and place them in the `/home/kni/rhcos_image_cache` directory:

```bash
$ curl -L ${RHCOS_PATH}${RHCOS_QEMU_URI} -o /home/kni/rhcos_image_cache/${RHCOS_QEMU_URI}

$ curl -L ${RHCOS_PATH}${RHCOS_OPENSTACK_URI} -o /home/kni/rhcos_image_cache/${RHCOS_OPENSTACK_URI}
```

12. Confirm SELinux type is of `httpd_sys_content_t` for the newly created files:

```bash
$ ls -Z /home/kni/rhcos_image_cache
```

13. Create the pod:

```bash
$ podman run -d --name rhcos_image_cache \
   -v /home/kni/rhcos_image_cache:/var/www/html \
   -p 8080:8080/tcp \n   registry.centos.org/centos/httpd-24-centos7:latest
```

The above command creates a caching webserver with the name `rhcos_image_cache`, which
serves the images for deployment. The first image \(\{(\texttt{RHCOS\_PATH})\{\texttt{RHCOS\_QEMU\_URI}\}\{\texttt{sha256}\}=(\texttt{RHCOS\_QEMU\_SHA\_UNCOMPRESSED})\) is the \texttt{bootstrapOSImage} and the second image \(\{(\texttt{RHCOS\_PATH})\{\texttt{RHCOS\_OPENSTACK\_URI}\}\{\texttt{sha256}\}=(\texttt{RHCOS\_OPENSTACK\_SHA\_COMPRESSED})\) is the \texttt{clusterOSImage} in the \texttt{install-config.yaml} file.

14. Generate the \texttt{bootstrapOSImage} and \texttt{clusterOSImage} configuration:

\begin{verbatim}
$ export BAREMETAL\_IP=$(ip addr show dev baremetal | awk '/inet {print $2} | cut -d"/" -f1)

$ export RHCOS\_OPENSTACK\_SHA256=$(zcat /home/kni/rhcos_image_cache/\{\texttt{RHCOS\_OPENSTACK\_URI}\} | sha256sum | awk '{print $1}')

$ export RHCOS\_QEMU\_SHA256=$(zcat /home/kni/rhcos_image_cache/\{\texttt{RHCOS\_QEMU\_URI}\} | sha256sum | awk '{print $1}')

$ export CLUSTER\_OS\_IMAGE="http://\{BAREMETAL\_IP\}:8080/\{RHCOS\_OPENSTACK\_URI\}?sha256=\{RHCOS\_OPENSTACK\_SHA256\}"

$ export BOOTSTRAP\_OS\_IMAGE="http://\{BAREMETAL\_IP\}:8080/\{RHCOS\_QEMU\_URI\}?sha256=\{RHCOS\_QEMU\_SHA256\}"

$ echo "\{RHCOS\_OPENSTACK\_SHA256\} \{RHCOS\_OPENSTACK\_URI\}" > /home/kni/rhcos_image_cache/rhcos-ootpa-latest.qcow2.md5sum

$ echo " bootstrapOSImage=\{BOOTSTRAP\_OS\_IMAGE\}"

$ echo " clusterOSImage=\{CLUSTER\_OS\_IMAGE\}"
\end{verbatim}

15. Add the required configuration to the \texttt{install-config.yaml} file under \texttt{platform.baremetal}:

\begin{verbatim}
platform:
  baremetal:
    bootstrapOSImage: http://\{BAREMETAL\_IP\}:8080/\{RHCOS\_QEMU\_URI\}?sha256=\{RHCOS\_QEMU\_SHA256\}
    clusterOSImage: http://\{BAREMETAL\_IP\}:8080/\{RHCOS\_OPENSTACK\_URI\}?sha256=\{RHCOS\_OPENSTACK\_SHA256\}
\end{verbatim}

See the "Configuration files" section for additional details.

### 8.3.6. Configuration files

#### 8.3.6.1. Configuring the install-config.yaml file

The \texttt{install-config.yaml} file requires some additional details. Most of the information is teaching the installer and the resulting cluster enough about the available hardware so that it is able to fully manage it.
1. Configure `install-config.yaml`. Change the appropriate variables to match the environment, including `pullSecret` and `sshKey`.

```yaml
apiVersion: v1
baseDomain: <domain>
metadata:
  name: <cluster-name>
networking:
  machineCIDR: <public-cidr>
  networkType: OVNKubernetes
compute:
  - name: worker
    replicas: 2
controlPlane:
  name: master
  replicas: 3
platform:
  baremetal: {}
platform:
  baremetal:
    apiVIP: <api-ip>
    ingressVIP: <wildcard-ip>
    provisioningNetworkInterface: <NIC1>
    provisioningNetworkCIDR: <CIDR>
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: ipmi://<out-of-band-ip>  # 2
      username: <user>
      password: <password>
      bootMACAddress: <NIC1-mac-address>
      rootDeviceHints:
        deviceName: "/dev/sda"
  - name: openshift-master-1
    role: master
    bmc:
      address: ipmi://<out-of-band-ip>  # 3
      username: <user>
      password: <password>
      bootMACAddress: <NIC1-mac-address>
      rootDeviceHints:
        deviceName: "/dev/sda"
  - name: openshift-master-2
    role: master
    bmc:
      address: ipmi://<out-of-band-ip>  # 4
      username: <user>
      password: <password>
      bootMACAddress: <NIC1-mac-address>
      rootDeviceHints:
        deviceName: "/dev/sda"
  - name: openshift-worker-0
    role: worker
    bmc:
```

CHAPTER 8. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL

1285
1. Scale the worker machines based on the number of worker nodes that are part of the OpenShift Container Platform cluster.

2. Create a directory to store cluster configs.

   ```
   $ mkdir ~/clusterconfigs
   $ cp install-config.yaml ~/clusterconfigs
   ```

3. Ensure all bare metal nodes are powered off prior to installing the OpenShift Container Platform cluster.

   ```
   $ ipmitool -I lanplus -U <user> -P <password> -H <management-server-ip> power off
   ```

4. Remove old bootstrap resources if any are left over from a previous deployment attempt.

   ```
   for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk '{print $2'}); do
     sudo virsh destroy $i;
     sudo virsh undefine $i;
     sudo virsh vol-delete $i --pool $i;
     sudo virsh vol-delete $i.ign --pool $i;
     sudo virsh pool-destroy $i;
     sudo virsh pool-undefine $i;
   done
   ```

8.3.6.2. Setting proxy settings within the `install-config.yaml` file (optional)

To deploy an OpenShift Container Platform cluster using a proxy, make the following changes to the `install-config.yaml` file.

```yaml
apiVersion: v1
baseDomain: <domain>
proxy:
  httpProxy: http://USERNAME:PASSWORD@proxy.example.com:PORT
```
The following is an example of `noProxy` with values.

```yaml
noProxy: .example.com,172.22.0.0/24,10.10.0.0/24
```

With a proxy enabled, set the appropriate values of the proxy in the corresponding key/value pair.

Key considerations:

- If the proxy does not have an HTTPS proxy, change the value of `httpsProxy` from `https://` to `http://`.
- If using a provisioning network, include it in the `noProxy` setting, otherwise the installer will fail.
- Set all of the proxy settings as environment variables within the provisioner node. For example, `HTTP_PROXY`, `HTTPS_PROXY`, and `NO_PROXY`.

### 8.3.6.3. Modifying the `install-config.yaml` file for no provisioning network (optional)

To deploy an OpenShift Container Platform cluster without a provisioning network, make the following changes to the `install-config.yaml` file.

```yaml
platform:
baremetal:
  apiVIP: <apiVIP>
  ingressVIP: <ingress/wildcard VIP>
  provisioningNetwork: "Disabled"
```

### 8.3.6.4. Modifying the `install-config.yaml` file for dual-stack network (optional)

To deploy an OpenShift Container Platform cluster with dual-stack networking, make the following changes to the `install-config.yaml` file.

```yaml
machineNetwork:
- cidr: {{ extcidrnet }}
- cidr: {{ extcidrnet6 }}
clusterNetwork:
- cidr: 10.128.0.0/14
  hostPrefix: 23
- cidr: fd02::/48
  hostPrefix: 64
serviceNetwork:
- 172.30.0.0/16
- fd03::/112
```

**NOTE**

In the above snippet, the network settings must match the settings for the cluster’s network environment. The `machineNetwork`, `clusterNetwork`, and `serviceNetwork` configuration settings must have two CIDR entries each. The first CIDR entry is the IPv4 setting and the second CIDR entry is the IPv6 setting.
IMPORTANT

The IPv4 entries must go before the IPv6 entries.

8.3.6.5. Configuring managed Secure Boot in the `install-config.yaml` file (optional)

To enable managed Secure Boot, add the `bootMode` configuration setting to each node:

**Example**

```yaml
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: ipmi://<out-of-band-ip>
      username: <user>
      password: <password>
      bootMACAddress: <NIC1-mac-address>
    rootDeviceHints:
      deviceName: "/dev/sda"
    bootMode: UEFISecureBoot
```

1 The `bootMode` setting is `UEFI` by default. Change it to `UEFISecureBoot` to enable managed Secure Boot.

**NOTE**

See "Configuring nodes" in the "Prerequisites" to ensure the nodes can support managed Secure Boot. If the nodes do not support managed Secure Boot, see "Configuring nodes for Secure Boot manually" in the "Configuring nodes" section. Configuring Secure Boot manually requires Redfish virtual media.

8.3.6.6. Additional `install-config` parameters

See the following tables for the required parameters, the `hosts` parameter, and the `bmc` parameter for the `install-config.yaml` file.

**Table 8.2. Required parameters**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>baseDomain</code></td>
<td></td>
<td>The domain name for the cluster. For example, <code>example.com</code>.</td>
</tr>
<tr>
<td><code>bootMode</code></td>
<td>UEFI</td>
<td>The boot mode for a node. Options are <code>legacy</code>, <code>UEFI</code>, and <code>UEFISecureBoot</code>. If <code>bootMode</code> is not set, Ironic sets it while inspecting the node.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>sshKey</strong></td>
<td></td>
<td>The <code>sshKey</code> configuration setting contains the key in the <code>~/.ssh/id_rsa.pub</code> file required to access the control plane nodes and worker nodes. Typically, this key is from the provisioner node.</td>
</tr>
<tr>
<td><strong>pullSecret</strong></td>
<td></td>
<td>The <code>pullSecret</code> configuration setting contains a copy of the pull secret downloaded from the Install OpenShift on Bare Metal page when preparing the provisioner node.</td>
</tr>
<tr>
<td><strong>metadata:</strong></td>
<td></td>
<td>The name to be given to the OpenShift Container Platform cluster. For example, <code>openshift</code>.</td>
</tr>
<tr>
<td><strong>name:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>networking:</strong></td>
<td></td>
<td>The public CIDR (Classless Inter-Domain Routing) of the external network. For example, <code>10.0.0.0/24</code>.</td>
</tr>
<tr>
<td><strong>machineCIDR:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>compute:</strong></td>
<td></td>
<td>The OpenShift Container Platform cluster requires a name be provided for worker (or compute) nodes even if there are zero nodes.</td>
</tr>
<tr>
<td><strong>- name:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>worker</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>compute:</strong></td>
<td></td>
<td>Replicas sets the number of worker (or compute) nodes in the OpenShift Container Platform cluster.</td>
</tr>
<tr>
<td><strong>replicas:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>2</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>controlPlane:</strong></td>
<td></td>
<td>The OpenShift Container Platform cluster requires a name for control plane (master) nodes.</td>
</tr>
<tr>
<td><strong>name:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>master</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>controlPlane:</strong></td>
<td></td>
<td>Replicas sets the number of control plane (master) nodes included as part of the OpenShift Container Platform cluster.</td>
</tr>
<tr>
<td><strong>replicas:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>3</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameters</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>provisioningNetworkInterface</td>
<td></td>
<td>The name of the network interface on control plane nodes connected to the provisioning network.</td>
</tr>
<tr>
<td>defaultMachinePlatform</td>
<td></td>
<td>The default configuration used for machine pools without a platform configuration.</td>
</tr>
<tr>
<td>apiVIP</td>
<td>api. &lt;clusternamem.clusterdomain&gt;</td>
<td>The VIP to use for internal API communication.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This setting must either be provided or pre-configured in the DNS so that the default name resolves correctly.</td>
</tr>
<tr>
<td>disableCertificateVerification</td>
<td>False</td>
<td><code>redfish</code> and <code>redfish-virtualmedia</code> need this parameter to manage BMC addresses. The value should be <code>True</code> when using a self-signed certificate for BMC addresses.</td>
</tr>
<tr>
<td>ingressVIP</td>
<td>test.apps. &lt;clusternamem.clusterdomain&gt;</td>
<td>The VIP to use for ingress traffic.</td>
</tr>
</tbody>
</table>

Table 8.3. Optional Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>provisioningDHCPRange</td>
<td>172.22.0.10,172.22.0.100</td>
<td>Defines the IP range for nodes on the <code>provisioning</code> network.</td>
</tr>
<tr>
<td>provisioningNetworkCIDR</td>
<td>172.22.0.0/24</td>
<td>The CIDR for the network to use for provisioning. This option is required when not using the default address range on the <code>provisioning</code> network.</td>
</tr>
<tr>
<td>clusterProvisioningIP</td>
<td>The third IP address of the <code>provisioningNetworkCIDR</code>.</td>
<td>The IP address within the cluster where the provisioning services run. Defaults to the third IP address of the <code>provisioning</code> subnet. For example, 172.22.0.3.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>bootstrapProvisioningIP</td>
<td>The second IP</td>
<td>The IP address on the bootstrap VM where the provisioning services run while the installer is deploying the control plane (master) nodes. Defaults to the second IP address of the provisioning subnet. For example, 172.22.0.2 or 2620:52:0:1307::2.</td>
</tr>
<tr>
<td>externalBridge</td>
<td>baremetal</td>
<td>The name of the baremetal bridge of the hypervisor attached to the baremetal network.</td>
</tr>
<tr>
<td>provisioningBridge</td>
<td>provisioning</td>
<td>The name of the provisioning bridge on the provisioner host attached to the provisioning network.</td>
</tr>
<tr>
<td>defaultMachinePlatform</td>
<td></td>
<td>The default configuration used for machine pools without a platform configuration.</td>
</tr>
<tr>
<td>bootstrapOSImage</td>
<td></td>
<td>A URL to override the default operating system image for the bootstrap node. The URL must contain a SHA-256 hash of the image. For example: <a href="https://mirror.openshift.com/rhcos-">https://mirror.openshift.com/rhcos-</a>&lt;version&gt;-qemu.qcow2.gz?sha256=&lt;uncompressed_sha256&gt;.</td>
</tr>
<tr>
<td>clusterOSImage</td>
<td></td>
<td>A URL to override the default operating system for cluster nodes. The URL must include a SHA-256 hash of the image. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-openstack.qcow2.gz?sha256=&lt;compressed_sha256&gt;.</td>
</tr>
<tr>
<td>provisioningNetwork</td>
<td></td>
<td>Set this parameter to Disabled to disable the requirement for a provisioning network. User may only do virtual media based provisioning, or bring up the cluster using assisted installation. If using power management, BMC’s must be accessible from the machine networks. User must provide two IP addresses on the external network that are used for the provisioning services. Set this parameter to Managed, which is the default, to fully manage the provisioning network, including DHCP, TFTP, and so on. Set this parameter to Unmanaged to still enable the provisioning network but take care of manual configuration of DHCP. Virtual media provisioning is recommended but PXE is still available if required.</td>
</tr>
<tr>
<td>httpProxy</td>
<td></td>
<td>Set this parameter to the appropriate HTTP proxy used within your environment.</td>
</tr>
<tr>
<td>httpsProxy</td>
<td></td>
<td>Set this parameter to the appropriate HTTPS proxy used within your environment.</td>
</tr>
</tbody>
</table>
### noProxy

Set this parameter to the appropriate list of exclusions for proxy usage within your environment.

### Hosts

The **hosts** parameter is a list of separate bare metal assets used to build the cluster.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong></td>
<td></td>
<td>The name of the <strong>BareMetalHost</strong> resource to associate with the details. For example, <strong>openshift-master-0</strong>.</td>
</tr>
<tr>
<td><strong>role</strong></td>
<td></td>
<td>The role of the bare metal node. Either <strong>master</strong> or <strong>worker</strong>.</td>
</tr>
<tr>
<td><strong>bmc</strong></td>
<td></td>
<td>Connection details for the baseboard management controller. See the BMC addressing section for additional details.</td>
</tr>
<tr>
<td><strong>bootMACAddress</strong></td>
<td></td>
<td>The MAC address of the NIC the host will use to boot on the <strong>provisioning</strong> network.</td>
</tr>
</tbody>
</table>

#### 8.3.6.7. BMC addressing

Most vendors support BMC addressing with the Intelligent Platform Management Interface (IPMI). IPMI does not encrypt communications. It is suitable for use within a data center over a secured or dedicated management network. Check with your vendor to see if they support Redfish network boot. Redfish delivers simple and secure management for converged, hybrid IT and the Software Defined Data Center (SDDC). Redfish is human readable and machine capable, and leverages common Internet and web services standards to expose information directly to the modern tool chain. If your hardware does not support Redfish network boot, use IPMI.

**IPMI**

Hosts using IPMI use the `ipmi://<out-of-band-ip>[:<port>]` address format, which defaults to port 623 if not specified. The following example demonstrates an IPMI configuration within the `install-config.yaml` file.

```yaml
platform:
baremetal:
hosts:
  - name: openshift-master-0
    role: master
    bmc:
```
Redfish network boot

To enable Redfish, use `redfish://` or `redfish+http://` to disable TLS. The installer requires both the host name or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the `install-config.yaml` file.

```
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the `disableCertificateVerification: True` configuration parameter within the `install-config.yaml` file.

```
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>
          disableCertificateVerification: True
```

8.3.6.8. BMC addressing for Dell iDRAC

The `address` field for each `bmc` entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

```
platform:
  baremetal:
    hosts:
      - name: <host name>
        role: <master | worker>
        bmc:
          address: <address> ①
          username: <user>
          password: <password>

① The `address` configuration setting specifies the protocol.
```
For Dell hardware, Red Hat supports integrated Dell Remote Access Controller (iDRAC) virtual media, Redfish network boot, and IPMI.

Table 8.4. BMC address formats for Dell iDRAC

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>iDRAC virtual media</td>
<td>idrac-virtualmedia://&lt;out-of-band-ip&gt;/redfish/v1/Systems/System.Embedded.1</td>
</tr>
<tr>
<td>Redfish network boot</td>
<td>redfish://&lt;out-of-band-ip&gt;/redfish/v1/Systems/System.Embedded.1</td>
</tr>
<tr>
<td>IPMI</td>
<td>ipmi://&lt;out-of-band-ip&gt;</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Use `idrac-virtualmedia` as the protocol for Redfish virtual media. `redfish-virtualmedia` will not work on Dell hardware. Dell’s `idrac-virtualmedia` uses the Redfish standard with Dell’s OEM extensions.

See the following sections for additional details.

**Redfish virtual media for Dell iDRAC**

For Redfish virtual media on Dell servers, use `idrac-virtualmedia://` in the `address` setting. Using `redfish-virtualmedia://` will not work.

The following example demonstrates using iDRAC virtual media within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
    - name: openshift-master-0
      role: master
      bmc:
        address: idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
        username: <user>
        password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the `disableCertificateVerification: True` configuration parameter within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
    - name: openshift-master-0
      role: master
      bmc:
        address: idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
        disableCertificateVerification: True
```

1294
Currently, Redfish is only supported on Dell with iDRAC firmware versions 4.20.20.20 through 04.40.00.00 for installer-provisioned installations on bare metal deployments. There is a known issue with version 04.40.00.00. With iDRAC 9 firmware version 04.40.00.00, the Virtual Console plug-in defaults to eHTML5, which causes problems with the InsertVirtualMedia workflow. Set the plug-in to HTML5 to avoid this issue. The menu path is: Configuration → Virtual console → Plug-in Type → HTML5.

Ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: Configuration → Virtual Media → Attach Mode → AutoAttach.

Use idrac-virtualmedia:// as the protocol for Redfish virtual media. Using redfish-virtualmedia:// will not work on Dell hardware, because the idrac-virtualmedia:// protocol corresponds to the idrac hardware type and the Redfish protocol in Ironic. Dell’s idrac-virtualmedia:// protocol uses the Redfish standard with Dell’s OEM extensions. Ironic also supports the idrac type with the WSMAN protocol. Therefore, you must specify idrac-virtualmedia:// to avoid unexpected behavior when electing to use Redfish with virtual media on Dell hardware.

Redfish network boot for iDRAC

To enable Redfish, use redfish:// or redfish+http:// to disable transport layer security (TLS). The installer requires both the host name or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the install-config.yaml file.

```yaml
platform:
  baremetal:
    hosts:
    - name: openshift-master-0
      role: master
    bmc:
      address: redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
      username: <user>
      password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include disableCertificateVerification: True in the bmc configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the disableCertificateVerification: True configuration parameter within the install-config.yaml file.

```yaml
platform:
  baremetal:
    hosts:
    - name: openshift-master-0
      role: master
    bmc:
      address: redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
      disableCertificateVerification: True
```
NOTE

Currently, Redfish is only supported on Dell hardware with iDRAC firmware versions 4.20.20.20 through 04.40.00.00 for installer-provisioned installations on bare metal deployments. There is a known issue with version 04.40.00.00. With iDRAC 9 firmware version 04.40.00.00, the Virtual Console plug-in defaults to eHTML5, which causes problems with the InsertVirtualMedia workflow. Set the plug-in to HTML5 to avoid this issue. The menu path is: Configuration → Virtual console → Plug-in Type → HTML5.

Ensure the OpenShift Container Platform cluster nodes have AutoAttach Enabled through the iDRAC console. The menu path is: Configuration → Virtual Media → Attach Mode → AutoAttach.

The redfish:// URL protocol corresponds to the redfish hardware type in Ironic.

8.3.6.9. BMC addressing for HPE iLO

The address field for each bmc entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

Table 8.5. BMC address formats for HPE iLO

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redfish virtual media</td>
<td>redfish-virtualmedia://&lt;out-of-band-ip&gt;/redfish/v1/Systems/1</td>
</tr>
<tr>
<td>Redfish network boot</td>
<td>redfish://&lt;out-of-band-ip&gt;/redfish/v1/Systems/1</td>
</tr>
<tr>
<td>IPMI</td>
<td>ipmi://&lt;out-of-band-ip&gt;</td>
</tr>
</tbody>
</table>

See the following sections for additional details.
Redfish virtual media for HPE iLO

To enable Redfish virtual media for HPE servers, use `redfish-virtualmedia://` in the `address` setting. The following example demonstrates using Redfish virtual media within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the `disableCertificateVerification: True` configuration parameter within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>
          disableCertificateVerification: True
```

NOTE

Redfish virtual media is not supported on 9th generation systems running iLO4, because Ironic does not support iLO4 with virtual media.

Redfish network boot for HPE iLO

To enable Redfish, use `redfish://` or `redfish+http://` to disable TLS. The installer requires both the host name or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the
disableCertificateVerification: True configuration parameter within the install-config.yaml file.

platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
          username: <user>
          password: <password>
          disableCertificateVerification: True

8.3.6.9.1. BMC addressing for Fujitsu iRMC

The address field for each bmc entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

platform:
  baremetal:
    hosts:
      - name: <host name>
        role: <master | worker>
        bmc:
          address: <address>
          username: <user>
          password: <password>

The address configuration setting specifies the protocol.

For Fujitsu hardware, Red Hat supports integrated Remote Management Controller (iRMC) and IPMI.

Table 8.6. BMC address formats for Fujitsu iRMC

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>iRMC</td>
<td>irmc://&lt;out-of-band-ip&gt;</td>
</tr>
<tr>
<td>IPMI</td>
<td>ipmi://&lt;out-of-band-ip&gt;</td>
</tr>
</tbody>
</table>

iRMC

Fujitsu nodes can use irmc://<out-of-band-ip> and defaults to port 623. The following example demonstrates an iRMC configuration within the install-config.yaml file.

platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
address: irmc://<out-of-band-ip>
username: <user>
password: <password>

NOTE
Currently Fujitsu supports iRMC S5 firmware version 3.05P and above for installer-provisioned installation on bare metal.

8.3.6.10. Root device hints

The rootDeviceHints parameter enables the installer to provision the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. The installer examines the devices in the order it discovers them, and compares the discovered values with the hint values. The installer uses the first discovered device that matches the hint value. The configuration can combine multiple hints, but a device must match all hints for the installer to select it.

Table 8.7. Subfields

<table>
<thead>
<tr>
<th>Subfield</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deviceName</td>
<td>A string containing a Linux device name like /dev/vda. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>hctl</td>
<td>A string containing a SCSI bus address like 0:0:0:0. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>model</td>
<td>A string containing a vendor-specific device identifier. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td>vendor</td>
<td>A string containing the name of the vendor or manufacturer of the device. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td>serialNumber</td>
<td>A string containing the device serial number. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>minSizeGigabytes</td>
<td>An integer representing the minimum size of the device in gigabytes.</td>
</tr>
<tr>
<td>wwn</td>
<td>A string containing the unique storage identifier. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>wwnWithExtension</td>
<td>A string containing the unique storage identifier with the vendor extension appended. The hint must match the actual value exactly.</td>
</tr>
</tbody>
</table>
### wwnVendorExtension
A string containing the unique vendor storage identifier. The hint must match the actual value exactly.

### rotational
A boolean indicating whether the device should be a rotating disk (true) or not (false).

**Example usage**

```yaml
- name: master-0
  role: master
  bmc:
    address: ipmi://10.10.0.3:6203
    username: admin
    password: redhat
  bootMACAddress: de:ad:be:ef:00:40
  rootDeviceHints:
    deviceName: "/dev/sda"
```

#### 8.3.6.11. Creating the OpenShift Container Platform manifests

1. Create the OpenShift Container Platform manifests.

   ```bash
   $ ./openshift-baremetal-install --dir ~/clusterconfigs create manifests
   INFO Consuming Install Config from target directory
   WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings
   WARNING Discarding the OpenShift Manifest that was provided in the target directory because its dependencies are dirty and it needs to be regenerated
   ```

#### 8.3.6.12. Configuring NTP for disconnected clusters (optional)

OpenShift Container Platform installs the **chrony** Network Time Protocol (NTP) service on the cluster nodes. Use the following procedure to configure NTP servers on the control plane nodes and configure worker nodes as NTP clients of the control plane nodes before deployment.

**Internet access**

- Router
- API VIP
- Ingress

OpenShift Container Platform nodes must agree on a date and time to run properly. When worker
nodes retrieve the date and time from the NTP servers on the control plane nodes, it enables the installation and operation of clusters that are not connected to a routable network and thereby do not have access to a higher stratum NTP server.

**Procedure**

1. Create a Butane config, `99-master-chrony-conf-override.bu`, including the contents of the `chrony.conf` file for the control plane nodes.

**NOTE**

See “Creating machine configs with Butane” for information about Butane.

**Butane config example**

```yaml
variant: openshift
version: 4.8.0
metadata:
  name: 99-master-chrony-conf-override
  labels:
    machineconfiguration.openshift.io/role: master
storage:
  files:
  - path: /etc/chrony.conf
    mode: 0644
    overwrite: true
    contents:
      inline: |
      # Use public servers from the pool.ntp.org project.
      # Please consider joining the pool (https://www.pool.ntp.org/join.html).
      # The Machine Config Operator manages this file
      server openshift-master-0.<cluster-name>.<domain> iburst
      server openshift-master-1.<cluster-name>.<domain> iburst
      server openshift-master-2.<cluster-name>.<domain> iburst
      stratumweight 0
      driftfile /var/lib/chrony/drift
      rtsync
      makestep 10 3
      bindcmdaddress 127.0.0.1
      bindcmdaddress ::1
      keyfile /etc/chrony.keys
      commandkey 1
      generatecommandkey
      noclientlog
      logchange 0.5
      logdir /var/log/chrony

      # Configure the control plane nodes to serve as local NTP servers
      # for all worker nodes, even if they are not in sync with an
      # upstream NTP server.

      # Allow NTP client access from the local network.
```
You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.

2. Use Butane to generate a MachineConfig object file, `99-master-chrony-conf-override.yaml`, containing the configuration to be delivered to the control plane nodes:

   ```bash
   $ butane 99-master-chrony-conf-override.bu -o 99-master-chrony-conf-override.yaml
   ```

3. Create a Butane config, `99-worker-chrony-conf-override.bu`, including the contents of the `chrony.conf` file for the worker nodes that references the NTP servers on the control plane nodes.

   **Butane config example**

   ```yaml
   variant: openshift
   version: 4.8.0
   metadata:
     name: 99-worker-chrony-conf-override
     labels:
       machineconfiguration.openshift.io/role: worker
   storage:
     files:
       - path: /etc/chrony.conf
         mode: 0644
         overwrite: true
         contents:
           inline:
             # The Machine Config Operator manages this file.
             server openshift-master-0.<cluster-name>.<domain> iburst 1
             server openshift-master-1.<cluster-name>.<domain> iburst
             server openshift-master-2.<cluster-name>.<domain> iburst
             stratumweight 0
             driftfile /var/lib/chrony/drift
             rtsync
             makestep 10 3
             bindcmdaddress 127.0.0.1
             bindcmdaddress ::1
             keyfile /etc/chrony.keys
             commandkey 1
             generatecommandkey
             noclientlog
             logchange 0.5
             logdir /var/log/chrony
   ```

   You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.
4. Use Butane to generate a `machineConfig` object file, `99-worker-chrony-conf-override.yaml`, containing the configuration to be delivered to the worker nodes:

```bash
```

5. Copy the `99-master-chrony-conf-override.yaml` file to the `~/clusterconfigs/manifests` directory.

```bash
$ cp 99-master-chrony-conf-override.yaml ~/clusterconfigs/manifests
```

```bash
$ cp 99-worker-chrony-conf-override.yaml ~/clusterconfigs/manifests
```

### 8.3.6.13. Configure network components to run on the control plane

Configure networking components to run exclusively on the control plane nodes. By default, OpenShift Container Platform allows any node in the machine config pool to host the `apiVIP` and `ingressVIP` virtual IP addresses. However, many environments deploy worker nodes in separate subnets from the control plane nodes. Consequently, you must place the `apiVIP` and `ingressVIP` virtual IP addresses exclusively with the control plane nodes.

**Procedure**

1. Change to the directory storing the `install-config.yaml` file.

```bash
$ cd ~/clusterconfigs
```

2. Switch to the `manifests` subdirectory.

```bash
$ cd manifests
```

```bash
$ touch cluster-network-avoid-workers-99-config.yaml
```

4. Open the `cluster-network-avoid-workers-99-config.yaml` file in an editor and enter a custom resource (CR) that describes the Operator configuration:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  name: 50-worker-fix-ipi-rwn
labels:
  machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    systemd:
      units:
        - name: nodeip-configuration.service
```
This manifest places the apiVIP and ingressVIP virtual IP addresses on the control plane nodes. Additionally, this manifest deploys the following processes on the control plane nodes only:

- **openshift-ingress-operator**
- **keepalived**

```yaml
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  nodePlacement:
    nodeSelector:
      matchLabels:
        node-role.kubernetes.io/master: ""
```

7. Consider backing up the `manifests` directory. The installer deletes the `manifests/` directory when creating the cluster.

8. Modify the `cluster-scheduler-02-config.yml` manifest to make the control plane nodes schedulable by setting the `mastersSchedulable` field to `true`. Control plane nodes are not schedulable by default. For example:
$ sed -i "s;mastersSchedulable: false;mastersSchedulable: true;g"
clusterconfigs/manifests/cluster-scheduler-02-config.yml

**NOTE**

If control plane nodes are not schedulable, deploying the cluster will fail.

9. Before deploying the cluster, ensure that the `api.<cluster-name>.<domain>` domain name is resolvable in the DNS. When you configure network components to run exclusively on the control plane, the internal DNS resolution no longer works for worker nodes, which is an expected outcome.

**IMPORTANT**

Failure to create a DNS record for the API precludes worker nodes from joining the cluster.

### 8.3.7. Creating a disconnected registry (optional)

In some cases, you might want to install an OpenShift Container Platform cluster using a local copy of the installation registry. This could be for enhancing network efficiency because the cluster nodes are on a network that does not have access to the internet.

A local, or mirrored, copy of the registry requires the following:

- A certificate for the registry node. This can be a self-signed certificate.
- A web server that a container on a system will serve.
- An updated pull secret that contains the certificate and local repository information.

**NOTE**

Creating a disconnected registry on a registry node is optional. The subsequent sections indicate that they are optional since they are steps you need to execute only when creating a disconnected registry on a registry node. You should execute all of the subsequent sub-sections labeled "(optional)" when creating a disconnected registry on a registry node.

#### 8.3.7.1. Preparing the registry node to host the mirrored registry (optional)

Make the following changes to the registry node.

**Procedure**

1. Open the firewall port on the registry node.

   ```
   $ sudo firewall-cmd --add-port=5000/tcp --zone=libvirt --permanent
   $ sudo firewall-cmd --add-port=5000/tcp --zone=public --permanent
   $ sudo firewall-cmd --reload
   ```

2. Install the required packages for the registry node.
Create the directory structure where the repository information will be held.

```bash
$ sudo mkdir -p /opt/registry/{auth,certs,data}
```

### 8.3.7.2. Generating the self-signed certificate (optional)

Generate a self-signed certificate for the registry node and put it in the `/opt/registry/certs` directory.

**Procedure**

1. Adjust the certificate information as appropriate.

```bash
$ host_fqdn=$( hostname --long )
$ cert_c="<Country Name>"   # Country Name (C, 2 letter code)
$ cert_s="<State>"          # Certificate State (S)
$ cert_l="<Locality>"       # Certificate Locality (L)
$ cert_o="<Organization>"   # Certificate Organization (O)
$ cert_ou="<Org Unit>"      # Certificate Organizational Unit (OU)
$ cert_cn="${host_fqdn}"   # Certificate Common Name (CN)
```

```bash
$ openssl req \
  -newkey rsa:4096 \
  -nodes \
  -sha256 \
  -keyout /opt/registry/certs/domain.key \
  -x509 \
  -days 365 \
  -out /opt/registry/certs/domain.crt \
  -addext "subjectAltName = DNS:${host_fqdn}" \
  -subj "/C=${cert_c}/ST=${cert_s}/L=${cert_l}/O=${cert_o}/OU=${cert_ou}/CN=${cert_cn}"
```

**NOTE**

When replacing `<Country Name>`, ensure that it only contains two letters. For example, `US`.

2. Update the registry node’s `ca-trust` with the new certificate.

```bash
$ sudo cp /opt/registry/certs/domain.crt /etc/pki/ca-trust/source/anchors/ 
$ sudo update-ca-trust extract
```

### 8.3.7.3. Creating the registry podman container (optional)

The registry container uses the `/opt/registry` directory for certificates, authentication files, and to store its data files.

The registry container uses `httpd` and needs an `htpasswd` file for authentication.

**Procedure**
1. Create an `htpasswd` file in `/opt/registry/auth` for the container to use.

   ```bash
   $ htpasswd -bBc /opt/registry/auth/htpasswd <user> <passwd>
   
   Replace `<user>` with the user name and `<passwd>` with the password.
   
2. Create and start the registry container.

   ```bash
   $ podman create \
   --name ocpdiscon-registry \
   -p 5000:5000 \
   -e "REGISTRY_AUTH=htpasswd" \
   -e "REGISTRY_AUTH_HTPASSWD_REALM=Registry" \
   -e "REGISTRY_HTTP_SECRET=ALongRandomSecretForRegistry" \
   -e "REGISTRY_AUTH_HTPASSWD_PATH=/auth/htpasswd" \
   -e "REGISTRY_HTTP_TLS_CERTIFICATE=/certs/domain.crt" \
   -e "REGISTRY_HTTP_TLS_KEY=/certs/domain.key" \
   -e "REGISTRY_COMPATIBILITY_SCHEMA1_ENABLED=true" \
   -v /opt/registry/data:/var/lib/registry:z \
   -v /opt/registry/auth:/auth:z \
   -v /opt/registry/certs:/certs:z \
   docker.io/library/registry:2
   
   $ podman start ocpdiscon-registry
   
   8.3.7.4. Copy and update the pull-secret (optional)
   
   Copy the pull secret file from the provisioner node to the registry node and modify it to include the authentication information for the new registry node.

   **Procedure**

   1. Copy the `pull-secret.txt` file.

      ```bash
      $ scp kni@provisioner:/home/kni/pull-secret.txt pull-secret.txt
      
      2. Update the `host_fqdn` environment variable with the fully qualified domain name of the registry node.

         ```bash
         $ host_fqdn=$( hostname --long )
         
         3. Update the `b64auth` environment variable with the base64 encoding of the http credentials used to create the `htpasswd` file.

         ```bash
         $ b64auth=$( echo -n '<username>:<passwd>' | openssl base64 )
         
         Replace `<username>` with the user name and `<passwd>` with the password.

         4. Set the `AUTHSTRING` environment variable to use the base64 authorization string. The `$USER` variable is an environment variable containing the name of the current user.

         ```bash
         $ AUTHSTRING="{"$host_fqdn:5000": {"auth": "$b64auth", "email": "$USER@redhat.com"}}"
         "}
5. Update the pull-secret.txt file.

```bash
$ jq ".auths += $AUTHSTRING" < pull-secret.txt > pull-secret-update.txt
```

8.3.7.5. Mirroring the repository (optional)

**Procedure**

1. Copy the oc binary from the provisioner node to the registry node.

```bash
$ sudo scp kni@provisioner:/usr/local/bin/oc /usr/local/bin
```

2. Mirror the remote install images to the local repository.

```bash
$ /usr/local/bin/oc adm release mirror \
-a pull-secret-update.txt \
--from=$UPSTREAM_REPO \
--to-release-image=$LOCAL_REG/$LOCAL_REPO:${VERSION} \
--to=$LOCAL_REG/$LOCAL_REPO
```

8.3.7.6. Modify the install-config.yaml file to use the disconnected registry (optional)

On the provisioner node, the install-config.yaml file should use the newly created pull-secret from the pull-secret-update.txt file. The install-config.yaml file must also contain the disconnected registry node’s certificate and registry information.

**Procedure**

1. Add the disconnected registry node’s certificate to the install-config.yaml file. The certificate should follow the "additionalTrustBundle: |" line and be properly indented, usually by two spaces.

```bash
$ echo "additionalTrustBundle: |" >> install-config.yaml
$ sed -e 's/^/  /' /opt/registry/certs/domain.crt >> install-config.yaml
```

2. Add the mirror information for the registry to the install-config.yaml file.

```bash
$ echo "imageContentSources:" >> install-config.yaml
$ echo "  - mirrors:" >> install-config.yaml
$ echo "    - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
$ echo "      source: quay.io/openshift-release-dev/ocp-v4.0-art-dev" >> install-config.yaml
$ echo "    - mirrors:" >> install-config.yaml
$ echo "      - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
$ echo "        source: registry.svc.ci.openshift.org/ocp/release" >> install-config.yaml
```

**NOTE**

Replace registry.example.com with the registry’s fully qualified domain name.
8.3.8. Deploying routers on worker nodes

During installation, the installer deploys router pods on worker nodes. By default, the installer installs two router pods. If the initial cluster has only one worker node, or if a deployed cluster requires additional routers to handle external traffic loads destined for services within the OpenShift Container Platform cluster, you can create a **yaml** file to set an appropriate number of router replicas.

**NOTE**

By default, the installer deploys two routers. If the cluster has at least two worker nodes, you can skip this section.

**NOTE**

If the cluster has no worker nodes, the installer deploys the two routers on the control plane nodes by default. If the cluster has no worker nodes, you can skip this section.

**Procedure**

1. Create a **router-replicas.yaml** file.

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: IngressController
   metadata:
     name: default
     namespace: openshift-ingress-operator
   spec:
     replicas: <num-of-router-pods>
     endpointPublishingStrategy:
       type: HostNetwork
     nodePlacement:
       nodeSelector:
         matchLabels:
           node-role.kubernetes.io/worker: ""
   
   **NOTE**

   Replace `<num-of-router-pods>` with an appropriate value. If working with just one worker node, set `replicas:` to 1. If working with more than 3 worker nodes, you can increase `replicas:` from the default value 2 as appropriate.

2. Save and copy the **router-replicas.yaml** file to the **clusterconfigs/openshift** directory.

   ```bash
   cp ~/router-replicas.yaml clusterconfigs/openshift/99_router-replicas.yaml
   ```

8.3.9. Validation checklist for installation

- OpenShift Container Platform installer has been retrieved.
- OpenShift Container Platform installer has been extracted.
- Required parameters for the **install-config.yaml** have been configured.
The **hosts** parameter for the `install-config.yaml` has been configured.

The **bmc** parameter for the `install-config.yaml` has been configured.

Conventions for the values configured in the **bmc address** field have been applied.

Created a disconnected registry (optional).

(Optional) Validate disconnected registry settings if in use.

(Optional) Deployed routers on worker nodes.

### 8.3.10. Deploying the cluster via the OpenShift Container Platform installer

Run the OpenShift Container Platform installer:

```
$ ./openshift-baremetal-install --dir ~/clusterconfigs --log-level debug create cluster
```

### 8.3.11. Following the installation

During the deployment process, you can check the installation’s overall status by issuing the `tail` command to the `.openshift_install.log` log file in the install directory folder.

```
$ tail -f /path/to/install-dir/.openshift_install.log
```

### 8.3.12. Verifying static IP address configuration

If the DHCP reservation for a cluster node specifies an infinite lease, after the installer successfully provisions the node, the dispatcher script checks the node’s network configuration. If the script determines that the network configuration contains an infinite DHCP lease, it creates a new connection using the IP address of the DHCP lease as a static IP address.

**NOTE**

The dispatcher script might run on successfully provisioned nodes while the provisioning of other nodes in the cluster is ongoing.

Verify the network configuration is working properly.

**Procedure**

1. Check the network interface configuration on the node.

2. Turn off the DHCP server and reboot the OpenShift Container Platform node and ensure that the network configuration works properly.

**Additional resources**

- See [OpenShift Container Platform upgrade channels and releases](#) for an explanation of the different release channels.
8.4. INSTALLER-PROVISIONED POST-INSTALLATION CONFIGURATION

After successfully deploying an installer-provisioned cluster, consider the following post-installation procedures.

8.4.1. Configuring NTP for disconnected clusters (optional)

OpenShift Container Platform installs the **chrony** Network Time Protocol (NTP) service on the cluster nodes. Use the following procedure to configure NTP servers on the control plane nodes and configure worker nodes as NTP clients of the control plane nodes after a successful deployment.

**Procedure**

1. Create a Butane config, `99-master-chrony-conf-override.bu`, including the contents of the `chrony.conf` file for the control plane nodes.

**NOTE**

See “Creating machine configs with Butane” for information about Butane.

**Butane config example**

```yaml
variant: openshift
version: 4.8.0
metadata:
  name: 99-master-chrony-conf-override
  labels:
    machineconfiguration.openshift.io/role: master
storage:
  files:
    - path: /etc/chrony.conf
      mode: 0644
      overwrite: true
      contents:
        # Use public servers from the pool.ntp.org project.
```

OpenShift Container Platform nodes must agree on a date and time to run properly. When worker nodes retrieve the date and time from the NTP servers on the control plane nodes, it enables the installation and operation of clusters that are not connected to a routable network and thereby do not have access to a higher stratum NTP server.
You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.

2. Use Butane to generate a `MachineConfig` object file, `99-master-chrony-conf-override.yaml`, containing the configuration to be delivered to the control plane nodes:

   ```bash
   $ butane 99-master-chrony-conf-override.bu -o 99-master-chrony-conf-override.yaml
   ```

3. Create a Butane config, `99-worker-chrony-conf-override.bu`, including the contents of the `chrony.conf` file for the worker nodes that references the NTP servers on the control plane nodes.

**Butane config example**

```yaml
variant: openshift
version: 4.8.0
metadata:
  name: 99-worker-chrony-conf-override
  labels:
    machineconfiguration.openshift.io/role: worker
storage:
  files:
    - path: /etc/chrony.conf
      mode: 0644
      overwrite: true
```

OpenShift Container Platform 4.8 Installing
You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.

4. Use Butane to generate a `MachineConfig` object file, `99-worker-chrony-conf-override.yaml`, containing the configuration to be delivered to the worker nodes:

```bash
```

5. Apply the `99-master-chrony-conf-override.yaml` policy to the control plane nodes.

```bash
$ oc apply -f 99-master-chrony-conf-override.yaml
```

Example output

```
machineconfig.machineconfiguration.openshift.io/99-master-chrony-conf-override created
```

6. Apply the `99-worker-chrony-conf-override.yaml` policy to the worker nodes.

```bash
$ oc apply -f 99-worker-chrony-conf-override.yaml
```

Example output

```
machineconfig.machineconfiguration.openshift.io/99-worker-chrony-conf-override created
```

7. Check the status of the applied NTP settings.

```bash
$ oc describe machineconfigpool
```

### 8.4.2. Enabling a provisioning network after installation

The assisted installer and installer-provisioned installation for bare metal clusters provide the ability to
deploy a cluster without a **provisioning** network. This capability is for scenarios such as proof-of-concept clusters or deploying exclusively with Redfish virtual media when each node’s baseboard management controller is routable via the **baremetal** network.

In OpenShift Container Platform 4.8 and later, you can enable a **provisioning** network after installation using the Cluster Baremetal Operator (CBO).

**Prerequisites**

- A dedicated physical network must exist, connected to all worker and control plane nodes.
- You must isolate the native, untagged physical network.
- The network cannot have a DHCP server when the **provisioningNetwork** configuration setting is set to **Managed**.
- You must connect the control plane nodes to the network with the same network interface, such as *eth0* or *eno1*.

**Procedure**

1. Identify the provisioning interface name for the cluster nodes. For example, *eth0* or *eno1*.

2. Enable the Preboot eXecution Environment (PXE) on the **provisioning** network interface of the cluster nodes.

3. Retrieve the current state of the **provisioning** network and save it to a provisioning configuration resource file:

   ```
   $ oc get provisioning -o yaml > enable-provisioning-nw.yaml
   ```

4. Modify the provisioning configuration resource file:

   ```
   $ vim ~/enable-provisioning-nw.yaml
   ```

   Scroll down to the **provisioningNetwork** configuration setting and change it from **Disabled** to **Managed**. Then, add the **provisioningOSDownloadURL**, **provisioningIP**, **provisioningNetworkCIDR**, **provisioningDHCPRange**, **provisioningInterface**, and **watchAllNameSpaces** configuration settings after the **provisioningNetwork** setting. Provide appropriate values for each setting.

   ```yaml
   apiVersion: v1
   items:
   - apiVersion: metal3.io/v1alpha1
     kind: Provisioning
     metadata:
       name: provisioning-configuration
     spec:
       provisioningNetwork: 1
       provisioningOSDownloadURL: 2
       provisioningIP: 3
       provisioningNetworkCIDR: 4
   ```
The `provisioningNetwork` is one of Managed, Unmanaged, or Disabled. When set to Managed, Metal3 manages the provisioning network and the CBO deploys the Metal3 pod with a configured DHCP server. When set to Unmanaged, the system administrator configures the DHCP server manually.

The `provisioningOSDownloadURL` is a valid HTTPS URL with a valid sha256 checksum that enables the Metal3 pod to download a qcow2 operating system image ending in `.qcow2.gz` or `.qcow2.xz`. This field is required whether the provisioning network is Managed, Unmanaged, or Disabled. For example:

The `provisioningIP` is the static IP address that the DHCP server and ironic use to provision the network. This static IP address must be within the provisioning subnet, and outside of the DHCP range. If you configure this setting, it must have a valid IP address even if the provisioning network is Disabled. The static IP address is bound to the metal3 pod. If the metal3 pod fails and moves to another server, the static IP address also moves to the new server.

The Classless Inter-Domain Routing (CIDR) address. If you configure this setting, it must have a valid CIDR address even if the provisioning network is Disabled. For example:

192.168.0.1/24.

The DHCP range. This setting is only applicable to a Managed provisioning network. Omit this configuration setting if the provisioning network is Disabled. For example:

192.168.0.64, 192.168.0.253.

The NIC name for the provisioning interface on cluster nodes. This setting is only applicable to Managed and Unmanaged provisioning networks. Omit this configuration setting if the provisioning network is Disabled.

Set this setting to `true` if you want metal3 to watch namespaces other than the default openshift-machine-api namespace. The default value is `false`.

5. Save the changes to the provisioning configuration resource file.

6. Apply the provisioning configuration resource file to the cluster:

   $ oc apply -f enable-provisioning-nw.yaml

### 8.4.3. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

#### Prerequisites

- On your load balancer, TCP over ports 6443, 443, and 80 must be available to any users of your system.
Load balance the API port, 6443, between each of the control plane nodes.

Load balance the application ports, 443 and 80, between all of the compute nodes.

On your load balancer, port 22623, which is used to serve ignition start-up configurations to nodes, is not exposed outside of the cluster.

Your load balancer must be able to access every machine in your cluster. Methods to allow this access include:

- Attaching the load balancer to the cluster’s machine subnet.
- Attaching floating IP addresses to machines that use the load balancer.

**IMPORTANT**

External load balancing services and the control plane nodes must run on the same L2 network, and on the same VLAN when using VLANs to route traffic between the load balancing services and the control plane nodes.

**Procedure**

1. Enable access to the cluster from your load balancer on ports 6443, 443, and 80. As an example, note this HAProxy configuration:

   A section of a sample HAProxy configuration

   ```
   ... 
   listen my-cluster-api-6443
     bind 0.0.0.0:6443
     mode tcp
     balance roundrobin
     server my-cluster-master-2 192.0.2.2:6443 check
     server my-cluster-master-0 192.0.2.3:6443 check
     server my-cluster-master-1 192.0.2.1:6443 check
   listen my-cluster-apps-443
     bind 0.0.0.0:443
     mode tcp
     balance roundrobin
     server my-cluster-worker-0 192.0.2.6:443 check
     server my-cluster-worker-1 192.0.2.5:443 check
     server my-cluster-worker-2 192.0.2.4:443 check
   listen my-cluster-apps-80
     bind 0.0.0.0:80
     mode tcp
     balance roundrobin
     server my-cluster-worker-0 192.0.2.7:80 check
     server my-cluster-worker-1 192.0.2.9:80 check
     server my-cluster-worker-2 192.0.2.8:80 check
   ```

2. Add records to your DNS server for the cluster API and apps over the load balancer. For example:

   `<load_balancer_ip_address> api.<cluster_name>.<base_domain>`
   `<load_balancer_ip_address> apps.<cluster_name>.<base_domain>`
3. From a command line, use **curl** to verify that the external load balancer and DNS configuration are operational.

   a. Verify that the cluster API is accessible:

   ```
   $ curl https://<loadbalancer_ip_address>:6443/version --insecure
   
   If the configuration is correct, you receive a JSON object in response:
   
   ```
   
   ```
   {
   "major": "1",
   "minor": "11+",
   "gitVersion": "v1.11.0+ad103ed",
   "gitCommit": "ad103ed",
   "gitTreeState": "clean",
   "buildDate": "2019-01-09T06:44:10Z",
   "goVersion": "go1.10.3",
   "compiler": "gc",
   "platform": "linux/amd64"
   }
   ```

   b. Verify that cluster applications are accessible:

   **NOTE**

   You can also verify application accessibility by opening the OpenShift Container Platform console in a web browser.

   ```
   $ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
   
   If the configuration is correct, you receive an HTTP response:
   
   HTTP/1.1 302 Found
   content-length: 0
   location: https://console-openshift-console.apps.<cluster-name>.<base_domain>/
   cache-control: no-cache
   referrer-policy: strict-origin-when-cross-origin
   set-cookie: csrf-token=39HoZgztDnzjKq/JuLJMeoKNIxfiVv2YgZc09c3TOBOU4NI6kDXaJH1LdicNhN1UsQWzon4Dor9GWGfopaTEQ==; Path=/; Secure
   x-content-type-options: nosniff
   x-dns-prefetch-control: off
   x-frame-options: DENY
   x-xss-protection: 1; mode=block
   date: Tue, 17 Nov 2020 08:42:10 GMT
   content-type: text/html; charset=utf-8
   set-cookie: 1e2670d92730b515ce3a1bb65da45062=9b714eb87e93cf34853e87a92d6894be; path=/; HttpOnly; Secure; SameSite=None
   cache-control: private
   ```

8.5. EXPANDING THE CLUSTER
After deploying an installer-provisioned OpenShift Container Platform cluster, you can use the following procedures to expand the number of worker nodes. Ensure that each prospective worker node meets the prerequisites.

NOTE
Expanding the cluster using RedFish Virtual Media involves meeting minimum firmware requirements. See Firmware requirements for installing with virtual media in the Prerequisites section for additional details when expanding the cluster using RedFish Virtual Media.

8.5.1. Preparing the bare metal node

Expanding the cluster requires a DHCP server. Each node must have a DHCP reservation.

RESERVING IP ADDRESSES SO THEY BECOME STATIC IP ADDRESSES
Some administrators prefer to use static IP addresses so that each node’s IP address remains constant in the absence of a DHCP server. To use static IP addresses in the OpenShift Container Platform cluster, reserve the IP addresses in the DHCP server with an infinite lease. After the installer provisions the node successfully, the dispatcher script will check the node’s network configuration. If the dispatcher script finds that the network configuration contains a DHCP infinite lease, it will recreate the connection as a static IP connection using the IP address from the DHCP infinite lease. NICs without DHCP infinite leases will remain unmodified.

Preparing the bare metal node requires executing the following procedure from the provisioner node.

Procedure
1. Get the oc binary, if needed. It should already exist on the provisioner node.

   [kni@provisioner ~]$ curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/openshift-client-linux-$VERSION.tar.gz | tar zxvf -
   oc

2. Power off the bare metal node via the baseboard management controller and ensure it is off.

3. Retrieve the user name and password of the bare metal node’s baseboard management controller. Then, create base64 strings from the user name and password. In the following example, the user name is root and the password is calvin.

   [kni@provisioner ~]$ echo -ne "root" | base64
   [kni@provisioner ~]$ echo -ne "calvin" | base64

4. Create a configuration file for the bare metal node.

   [kni@provisioner ~]$ vim bmh.yaml

---
[kni@provisioner ~]$ oc -n openshift-machine-api create -f bmh.yaml

secret/openshift-worker-<num>-bmc-secret created
baremetalhost.metal3.io/openshift-worker-<num> created

Where <num> will be the worker number.

6. Power up and inspect the bare metal node.

[kni@provisioner ~]$ oc -n openshift-machine-api get bmh openshift-worker-<num>

Where <num> is the worker node number.
8.5.1.1. Diagnosing a duplicate MAC address when provisioning a new host in the cluster

If the MAC address of an existing bare-metal node in the cluster matches the MAC address of a bare-metal host you are attempting to add to the cluster, the Bare Metal Operator associates the host with the existing node. If the host enrollment, inspection, cleaning, or other Ironic steps fail, the Bare Metal Operator retries the installation continuously. A registration error is displayed for the failed bare-metal host.

You can diagnose a duplicate MAC address by examining the bare-metal hosts that are running in the openshift-machine-api namespace.

**Prerequisites**

- Install an OpenShift Container Platform cluster on bare metal.
- Install the OpenShift Container Platform CLI `oc`.
- Log in as a user with `cluster-admin` privileges.

**Procedure**

To determine whether a bare-metal host that fails provisioning has the same MAC address as an existing node, do the following:

1. Get the bare-metal hosts running in the openshift-machine-api namespace:

   ```
   $ oc get bmh -n openshift-machine-api
   ```

   **Example output**

   ```
   NAME                 STATUS   PROVISIONING STATUS      CONSUMER
   openshift-master-0   OK       externally provisioned   openshift-zpwpq-master-0
   openshift-master-1   OK       externally provisioned   openshift-zpwpq-master-1
   openshift-master-2   OK       externally provisioned   openshift-zpwpq-master-2
   openshift-worker-0   OK       provisioned              openshift-zpwpq-worker-0-lv84n
   openshift-worker-1   OK       provisioned              openshift-zpwpq-worker-0-zd8lm
   openshift-worker-2   error    registering
   ```

2. To see more detailed information about the status of the failing host, run the following command replacing `<bare_metal_host_name>` with the name of the host:

   ```
   $ oc get -n openshift-machine-api bmh <bare_metal_host_name> -o yaml
   ```

   **Example output**

   ```
   ... status:
   errorCount: 12
   errorMessage: MAC address b4:96:91:1d:7c:20 conflicts with existing node openshift-
   ```
8.5.2. Provisioning the bare metal node

Provisioning the bare metal node requires executing the following procedure from the provisioner node.

Procedure

1. Ensure the PROVISIONING STATUS is ready before provisioning the bare metal node.

   $ oc -n openshift-machine-api get bmh openshift-worker-<num>

   Where <num> is the worker node number.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>PROVISIONING STATUS</th>
<th>CONSUMER</th>
<th>BMC</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-worker-&lt;num&gt;</td>
<td>OK</td>
<td>ready</td>
<td></td>
<td>ipmi://&lt;out-of-band-ip&gt; unknown</td>
</tr>
<tr>
<td></td>
<td></td>
<td>true</td>
<td></td>
<td>true</td>
</tr>
</tbody>
</table>

2. Get a count of the number of worker nodes.

   $ oc get nodes

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>provisioner.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-1.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-2.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-3.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-worker-0.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-worker-1.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
</tbody>
</table>

3. Get the machine set.

   $ oc get machinesets -n openshift-machine-api

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>READY</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-worker-0.example.com</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>55m</td>
</tr>
<tr>
<td>openshift-worker-1.example.com</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>55m</td>
</tr>
</tbody>
</table>

4. Increase the number of worker nodes by one.

   $ oc scale --replicas=<num> machineset <machineset> -n openshift-machine-api

   Replace <num> with the new number of worker nodes. Replace <machineset> with the name of the machine set from the previous step.

5. Check the status of the bare metal node.

   $ oc -n openshift-machine-api get bmh openshift-worker-<num>
Where `<num>` is the worker node number. The status changes from `ready` to `provisioning`.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>PROVISIONING STATUS</th>
<th>CONSUMER</th>
<th>BMC</th>
</tr>
</thead>
</table>

The `provisioning` status remains until the OpenShift Container Platform cluster provisions the node. This can take 30 minutes or more. Once complete, the status will change to `provisioned`.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>PROVISIONING STATUS</th>
<th>CONSUMER</th>
<th>BMC</th>
</tr>
</thead>
</table>

6. Once provisioned, ensure the bare metal node is ready.

$ oc get nodes

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>Age</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>provisioner.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-1.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-2.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-master-3.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-worker-0.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-worker-1.openshift.example.com</td>
<td>Ready</td>
<td>master</td>
<td>30h</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>openshift-worker-&lt;num&gt;.openshift.example.com</td>
<td>Ready</td>
<td>worker</td>
<td>3m27s</td>
<td>v1.16.2</td>
</tr>
</tbody>
</table>

You can also check the kubelet.

$ ssh openshift-worker-<num>

[kni@openshift-worker-<num>]$ journalctl -fu kubelet

**8.6. TROUBLESHOOTING**

**8.6.1. Troubleshooting the installer workflow**

Prior to troubleshooting the installation environment, it is critical to understand the overall flow of the installer-provisioned installation on bare metal. The diagrams below provide a troubleshooting flow with a step-by-step breakdown for the environment.
Workflow 1 of 4 illustrates a troubleshooting workflow when the `install-config.yaml` file has errors or the Red Hat Enterprise Linux CoreOS (RHCOS) images are inaccessible. Troubleshooting suggestions can be found at Troubleshooting `install-config.yaml`.

Workflow 2 of 4 illustrates a troubleshooting workflow for bootstrap VM issues, bootstrap VMs that cannot boot up the cluster nodes, and inspecting logs. When installing a OpenShift Container Platform cluster without the provisioning network, this workflow does not apply.
Workflow 3 of 4 illustrates a troubleshooting workflow for cluster nodes that will not PXE boot. If installing using RedFish Virtual Media, each node must meet minimum firmware requirements for the installer to deploy the node. See Firmware requirements for installing with virtual media in the Prerequisites section for additional details.
Workflow 4 of 4 illustrates a troubleshooting workflow from a non-accessible API to a validated installation.

8.6.2. Troubleshooting install-config.yaml

The `install-config.yaml` configuration file represents all of the nodes that are part of the OpenShift Container Platform cluster. The file contains the necessary options consisting of but not limited to `apiVersion`, `baseDomain`, `imageContentSources` and virtual IP addresses. If errors occur early in the deployment of the OpenShift Container Platform cluster, the errors are likely in the `install-config.yaml` configuration file.

Procedure

1. Use the guidelines in YAML-tips.
2. Verify the YAML syntax is correct using syntax-check.
3. Verify the Red Hat Enterprise Linux CoreOS (RHCOS) QEMU images are properly defined and accessible via the URL provided in the `install-config.yaml`. For example:

   ```sh
   $ curl -s -o /dev/null -I -w "%(http_code)\n" http://webserver.example.com:8080/rhcos-44.81.202004250133-0-qemu.x86_64.qcow2.gz?
   sha256=7d884b46ee54fe87bcb3893bf2aa99af3b2d31f2e19ab5529c60636fd0f1ce7
   ``

   If the output is **200**, there is a valid response from the webserver storing the bootstrap VM image.

8.6.3. Bootstrap VM issues

The OpenShift Container Platform installer spawns a bootstrap node virtual machine, which handles provisioning the OpenShift Container Platform cluster nodes.

Procedure

1. About 10 to 15 minutes after triggering the installer, check to ensure the bootstrap VM is operational using the `virsh` command:

   ```sh
   $ sudo virsh list
   ```

<table>
<thead>
<tr>
<th>Id</th>
<th>Name</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>openshift-xf6fq-bootstrap</td>
<td>running</td>
</tr>
</tbody>
</table>

   **NOTE**

   The name of the bootstrap VM is always the cluster name followed by a random set of characters and ending in the word "bootstrap."

   If the bootstrap VM is not running after 10-15 minutes, troubleshoot why it is not running. Possible issues include:

   2. Verify `libvirtd` is running on the system:
If the bootstrap VM is operational, log into it.

3. Use the `virsh console` command to find the IP address of the bootstrap VM:

   ```bash
   $ sudo virsh console example.com
   ```

   ```console
   Connected to domain example.com
   Escape character is ^]  
   Red Hat Enterprise Linux CoreOS 43.81.202001142154.0 (Ootpa) 4.3
   SSH host key: SHA256:BRWJktXZgQQRY5zjuAV0IKZ4WM7i4TiUyMVanqu9Pqg (ED25519)
   SSH host key: SHA256:7+iKGA7VtG5szmk2jB5g/5EZ+SNCj3a2g23o0lilio (ECDSA)
   SSH host key: SHA256:DH5VWhhVvIaOTaLsYiVNse9ca+ZSW/30OOMed8rIGOC (RSA)
   ens4: 172.22.0.2 fe80::1d05:e52e:be5d:263f
   localhost login:
   ```

   **IMPORTANT**

   When deploying an OpenShift Container Platform cluster without the `provisioning` network, you must use a public IP address and not a private IP address like `172.22.0.2`.

4. Once you obtain the IP address, log in to the bootstrap VM using the `ssh` command:

   ```bash
   $ ssh core@172.22.0.2
   ```

   If you are not successful logging in to the bootstrap VM, you have likely encountered one of the following scenarios:

   - You cannot reach the `172.22.0.0/24` network. Verify network connectivity on the provisioner host specifically around the `provisioning` network bridge. This will not be the issue if you are not using the `provisioning` network.
• You cannot reach the bootstrap VM via the public network. When attempting to SSH via 
  baremetal network, verify connectivity on the provisioner host specifically around the 
  baremetal network bridge.

• You encountered Permission denied (publickey,password,keyboard-interactive). When 
  attempting to access the bootstrap VM, a Permission denied error might occur. Verify that the 
  SSH key for the user attempting to log into the VM is set within the install-config.yaml file.

8.6.3.1. Bootstrap VM cannot boot up the cluster nodes

During the deployment, it is possible for the bootstrap VM to fail to boot the cluster nodes, which 
prevents the VM from provisioning the nodes with the RHCOS image. This scenario can arise due to:

• A problem with the install-config.yaml file.

• Issues with out-of-band network access via the baremetal network.

To verify the issue, there are three containers related to ironic:

• ironic-api
• ironic-conductor
• ironic-inspector

Procedure

1. Log in to the bootstrap VM:

   $ ssh core@172.22.0.2

2. To check the container logs, execute the following:

   [core@localhost ~]$ sudo podman logs -f <container-name>

Replace <container-name> with one of ironic-api, ironic-conductor, or ironic-inspector. If you 
encounter an issue where the control plane nodes are not booting up via PXE, check the 
ironic-conductor pod. The ironic-conductor pod contains the most detail about the attempt 
to boot the cluster nodes, because it attempts to log in to the node over IPMI.

Potential reason

The cluster nodes might be in the ON state when deployment started.

Solution

Power off the OpenShift Container Platform cluster nodes before you begin the installation over IPMI:

   $ ipmitool -l lanplus -U root -P <password> -H <out-of-band-ip> power off

8.6.3.2. Inspecting logs

When experiencing issues downloading or accessing the RHCOS images, first verify that the URL is 
correct in the install-config.yaml configuration file.
Example of internal webserver hosting RHCOS images

```
bootstrapOSImage: http://<ip:port>/rhcos-43.81.202001142154.0-qemu.x86_64.qcow2.gz?
sha256=9d999f55f1d44f7ed7c068508e5deedcd04dc3c06d95d34d36bf1cd127837e0c
clusterOSImage: http://<ip:port>/rhcos-43.81.202001142154.0-openstack.x86_64.qcow2.gz?
sha256=a1bda656fa0892f7b936fd666a6086bd6daed5dafeced7a1e811abb78e3b0
```

The *ipa-downloader* and *coreos-downloader* containers download resources from a webserver or the external *quay.io* registry, whichever the *install-config.yaml* configuration file specifies. Verify the following two containers are up and running and inspect their logs as needed:

- *ipa-downloader*
- *coreos-downloader*

### Procedure

1. Log in to the bootstrap VM:

   ```
   $ ssh core@172.22.0.2
   ```

2. Check the status of the *ipa-downloader* and *coreos-downloader* containers within the bootstrap VM:

   ```
   [core@localhost ~]$ podman logs -f ipa-downloader
   [core@localhost ~]$ podman logs -f coreos-downloader
   ```

   If the bootstrap VM cannot access the URL to the images, use the *curl* command to verify that the VM can access the images.

3. To inspect the *bootkube* logs that indicate if all the containers launched during the deployment phase, execute the following:

   ```
   [core@localhost ~]$ journalctl -xe
   [core@localhost ~]$ journalctl -b -f -u bootkube.service
   ```

4. Verify all the pods, including *dnsmasq*, *mariadb*, *httpd*, and *ironic*, are running:

   ```
   [core@localhost ~]$ sudo podman ps
   ```

5. If there are issues with the pods, check the logs of the containers with issues. To check the log of the *ironic-api*, execute the following:

   ```
   [core@localhost ~]$ sudo podman logs <ironic-api>
   ```

### 8.6.4. Cluster nodes will not PXE boot

When OpenShift Container Platform cluster nodes will not PXE boot, execute the following checks on the cluster nodes that will not PXE boot. This procedure does not apply when installing a OpenShift Container Platform cluster without the *provisioning* network.
Procedure

1. Check the network connectivity to the **provisioning** network.

2. Ensure PXE is enabled on the NIC for the **provisioning** network and PXE is disabled for all other NICs.

3. Verify that the **install-config.yaml** configuration file has the proper hardware profile and boot MAC address for the NIC connected to the **provisioning** network. For example:

   control plane node settings
   
   ```yaml
   bootMACAddress: 24:6E:96:1B:96:90 # MAC of bootable provisioning NIC
   hardwareProfile: default          #control plane node settings
   ```

   Worker node settings
   
   ```yaml
   bootMACAddress: 24:6E:96:1B:96:90 # MAC of bootable provisioning NIC
   hardwareProfile: unknown          #worker node settings
   ```

8.6.5. The API is not accessible

When the cluster is running and clients cannot access the API, domain name resolution issues might impede access to the API.

Procedure

1. **Hostname Resolution**: Check the cluster nodes to ensure they have a fully qualified domain name, and not just **localhost.localdomain**. For example:

   ```bash
   $ hostname
   
   If a hostname is not set, set the correct hostname. For example:
   
   ```bash
   $ hostnamectl set-hostname <hostname>
   ```

2. **Incorrect Name Resolution**: Ensure that each node has the correct name resolution in the DNS server using **dig** and **nslookup**. For example:

   ```bash
   $ dig api.<cluster-name>.example.com
   ; <<>> DiG 9.11.4-P2-RedHat-9.11.4-26.P2.el8 <<>> api.<cluster-name>.example.com
   ;; global options: +cmd
   ;; Got answer:
   ;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 37551
   ;; flags: qr aa rd ra QUERY: 1, ANSWER: 1, AUTHORITY: 1, ADDITIONAL: 2
   
   ;; OPT PSEUDOSECTION:
   ; EDNS: version: 0, flags:; udp: 4096
   ; COOKIE: 866929d2f8e8563582af23f05ec44203d313e50948d43f60 (good)
   ;; QUESTION SECTION:
   ;api.<cluster-name>.example.com. IN A
   ```
The output in the foregoing example indicates that the appropriate IP address for the API
<cluster-name>.example.com VIP is 10.19.13.86. This IP address should reside on the
baremetal network.

8.6.6. Cleaning up previous installations

In the event of a previous failed deployment, remove the artifacts from the failed attempt before attempting to deploy OpenShift Container Platform again.

Procedure

1. Power off all bare metal nodes prior to installing the OpenShift Container Platform cluster:

   $ ipmitool -I lanplus -U <user> -P <password> -H <management-server-ip> power off

2. Remove all old bootstrap resources if any are left over from a previous deployment attempt:

   for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk '{print $2}');
do
      sudo virsh destroy $i;
      sudo virsh undefine $i;
      sudo virsh vol-delete $i --pool $i;
      sudo virsh vol-delete $i.ign --pool $i;
      sudo virsh pool-destroy $i;
      sudo virsh pool-undefine $i;
done

3. Remove the following from the clusterconfigs directory to prevent Terraform from failing:

   $ rm -rf ~/clusterconfigs/auth ~/clusterconfigs/terraform* ~/clusterconfigs/tls
   ~/clusterconfigs/metadata.json

8.6.7. Issues with creating the registry

When creating a disconnected registry, you might encounter a "User Not Authorized" error when attempting to mirror the registry. This error might occur if you fail to append the new authentication to the existing pull-secret.txt file.

Procedure
1. Check to ensure authentication is successful:

```
$ /usr/local/bin/oc adm release mirror \
  -a pull-secret-update.json \
  --from=${UPSTREAM_REPO} \
  --to-release-image=${LOCAL_REG}/${LOCAL_REPO}:${VERSION} \
  --to=${LOCAL_REG}/${LOCAL_REPO}
```

**NOTE**

Example output of the variables used to mirror the install images:

```
UPSTREAM_REPO=${RELEASE_IMAGE}
LOCAL_REG=<registry_FQDN>:<registry_port>
LOCAL_REPO='ocp4/openshift4'
```

The values of `RELEASE_IMAGE` and `VERSION` were set during the Retrieving OpenShift Installer step of the Setting up the environment for an OpenShift installation section.

2. After mirroring the registry, confirm that you can access it in your disconnected environment:

```
$ curl -k -u <user>:<password> https://registry.example.com:<registry-port>/v2/_catalog
{"repositories":["<Repo-Name>"]}
```

### 8.6.8. Miscellaneous issues

#### 8.6.8.1. Addressing the runtime network not ready error

After the deployment of a cluster you might receive the following error:

```
```

The Cluster Network Operator is responsible for deploying the networking components in response to a special object created by the installer. It runs very early in the installation process, after the control plane (master) nodes have come up, but before the bootstrap control plane has been torn down. It can be indicative of more subtle installer issues, such as long delays in bringing up control plane (master) nodes or issues with `apiserver` communication.

**Procedure**

1. Inspect the pods in the `openshift-network-operator` namespace:

```
$ oc get all -n openshift-network-operator
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>pod/network-operator-69d7b577-9b89v</td>
<td>0/1 ContainerCreating</td>
<td>0</td>
<td>149m</td>
</tr>
</tbody>
</table>

2. On the provisioner node, determine that the network configuration exists:
If it does not exist, the installer did not create it. To determine why the installer did not create it, execute the following:

```
$ openshift-install create manifests
```

3. Check that the **network-operator** is running:

```
$ kubectl -n openshift-network-operator get pods
```

4. Retrieve the logs:

```
$ kubectl -n openshift-network-operator logs -l "name=network-operator"
```

On high availability clusters with three or more control plane (master) nodes, the Operator will perform leader election and all other Operators will sleep. For additional details, see Troubleshooting.

### 8.6.8.2. Cluster nodes not getting the correct IPv6 address over DHCP

If the cluster nodes are not getting the correct IPv6 address over DHCP, check the following:

1. Ensure the reserved IPv6 addresses reside outside the DHCP range.

2. In the IP address reservation on the DHCP server, ensure the reservation specifies the correct DHCP Unique Identifier (DUID). For example:

```
# This is a dnsmasq dhcp reservation, 'id:00:03:00:01' is the client id and '18:db:f2:8c:d5:9f' is the MAC Address for the NIC
id:00:03:00:01:18:db:f2:8c:d5:9f,openshift-master-1,[2620:52:0:1302::6]
```

3. Ensure that route announcements are working.

4. Ensure that the DHCP server is listening on the required interfaces serving the IP address ranges.

### 8.6.8.3. Cluster nodes not getting the correct hostname over DHCP
During IPv6 deployment, cluster nodes must get their hostname over DHCP. Sometimes the `NetworkManager` does not assign the hostname immediately. A control plane (master) node might report an error such as:

```
Failed Units: 2
NetworkManager-wait-online.service
nodeip-configuration.service
```

This error indicates that the cluster node likely booted without first receiving a hostname from the DHCP server, which causes `kubelet` to boot with a `localhost.localdomain` hostname. To address the error, force the node to renew the hostname.

**Procedure**

1. Retrieve the **hostname**:
   ```
   [core@master-X ~]$ hostname
   ```
   
   If the hostname is `localhost`, proceed with the following steps.
   
   **NOTE**
   
   Where X is the control plane node (also known as the master node) number.

2. Force the cluster node to renew the DHCP lease:
   ```
   [core@master-X ~]$ sudo nmcli con up "<bare-metal-nic>"
   ```
   
   Replace `<bare-metal-nic>` with the wired connection corresponding to the `baremetal` network.

3. **Check hostname** again:
   ```
   [core@master-X ~]$ hostname
   ```

4. If the hostname is still `localhost.localdomain`, restart `NetworkManager`:
   ```
   [core@master-X ~]$ sudo systemctl restart NetworkManager
   ```

5. If the hostname is still `localhost.localdomain`, wait a few minutes and check again. If the hostname remains `localhost.localdomain`, repeat the previous steps.

6. Restart the **nodeip-configuration** service:
   ```
   [core@master-X ~]$ sudo systemctl restart nodeip-configuration.service
   ```

   This service will reconfigure the `kubelet` service with the correct hostname references.

7. Reload the unit files definition since the kubelet changed in the previous step:
   ```
   [core@master-X ~]$ sudo systemctl daemon-reload
   ```

8. Restart the **kubelet** service:
Ensure kubelet booted with the correct hostname:

```
[core@master-X ~]$ sudo systemctl restart kubelet.service
```

If the cluster node is not getting the correct hostname over DHCP after the cluster is up and running, such as during a reboot, the cluster will have a pending csr. Do not approve a csr, or other issues might arise.

Addressing a csr

1. Get CSRs on the cluster:

```
$ oc get csr
```

2. Verify if a pending csr contains Subject Name: localhost.localdomain:

```
$ oc get csr <pending_csr> -o jsonpath='{.spec.request}' | base64 --decode | openssl req -noout -text
```

3. Remove any csr that contains Subject Name: localhost.localdomain:

```
$ oc delete csr <wrong_csr>
```

8.6.8.4. Routes do not reach endpoints

During the installation process, it is possible to encounter a Virtual Router Redundancy Protocol (VRRP) conflict. This conflict might occur if a previously used OpenShift Container Platform node that was once part of a cluster deployment using a specific cluster name is still running but not part of the current OpenShift Container Platform cluster deployment using that same cluster name. For example, a cluster was deployed using the cluster name openshift, deploying three control plane (master) nodes and three worker nodes. Later, a separate install uses the same cluster name openshift, but this redeployment only installed three control plane (master) nodes, leaving the three worker nodes from a previous deployment in an ON state. This might cause a Virtual Router Identifier (VRID) conflict and a VRRP conflict.

1. Get the route:

```
$ oc get route oauth-openshift
```

2. Check the service endpoint:

```
$ oc get svc oauth-openshift
```

```
NAME              TYPE        CLUSTER-IP      EXTERNAL-IP   PORT(S)   AGE
oauth-openshift   ClusterIP   172.30.19.162   <none>        443/TCP   59m
```

3. Attempt to reach the service from a control plane (master) node:

```
[core@master0 ~]$ curl -k https://172.30.19.162
```
Identify the authentication-operator errors from the provisioner node:

```
$ oc logs deployment/authentication-operator -n openshift-authentication-operator
```

4. Identify the **authentication-operator** errors from the **provisioner** node:

Solution

1. Ensure that the cluster name for every deployment is unique, ensuring no conflict.

2. Turn off all the rogue nodes which are not part of the cluster deployment that are using the same cluster name. Otherwise, the authentication pod of the OpenShift Container Platform cluster might never start successfully.

### 8.6.8.5. Failed Ignition during Firstboot

During the Firstboot, the Ignition configuration may fail.

**Procedure**

1. Connect to the node where the Ignition configuration failed:

   Failed Units: 1
   machine-config-daemon-firstboot.service

2. Restart the **machine-config-daemon-firstboot** service:

   `[core@worker-X ~]$ sudo systemctl restart machine-config-daemon-firstboot.service`

### 8.6.8.6. NTP out of sync

The deployment of OpenShift Container Platform clusters depends on NTP synchronized clocks among the cluster nodes. Without synchronized clocks, the deployment may fail due to clock drift if the time difference is greater than two seconds.
Procedure

1. Check for differences in the **AGE** of the cluster nodes. For example:

   $ oc get nodes

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0.cloud.example.com</td>
<td>Ready</td>
<td>master</td>
<td>145m</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>master-1.cloud.example.com</td>
<td>Ready</td>
<td>master</td>
<td>135m</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>master-2.cloud.example.com</td>
<td>Ready</td>
<td>master</td>
<td>145m</td>
<td>v1.16.2</td>
</tr>
<tr>
<td>worker-2.cloud.example.com</td>
<td>Ready</td>
<td>worker</td>
<td>100m</td>
<td>v1.16.2</td>
</tr>
</tbody>
</table>

2. Check for inconsistent timing delays due to clock drift. For example:

   $ oc get bmh -n openshift-machine-api

   master-1   error registering master-1  ipmi://<out-of-band-ip>

   $ sudo timedatectl

   Local time: Tue 2020-03-10 18:20:02 UTC
   Universal time: Tue 2020-03-10 18:20:02 UTC
   RTC time: Tue 2020-03-10 18:36:53
   Time zone: UTC (UTC, +0000)
   System clock synchronized: no
   NTP service: active
   RTC in local TZ: no

Addressing clock drift in existing clusters

1. Create a Butane config file including the contents of the `chrony.conf` file to be delivered to the nodes. In the following example, create `99-master-chrony.bu` to add the file to the control plane nodes. You can modify the file for worker nodes or repeat this procedure for the worker role.

   ```
   variant: openshift
   version: 4.8.0
   metadata:
     name: 99-master-chrony
     labels:
       machineconfiguration.openshift.io/role: master
   storage:
     files:
     - path: /etc/chrony.conf
       mode: 0644
       overwrite: true
       contents:
         inline: |
   ```

   **NOTE**

   See "Creating machine configs with Butane" for information about Butane.
Replace `<NTP-server>` with the IP address of the NTP server.

2. Use Butane to generate a `MachineConfig` object file, `99-master-chrony.yaml`, containing the configuration to be delivered to the nodes:

   ```
   $ butane 99-master-chrony.bu -o 99-master-chrony.yaml
   ```

3. Apply the `MachineConfig` object file:

   ```
   $ oc apply -f 99-master-chrony.yaml
   ```

4. Ensure the `System clock synchronized` value is `yes`:

   ```
   $ sudo timedatectl
   ```

   ```
   Local time: Tue 2020-03-10 19:10:02 UTC
   Universal time: Tue 2020-03-10 19:10:02 UTC
   RTC time: Tue 2020-03-10 19:36:53
   Time zone: UTC (UTC, +0000)
   System clock synchronized: yes
   NTP service: active
   RTC in local TZ: no
   ```

To setup clock synchronization prior to deployment, generate the manifest files and add this file to the `openshift` directory. For example:

```
$ cp chrony-masters.yaml ~/clusterconfigs/openshift/99_masters-chrony-configuration.yaml
```

Then, continue to create the cluster.

### 8.6.9. Reviewing the installation

After installation, ensure the installer deployed the nodes and pods successfully.

**Procedure**

1. When the OpenShift Container Platform cluster nodes are installed appropriately, the following `Ready` state is seen within the `STATUS` column:
2. Confirm the installer deployed all pods successfully. The following command removes any pods that are still running or have completed as part of the output.

```
$ oc get nodes

NAME           STATUS   ROLES           AGE     VERSION
master-0.example.com   Ready   master,worker   4h   v1.16.2
master-1.example.com   Ready   master,worker   4h   v1.16.2
master-2.example.com   Ready   master,worker   4h   v1.16.2

$ oc get pods --all-namespaces | grep -iv running | grep -iv complete
```
9.1. PREPARING TO INSTALL WITH Z/VM ON IBM Z AND LINUXONE

9.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

9.1.2. Choosing a method to install OpenShift Container Platform with z/VM on IBM Z or LinuxONE

You can install a cluster with z/VM on IBM Z or LinuxONE infrastructure that you provision, by using one of the following methods:

- Installing a cluster with z/VM on IBM Z and LinuxONE: You can install OpenShift Container Platform with z/VM on IBM Z or LinuxONE infrastructure that you provision.
- Installing a cluster with z/VM on IBM Z and LinuxONE in a restricted network: You can install OpenShift Container Platform with z/VM on IBM Z or LinuxONE infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

9.2. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND LINUXONE

In OpenShift Container Platform version 4.8, you can install a cluster on IBM Z or LinuxONE infrastructure that you provision.

**NOTE**

While this document refers only to IBM Z, all information in it also applies to LinuxONE.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

9.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.

- You provisioned persistent storage using NFS for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 9.2.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 9.2.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

#### 9.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 9.1. Default monitoring stack components**
### Hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

#### IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

### 9.2.3.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

1. 1 physical core (IFL) provides 2 logical cores (threads) when SMT-2 is enabled. The hypervisor can provide 2 or more vCPUs.

### 9.2.3.3. Minimum IBM Z system requirements

You can install OpenShift Container Platform version 4.8 on the following IBM hardware:

- IBM Z, versions 13, 14, or 15
- LinuxONE, any version

#### Hardware requirements

- 1 LPAR with 6 IFLs that supports SMT2
Operating system requirements

- One instance of z/VM 7.1 or later

On your z/VM instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

9.2.3.4. Preferred IBM Z system requirements

Hardware requirements

- 3 LPARs with 6 IFLs each that support SMT2
- 1 or 2 OSA or RoCE network adapters, or both
- Hipersockets, which are attached to a node either directly as a device or by bridging with one z/VM VSWITCH to be transparent to the z/VM guest. To directly connect Hipersockets to a node, you must set up a gateway to the external network via a RHEL 8 guest to bridge to the Hipersockets network.

Operating system requirements

- 2 or 3 instances of z/VM 7.1 or later for high availability

On your z/VM instances, set up:
3 guest virtual machines for OpenShift Container Platform control plane machines, one per z/VM instance

At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the z/VM instances

1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane using the CP command `SET SHARE`. Do the same for infrastructure plane machines if they exist. See `SET SHARE` in IBM Documentation.

**IBM Z network connectivity requirements**

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

**Disk storage for the z/VM guest virtual machines**

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV and High Performance FICON (zHPF) to ensure optimal performance.
- FCP attached disk storage

**Storage / Main Memory**

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

**9.2.3.5. Managing certificate signing requests**

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machineApprover` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

**Additional resources**

- See Bridging a HiperSockets LAN with a z/VM Virtual Switch in the IBM Knowledge Center.
- See Scaling HyperPAV alias devices on Linux guests on z/VM for performance optimization.

**9.2.3.6. Networking requirements for user-provisioned infrastructure**

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.
9.2.3.6.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have Internet access to pull images for platform containers and provide telemetry data to Red Hat.

**Table 9.2. Ports used for all-machine to all-machine communications**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>

Additional resources

- Configuring chrony time service

9.2.3.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>..<cluster_name>..<base_domain>`.

Table 9.5. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;..&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;..&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
### Component | Record | Description
--- | --- | ---
Routes | *.apps.<cluster_name>.<base_domain>. | A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

For example, console-openshift-console.apps.<cluster_name>.<base_domain> is used as a wildcard route to the OpenShift Container Platform console.

Bootstrap machine | bootstrap.<cluster_name>.<base_domain>. | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.

Control plane machines | <master><n>.<cluster_name>.<base_domain>. | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.

Compute machines | <worker><n>.<cluster_name>.<base_domain>. | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

---

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

### 9.2.3.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.
Example 9.1. Sample DNS zone database

```dns
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.

ns1.example.com.  IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5

helper.example.com. IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5

api.ocp4.example.com. IN A 192.168.1.5
api-int.ocp4.example.com. IN A 192.168.1.5

*.apps.ocp4.example.com. IN A 192.168.1.5

bootstrap.ocp4.example.com. IN A 192.168.1.96

master0.ocp4.example.com. IN A 192.168.1.97
master1.ocp4.example.com. IN A 192.168.1.98
master2.ocp4.example.com. IN A 192.168.1.99

worker0.ocp4.example.com. IN A 192.168.1.11
worker1.ocp4.example.com. IN A 192.168.1.17

;EOF
```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

2. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

3. Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 9.2. Sample DNS zone database for reverse records

```$TTL 1W
@ IN SOA ns1.example.com. root (
  2019070700 ; serial
  3H ; refresh (3 hours)
  30M ; retry (30 minutes)
  2W ; expiry (2 weeks)
  1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF```

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.
NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

9.2.3.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **NOTE**

   Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

<p>| Table 9.6. API load balancer |
|-------------------------------|------------------------|-----------------|-----------------|-----------------|</p>
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.
2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 9.2.3.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.
NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 9.3. Sample API and application ingress load balancer configuration

```
global
   log 127.0.0.1 local2
   pidfile /var/run/haproxy.pid
   maxconn 4000

daemon
defaults
   mode http
   log global
   option dontlognull
   option http-server-close
   option redispatch
   retries 3
   timeout http-request 10s
   timeout queue 1m
   timeout connect 10s
   timeout client 1m
   timeout server 1m
   timeout http-keep-alive 10s
   timeout check 10s
   maxconn 3000

frontend stats
   bind *:1936
   mode http
   log global
   maxconn 10
   stats enable
   stats hide-version
   stats refresh 30s
   stats show-node
   stats show-desc Stats for ocp4 cluster 1
   stats auth admin:ocp4
   stats uri /stats

listen api-server-6443 2
   bind *:6443
   mode tcp
   server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup 3
   server master0 master0.ocp4.example.com:6443 check inter 1s
   server master1 master1.ocp4.example.com:6443 check inter 1s
   server master2 master2.ocp4.example.com:6443 check inter 1s

listen machine-config-server-22623 4
   bind *:22623
   mode tcp
   server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 5
   server master0 master0.ocp4.example.com:22623 check inter 1s
   server master1 master1.ocp4.example.com:22623 check inter 1s
   server master2 master2.ocp4.example.com:22623 check inter 1s
```
In the example, the cluster name is ocp4.

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltupe` on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

### 9.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in
preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

**Prerequisites**

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

**Procedure**

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.
4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.
5. Setup the required DNS infrastructure for your cluster.
   - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.
6. Validate your DNS configuration.
   - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.
7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.
NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

9.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

      $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>

      Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

      Example output

      api.ocp4.example.com. 0 IN A 192.168.1.5

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

      $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>

      Example output

      api-int.ocp4.example.com. 0 IN A 192.168.1.5

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

      $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>

      Example output
NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace random with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```bash
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocep4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

   a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.

2. Provides the record name for the Kubernetes API.
NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

9.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   $ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the /openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> ①

   ① Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
3. Verify that the credentials were applied.

   $ gcloud auth list

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

## 9.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

### Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

### Procedure

1. Access the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. From the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
9.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.8. Download and install the new version of oc.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the **Command line interface** section, select **Linux** from the drop-down menu and click **Download command-line tools**.

4. Unpack the archive:

   ```
   $ tar xvzf <file>
   ```

5. Place the `oc` binary in a directory that is on your **PATH**.
   To check your **PATH**, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the CLI, it is available using the `oc` command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the **Command line interface** section, select **Windows** from the drop-down menu and click **Download command-line tools**.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```
After you install the CLI, it is available using the `oc` command:

```
C:> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the Command line interface section, select MacOS from the drop-down menu and click Download command-line tools.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH.  
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 9.2.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

NOTE

For some platform types, you can alternatively run `/openshift-install create install-config --dir=<installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

9.2.9.1. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: s390x
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: s390x
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to Disabled. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the hyperthreading parameter has no effect.

IMPORTANT

If you disable hyperthreading, whether in the BIOS or in the install-config.yaml, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to
manage the traffic.

10 The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \((2^{32} - 23) - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

11 The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

12 You must set the platform to none. You cannot provide additional platform configuration variables for IBM Z infrastructure.

13 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

14 The pull secret that you obtained from the Red Hat OpenShift Cluster Manager site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15 The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

### 9.2.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the ec2.<region>.amazonaws.com, elasticloadbalancing.<region>.amazonaws.com, and s3.<region>.amazonaws.com endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpProxy value.

2. A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then httpProxy is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpsProxy value.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless
the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

9.2.9.3. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

**Prerequisites**

- You have an existing `install-config.yaml` file.

**Procedure**

- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.
NOTE

The minimum for control plane nodes is 21 GB. For three control plane nodes this is the memory equivalent of a minimum five node cluster.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the mastersSchedulable parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to true. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

9.2.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir=<installation_directory>
   ```
Example output

INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift

1. For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-* .yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-* .yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
   name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone:
       id: mycluster-100419-private-zone
     publicZone:
       id: example.openshift.com
   status: {}
   ```

   1 2 Remove this section completely.
If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

9.2.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on z/VM guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS z/VM guest virtual machines have rebooted.

Complete the following steps to create the machines.

Prerequisites

- An HTTP or HTTPS server running on your provisioning machine that is accessible to the machines you create.

Procedure

1. Log in to Linux on your provisioning machine.

2. Obtain the Red Hat Enterprise Linux CoreOS (RHCOS) kernel, initramfs, and rootfs files from the RHCOS image mirror.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.
The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

**NOTE**

The rootfs image is the same for FCP and DASD.

3. Create parameter files. The following parameters are specific for a particular virtual machine:

- For `ip=`, specify the following seven entries:
  i. The IP address for the machine.
  ii. An empty string.
  iii. The gateway.
  iv. The netmask.
  v. The machine host and domain name in the form `hostname.domainname`. Omit this value to let RHCOS decide.
  vi. The network interface name. Omit this value to let RHCOS decide.
  vii. If you use static IP addresses, specify `none`.

- For `coreos.inst.ignition_url=`, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

- For `coreos.live.rootfs_url=`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

- For installations on DASD-type disks, complete the following tasks:
  i. For `coreos.inst.install_dev=`, specify `dasda`.
  ii. Use `rd.dasd=` to specify the DASD where RHCOS is to be installed.
  iii. Leave all other parameters unchanged.

Example parameter file, `bootstrap-0.parm`, for the bootstrap machine:

```
rd.neednet=1 console=ttysclp0 coreos.inst.install_dev=dasda
coreos.live.rootfs_url=http://
cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/bootstrap.ign
ip=172.18.78.2::172.18.78.1:255.255.255.0::none nameserver=172.18.78.1
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1.portno=0 zfcp.allow_lun_scan=0
cio忽略=all,
!condev rd.dasd=0.0.3490
```
For installations on FCP-type disks, complete the following tasks:

i. Use \texttt{rd.zfcp=\langle adapter\rangle,\langle wwpn\rangle,\langle lun\rangle} to specify the FCP disk where RHCOS is to be installed. For multipathing repeat this step for each additional path.

\textbf{NOTE}

When you install with multiple paths, you must enable multipathing directly after the installation, not at a later point in time, as this can cause problems.

ii. Set the install device as: \texttt{coreos.inst.install_dev=\texttt{sda}}.

\textbf{NOTE}

If additional LUNs are configured with NPIV, FCP requires \texttt{zfcp.allow_lun_scan=0}. If you must enable \texttt{zfcp.allow_lun_scan=1} because you use a CSI driver, for example, you must configure your NPIV so that each node cannot access the boot partition of another node.

iii. Leave all other parameters unchanged.

\textbf{IMPORTANT}

Additional post-installation steps are required to fully enable multipathing. For more information, see "Enabling multipathing with kernel arguments on RHCOS" in \textit{Post-installation machine configuration tasks}.

The following is an example parameter file \texttt{worker-1.parm} for a worker node with multipathing:

\begin{verbatim}
rd.neednet=1 console=ttysclp0 coreos.inst.install_dev=sda
coreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/worker.ign
ip=172.18.78.2::172.18.78.1:255.255.255.0:::none nameserver=172.18.78.1
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 zfcp.allow_lun_scan=0
cio_ignore=all,
!condev
rd.zfcp=0.0.1987,0x50050763070bc5e3,0x4008400B00000000
rd.zfcp=0.0.19C7,0x50050763070bc5e3,0x4008400B00000000
rd.zfcp=0.0.1987,0x50050763071bc5e3,0x4008400B00000000
rd.zfcp=0.0.19C7,0x50050763071bc5e3,0x4008400B00000000
\end{verbatim}

4. Transfer the initramfs, kernel, parameter files, and RHCOS images to z/VM, for example with FTP. For details about how to transfer the files with FTP and boot from the virtual reader, see \textit{Installing under Z/VM}.

5. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node. See \texttt{PUNCH} in IBM Documentation.
TIP

You can use the CP PUNCH command or, if you use Linux, the `vmur` command to transfer files between two z/VM guest virtual machines.

7. IPL the bootstrap machine from the reader:

   ```
   $ ipl c
   ```

   See IPL in IBM Documentation.

8. Repeat this procedure for the other machines in the cluster.

9.2.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```
   $ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \  
   --log-level=info
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.21.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
```
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 9.2.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   `system:admin`

### 9.2.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.
Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>NotReady</td>
<td>worker</td>
<td>76s</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>NotReady</td>
<td>worker</td>
<td>70s</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
OpenShift Container Platform 4.8 Installing

NOTE
For clusters running on platforms that are not machine API enabled, such as bare
metal and other user-provisioned infrastructure, you must implement a method
of automatically approving the kubelet serving certificate requests (CSRs). If a
request is not approved, then the oc exec, oc rsh, and oc logs commands
cannot succeed, because a serving certificate is required when the API server
connects to the kubelet. Any operation that contacts the Kubelet endpoint
requires this certificate approval to be in place. The method must watch for new
CSRs, confirm that the CSR was submitted by the node-bootstrapper service
account in the system:node or system:admin groups, and confirm the identity
of the node.
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

NOTE
Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

1374

<csr_name> is the name of a CSR from the list of current CSRs.


To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  73m  v1.21.0
master-1  Ready     master  73m  v1.21.0
master-2  Ready     master  74m  v1.21.0
worker-0  Ready     worker  11m  v1.21.0
worker-1  Ready     worker  11m  v1.21.0
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 9.2.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

```
NAME                                       VERSION AVAILABLE PROGRESSING DEGRADED SINCE
authentication                             4.8.0   True     False    False    3h56m
baremetal                                  4.8.0   True     False    False    29h
cloud-credential                           4.8.0   True     False    False    29h
cluster-autoscaler                         4.8.0   True     False    False    29h
config-operator                            4.8.0   True     False    False    6h39m
```
2. Configure the Operators that are not available.

9.2.15.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

9.2.15.1.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Z.
- You have provisioned persistent storage for your cluster.
IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the spec.storage.pvc in the configs.imageregistry/cluster resource.

   NOTE

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   $ oc get pod -n openshift-image-registry

   NOTE

   If the storage type is emptyDIR, the replica number cannot be greater than 1.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   Example output

   storage:
   pvc:
   claim:

   Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:

     $ oc edit configs.imageregistry/cluster

     Then, change the line

     managementState: Removed
managementState: Managed

9.2.15.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  ```$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":{"storage":{"emptyDir":{}}}}'```

  **WARNING**
  Configure this option for only non-production clusters.

  If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  ```Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found```  

  Wait a few minutes and run the command again.

9.2.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```$ watch -n5 oc get clusteroperators```

   **Example output**

   ```
   NAME               VERSION AVAILABLE PROGRESSING DEGRADED
   ```
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kublet certificates. See the documentation for Recovering from expired control plane certificates for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

   ```
   NAMESPACE                  NAME                                            READY   STATUS 
   RESTARTS   AGE            
   openshift-apiserver-operator openshift-apiserver-operator-85cb746d55-zqhs8 1/1
   Running     1          9m
   openshift-apiserver apiserver-67b9g 1/1 Running      0
   3m
   openshift-apiserver apiserver-ljcmx 1/1 Running      0
   1m
   openshift-apiserver apiserver-z25h4 1/1 Running      0
   2m
   openshift-authentication-operator authentication-operator-69d5d8bf84-vh2n8 1/1
   Running     0          5m
   ...
   ```

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```bash
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   **NOTE**

   When installing with multipath, it is strongly recommended to enable it at installation time, and not at a later time, which can cause problems.
See “Enabling multipathing with kernel arguments on RH COS” in the Installing on bare metal documentation for more information.

a. All the worker nodes are restarted. To monitor the process, enter the following command:

```
$ oc get nodes -w
```

**NOTE**

If you have additional machine types such as infrastructure nodes, repeat the process for these types.

### 9.2.17. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

**Prerequisites**

- The oc CLI tool installed.

**Procedure**

1. Log in to the cluster:

```
$ oc login -u <username>
```

2. On the node you want to gather hardware information about, start a debugging container:

```
$ oc debug node/<nodename>
```

3. Change to the /host file system and start toolbox:

```
$ chroot /host
$ toolbox
```

4. Collect the dbginfo data:

```
$ dbginfo.sh
```

5. You can then retrieve the data, for example, using scp.

**Additional resources**

- How to generate SOSREPORT within OpenShift4 nodes without SSH.

### 9.2.18. Next steps

- Enabling multipathing with kernel arguments on RH COS.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
9.3. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND LINUXONE IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.8, you can install a cluster on IBM Z and LinuxONE infrastructure that you provision in a restricted network.

NOTE

While this document refers to only IBM Z, all information in it also applies to LinuxONE.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

9.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You created a mirror registry for installation in a restricted network and obtained the imageContentSources data for your version of OpenShift Container Platform.
- Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

IMPORTANT

Ensure that installation steps are done from a machine with access to the installation media.

- You provisioned persistent storage using NFS for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

9.3.2. About installations in restricted networks

In OpenShift Container Platform 4.8, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.
If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

9.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

9.3.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

9.3.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

Table 9.8. Default monitoring stack components

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>
IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

9.3.3.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

1. 1 physical core (IFL) provides 2 logical cores (threads) when SMT-2 is enabled. The hypervisor can provide 2 or more vCPUs.

9.3.3.3. Minimum IBM Z system requirements

You can install OpenShift Container Platform version 4.8 on the following IBM hardware:

- IBM Z, versions 13, 14, or 15
- LinuxONE, any version

Hardware requirements

- 1 LPAR with 6 IFLs that supports SMT2
- 1 OSA or RoCE network adapter

Operating system requirements

- One instance of z/VM 7.1 or later

On your z/VM instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

IBM Z network connectivity requirements

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:
• A direct-attached OSA or RoCE network adapter

• A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

**Disk storage for the z/VM guest virtual machines**

• FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV to ensure optimal performance.

• FCP attached disk storage

**Storage / Main Memory**

• 16 GB for OpenShift Container Platform control plane machines

• 8 GB for OpenShift Container Platform compute machines

• 16 GB for the temporary OpenShift Container Platform bootstrap machine

**9.3.3.4. Preferred IBM Z system requirements**

**Hardware requirements**

• 3 LPARs with 6 IFLs each that support SMT2

• 1 or 2 OSA or RoCE network adapters, or both

• Hipersockets, which are attached to a node either directly as a device or by bridging with one z/VM VSWITCH to be transparent to the z/VM guest. To directly connect Hipersockets to a node, you must set up a gateway to the external network via a RHEL 8 guest to bridge to the Hipersockets network.

**Operating system requirements**

• 2 or 3 instances of z/VM 7.1 or later for high availability

On your z/VM instances, set up:

• 3 guest virtual machines for OpenShift Container Platform control plane machines, one per z/VM instance

• At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the z/VM instances

• 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

• To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane using the CP command `SET SHARE`. Do the same for infrastructure plane machines if they exist. See `SET SHARE` in IBM Documentation.

**IBM Z network connectivity requirements**

To install on IBM Z under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

• A direct-attached OSA or RoCE network adapter
A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines
- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV and High Performance FICON (zHPF) to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory
- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

9.3.3.5. Managing certificate signing requests
Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources
- See Bridging a HiperSockets LAN with a z/VM Virtual Switch in the IBM Knowledge Center.
- See Scaling HyperPAV alias devices on Linux guests on z/VM for performance optimization.

9.3.3.6. Networking requirements for user-provisioned infrastructure
All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

9.3.3.6.1. Setting the cluster node hostnames through DHCP
On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as `localhost` or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

9.3.3.6.2. Network connectivity requirements

OpenShift Container Platform 4.8 Installing
You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

### Table 9.9. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>N/A</td>

**Additional resources**

- Configuring chrony time service

**9.3.3.7. User-provisioned DNS requirements**
In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 9.12. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

**9.3.3.7.1. Example DNS configuration for user-provisioned clusters**

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.
Example 9.4. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
; ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
; helper.example.com. IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5

master1.ocp4.example.com. IN A 192.168.1.98 6
master2.ocp4.example.com. IN A 192.168.1.99 7
; worker0.ocp4.example.com. IN A 192.168.1.11 8
worker1.ocp4.example.com. IN A 192.168.1.17 9
; ;EOF
```

1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

2 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

3 Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 9.5. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (  
   2019070700 ; serial  
   3H ; refresh (3 hours)  
   30M ; retry (30 minutes)  
   2W ; expiry (2 weeks)  
   1W ) ; minimum (1 week)  
IN NS ns1.example.com.  
;  
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1  
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2  
;  
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3  
;  
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4  
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5  
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6  
;  
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7  
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8  
;  
; EOF
```

1. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3. Provides reverse DNS resolution for the bootstrap machine.

4. Provides reverse DNS resolution for the control plane machines.

5. Provides reverse DNS resolution for the control plane machines.

6. Provides reverse DNS resolution for the compute machines.

7. Provides reverse DNS resolution for the compute machines.
A PTR record is not required for the OpenShift Container Platform application wildcard.

### 9.3.3.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **NOTE**
   
   Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

   **NOTE**
   
   The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.
2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 9.3.3.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAPProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.
NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 9.6. Sample API and application ingress load balancer configuration

```
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode http
log global
option dontlognull
option http-server-close
option redispatch
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
timeout server 1m
timeout http-keep-alive 10s
timeout check 10s
maxconn 3000
frontend stats
bind *:1936
mode http
log global
maxconn 10
stats enable
stats hide-version
stats refresh 30s
stats show-node
stats show-desc Stats for ocp4 cluster
stats auth admin:ocp4
stats uri /stats
listen api-server-6443
bind *:6443
mode tcp
server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
server master0 master0.ocp4.example.com:6443 check inter 1s
server master1 master1.ocp4.example.com:6443 check inter 1s
server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
server master0 master0.ocp4.example.com:22623 check inter 1s
server master1 master1.ocp4.example.com:22623 check inter 1s
server master2 master2.ocp4.example.com:22623 check inter 1s
```
In the example, the cluster name is `ocp4`.

Port `6443` handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port `22623` handles the machine config server traffic and points to the control plane machines.

Port `443` handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port `80` handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports `6443, 22623, 443, and 80` by running `netstat -nltupe` on the HAProxy node.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

9.3.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in...
preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**

   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**

   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

4. Setup the required DNS infrastructure for your cluster.
a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.

b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.

   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.

   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

   See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   NOTE

   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

9.3.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.
Example output

```bash
api.ocep4.example.com. 0 IN A 192.168.1.5
```

b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```bash
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```bash
api-int.ocep4.example.com. 0 IN A 192.168.1.5
```

c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```bash
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```bash
random.apps.ocep4.example.com. 0 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```bash
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```bash
console-openshift-console.apps.ocep4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```bash
bootstrap.ocep4.example.com. 0 IN A 192.168.1.96
```
e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.
2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

9.3.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.
If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>  # 1
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>  
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

2. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

```bash
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

3. Verify that the credentials were applied.

```bash
$ gcloud auth list
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 9.3.7. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```bash
$ mkdir <installation_directory>
```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample install-config.yaml file template that is provided and save it in the <installation_directory>.

NOTE

You must name this configuration file install-config.yaml.

NOTE

For some platform types, you can alternatively run ./openshift-install create install-config --dir=<installation_directory> to generate an install-config.yaml file. You can provide details about your cluster configuration at the prompts.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the next step of the installation process. You must back it up now.

9.3.7.1. Sample install-config.yaml file for IBM Z

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
architecture: s390x
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
architecture: s390x
metadata:
  name: test
networking:
clusterNetwork:
  - cidr: 10.128.0.0/14
hostPrefix: 23
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to `Disabled`. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the `hyperthreading` parameter has no effect.

**IMPORTANT**

If you disable `hyperthreading`, whether in the BIOS or in the `install-config.yaml`, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to `0` when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.
NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

7. The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8. The cluster name that you specified in your DNS records.

9. A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

10. The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \(2^{(32 - 23)} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

11. The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

12. You must set the platform to none. You cannot provide additional platform configuration variables for IBM Z infrastructure.

13. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

14. For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

15. The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

16. Add the `additionalTrustBundle` parameter and value. The value must be the contents of the certificate file that you used for your mirror registry, which can be an exiting, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.
9.3.7.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  
  noProxy: example.com
additionalTrustBundle: |  
  -----BEGIN CERTIFICATE-----  
  <MY_TRUSTED_CA_CERT>  
  -----END CERTIFICATE-----  
  ...
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpProxy value.

2. A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then httpProxy is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpsProxy value.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

**NOTE**

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**

Only the Proxy object named cluster is supported, and no additional proxies can be created.

9.3.7.3. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

**Prerequisites**

- You have an existing install-config.yaml file.

**Procedure**
- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

**NOTE**

The minimum for control plane nodes is 21 GB. For three control plane nodes this is the memory equivalent of a minimum five node cluster.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the `Load balancing requirements for user-provisioned infrastructure` section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to `true`. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

### 9.3.8. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the install-config.yaml installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   $ ./openshift-install create manifests --dir=<installation_directory>

   Example output

   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift

   For <installation_directory>, specify the installation directory that contains the install-config.yaml file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the mastersSchedulable parameter in the <installation_directory>/manifests/cluster-scheduler-02-config.yml Kubernetes manifest file is set to false. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the <installation_directory>/manifests/cluster-scheduler-02-config.yml file.
b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
     name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
       id: mycluster-100419-private-zone
     publicZone: 2
       id: example.openshift.com
   status: {}
   ``

Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```shell
   $ ./openshift-install create ignition-configs --dir=<installation_directory>
   ``

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   ├── kubeadmin-password
   │   │   └── bootstrap.ign
   │   └── kubeconfig
   │       └── master.ign
   │           └── metadata.json
   └── worker.ign
   ```

9.3.9. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on z/VM guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform
installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS z/VM guest virtual machines have rebooted.

Complete the following steps to create the machines.

Prerequisites

- An HTTP or HTTPS server running on your provisioning machine that is accessible to the machines you create.

Procedure

1. Log in to Linux on your provisioning machine.

2. Obtain the Red Hat Enterprise Linux CoreOS (RHCOS) kernel, initramfs, and rootfs files from the RHCOS image mirror.

   **IMPORTANT**
   
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - **kernel**: `rhcos-<version>-live-kernel-<architecture>`
   - **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
   - **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

   **NOTE**
   
   The rootfs image is the same for FCP and DASD.

3. Create parameter files. The following parameters are specific for a particular virtual machine:

   - For `ip=`, specify the following seven entries:
     
     i. The IP address for the machine.

     ii. An empty string.

     iii. The gateway.

     iv. The netmask.

     v. The machine host and domain name in the form `hostname.domainname`. Omit this value to let RHCOS decide.

     vi. The network interface name. Omit this value to let RHCOS decide.
vii. If you use static IP addresses, specify none.

- For `coreos.inst.ignition_url`, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

- For `coreos.live.rootfs_url`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

- For installations on DASD-type disks, complete the following tasks:
  i. For `coreos.inst.install_dev`, specify `dasda`.
  ii. Use `rd.dasd` to specify the DASD where RHCOS is to be installed.
  iii. Leave all other parameters unchanged.

   Example parameter file, `bootstrap-0.parm`, for the bootstrap machine:

   ```
   rd.neednet=1 console=ttyScl0
   coreos.inst.install_dev=dasda
   coreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img
   coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/bootstrap.ign
   ip=172.18.78.2::172.18.78.1:255.255.255.0:::none
   nameserver=172.18.78.1
   rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0
   zfcp.allow_lun_scan=0
   cio.ignore=all,
   !condev rd.dasd=0.0.3490
   ```

- For installations on FCP-type disks, complete the following tasks:
  i. Use `rd.zfcp=<adapter>,<wwpn>,<lun>` to specify the FCP disk where RHCOS is to be installed. For multipathing repeat this step for each additional path.

   **NOTE**
   
   When you install with multiple paths, you must enable multipathing directly after the installation, not at a later point in time, as this can cause problems.

  ii. Set the install device as: `coreos.inst.install_dev=sd`.

   **NOTE**
   
   If additional LUNs are configured with NPIV, FCP requires `zfcp.allow_lun_scan=0`. If you must enable `zfcp.allow_lun_scan=1` because you use a CSI driver, for example, you must configure your NPIV so that each node cannot access the boot partition of another node.

  iii. Leave all other parameters unchanged.

   **IMPORTANT**
   
   Additional post-installation steps are required to fully enable multipathing. For more information, see "Enabling multipathing with kernel arguments on RHCOS" in Post-installation machine configuration tasks.
The following is an example parameter file `worker-1.parm` for a worker node with multipathing:

```
rd.neednet=1 console=ttyscp0 coreos.install_dev=sda
coreos.live.roots_url=http://cl1.provide.example.com:8080/assets/rhcos-live-roots.s390x.img
coreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/worker.ign
ip=172.18.78.2::172.18.78.1:255.255.255.0::none nameserver=172.18.78.1
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 zfcp.allow_lun_scan=0
cio.ignore=all,
condev
rd.zfcp=0.0.1987,0x50050763070bc5e3,0x4008400B00000000
rd.zfcp=0.0.19C7,0x50050763070bc5e3,0x4008400B00000000
rd.zfcp=0.0.1987,0x50050763071bc5e3,0x4008400B00000000
rd.zfcp=0.0.19C7,0x50050763071bc5e3,0x4008400B00000000
```

4. Transfer the initramfs, kernel, parameter files, and RHCOS images to z/VM, for example with FTP. For details about how to transfer the files with FTP and boot from the virtual reader, see `Installing under Z/VM`.

5. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node.
   See `PUNCH` in IBM Documentation.

   **TIP**

   You can use the CP PUNCH command or, if you use Linux, the `vmur` command to transfer files between two z/VM guest virtual machines.

7. IPL the bootstrap machine from the reader:

   ```
   $ ipl c
   ```

   See `IPL` in IBM Documentation.

8. Repeat this procedure for the other machines in the cluster.

### 9.3.10. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

1. Monitor the bootstrap process:

   ```
   $ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ 
   --log-level=info
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.21.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 9.3.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   
   Example output
   
   system:admin
   ```

9.3.12. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   
   Example output
   
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.21.0
   master-1  Ready     master  63m  v1.21.0
   master-2  Ready     master  64m  v1.21.0
   worker-0  NotReady  worker  76s  v1.21.0
   worker-1  NotReady  worker  70s  v1.21.0
   
   The output lists all of the machines that you created.
   
   **NOTE**
   
   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   
   Example output
   
   NAME  AGE  REQUESTOR  CONDITION
   ```
In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

   **NOTE**

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

   - To approve them individually, run the following command for each valid CSR:

     ```
     $ oc adm certificate approve <csr_name>
     ```

     `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     ```
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
     ```

     **NOTE**

     Some Operators might not become available until some CSRs are approved.
OpenShift Container Platform 4.8 Installing

4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
6. After all client and server CSRs have been approved, the machines have the Ready status.
Verify this by running the following command:
$ oc get nodes

Example output
NAME
master-0
master-1
master-2
worker-0
worker-1

STATUS ROLES AGE VERSION
Ready master 73m v1.21.0
Ready master 73m v1.21.0
Ready master 74m v1.21.0
Ready worker 11m v1.21.0
Ready worker 11m v1.21.0

NOTE
It can take a few minutes after approval of the server CSRs for the machines to
transition to the Ready status.
Additional information
For more information on CSRs, see Certificate Signing Requests .

1416


9.3.13. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   $ watch -n5 oc get clusteroperators

Example output

<table>

2. Configure the Operators that are not available.

9.3.13.1. Disabling the default OperatorHub sources
Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

  TIP

  Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

9.3.13.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

9.3.13.2.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have a cluster on IBM Z.
- You have provisioned persistent storage for your cluster.

  IMPORTANT

  OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.

  - Must have 100Gi capacity.

Procedure
1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry
   ```

   **NOTE**
   
   If the storage type is `emptyDIR`, the replica number cannot be greater than 1.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

   **Example output**

   ```
   storage:
   pvc:
   claim:
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   ```

5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:

     ```
     $ oc edit configs.imageregistry/cluster
     ```

     Then, change the line

     ```
     managementState: Removed
     ```

     to

     ```
     managementState: Managed
     ```

9.3.13.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

   **Procedure**
Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
{"storage":{"emptyDir":{}}}')
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 9.3.14. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>

1420
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```
**Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 3m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 1m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 2m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 0 5m</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

**NOTE**

When installing with multipath, it is strongly recommended to enable it at installation time, and not at a later time, which can cause problems.

See "Enabling multipathing with kernel arguments on RHCOS" in the *Installing on bare metal* documentation for more information.

a. All the worker nodes are restarted. To monitor the process, enter the following command:

```
$ oc get nodes -w
```

**NOTE**

If you have additional machine types such as infrastructure nodes, repeat the process for these types.

4. Register your cluster on the [Cluster registration](#) page.

### 9.3.15. Collecting debugging information
You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

**Prerequisites**

- The `oc` CLI tool installed.

**Procedure**

1. Log in to the cluster:
   
   ```bash
   $ oc login -u <username>
   ```

2. On the node you want to gather hardware information about, start a debugging container:
   
   ```bash
   $ oc debug node/<nodename>
   ```

3. Change to the `/host` file system and start `toolbox`:
   
   ```bash
   $ chroot /host
   $ toolbox
   ```

4. Collect the `dbginfo` data:
   
   ```bash
   $ dbginfo.sh
   ```

5. You can then retrieve the data, for example, using `scp`.

**Additional resources**

- [How to generate SOSREPORT within OpenShift Container Platform version 4 nodes without SSH](#)

**Next steps**

- Customize your cluster.

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
CHAPTER 10. INSTALLING WITH RHEL KVM ON IBM Z AND LINUXONE

10.1. PREPARING TO INSTALL WITH RHEL KVM ON IBM Z AND LINUXONE

10.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

10.1.2. Choosing a method to install OpenShift Container Platform with RHEL KVM on IBM Z or LinuxONE

You can install a cluster with RHEL KVM on IBM Z or LinuxONE infrastructure that you provision, by using one of the following methods:

- **Installing a cluster with RHEL KVM on IBM Z and LinuxONE** You can install OpenShift Container Platform with KVM on IBM Z or LinuxONE infrastructure that you provision.

- **Installing a cluster with RHEL KVM on IBM Z and LinuxONE in a restricted network** You can install OpenShift Container Platform with RHEL KVM on IBM Z or LinuxONE infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

10.2. INSTALLING A CLUSTER WITH RHEL KVM ON IBM Z AND LINUXONE

In OpenShift Container Platform version 4.8, you can install a cluster on IBM Z or LinuxONE infrastructure that you provision.

NOTE

While this document refers only to IBM Z, all information in it also applies to LinuxONE.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

10.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
You read the documentation on selecting a cluster installation method and preparing it for users.

Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.

You provisioned persistent storage using NFS for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

If you use a firewall, you configured it to allow the sites that your cluster requires access to.

You provisioned a RHEL Kernel Virtual Machine (KVM) system that is hosted on the logical partition (LPAR) and based on RHEL 8.3 or higher.

NOTE

Be sure to also review this site list if you are configuring a proxy.

10.2.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

10.2.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

One or more KVM host machines based on RHEL 8.3 or later. Each RHEL KVM host machine must have libvirt installed and running. The virtual machines are provisioned under each RHEL KVM host machine.
10.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following nodes:

**Table 10.1. Default monitoring stack components**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different RHEL instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

See Red Hat Enterprise Linux technology capabilities and limits .

10.2.3.2. Network connectivity requirements

The OpenShift Container Platform installer creates the Ignition files, which are necessary for all the Red Hat Enterprise Linux CoreOS (RHCOS) virtual machines. The automated installation of OpenShift Container Platform is performed by the bootstrap machine. It starts the installation of OpenShift Container Platform on each node, starts the Kubernetes cluster, and then finishes. During this bootstrap, the virtual machine must have an established network connection either through a Dynamic Host Configuration Protocol (DHCP) server or static IP address.

10.2.3.3. IBM Z network connectivity requirements

To install on IBM Z under RHEL KVM, you need:

- A RHEL KVM host configured with an OSA or RoCE network adapter.
- Either a RHEL KVM host that is configured to use bridged networking in libvirt or MacVTap to connect the network to the guests.

See Types of virtual network connections .

10.2.3.4. Host machine resource requirements
The RHEL KVM host in your environment must meet the following requirements to host the virtual machines that you plan for the OpenShift Container Platform environment. See Getting started with virtualization.

You can install OpenShift Container Platform version 4.8 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s
- LinuxONE, any version

### 10.2.3.5. Minimum IBM Z system environment

#### Hardware requirements

- 1 LPAR with 6 IFLs that supports SMT2
- 1 OSA or RoCE network adapter

#### Operating system requirements

- One LPAR running RHEL 8.3 or later with KVM, which is managed via libvirt

On your RHEL KVM host, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

### 10.2.3.6. Minimum resource requirements

Each cluster virtual machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

[1] 1 physical core (IFL) provides 2 logical cores (threads) when SMT-2 is enabled. The hypervisor can provide 2 or more vCPUs.

### 10.2.3.7. Preferred IBM Z system environment

#### Hardware requirements

- 3 LPARs with 6 IFLs each that support SMT2
- 1 or 2 OSA or RoCE network adapters, or both

#### Operating system requirements
• For high availability, 2 or 3 LPARs running RHEL 8.3 or later with KVM, which are managed via libvirt.

On your RHEL KVM host, set up:

• 3 guest virtual machines for OpenShift Container Platform control plane machines, distributed across the RHEL KVM host machines
• At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the RHEL KVM host machines
• 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

10.2.3.8. Preferred resource requirements

The preferred requirements for each cluster virtual machine are:

<table>
<thead>
<tr>
<th>Virtual Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>8</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>6</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

10.2.3.9. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

10.2.3.10. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

10.2.3.10.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as `localhost` or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

10.2.3.10.2. Network connectivity requirements
You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have Internet access to pull images for platform containers and provide telemetry data to Red Hat.

**NOTE**

The RHEL KVM host must be configured to use bridged networking in libvirt or MacVTap to connect the network to the virtual machines. The virtual machines must have access to the network, which is attached to the RHEL KVM host. Virtual Networks, for example network address translation (NAT), within KVM are not a supported configuration.

Table 10.2. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>

Additional resources

- Configuring chrony time service

10.2.3.11. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.`

Table 10.5. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Component</td>
<td>Record</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
<td></td>
</tr>
<tr>
<td>IMPORTANT</td>
<td>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</td>
<td></td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.
TIP

You can use the `dig` command to verify name and reverse name resolution. See the section on `Validating DNS resolution for user-provisioned infrastructure` for detailed validation steps.

10.2.3.11.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```
$TTL 1W

```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE
In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster
The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 10.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```
Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

10.2.3.12. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. API load balancer: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

NOTE

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 10.6. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 10.7. Application ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

10.2.3.12.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 10.3. Sample API and application ingress load balancer configuration

```
global
  log    127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
daemon
defaults
  mode http
  log global
  option dontlognull
  option http-server-close
  option redispatch
  retries 3
  timeout http-request 10s
  timeout queue 1m
  timeout connect 10s
  timeout client 1m
  timeout server 1m
  timeout http-keep-alive 10s
  timeout check 10s
  maxconn 3000
frontend stats
  bind *:1936
  mode http
  log global
  maxconn 10
  stats enable
```
In the example, the cluster name is ocp4.

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.
If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltupe` on the HAProxy node.

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

10.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines section for more information about static IP provisioning and advanced networking options.
c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Choose to perform either a fast track installation of Red Hat Enterprise Linux CoreOS (RHCOS) or a full installation of Red Hat Enterprise Linux CoreOS (RHCOS). For the full installation you must set up an HTTP or HTTPS server to provide Ignition files and install images to the cluster nodes. For the fast track installation an HTTP or HTTPS server is not required, however, a DHCP server is required. See sections "Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines" and "Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines".

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.
10.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```bash
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>  
   Example output
   api.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```bash
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>  
   Example output
   api-int.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   c. Test an example *.apps.<cluster_name>.<base_domain> DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```bash
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>  
   Example output
   random.apps.ocp4.example.com. 0 IN A 192.168.1.5
   ```
NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace random with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.

2. Provides the record name for the Kubernetes API.
NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96

Example output

96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

10.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

$ ssh-keygen -t ed25519 -N " -f <path>/<file_name>

Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   `$ cat <path>/<file_name>.pub`

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   `$ cat ~/.ssh/id_rsa.pub`

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   `$ eval "$(ssh-agent -s)"`

   Example output

   Agent pid 31874

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the ssh-agent:

   `$ ssh-add <path>/<file_name> ①`

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

   `$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"`
3. Verify that the credentials were applied.

```
$ gcloud auth list
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

10.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. From the Pull Secret page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
10.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.8. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the Command line interface section, select Linux from the drop-down menu and click Download command-line tools.
4. Unpack the archive:
   
   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.
   
   To check your PATH, execute the following command:

   $ echo $PATH

   After you install the CLI, it is available using the oc command:

   $ oc <command>

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the Command line interface section, select Windows from the drop-down menu and click Download command-line tools.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   
   To check your PATH, open the command prompt and execute the following command:

   C:\> path
After you install the CLI, it is available using the oc command:

C:> oc <command>

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the Command line interface section, select MacOS from the drop-down menu and click Download command-line tools.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

After you install the CLI, it is available using the oc command:

$ oc <command>

10.2.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

10.2.9.1. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
- hyperthreading: Enabled
  name: worker
  replicas: 0
  architecture: s390x
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: s390x
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
```
networkType: OpenShiftSDN
serviceNetwork: 172.30.0.0/16
platform:
  none: {}
fips: false
pullSecret: '{"auths": ...} 
sshKey: 'ssh-ed25519 AAAA...'

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to Disabled. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

   NOTE

   Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the hyperthreading parameter has no effect.

   IMPORTANT

   If you disable hyperthreading, whether in the BIOS or in the install-config.yaml, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4. You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

   NOTE

   If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

5. The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

6. The cluster name that you specified in your DNS records.

7. A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to
manage the traffic.

10. The subnet prefix length to assign to each individual node. For example, if the `hostPrefix` is set to `23`, then each node is assigned a `/23` subnet out of the given `cidr`, which allows for $510 (2^{32 - 23} - 2)$ pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

11. The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

12. You must set the platform to `none`. You cannot provide additional platform configuration variables for IBM Z infrastructure.

13. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

   **IMPORTANT**

   The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

14. The pull secret that you obtained from the Red Hat OpenShift Cluster Manager site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15. The SSH public key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

### 10.2.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the ec2.<region>.amazonaws.com, elasticloadbalancing.<region>.amazonaws.com, and s3.<region>.amazonaws.com endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----

1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpProxy value.

2 A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then httpProxy is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpsProxy value.

3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4 If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless
the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

10.2.9.3. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites
- You have an existing install-config.yaml file.

Procedure
- Ensure that the number of compute replicas is set to 0 in your install-config.yaml file, as shown in the following compute stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

NOTE
You must set the value of the replicas parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.
NOTE

The minimum for control plane nodes is 21 GB. For three control plane nodes this is the memory equivalent of a minimum five node cluster.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the mastersSchedulable parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to true. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

10.2.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program.

- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir=<installation_directory>
   ```
Example output

INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift

1. For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
   name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
       id: mycluster-100419-private-zone
     publicZone: 2
       id: example.openshift.com
   status: {}
   ```

   1 2 Remove this section completely.
If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir=<installation_directory>  
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```plaintext
   ├── auth
   │   └── kubeadmin-password
   │       └── kubeconfig
   │           └── bootstrap.ign
   │               └── master.ign
   │                   └── metadata.json
   └── worker.ign
   ```

10.2.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) as Red Hat Enterprise Linux (RHEL) guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

You can perform a fast-track installation of RHCOS that uses a prepackaged QEMU copy-on-write (QCOW2) disk image. Alternatively, you can perform a full installation on a new QCOW2 disk image.

10.2.11.1. Fast-track installation by using a prepackaged QCOW2 disk image

Complete the following steps to create the machines in a fast-track installation of Red Hat Enterprise Linux CoreOS (RHCOS), importing a prepackaged Red Hat Enterprise Linux CoreOS (RHCOS) QEMU copy-on-write (QCOW2) disk image.

**Prerequisites**

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- A DHCP server that provides IP addresses.

**Procedure**
1. Obtain the RHEL QEMU copy-on-write (QCOW2) disk image file from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

2. Download the QCOW2 disk image and Ignition files to a common directory on the RHEL KVM host.
   For example: `/var/lib/libvirt/images`

**NOTE**

The Ignition files are generated by the OpenShift Container Platform installer.

3. Create a new disk image with the QCOW2 disk image backing file for each KVM guest node.

   ```
   $ qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/{source_rhcos_qemu}/var/lib/libvirt/images/{vmname}.qcow2 {size}
   ```

4. Create the new KVM guest nodes using the Ignition file and the new disk image.

   ```
   $ virt-install --noautoconsole \
   --connect qemu:///system \
   --name {vn_name} \
   --memory {memory} \
   --vcpus {vcpus} \
   --disk {disk} \
   --import \
   --network network={network},mac={mac} \
   --qemu-commandline="-drive \
   if=none,id=ignition,format=raw,file={ign_file},readonly=on -device virtio-\n   blk,serial=ignition,drive=ignition"
   ```

### 10.2.11.2. Full installation on a new QCOW2 disk image

Complete the following steps to create the machines in a full installation on a new QEMU copy-on-write (QCOW2) disk image.

**Prerequisites**

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- An HTTP or HTTPS server is set up.

**Procedure**
1. Obtain the RHEL kernel, initramfs, and rootfs files from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>.img`
- **initramfs**: `rhcos-<version>-live-initramfs-<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs-<architecture>.img`

2. Move the downloaded RHEL live kernel, initramfs, and rootfs as well as the Ignition files to an HTTP or HTTPS server before you launch `virt-install`.

**NOTE**

The Ignition files are generated by the OpenShift Container Platform installer.

3. Create the new KVM guest nodes using the RHEL kernel, initramfs, and Ignition files, the new disk image, and adjusted parm line arguments.

- For `--location`, specify the location of the kernel/initrd on the HTTP or HTTPS server.
- For `coreos.inst.ignition_url=`, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.
- For `coreos.live.rootfs_url=`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

```
$ virt-install --connect qemu:///system --name {vn_name} --vcpus {vcpus} --memory {memory_mb} --disk {vn_name}.qcow2,size={image_size| default(10,true)} --network network={virt_network_parm} --boot hd --location {media_location},kernel={rhcos_kernel},initrd={rhcos_initrd} --extra-args "rd.neednet=1 coreos.inst=yes coreos.inst.install_dev=vda coreos.live.rootfs_url={rhcos_liveos} ip={ip}::{default_gateway}:{subnet_mask_length}: {vn_name}:enc1:none:{MTU} nameserver={dns} coreos.inst.ignition_url={rhcos_ign}" --noautoconsole --wait
```

**10.2.12. Waiting for the bootstrap process to complete**
The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.

- You have configured suitable network, DNS and load balancing infrastructure.

- You have obtained the installation program and generated the Ignition config files for your cluster.

- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```
   $ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ 1
   --log-level=info 2
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   Example output

   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.21.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point.
   You can also remove or reformat the bootstrap machine itself.

10.2.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container
Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   system:admin
   ``

10.2.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ``

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.21.0
   master-1  Ready     master  63m  v1.21.0
   master-2  Ready     master  64m  v1.21.0
   worker-0  NotReady  worker  76s  v1.21.0
   worker-1  NotReady  worker  70s  v1.21.0
   ``

   The output lists all of the machines that you created.
NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

   $ oc get csr

   Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

   NOTE

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

   NOTE

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

   • To approve them individually, run the following command for each valid CSR:

     $ oc adm certificate approve <csr_name> ①

     ① <csr_name> is the name of a CSR from the list of current CSRs.

   • To approve all pending CSRs, run the following command:
Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

   $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     $ oc adm certificate approve <csr_name>

     <csr_name> is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

   $ oc get nodes

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>
NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

10.2.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>

10.2.15.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

10.2.15.1.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

**NOTE**

When using shared storage, review your security settings to prevent outside access.
2. Verify that you do not have a registry pod:

```bash
$ oc get pod -n openshift-image-registry
```

**NOTE**

If the storage type is `emptyDir`, the replica number cannot be greater than 1.

3. Check the registry configuration:

```bash
$ oc edit configs.imageregistry.operator.openshift.io
```

**Example output**

```yaml
storage:
  pvc:
    claim:

Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

```bash
$ oc get clusteroperator image-registry
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

  ```bash
  $ oc edit configs.imageregistry/cluster
  ```

  Then, change the line

  ```yaml
  managementState: Removed
  ```

  to

  ```yaml
  managementState: Managed
  ```

10.2.15.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {
  "storage": {"emptyDir":{}}}}'
  ```
If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

10.2.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>

</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover `kubelet` certificates. See the documentation for `Recovering from expired control plane certificates` for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

   ```
   NAME                                            READY   STATUS      RESTARTS   AGE
   openshift-apiserver-operator-85cb746d55-zqhs8   1/1      Running     0          6h34m
   ```
b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```bash
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

**NOTE**

When installing with multipath, it is strongly recommended to enable it at installation time, and not at a later time, which can cause problems.

See “Enabling multipathing with kernel arguments on RHCOS” in the *Installing on bare metal* documentation for more information.

### 10.2.17. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

**Prerequisites**

- The `oc` CLI tool installed.

**Procedure**

1. Log in to the cluster:

   ```bash
   $ oc login -u <username>
   ```

2. On the node you want to gather hardware information about, start a debugging container:

   ```bash
   $ oc debug node/<nodename>
   ```
3. Change to the `/host` file system and start `toolbox`:
   
   ```
   $ chroot /host
   $ toolbox
   ```

4. Collect the `dbginfo` data:
   
   ```
   $ dbginfo.sh
   ```

5. You can then retrieve the data, for example, using `scp`.

**Additional resources**

- How to generate SOSREPORT within OpenShift4 nodes without SSH.

### 10.2.18. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

### 10.3. INSTALLING A CLUSTER WITH RHEL KVM ON IBM Z AND LINUXONE IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.8, you can install a cluster on IBM Z and LinuxONE infrastructure that you provision in a restricted network.

**NOTE**

While this document refers to only IBM Z, all information in it also applies to LinuxONE.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

### 10.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You created a registry on your mirror host and obtained the `imageContentSources` data for your version of OpenShift Container Platform.
- You must move or remove any existing installation files, before you begin the installation process. This ensures that the required installation files are created and updated during the installation process.
Ensure that installation steps are done from a machine with access to the installation media.

- You provisioned persistent storage using NFS for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

- You provisioned a RHEL Kernel Virtual Machine (KVM) system that is hosted on the logical partition (LPAR) and based on RHEL 8.3 or higher.

Be sure to also review this site list if you are configuring a proxy.

10.3.2. About installations in restricted networks

In OpenShift Container Platform 4.8, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

10.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.

- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

10.3.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.
One or more KVM host machines based on RHEL 8.3 or later. Each RHEL KVM host machine must have libvirt installed and running. The virtual machines are provisioned under each RHEL KVM host machine.

### 10.3.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following nodes:

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different RHEL instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

See [Red Hat Enterprise Linux technology capabilities and limits](#).

### 10.3.3.2. Network connectivity requirements

The OpenShift Container Platform installer creates the Ignition files, which are necessary for all the Red Hat Enterprise Linux CoreOS (RHCOS) virtual machines. The automated installation of OpenShift Container Platform is performed by the bootstrap machine. It starts the installation of OpenShift Container Platform on each node, starts the Kubernetes cluster, and then finishes. During this bootstrap, the virtual machine must have an established network connection either through a Dynamic Host Configuration Protocol (DHCP) server or static IP address.

### 10.3.3.3. IBM Z network connectivity requirements

To install on IBM Z under RHEL KVM, you need:

- A RHEL KVM host configured with an OSA or RoCE network adapter.
- Either a RHEL KVM host that is configured to use bridged networking in libvirt or MacVTap to connect the network to the guests.

See [Types of virtual network connections](#).
10.3.3.4. Host machine resource requirements

The RHEL KVM host in your environment must meet the following requirements to host the virtual machines that you plan for the OpenShift Container Platform environment. See Getting started with virtualization.

You can install OpenShift Container Platform version 4.8 on the following IBM hardware:

- IBM z15 (all models), IBM z14 (all models), IBM z13, and IBM z13s
- LinuxONE, any version

10.3.3.5. Minimum IBM Z system environment

Hardware requirements

- 1 LPAR with 6 IFLs that supports SMT2
- 1 OSA or RoCE network adapter

Operating system requirements

- One LPAR running RHEL 8.3 or later with KVM, which is managed via libvirt

On your RHEL KVM host, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

10.3.3.6. Minimum resource requirements

Each cluster virtual machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

[1] 1 physical core (IFL) provides 2 logical cores (threads) when SMT-2 is enabled. The hypervisor can provide 2 or more vCPUs.

10.3.3.7. Preferred IBM Z system environment

Hardware requirements

- 3 LPARs with 6 IFLs each that support SMT2
- 1 or 2 OSA or RoCE network adapters, or both
Operating system requirements

- For high availability, 2 or 3 LPARs running RHEL 8.3 or later with KVM, which are managed via libvirt.

On your RHEL KVM host, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines, distributed across the RHEL KVM host machines
- At least 6 guest virtual machines for OpenShift Container Platform compute machines, distributed across the RHEL KVM host machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

10.3.3.8. Preferred resource requirements

The preferred requirements for each cluster virtual machine are:

<table>
<thead>
<tr>
<th>Virtual Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>8</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>6</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

10.3.3.9. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

10.3.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
• You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**

   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**

   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Choose to perform either a fast track installation of Red Hat Enterprise Linux CoreOS (RHCOS) or a full installation of Red Hat Enterprise Linux CoreOS (RHCOS). For the full installation you must set up an HTTP or HTTPS server to provide Ignition files and install images to the cluster nodes. For the fast track installation an HTTP or HTTPS server is not required, however, a DHCP server is required. See sections "Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines" and "Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines".

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.

   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   NOTE
   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

10.3.4.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in initramfs during boot to fetch their Ignition config files.

10.3.4.1.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as localhost or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

10.3.4.1.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.
IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have Internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 10.9. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>

<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

Additional resources

- Configuring chrony time service

10.3.4.2. User-provisioned DNS requirements
In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 10.12. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

### 10.3.4.2.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.
Example 10.4. Sample DNS zone database

```dns
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
;
helper.example.com. IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5
;
api.ocp4.example.com. IN A 192.168.1.5 1
api-int.ocp4.example.com. IN A 192.168.1.5 2
;
*.apps.ocp4.example.com. IN A 192.168.1.5 3
;
bootstrap.ocp4.example.com. IN A 192.168.1.96 4
;
master0.ocp4.example.com. IN A 192.168.1.97 5
master1.ocp4.example.com. IN A 192.168.1.98 6
master2.ocp4.example.com. IN A 192.168.1.99 7
;
worker0.ocp4.example.com. IN A 192.168.1.11 8
worker1.ocp4.example.com. IN A 192.168.1.17 9
;
;EOF
```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
2. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
3. Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 10.5. Sample DNS zone database for reverse records

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

1. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3. Provides reverse DNS resolution for the bootstrap machine.

4. Provides reverse DNS resolution for the control plane machines.

5. Provides reverse DNS resolution for the control plane machines.

6. Provides reverse DNS resolution for the control plane machines.

7. Provides reverse DNS resolution for the compute machines.

8. Provides reverse DNS resolution for the compute machines.
A PTR record is not required for the OpenShift Container Platform application wildcard.

10.3.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the **ssh-agent**:

```bash
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

2. Set the **GOOGLE_APPLICATION_CREDENTIALS** environment variable to the full path to your service account private key file.

```bash
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

3. Verify that the credentials were applied.

```bash
$ gcloud auth list
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**10.3.6. Manually creating the installation configuration file**
For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>

   ***IMPORTANT***

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   ***NOTE***

   You must name this configuration file `install-config.yaml`.

   ***NOTE***

   For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   ***IMPORTANT***

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

10.3.6.1. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
```
baseDomain: example.com
compute:
- hyperthreading: Enabled
  name: worker
  replicas: 0
  architecture: s390x
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: s390x
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {}
fips: false
pullSecret: "{"auths":"{\"<local_registry>\": {"auth": ","email": "you@example.com\"}}\"}"
sshKey: 'ssh-ed25519 AAAA...
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
  -----END CERTIFICATE-----
imageContentSources:
- mirrors:
  source: quay.io/openshift-release-dev/ocp-release
- mirrors:
  source: quay.io/openshift-release-dev/ocp-v4.0-art-dev

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the
cluster name.

2 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of
mappings. To meet the requirements of the different data structures, the first line of the compute
section must begin with a hyphen, -, and the first line of the **controlPlane** section must not.
Although both sections currently define a single machine pool, it is possible that future versions of
OpenShift Container Platform will support defining multiple compute pools during installation.
Only one control plane pool is used.

3 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By
default, SMT is enabled to increase the performance of the cores in your machines. You can
disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all
cluster machines; this includes both control plane and compute machines.
Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the `hyperthreading` parameter has no effect.

**IMPORTANT**

If you disable `hyperthreading`, whether in the BIOS or in the `install-config.yaml`, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

**NOTE**

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to **23**, then each node is assigned a `/23` subnet out of the given `cidr`, which allows for $510 \ (2^{32} - 23) - 2$ pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z infrastructure.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.
For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`.

The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

Add the `additionalTrustBundle` parameter and value. The value must be the contents of the certificate file that you used for your mirror registry, which can be an exiting, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

### 10.3.6.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

**Procedure**
1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
noProxy: example.com
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an `httpProxy` value.

2. A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then `httpProxy` is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an `httpsProxy` value.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.
10.3.6.3. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing `install-config.yaml` file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

```
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

**NOTE**

The minimum for control plane nodes is 21 GB. For three control plane nodes this is the memory equivalent of a minimum five node cluster.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the `Load balancing requirements for user-provisioned infrastructure` section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to `true`. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.
10.3.7. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir=<installation_directory>  
   ```

   **Example output**

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

   1 For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```
Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
     name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
       id: mycluster-100419-private-zone
     publicZone: 2
       id: example.openshift.com
   status: {}
   ```

   1. Remove this section completely.

   If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir=<installation_directory> 1
   ```

   1. For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```bash
   ├── auth
   │   └── kubeadmin-password
   ├── kubeconfig
   ├── bootstrap.ign
   ├── master.ign
   └── metadata.json
   └── worker.ign
   ```
10.3.8. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) as Red Hat Enterprise Linux (RHEL) guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

You can perform a fast-track installation of RHCOS that uses a prepackaged QEMU copy-on-write (QCOW2) disk image. Alternatively, you can perform a full installation on a new QCOW2 disk image.

10.3.8.1. Fast-track installation by using a prepackaged QCOW2 disk image

Complete the following steps to create the machines in a fast-track installation of Red Hat Enterprise Linux CoreOS (RHCOS), importing a prepackaged Red Hat Enterprise Linux CoreOS (RHCOS) QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- A DHCP server that provides IP addresses.

Procedure

1. Obtain the RHEL QEMU copy-on-write (QCOW2) disk image file from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   IMPORTANT

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

2. Download the QCOW2 disk image and Ignition files to a common directory on the RHEL KVM host.
   For example: /var/lib/libvirt/images

   NOTE

   The Ignition files are generated by the OpenShift Container Platform installer.

3. Create a new disk image with the QCOW2 disk image backing file for each KVM guest node.

   $ qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/{source_rhcos_qemu} /var/lib/libvirt/images/{vmname}.qcow2 {size}
4. Create the new KVM guest nodes using the Ignition file and the new disk image.

$ virt-install --noautoconsole
   --connect qemu:///system
   --name {vn_name}
   --memory {memory}
   --vcpus {vcpus}
   --disk {disk}
   --import
   --network network={network},mac={mac}
   --qemu-commandline="-drive
   if=none,id=ignition,format=raw,file={ign_file},readonly=on -device virtio-
   blk,serial=ignition,drive=ignition"

10.3.8.2. Full installation on a new QCOW2 disk image

Complete the following steps to create the machines in a full installation on a new QEMU copy-on-write (QCOW2) disk image.

Prerequisites

- At least 1 LPAR running RHEL 8.3 with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- An HTTP or HTTPS server is set up.

Procedure

1. Obtain the RHEL kernel, initramfs, and rootfs files from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   IMPORTANT
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - kernel: rhcos-<version>-live-kernel-<architecture>
   - initramfs: rhcos-<version>-live-initramfs.<architecture>.img
   - rootfs: rhcos-<version>-live-rootfs.<architecture>.img

2. Move the downloaded RHEL live kernel, initramfs, and rootfs as well as the Ignition files to an HTTP or HTTPS server before you launch virt-install.
NOTE

The Ignition files are generated by the OpenShift Container Platform installer.

3. Create the new KVM guest nodes using the RHEL kernel, initramfs, and Ignition files, the new disk image, and adjusted parm line arguments.

- For `--location`, specify the location of the kernel/initrd on the HTTP or HTTPS server.

- For `coreos.inst.ignition_url=`, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

- For `coreos.live.rootfs_url=`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

```
$ virt-install \
   --connect qemu:///system \ 
   --name {vn_name} \ 
   --vcpus {vcpus} \ 
   --memory {memory_mb} \ 
   --disk {vn_name}.qcow2,size={image_size| default(10,true)} \ 
   --network network={virt_network_parm} \ 
   --boot hd \ 
   --location {media_location},kernel={rhcos_kernel},initrd={rhcos_initrd} \ 
   --extra-args "rd.neednet=1 coreos.inst=yes coreos.inst.install_dev=vda \ 
   coreos.live.rootfs_url={rhcos_liveos} ip={ip}::{default_gateway}:{subnet_mask_length}: \ 
   {vn_name}:enc1:none:{MTU} nameserver={dns} coreos.inst.ignition_url={rhcos_ign}" \ 
   --noautoconsole \ 
   --wait
```

10.3.9. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \  
  --log-level=info

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Example output**

```plaintext
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.21.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

## 10.3.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   1

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```
10.3.11. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   
   Example output
   
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.21.0
   master-1  Ready     master  63m  v1.21.0
   master-2  Ready     master  64m  v1.21.0
   worker-0  NotReady  worker  76s  v1.21.0
   worker-1  NotReady  worker  70s  v1.21.0
   
   The output lists all of the machines that you created.
   ```

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   
   Example output
   
   NAME        AGE     REQUESTOR                                      CONDITION
   csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   ...
   
   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.
OpenShift Container Platform 4.8 Installing

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in
Pending status, approve the CSRs for your cluster machines:

NOTE
Because the CSRs rotate automatically, approve your CSRs within an hour of
adding the machines to the cluster. If you do not approve them within an hour, the
certificates will rotate, and more than two certificates will be present for each
node. You must approve all of these certificates. Once the client CSR is
approved, the Kubelet creates a secondary CSR for the serving certificate, which
requires manual approval. Then, subsequent serving certificate renewal requests
are automatically approved by the machine-approver if the Kubelet requests a
new certificate with identical parameters.

NOTE
For clusters running on platforms that are not machine API enabled, such as bare
metal and other user-provisioned infrastructure, you must implement a method
of automatically approving the kubelet serving certificate requests (CSRs). If a
request is not approved, then the oc exec, oc rsh, and oc logs commands
cannot succeed, because a serving certificate is required when the API server
connects to the kubelet. Any operation that contacts the Kubelet endpoint
requires this certificate approval to be in place. The method must watch for new
CSRs, confirm that the CSR was submitted by the node-bootstrapper service
account in the system:node or system:admin groups, and confirm the identity
of the node.
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

NOTE
Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending

1494


5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     $ oc adm certificate approve <csr_name>  

     **<csr_name>** is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

   $ oc get nodes

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

**10.3.12. Initial Operator configuration**

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**
1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>

2. Configure the Operators that are not available.

**10.3.12.1. Disabling the default OperatorHub sources**

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:
TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Global Configuration → OperatorHub** page, click the **Sources** tab, where you can create, delete, disable, and enable individual sources.

10.3.12.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

10.3.12.2.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.
2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry
   ```

   **NOTE**

   If the storage type is `emptyDIR`, the replica number cannot be greater than 1.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

   **Example output**

   ```yaml
   storage:
   pvc:
   claim:
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```bash
   $ oc get clusteroperator image-registry
   ```

5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:

     ```bash
     $ oc edit configs.imageregistry/cluster
     ```

     Then, change the line

     ```yaml
     managementState: Removed
     ```

     to

     ```yaml
     managementState: Managed
     ```

### 10.3.12.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir":{}}}'}

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 10.3.13. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.8.0</td>

<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h30m</td>
</tr>
<tr>
<td>insights</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>kube-apiserver</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>kube-controller-manager</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

### IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

### Example output
### Chapter 10. Installing with RHEL KVM on IBM Z and LinuxONE

#### 10.3.14. Collecting debugging information

You can gather debugging information that might help you to troubleshoot and debug certain issues with an OpenShift Container Platform installation on IBM Z.

**Prerequisites**

- The **oc** CLI tool installed.

**Procedure**

1. Log in to the cluster:

   ```bash
   $ oc login -u <username>
   ```

2. On the node you want to gather hardware information about, start a debugging container:

   ```bash
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

   3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   **NOTE**

   When installing with multipath, it is strongly recommended to enable it at installation time, and not at a later time, which can cause problems.

   See "Enabling multipathing with kernel arguments on RHCOS" in the *Installing on bare metal* documentation for more information.
3. Change to the /host file system and start **toolbox**:

   ```
   $ chroot /host
   $ toolbox
   ``

4. Collect the **dbginfo** data:

   ```
   $ dbginfo.sh
   ``

5. You can then retrieve the data, for example, using **scp**.

Additional resources

- How to generate SOSREPORT within OpenShift Container Platform version 4 nodes without SSH.

10.3.15. Next steps

- Customize your cluster.

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
CHAPTER 11. INSTALLING ON IBM POWER SYSTEMS

11.1. PREPARING TO INSTALL ON IBM POWER SYSTEMS

11.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

11.1.2. Choosing a method to install OpenShift Container Platform on IBM Power Systems

You can install a cluster on IBM Power Systems infrastructure that you provision, by using one of the following methods:

- **Installing a cluster on IBM Power Systems**: You can install OpenShift Container Platform on IBM Power Systems infrastructure that you provision.
- **Installing a cluster on IBM Power Systems in a restricted network**: You can install OpenShift Container Platform on IBM Power Systems infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

11.2. INSTALLING A CLUSTER ON IBM POWER SYSTEMS

In OpenShift Container Platform version 4.8, you can install a cluster on IBM Power Systems infrastructure that you provision.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

11.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned persistent storage using NFS for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**
Be sure to also review this site list if you are configuring a proxy.

### 11.2.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 11.2.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

#### 11.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

<table>
<thead>
<tr>
<th>Table 11.1. Default monitoring stack components</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hosts</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.

The workloads requested by OpenShift Container Platform users run on the compute machines.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

11.2.3.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

1. 1 vCPU is equivalent to 1 physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. As with all user-provisioned installations, if you choose to use RHEL 7 compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

11.2.3.3. Minimum IBM Power Systems requirements
You can install OpenShift Container Platform version 4.8 on the following IBM hardware:

- IBM POWER8 or POWER9 processor-based systems

**Hardware requirements**

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

**Operating system requirements**

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

**Disk storage for the IBM Power guest virtual machines**

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM VNIC

**Storage / main memory**

- 120 GB / 16 GB for OpenShift Container Platform control plane machines
- 120 GB / 8 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

### 11.2.3.4. Recommended IBM Power system requirements

**Hardware requirements**

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

**Operating system requirements**

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

**Disk storage for the IBM Power guest virtual machines**
Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**
- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM VNIC

**Storage / main memory**
- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

**11.2.3.5. Managing certificate signing requests**

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

**11.2.3.6. Networking requirements for user-provisioned infrastructure**

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

**11.2.3.6.1. Setting the cluster node hostnames through DHCP**

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as `localhost` or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

**11.2.3.6.2. Network connectivity requirements**

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.
**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have Internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 11.2. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>

11.2.3.7. User-provisioned DNS requirements
In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.`

Table 11.5. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</code>.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</code>.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td><code>.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td><code>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane</td>
<td><code>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td><code>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

**11.2.3.7.1. Example DNS configuration for user-provisioned clusters**

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.
Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 11.2. Sample DNS zone database for reverse records

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
 3H ; refresh (3 hours)
 30M ; retry (30 minutes)
 2W ; expiry (2 weeks)
 1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

1. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
2. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
3. Provides reverse DNS resolution for the bootstrap machine.
4 5 6 Provides reverse DNS resolution for the control plane machines.
7 8 Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

11.2.3.8. Load balancing requirements for user-provisioned infrastructure
Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **NOTE**
   Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

**Table 11.6. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:
- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 11.7. Application ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

11.2.3.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Example 11.3. Sample API and application ingress load balancer configuration

global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode http
log global
option dontlognull
option http-server-close
option redispatch
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
timeout server 1m
timeout http-keep-alive 10s
timeout check 10s
maxconn 3000
frontend stats
bind *:1936
mode http
log global
maxconn 10
stats enable
stats hide-version
stats refresh 30s
stats show-node
stats show-desc Stats for ocp4 cluster
stats auth admin:ocp4
stats uri /stats
listen api-server-6443
bind *:6443
mode tcp
server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
server master0 master0.ocp4.example.com:6443 check inter 1s
server master1 master1.ocp4.example.com:6443 check inter 1s
server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
server master0 master0.ocp4.example.com:22623 check inter 1s
server master1 master1.ocp4.example.com:22623 check inter 1s
server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443
bind *:443
mode tcp
balance source
server worker0 worker0.ocp4.example.com:443 check inter 1s
server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80
In the example, the cluster name is **ocp4**.

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltupe` on the HAProxy node.

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

### 11.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.
Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**
   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**
   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

4. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

**NOTE**

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

### 11.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
   
   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```sh
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   **Example output**

   ```
   api.ocp4.example.com. 0 IN A 192.168.1.5
   ```
b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

**Example output**

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

**Example output**

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.
2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

### 11.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.
IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name> 1
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   **NOTE**

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      ```
      $ eval "$(ssh-agent -s)"
      ```

      Example output
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the **ssh-agent**:

   ```
   $ ssh-add <path>/<file_name>
   ```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

2. Set the **GOOGLE_APPLICATION_CREDENTIALS** environment variable to the full path to your service account private key file.

   ```
   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
   ```

3. Verify that the credentials were applied.

   ```
   $ gcloud auth list
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**11.2.7. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

    $ tar xvf openshift-install-linux.tar.gz

5. From the Pull Secret page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

11.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.8. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the Command line interface section, select Linux from the drop-down menu and click Download command-line tools.

4. Unpack the archive:

    $ tar xvf <file>

5. Place the oc binary in a directory that is on your PATH.

    To check your PATH, execute the following command:
$ echo $PATH

After you install the CLI, it is available using the **oc** command:

$ oc <command>

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the **Command line interface** section, select **Windows** from the drop-down menu and click **Download command-line tools**.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.
   
   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the **Command line interface** section, select **MacOS** from the drop-down menu and click **Download command-line tools**.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your **PATH**.

   To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the CLI, it is available using the **oc** command:

```
$ oc <command>
```
11.2.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

11.2.9.1. Sample `install-config.yaml` file for IBM Power Systems

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the `hyperthreading` parameter has no effect.

**IMPORTANT**

If you disable `hyperthreading`, whether in the BIOS or in the `install-config.yaml`, ensure that your capacity planning accounts for the dramatically decreased machine performance.
You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute nodes.

**NOTE**

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to **23**, then each node is assigned a /23 subnet out of the given `cidr`, which allows for **510** (\(2^{(32 - 23)} - 2\)) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Power Systems infrastructure.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

The pull secret that you obtained from the Red Hat OpenShift Cluster Manager site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.
11.2.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

- **1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an `httpProxy` value.
A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then **httpProxy** is used for both HTTP and HTTPS connections. If you use an

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `. to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 11.2.9.3. Configuring a three-node cluster

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

**Prerequisites**

- You have an existing **install-config.yaml** file.

**Procedure**

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```yaml
compute:
  - name: worker
    platform: {}
```
NOTE

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to `true`. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

**11.2.10. Creating the Kubernetes manifest and Ignition config files**

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.

- You created the `install-config.yaml` installation configuration file.
Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   $ ./openshift-install create manifests --dir=<installation_directory>  

   **Example output**

   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
   name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone:  
   ```
6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

### 11.2.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Power Systems infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Follow either the steps to use an ISO image or network PXE booting to install RHCOS on the machines.

#### 11.2.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

**Procedure**

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your `bootstrap.ign` Ignition config file:

   ```
   $ sha512sum <installation_directory>/bootstrap.ign
   
   Example output
   
   a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78dd011
   6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
   installation_directory/bootstrap.ign
   
   The digests are provided to the *coreos-installer* in a later step to validate the authenticity of the Ignition config files on the cluster nodes.
   
2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```
   $ curl -k http://<HTTP_server>/bootstrap.ign
   
   Example output
   
   Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the *RHCOS image mirror* page.
IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

*rhcors-<version>-live.<architecture>.iso*

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:
   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device> --ignition-hash=SHA512-<digest>  
```

   1. You must run the `coreos-installer` command by using `sudo`, because the core user does not have the required root privileges to perform the installation.

   2. The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.

NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running `coreos-installer`.

The following example initializes a bootstrap node installation to the `/dev/sda` device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
8. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

10. Continue to create the other machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 11.2.11.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

#### 11.2.11.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.
**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

### Table 11.8. Networking and bonding options for ISO installations

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
</table>
| To configure an IP address, either use DHCP (`ip=dhcp`) or set an individual static IP address (`ip=10.10.10.2`) on each node. This example sets: | `ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41` |
| - The node’s IP address to **10.10.10.2**                                    |                                                                          |
| - The gateway address to **10.10.10.254**                                    |                                                                          |
| - The netmask to **255.255.255.0**                                           |                                                                          |
| - The hostname to **core0.example.com**                                       |                                                                          |
| - The DNS server address to **4.4.4.41**                                      |                                                                          |
| - The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically. |                                                                          |

**NOTE**

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.
### Description
Specify multiple network interfaces by specifying multiple `ip=` entries.

### Examples
```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

### Description
Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the `enp1s0` interface has a static networking configuration and DHCP is disabled for `enp2s0`, which is not used.

### Examples
```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=:::core0.example.com:enp2s0:none
```

### Description
You can combine DHCP and static IP configurations on systems with multiple network interfaces.

### Examples
```
ip=enp1s0:dhcp
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

### Description
Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

### Examples
To configure a VLAN on a network interface and use a static IP address:
```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0
```

To configure a VLAN on a network interface and to use DHCP:
```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

### Description
You can provide multiple DNS servers by adding a `nameserver=` entry for each server.

### Examples
```
nameserver=1.1.1.1
nameserver=8.8.8.8
```
Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples:

- The syntax for configuring a bonded interface is:
  
  ```
  bond=name[:network_interfaces][:options]
  ```

  `name` is the bonding device name (`bond0`), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.

Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp
```

To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

### 11.2.11.1.2. `coreos-installer` options for ISO installations

You can install RHCOS by running `coreos-installer install <options> <device>` at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the `coreos-installer` command.

**Table 11.9. `coreos-installer` subcommands, command-line options, and arguments**

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
</table>
```bash
$ coreos-installer install <options> <device>
```

Embed an Ignition config in an ISO image.

**coreos-installer install subcommand options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-u, --image-url &lt;url&gt;</td>
<td>Specify the image URL manually.</td>
</tr>
<tr>
<td>-f, --image-file &lt;path&gt;</td>
<td>Specify a local image file manually. Used for debugging.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>Embed an Ignition config from a file.</td>
</tr>
<tr>
<td>-I, --ignition-url &lt;URL&gt;</td>
<td>Embed an Ignition config from a URL.</td>
</tr>
<tr>
<td>--ignition-hash &lt;digest&gt;</td>
<td>Digest type-value of the Ignition config.</td>
</tr>
<tr>
<td>-p, --platform &lt;name&gt;</td>
<td>Override the Ignition platform ID for the installed system.</td>
</tr>
<tr>
<td>--append-karg &lt;arg&gt;…</td>
<td>Append a default kernel argument to the installed system.</td>
</tr>
<tr>
<td>--delete-karg &lt;arg&gt;…</td>
<td>Delete a default kernel argument from the installed system.</td>
</tr>
<tr>
<td>-n, --copy-network</td>
<td>Copy the network configuration from the install environment.</td>
</tr>
<tr>
<td></td>
<td>+</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--network-dir &lt;path&gt;</td>
<td>For use with <code>--copy-network</code>. Default is <code>/etc/NetworkManager/system-connections/</code>.</td>
</tr>
<tr>
<td>--save-partlabel &lt;lx&gt;..</td>
<td>Save partitions with this label glob.</td>
</tr>
<tr>
<td>--save-partindex &lt;id&gt;...</td>
<td>Save partitions with this number or range.</td>
</tr>
<tr>
<td>--insecure</td>
<td>Skip signature verification.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>&lt;device&gt;</td>
<td>The destination device.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$ coreos-installer iso ignition embed &lt;options&gt; --ignition-file &lt;file_path&gt; &lt;ISO_image&gt;</td>
<td>Embed an Ignition config in an ISO image.</td>
</tr>
<tr>
<td>coreos-installer iso ignition show &lt;options&gt; &lt;ISO_image&gt;</td>
<td>Show the embedded Ignition config from an ISO image.</td>
</tr>
<tr>
<td>coreos-installer iso ignition remove &lt;options&gt; &lt;ISO_image&gt;</td>
<td>Remove the embedded Ignition config from an ISO image.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f, --force</td>
<td>Overwrite an existing Ignition config.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos-installer pxe ignition wrap &lt;options&gt;</td>
<td>Wrap an Ignition config in an image.</td>
</tr>
</tbody>
</table>
**coreos-installer pxe ignition unwrap**

<options> <image_name>

Show the wrapped Ignition config in an image.

**coreos-installer PXE Ignition subcommand options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

Note that not all of these options are accepted by all subcommands.

11.2.11.1.3. **coreos.inst boot options for ISO or PXE installations**

You can automatically invoke `coreos-installer` options at boot time by passing `coreos.inst` boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the `coreos.inst` options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing TAB while the RHEL CoreOS (Live) menu option is highlighted.

- For PXE or iPXE installations, the `coreos.inst` options must be added to the APPEND line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer `coreos.inst` boot options for ISO and PXE installations.

**Table 11.10. coreos.inst boot options**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>coreos.inst.save_partindex</strong></td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td><strong>coreos.inst.insecure</strong></td>
<td>Optional: Permits the OS image that is specified by <code>coreos.inst.image_url</code> to be unsigned.</td>
</tr>
<tr>
<td><strong>coreos.inst.image_url</strong></td>
<td>Optional: Download and install the specified RHCOS image.</td>
</tr>
<tr>
<td></td>
<td>- This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>- While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>- If you are using <code>coreos.inst.image_url</code>, you must also use <code>coreos.inst.insecure</code>. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>- Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td><strong>coreos.inst.skip_reboot</strong></td>
<td>Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td><strong>coreos.inst.platform_id</strong></td>
<td>Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: <code>coreos.inst.platform_id=vmware</code>.</td>
</tr>
<tr>
<td><strong>ignition.config.url</strong></td>
<td>Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how <code>coreos-installer</code> is invoked, or to run code before or after the installation. This is different from <code>coreos.inst.ignition_url</code>, which is the Ignition config for the installed system.</td>
</tr>
</tbody>
</table>
11.2.11.2. Installing RHCOS by using PXE booting

You can use PXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   IMPORTANT
   
   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   $ curl -k http://<HTTP_server>/bootstrap.ign

   Example output

   Replace bootstrap.ign with master.ign or worker.ign in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS kernel, initramfs and rootfs files from the Product Downloads page on the Red Hat customer portal or the RHCOS image mirror page.
IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: rhcos-<version>-live-kernel-<architecture>
- **initramfs**: rhcos-<version>-live-initramfs.<architecture>.img
- **rootfs**: rhcos-<version>-live-rootfs.<architecture>.img

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE installation for the RHCOS images and begin the installation.

   Modify the following example menu entry for your environment and verify that the image and Ignition files are properly accessible:

   ```
   DEFAULT pxeboot
   TIMEOUT 20
   PROMPT 0
   LABEL pxeboot
       KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
       APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
   ```

   1. **Specify the location of the live kernel file that you uploaded to your HTTP server.** The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

   2. **If you use multiple NICs, specify a single interface in the ip option.** For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

   3. **Specify the locations of the RHCOS files that you uploaded to your HTTP server.** The `initrd` parameter value is the location of the initramfs file, the `coreos.live.rootfs_url` parameter value is the location of the rootfs file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.
NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?.

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Continue to create the machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the `core` user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

11.2.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites
Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   
   ```bash
   $ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete \ 
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```bash
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.21.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

11.2.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   system:admin
   ```

**11.2.14. Approving the certificate signing requests for your machines**

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.21.0
   master-1  Ready     master  63m  v1.21.0
   master-2  Ready     master  64m  v1.21.0
   worker-0  NotReady  worker  76s  v1.21.0
   worker-1  NotReady  worker  70s  v1.21.0
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.
2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>...</td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   ```
   $ oc adm certificate approve <csr_name>
   ```

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  ```

  <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:
4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

$ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:
  
  $ oc adm certificate approve <csr_name>  

  <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

$ oc get nodes

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>
NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

11.2.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>
<thead>
<tr>
<th>NAME</th>

</table>
11.2.15.1 Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

11.2.15.1.1 Configuring registry storage for IBM Power Systems

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` role.
- You have a cluster on IBM Power Systems.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:
$ oc get pod -n openshift-image-registry

**NOTE**

If the storage type is `emptyDir`, the replica number cannot be greater than 1.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   **Example output**

   ```yaml
   storage:
   pvc:
   claim:
   ``

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   $ oc get clusteroperator image-registry

5. Ensure that your registry is set to managed to enable building and pushing of images.
   
   - Run:
     
     $ oc edit configs.imageregistry/cluster

     Then, change the line

     ```yaml
     managementState: Removed
     ```

     to

     ```yaml
     managementState: Managed
     ```

### 11.2.15.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {
  "storage": {"emptyDir":{}}}}'
  ```
11.2.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>
<thead>
<tr>

</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

### IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

### Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td></td>
</tr>
</tbody>
</table>
b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```bash
$ oc logs <pod_name> -n <namespace> 1
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. Additional steps are required to enable multipathing. Do not enable multipathing during installation.

See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* documentation for more information.

a. To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```bash
$ bootlist -m normal -o
```

b. To update the boot list for normal mode and add alternate device names, enter the following command:

```bash
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
```

If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

c. All the worker nodes are restarted. To monitor the process, enter the following command:

```bash
$ oc get nodes -w
```

### NOTE

If you have additional machine types such as infrastructure nodes, repeat the process for these types.
Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

11.3. INSTALLING A CLUSTER ON IBM POWER SYSTEMS IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.8, you can install a cluster on IBM Power Systems infrastructure that you provision in a restricted network.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

11.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You created a mirror registry for installation in a restricted network and obtained the imageContentSources data for your version of OpenShift Container Platform.
- Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

**IMPORTANT**

Ensure that installation steps are performed on a machine with access to the installation media.

- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

11.3.2. About installations in restricted networks

In OpenShift Container Platform 4.8, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.
To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

### 11.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

### 11.3.3. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the [Red Hat OpenShift Cluster Manager (OCM)](https://openshift.redhat.com/).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use **subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the [Red Hat OpenShift Cluster Manager](https://openshift.redhat.com/) page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](https://quay.io) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 11.3.4. Requirements for a cluster with user-provisioned infrastructure
For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

### 11.3.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 11.11. Default monitoring stack components**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

### 11.3.4.2. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

---

[1]: vCPU is equivalent to 1 physical core when simultaneous multithreading (SMT)
1. 1 vCPU is equivalent to 1 physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. As with all user-provisioned installations, if you choose to use RHEL 7 compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

### 11.3.4.3. Minimum IBM Power Systems requirements

You can install OpenShift Container Platform version 4.8 on the following IBM hardware:

- IBM POWER8 or POWER9 processor-based systems

#### Hardware requirements

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

#### Operating system requirements

- One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

#### Disk storage for the IBM Power guest virtual machines

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

#### Network for the PowerVM guest virtual machines

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM VNIC

#### Storage / main memory

- 120 GB / 16 GB for OpenShift Container Platform control plane machines
- 120 GB / 8 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

### 11.3.4.4. Recommended IBM Power system requirements

#### Hardware requirements

- 6 IBM Power bare metal servers or 6 LPARs across multiple PowerVM servers

#### Operating system requirements
One instance of an IBM POWER8 or POWER9 processor-based system

On your IBM Power instance, set up:

- 3 guest virtual machines for OpenShift Container Platform control plane machines
- 2 guest virtual machines for OpenShift Container Platform compute machines
- 1 guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

**Disk storage for the IBM Power guest virtual machines**

- Storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**

- Virtualized by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM VNIC

**Storage / main memory**

- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

### 11.3.4.5. Managing certificate signing requests

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 11.3.4.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

#### 11.3.4.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.
11.3.4.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

Table 11.12. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>

</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

Additional resources

- Configuring chrony time service

11.3.4.7. User-provisioned DNS requirements
In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 11.15. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
Routes

*.apps.<cluster_name>.<base_domain>.

A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

For example, console-openshift-console.apps.<cluster_name>.<base_domain> is used as a wildcard route to the OpenShift Container Platform console.

Bootstrap machine

bootstrap.<cluster_name>.<base_domain>.

A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.

Control plane machines

<master><n>.<cluster_name>.<base_domain>.

DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.

Compute machines

<worker><n>.<cluster_name>.<base_domain>.

DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the dig command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

11.3.4.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is ocp4 and the base domain is example.com.

Example DNS A record configuration for a user-provisioned cluster
The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 11.4. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.

ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5

helper.example.com. IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5

api.ocp4.example.com. IN A 192.168.1.5
api-int.ocp4.example.com. IN A 192.168.1.5

*.apps.ocp4.example.com. IN A 192.168.1.5

bootstrap.ocp4.example.com. IN A 192.168.1.96

master0.ocp4.example.com. IN A 192.168.1.97
master1.ocp4.example.com. IN A 192.168.1.98
master2.ocp4.example.com. IN A 192.168.1.99

worker0.ocp4.example.com. IN A 192.168.1.11
worker1.ocp4.example.com. IN A 192.168.1.7

:EOF
```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

2. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

3. Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

4 Provides name resolution for the bootstrap machine.

5 6 7 Provides name resolution for the control plane machines.

8 9 Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 11.5. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (  
2019070700 ; serial  
3 3H  ; refresh (3 hours)  
30M  ; retry (30 minutes)  
2W  ; expiry (2 weeks)  
1W ) ; minimum (1 week)  
IN NS ns1.example.com.  
;  
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1  
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2  
;  
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3  
;  
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4  
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5  
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6  
;  
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7  
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8  
;  
;EOF
```

1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3 Provides reverse DNS resolution for the bootstrap machine.

4 5 6 Provides reverse DNS resolution for the control plane machines.
 Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

### 11.3.4.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **NOTE**

   Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

**Table 11.16. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 11.17. Application ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

11.3.4.8.1. Example load balancer configuration for user-provisioned clusters
This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**Example 11.6. Sample API and application ingress load balancer configuration**

```plaintext
global
log         127.0.0.1 local2
pidfile     /var/run/haproxy.pid
maxconn     4000
daemon
defaults
mode                    http
log                     global
option                  dontlognull
option http-server-close
option                  redispatch
retries                 3
timeout http-request    10s
timeout queue           1m
timeout connect         10s
timeout client          1m
timeout server          1m
timeout http-keep-alive 10s
timeout check           10s
maxconn                 3000
frontend stats
bind *:1936
mode            http
log             global
maxconn 10
stats enable
stats hide-version
stats refresh 30s
stats show-node
stats show-desc Stats for ocp4 cluster
stats auth admin:ocp4
stats uri /stats
listen api-server-6443
bind *:6443
mode tcp
server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
server master0 master0.ocp4.example.com:6443 check inter 1s
server master1 master1.ocp4.example.com:6443 check inter 1s
server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
```
In the example, the cluster name is ocp4.

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -nltpu on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running setsebool -P haproxy_connect_any=1.
11.3.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**

   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**

   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.
3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

4. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   **NOTE**
   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

11.3.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

   **IMPORTANT**
   The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
```

Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap-node.<cluster_name>.<base_domain>
```

Example output

```
bootstrap-node.<cluster_name>.<base_domain>. 0 IN A 192.168.1.5
```
Example output

```bash
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>

bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```bash
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.

2. Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```bash
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

11.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes.
through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   $ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.
NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name>
```

   1. Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

```
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>
```

3. Verify that the credentials were applied.

```
$ gcloud auth list
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

11.3.8. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```bash
$ mkdir <installation_directory>
```

**IMPORTANT**

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

**NOTE**

You must name this configuration file `install-config.yaml`.

**NOTE**

For some platform types, you can alternatively run `./openshift-install create install-config --dir=<installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

**11.3.8.1. Sample install-config.yaml file for IBM Power Systems**

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
name: worker
replicas: 0
architecture: ppc64le
controlPlane:
  hyperthreading: Enabled
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not.

Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

**IMPORTANT**

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml**, ensure that your capacity planning accounts for the dramatically decreased machine performance.
You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute

**NOTE**

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 ($2^{32} - 23 - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to none. You cannot provide additional platform configuration variables for IBM Power Systems infrastructure.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

For <local_registry>, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, registry.example.com or registry.example.com:5000. For <credentials>, specify the base64-encoded user name and password for your mirror registry.

The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
16. Provide the contents of the certificate file that you used for your mirror registry.

17. Provide the `imageContentSources` section from the output of the command to mirror the repository.

11.3.8.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[]`.cidr, `networking.clusterNetwork[]`.cidr, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----

...```

...
1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpProxy value.

2. A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then httpProxy is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpsProxy value.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

**NOTE**
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**
Only the Proxy object named cluster is supported, and no additional proxies can be created.

**11.3.8.3. Configuring a three-node cluster**

You can optionally deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

**Prerequisites**

- You have an existing install-config.yaml file.

**Procedure**
- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the `Load balancing requirements for user-provisioned infrastructure` section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to true. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

11.3.9. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for `Recovering from expired control plane certificates` for more information.
Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir=<installation_directory>  
   ```

   **Example output**

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   **Example output**

   ```
   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.
   ```

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```
   apiVersion: config.openshift.io/v1
   ```
kind: DNS
metadata:
  creationTimestamp: null
name: cluster
spec:
  baseDomain: example.openshift.com
  privateZone:
    id: mycluster-100419-private-zone
  publicZone:
    id: example.openshift.com
status: {}

Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   $ ./openshift-install create ignition-configs --dir=<installation_directory>  

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

11.3.10. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Power Systems infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Follow either the steps to use an ISO image or network PXE booting to install RHCOS on the machines.

11.3.10.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.
Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your `bootstrap.ign` Ignition config file:

   ```
   $ sha512sum <installation_directory>/bootstrap.ign
   a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf0116e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
   installation_directory/bootstrap.ign
   
   The digests are provided to the `coreos-installer` in a later step to validate the authenticity of the Ignition config files on the cluster nodes.
   
   IMPORTANT
   
   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.
   
2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```
   $ curl -k http://<HTTP_server>/bootstrap.ign
   
   The digest for the config file is provided in the command output.
   
   Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.
4. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

`rhcos-<version>-live.<architecture>.iso`

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:

- Burn the ISO image to a disk and boot it directly.
- Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

**NOTE**

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```bash
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device> --ignition-hash=SHA512-<digest>
```

1. You must run the `coreos-installer` command by using `sudo`, because the `core` user does not have the required root privileges to perform the installation.

2. The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.

**NOTE**

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running `coreos-installer`.
The following example initializes a bootstrap node installation to the /dev/sda device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=SHA512-a5a2d438792232739b60a66b44202a1d1d248fc01cf156c46d4a79f552b6bad47b8c8cc78ddf0116e80c59d2ea9e32ba53bc807afbeca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

10. Continue to create the other machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the `core` user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

11.3.10.1.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.
11.3.10.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

Table 11.18. Networking and bonding options for ISO installations
To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. This example sets:

- The node’s IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The hostname to **core0.example.com**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

**NOTE**

When you use DHCP to configure IP addressing for the RHOCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHOCOS nodes through your DHCP server configuration.

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify multiple network interfaces by specifying multiple ip= entries.</td>
<td>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none nameserver=4.4.4.41</td>
</tr>
<tr>
<td>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used.</td>
<td>ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none ip=:::core0.example.com:enp2s0:none</td>
</tr>
<tr>
<td>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</td>
<td>ip=enp1s0:dhcp ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0:none</td>
</tr>
<tr>
<td>Description</td>
<td>Examples</td>
</tr>
<tr>
<td>-------------</td>
<td>----------</td>
</tr>
</tbody>
</table>
| Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter. | To configure a VLAN on a network interface and use a static IP address:  
```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none  
vlan=enp2s0.100:enp2s0
```
| | To configure a VLAN on a network interface and to use DHCP:  
```
ip=enp2s0.100:dhcp  
vlan=enp2s0.100:enp2s0
```
| You can provide multiple DNS servers by adding a `nameserver=` entry for each server. | `nameserver=1.1.1.1`  
`nameserver=8.8.8.8` |
| Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples: | To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:  
```
bond=bond0:em1,em2:mode=active-backup  
ip=bond0:dhcp
```
| - The syntax for configuring a bonded interface is:  
`bond=name[:network_interfaces][:options]`  
name is the bonding device name (bond0), `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options. | To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:  
```
bond=bond0:em1,em2:mode=active-backup  
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```  
- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface. |
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface with a VLAN and to use DHCP:

```plaintext
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:

```plaintext
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

11.3.10.1.2. *coreos-installer* options for ISO installations

You can install RHCOS by running `coreos-installer install <options> <device>` at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the `coreos-installer` command.

**Table 11.19. coreos-installer subcommands, command-line options, and arguments**

<table>
<thead>
<tr>
<th>coreos-installer install subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Subcommand</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>$ coreos-installer install &lt;options&gt; &lt;device&gt;</td>
<td>Embed an Ignition config in an ISO image.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>coreos-installer install subcommand options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Option</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-u, --image-url &lt;url&gt;</td>
<td>Specify the image URL manually.</td>
</tr>
<tr>
<td>-f, --image-file &lt;path&gt;</td>
<td>Specify a local image file manually. Used for debugging.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>Embed an Ignition config from a file.</td>
</tr>
<tr>
<td>-l, --ignition-url &lt;URL&gt;</td>
<td>Embed an Ignition config from a URL.</td>
</tr>
<tr>
<td>--ignition-hash &lt;digest&gt;</td>
<td>Digest <em>type-value</em> of the Ignition config.</td>
</tr>
</tbody>
</table>
Override the Ignition platform ID for the installed system.

Append a default kernel argument to the installed system.

Delete a default kernel argument from the installed system.

Copy the network configuration from the install environment.

+ IMPORTANT

The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

For use with `-n`. Default is `/etc/NetworkManager/system-connections/`.

Save partitions with this label glob.

Save partitions with this number or range.

Skip signature verification.

Allow Ignition URL without HTTPS or hash.

Target CPU architecture. Default is `x86_64`.

Do not clear partition table on error.

Print help information.

**coreos-install install subcommand argument**

11.3.10.1.1.3. coreos.inst boot options for ISO or PXE installations

You can automatically invoke coreos-installer options at boot time by passing coreos.inst boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the coreos.inst options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing TAB while the RHEL CoreOS (Live) menu option is highlighted.

- For PXE or iPXE installations, the coreos.inst options must be added to the APPEND line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer coreos.inst boot options for ISO and PXE installations.

Table 11.20. coreos.inst boot options

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>coreos.inst.image_url</code></td>
<td>Optional: Download and install the specified RHCOS image.</td>
</tr>
<tr>
<td></td>
<td>- This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>- While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>- If you are using <code>coreos.inst.image_url</code>, you must also use <code>coreos.inst.insecure</code>. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>- Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td><code>coreos.inst.skip_reboot</code></td>
<td>Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td><code>coreos.inst.platform_id</code></td>
<td>Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is <code>metal</code>. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: <code>coreos.inst.platform_id=vmware</code>.</td>
</tr>
<tr>
<td><code>ignition.config.url</code></td>
<td>Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how <code>coreos-installer</code> is invoked, or to run code before or after the installation. This is different from <code>coreos.inst.ignition_url</code>, which is the Ignition config for the installed system.</td>
</tr>
</tbody>
</table>

### 11.3.10.2. Installing RHCOS by using PXE booting

You can use PXE booting to install RHCOS on the machines.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
You have configured suitable PXE infrastructure.

You have an HTTP server that can be accessed from your computer, and from the machines that you create.

You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

**Procedure**

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.
   
   **IMPORTANT**
   
   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```bash
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ``

   **Example output**

   Replace *bootstrap.ign* with *master.ign* or *worker.ign* in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS **kernel**, **initramfs** and **rootfs** files from the *Product Downloads* page on the Red Hat customer portal or the *RHCOS image mirror* page.

   **IMPORTANT**

   The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - **kernel**: `rhcos-<version>-live-kernel-<architecture>`
   - **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
   - **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`
4. Upload the rootfs, kernel, and initramfs files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE installation for the RHCOS images and begin the installation.

Modify the following example menu entry for your environment and verify that the image and Ignition files are properly accessible:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
    KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
    APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
    coreos.inst.install_dev=/dev/sda coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
```

1. Specify the location of the live kernel file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2. If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set `ip=eno1:dhcp`.

3. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The initrd parameter value is the location of the initramfs file, the coreos.live.rootsfs_url parameter value is the location of the rootfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the APPEND line to configure networking or other boot options.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more console= arguments to the APPEND line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](https://example.com).

7. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.
8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the core user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 11.3.11. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

**Procedure**

1. Monitor the bootstrap process:

```
$ ./openshift-install --dir=<installation_directory> wait-for bootstrap-complete --log-level=info
```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.21.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

11.3.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```

**Example output**

```
system:admin
```
11.3.13. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>NotReady</td>
<td>worker</td>
<td>76s</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>NotReady</td>
<td>worker</td>
<td>70s</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

   Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:
NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name> 1
  
  1 <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```bash
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal Pending</td>
<td></td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal Pending</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:
   - To approve them individually, run the following command for each valid CSR:
     
     `$ oc adm certificate approve <csr_name>`

     `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:
     
     `$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve`

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

   `$ oc get nodes`

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

11.3.14. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   `$ watch -n5 oc get clusteroperators`
11.3.14.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

```
$ oc patch OperatorHub cluster --type json -p 
   
   ["op": "add", "path": "/spec/disableAllDefaultSources", "value": true]
```

2. Configure the Operators that are not available.
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

11.3.14.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

11.3.14.2.1. Changing the image registry’s management state

To start the image registry, you must change the Image Registry Operator configuration’s managementState from Removed to Managed.

Procedure

- Change managementState Image Registry Operator configuration from Removed to Managed. For example:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"managementState":"Managed"}}'
  ```

11.3.14.2.2. Configuring registry storage for IBM Power Systems

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the cluster-admin role.
- You have a cluster on IBM Power Systems.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Container Storage.

IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have 100Gi capacity.
Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry
   ```

   **NOTE**
   If the storage type is `emptyDIR`, the replica number cannot be greater than 1.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

   **Example output**

   ```
   storage:
   pvc:
   claim:
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   ```

5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:

     ```
     $ oc edit configs.imageregistry/cluster
     ```

     Then, change the line

     ```
     managementState: Removed
     ```

     to

     ```
     managementState: Managed
     ```

11.3.14.2.3. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.
Procedure

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  {"storage":{"emptyDir":[]}}}'
  ```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

11.3.15. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

  ```bash
  $ watch -n5 oc get clusteroperators
  ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h56m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h39m</td>
</tr>
<tr>
<td>console</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h59m</td>
</tr>
<tr>
<td>csi-snapshot-controller</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h12m</td>
</tr>
<tr>
<td>dns</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>4h15m</td>
</tr>
<tr>
<td>etcd</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>image-registry</td>
<td>4.8.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h59m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir=<installation_directory> wait-for install-complete
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Reconciling from expired control plane certificates for more information.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```
Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>Running</td>
<td></td>
<td>1</td>
<td>9m</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>3m</td>
<td></td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>1m</td>
<td></td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>2m</td>
<td></td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td>Running</td>
<td></td>
<td>0</td>
<td>5m</td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```bash
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. Additional steps are required to enable multipathing. Do not enable multipathing during installation.

See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* documentation for more information.

a. To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```bash
$ bootlist -m normal -o
```

b. To update the boot list for normal mode and add alternate device names, enter the following command:

```bash
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
```

sdc
sdd
sde

If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

c. All the worker nodes are restarted. To monitor the process, enter the following command:

```bash
$ oc get nodes -w
```
NOTE

If you have additional machine types such as infrastructure nodes, repeat the process for these types.

4. Register your cluster on the Cluster registration page.

Next steps

- Customize your cluster.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
12.1. PREPARING TO INSTALL ON OPENSTACK

12.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

12.1.2. Choosing a method to install OpenShift Container Platform on OpenStack

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See Installation process for more information about installer-provisioned and user-provisioned installation processes.

12.1.2.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on Red Hat OpenStack Platform (RHOSP) infrastructure that is provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- **Installing a cluster on OpenStack with customizations** You can install a customized cluster on RHOSP. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available post-installation.

- **Installing a cluster on OpenStack with Kuryr** You can install a customized OpenShift Container Platform cluster on RHOSP that uses Kuryr SDN. Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

- **Installing a cluster on OpenStack in a restricted network** You can install OpenShift Container Platform on RHOSP in a restricted or disconnected network by creating an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

12.1.2.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on RHOSP infrastructure that you provision, by using one of the following methods:

- **Installing a cluster on OpenStack on your own infrastructure** You can install OpenShift Container Platform on user-provisioned RHOSP infrastructure. By using this installation method, you can integrate your cluster with existing infrastructure and modifications. For
installations on user-provisioned infrastructure, you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. You can use the provided Ansible playbooks to assist with the deployment process.

- **Installing a cluster on OpenStack with Kuryr on your own infrastructure** You can install OpenShift Container Platform on user-provisioned RHOSP infrastructure that uses Kuryr SDN.

- **Installing a cluster on OpenStack on your own SR-IOV infrastructure** You can install OpenShift Container Platform on user-provisioned RHOSP infrastructure that uses single-root input/output virtualization (SR-IOV) networks to run compute machines.

### 12.2. INSTALLING A CLUSTER ON OPENSTACK WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.8, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP). To customize the installation, modify parameters in the `install-config.yaml` before you install the cluster.

#### 12.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You read the documentation on selecting a cluster installation method and preparing it for users.

- You verified that OpenShift Container Platform 4.8 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

- You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.

- You have the metadata service enabled in RHOSP.

#### 12.2.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>Resource</td>
<td>Value</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

12.2.2.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.
12.2.2.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

12.2.3. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to obtain the images that are necessary to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.2.4. Enabling Swift on RHOSP

Swift is operated by a user account with the swiftoperator role. Add the role to an account before you run the installation program.
IMPORTANT

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On Ceph RGW, the account in url option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the `swiftoperator` role to the account that will access Swift:

   ```bash
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

   Your RHOSP deployment can now use Swift for the image registry.

12.2.5. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the ‘External’ network:

   ```bash
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   **Example output**

   ```
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```
A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

**IMPORTANT**

If the external network’s CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the `install-config.yaml` file before you start the installation process.

The default network ranges are:

<table>
<thead>
<tr>
<th>Network</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>machineNetwork</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td>serviceNetwork</td>
<td>172.30.0.0/16</td>
</tr>
<tr>
<td>clusterNetwork</td>
<td>10.128.0.0/14</td>
</tr>
</tbody>
</table>

**WARNING**

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

**NOTE**

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

### 12.2.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

**IMPORTANT**

Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.
If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
    dev-env:
      region_name: RegionOne
      auth:
        username: 'devuser'
        password: XXX
        project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   
   a. Copy the certificate authority file to your machine.
   
   ```
   $ sudo cp ca.crt.pem /etc/pki/ca-trust/source/anchors/
   ```
   
   b. Add the machine to the certificate authority trust bundle:
   
   ```
   $ sudo update-ca-trust extract
   ```
   
   c. Update the trust bundle:
   
   ```
   $ sudo update-ca-trust extract
   ```
   
   d. Add the cacerts key to the clouds.yaml file. The value must be an absolute, non-root-accessible path to the CA certificate:
   
   ```
   clouds:
     shiftstack:
       ...
     cacart: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
   ```

   **TIP**
   
   After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the ca-cert.pem key in the cloud-provider-config keymap. On a command line, run:
   
   ```
   $ oc edit configmap -n openshift-config cloud-provider-config
   ```

3. Place the clouds.yaml file in one of the following locations:
   
   a. The value of the OS_CLIENT_CONFIG_FILE environment variable
b. The current directory

c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`
The installation program searches for `clouds.yaml` in that order.

12.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   `$ tar xvf openshift-install-linux.tar.gz`

5. From the Pull Secret page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

12.2.8. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP), Red Hat OpenStack Platform (RHOSP).
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your bastion host.

- Have the `imageContentSources` values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir=<installation_directory>
   ```

   IMPORTANT

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      NOTE

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `gcp` as the platform to target.

      iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

      iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

      v. Select the region to deploy the cluster to.

      vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
vii. Select **openstack** as the platform to target.

viii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

ix. Specify the floating IP address to use for external access to the OpenShift API.

x. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

xi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

xii. Enter a name for your cluster. The name must be 14 or fewer characters long.

xiii. Paste the pull secret that you obtained from the Pull Secret page on the Red Hat OpenShift Cluster Manager site.

2. In the **install-config.yaml** file, set the value of **platform.openstack.clusterOSImage** to the image location or name. For example:

   ```yaml
   platform:
     openstack:
       clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?
       sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c10a812b068b16f7265d
   ```

3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

   a. Update the **pullSecret** value to contain the authentication information for your registry:

   ```yaml
   pullSecret: "{"auths":{"<bastion_host_name>:5000": {"auth": "<credentials>"},"email": "you@example.com"}}"
   ```

   For `<bastion_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded username and password for your mirror registry.

   b. Add the **additionalTrustBundle** parameter and value.

   ```yaml
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
   ```

   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

   c. Define the network and subnets for the VPC to install the cluster in under the parent **platform.gcp** field:
For **platform.gcp.network**, specify the name for the existing Google VPC. For **platform.gcp.controlPlaneSubnet** and **platform.gcp.computeSubnet**, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

d. Add the image content resources, which look like this excerpt:

```
imageContentSources:
  - mirrors:
    - <bastion_host_name>:5000/<repo_name>/release
      source: quay.example.com/openshift-release-dev/ocp-release
    - mirrors:
      - <bastion_host_name>:5000/<repo_name>/release
      source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 12.2.8.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the ec2.<region>.amazonaws.com, elasticloadbalancing.<region>.amazonaws.com, and s3.<region>.amazonaws.com endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
noProxy: example.com
additionalTrustBundle:
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpProxy value.

2. A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then httpProxy is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpsProxy value.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless
the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 12.2.9. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 12.2.9.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from <a href="https://cloud.redhat.com/openshift/install/pull-secret">https://cloud.redhat.com/openshift/install/pull-secret</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{   &quot;auths&quot;:{     &quot;cloud.openshift.com&quot;:{       &quot;auth&quot;:&quot;b3Blb=&quot;,       &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;     },     &quot;quay.io&quot;:{       &quot;auth&quot;:&quot;b3Blb=&quot;,       &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;     }   } }</td>
</tr>
</tbody>
</table>
12.2.9.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.3. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>

</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

**NOTE**

Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

### 12.2.9.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

#### Table 12.4. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or <code>Disabled</code></td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><code>worker</code></td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong>  If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <strong>compute.platform</strong> parameter value.</td>
<td><strong>aws</strong>, <strong>azure</strong>, <strong>gcp</strong>, <strong>openstack</strong>, <strong>ovirt</strong>, <strong>vsphere</strong>, or <strong>{}</strong></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision. The only supported value is <strong>3</strong>, which is the default value.</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
</tbody>
</table>
### 12.2.9.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 12.5. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.rootVolume.size</td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td>compute.platform.openstack.rootVolume.type</td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>Parameter</td>

<td>-------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| controlPlane.plat
form.openstack.rootVolume.size   | For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage. | Integer, for example 30.                                               |
| controlPlane.plat
form.openstack.rootVolume.type  | For control plane machines, the root volume’s type.                        | String, for example performance.                                       |
| platform.openst
ack.cloud                                           | The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file. | String, for example MyCloud.                                           |
| platform.openst
ack.externalNetwork                                             | The RHOSP external network name to be used for installation.               | String, for example external.                                          |
| platform.openst
ack.computeFlavor                                             | The RHOSP flavor to use for control plane and compute machines.            | String, for example m1.xlarge.                                         |

This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.

### 12.2.9.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

**Table 12.6. Optional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>

<tr>
<td>platform.openstack.clusterOSImageProperties</td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image. You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi. You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;]').</td>
</tr>
<tr>
<td>platform.openstack.defaultMachinePlatform</td>
<td>The default machine pool platform configuration.</td>
<td>{ &quot;type&quot;: &quot;ml.large&quot;, &quot;rootVolume&quot;: { &quot;size&quot;: 30, &quot;type&quot;: &quot;performance&quot; } }</td>
</tr>
<tr>
<td>platform.openstack.ingressFloatingIP</td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.apiFloatingIP</td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.externalDNS</td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;]</td>
</tr>
</tbody>
</table>
The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.

The first item in `networking.machineNetwork` must match the value of `machinesSubnet`.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

A UUID as a string. For example, `fa806b2f-ac49-4bce-b9db-124bc64209bf`.

### 12.2.9.6. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.openstack.machinesSubnet</code></td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use.</td>
<td>A UUID as a string. For example, <code>fa806b2f-ac49-4bce-b9db-124bc64209bf</code>.</td>
</tr>
<tr>
<td><code>networking.machineNetwork</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>platform.gcp.network</code></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.gcp.type</code></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><code>platform.gcp.zones</code></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>platform.gcp.controlPlaneSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>platform.gcp.computeSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.name</code></td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.location</td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.name</td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.location</td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

12.2.9.7. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:
- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

### 12.2.9.8. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `install-config.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
You created an `install-config.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `install-config.yaml` file, edit the flavors for machines:
   a. If you want to use bare-metal control plane machines, change the value of `controlPlane.platform.openstack.type` to a bare metal flavor.
   b. Change the value of `compute.platform.openstack.type` to a bare metal flavor.
   c. If you want to deploy your machines on a pre-existing network, change the value of `platform.openstack.machinesSubnet` to the RHOSP subnet UUID of the network. Control plane and compute machines must use the same subnet.

**An example bare metal install-config.yaml file**

```yaml
controlPlane:
  platform:
    openstack:
      type: <bare_metal_control_plane_flavor> ①

compute:
- architecture: amd64
  hyperthreading: Enabled
  name: worker
  platform:
    openstack:
      type: <bare_metal_compute_flavor> ②
      replicas: 3

platform:
  openstack:
    machinesSubnet: <subnet_UUID> ③
```

1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
2. Change this value to a bare metal flavor to use for compute machines.
3. If you want to use a pre-existing network, change this value to the UUID of the RHOSP subnet.

Use the updated `install-config.yaml` file to complete the installation process. The compute machines that are created during deployment use the flavor that you added to the file.
NOTE
The installer may time out while waiting for bare metal machines to boot.
If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

12.2.9.9. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the Internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE
A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

12.2.9.9.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The RHOSP networking service (Neutron) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the port security and allowed address pairs extensions enabled.
- The provider network can be shared with other tenants.

TIP
Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP
To create a network for a project that is named "openshift," enter the following command

```bash
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```bash
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.
Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is 169.254.169.254 by default. Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

  ```
  $ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
  ```

- Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

### 12.2.9.9.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on a Red Hat OpenStack Platform (RHOSP) provider network. 

#### Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

#### Procedure

1. In a text editor, open the `install-config.yaml` file.
2. Set the value of the `platform.openstack.apiVIP` property to the IP address for the API VIP.
3. Set the value of the `platform.openstack.ingressVIP` property to the IP address for the Ingress VIP.
4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.
5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

#### IMPORTANT

The `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

### Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIP: 192.0.2.13
    ingressVIP: 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
```
WARNING

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.

**TIP**

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see Understanding multiple networks.

12.2.9.10. Sample customized `install-config.yaml` file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: ml.large
        replicas: 3
    metadata:
      name: example
      networking:
        clusterNetwork:
          - cidr: 10.128.0.0/14
```
12.2.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   1 Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   $ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
3. Verify that the credentials were applied.

```bash
$ gcloud auth list
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 12.2.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

#### 12.2.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```bash
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```bash
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

   **NOTE**

   If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:

   - `platform.openstack.ingressFloatingIP`
   - `platform.openstack.apiFloatingIP`
If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

**12.2.11.2. Completing installation without floating IP addresses**

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

**12.2.12. Deploying the cluster**

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:

   - The GOOGLE_CREDENTIALS, GOOGLE_CLOUD_KEYFILE_JSON, or GCLOUD_KEYFILE_JSON environment variables
   - The ~/.gcp/osServiceAccount.json file
   - The gcloud cli default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   $ ./openshift-install create cluster --dir=<installation_directory> \  
   --log-level=info  

For <installation_directory>, specify the location of your customized ./install-config.yaml file.

To view different installation details, specify warn, debug, or error instead of info.

NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

Example output

...  
INFO Install complete!  
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'  
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com  
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"  
INFO Time elapsed: 36m22s

NOTE

The cluster access and credential information also outputs to <installation_directory>/openshift_install.log when an installation succeeds.
IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kublet certificates. See the documentation for Recovering from expired control plane certificates for more information.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.

   - If you assigned the Owner role to your service account, you can remove that role and replace it with the Viewer role.
   - If you included the Service Account Key Admin role, you can remove it.

12.2.13. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

   The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster’s version:

   $ oc get clusterversion

4. View your Operators’ status:

   $ oc get clusteroperator

5. View all running pods in the cluster:
12.2.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   Example output

   

   ```
   system:admin
   ```

**12.2.15. Next steps**

- Customize your cluster.
- If necessary, you can opt out of remote health reporting .
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses .

### 12.3. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR

In OpenShift Container Platform version 4.8, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP) that uses Kuryr SDN. To customize the installation, modify parameters in the `install-config.yaml` before you install the cluster.

### 12.3.1. Prerequisites
• You reviewed details about the OpenShift Container Platform installation and update processes.

• You read the documentation on selecting a cluster installation method and preparing it for users.

• You verified that OpenShift Container Platform 4.8 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

• You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.

12.3.2. About Kuryr SDN

Kuryr is a container network interface (CNI) plug-in solution that uses the Neutron and Octavia Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the openshift-kuryr namespace:

- **kuryr-controller** - a single service instance installed on a master node. This is modeled in OpenShift Container Platform as a Deployment object.

- **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a DaemonSet object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

• The RHOSP version is less than 16.

• The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or
• The **ovn-octavia** Octavia driver is disabled.

• The deployment uses a large number of TCP services on few hypervisors.

### 12.3.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster’s minimum requirements:

**Table 12.8. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3 - plus the expected number of Services of LoadBalancer type</td>
</tr>
<tr>
<td>Ports</td>
<td>1500 - 1 needed per Pod</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>Networks</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>250 - 1 needed per Service and per NetworkPolicy</td>
</tr>
<tr>
<td>Security group rules</td>
<td>1000</td>
</tr>
<tr>
<td>Load balancers</td>
<td>100 - 1 needed per Service</td>
</tr>
<tr>
<td>Load balancer listeners</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
<tr>
<td>Load balancer pools</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.
IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

IMPORTANT

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods’ booting time.

- Each network policy is mapped into an RHOSP security group, and depending on the **NetworkPolicy** spec, one or more rules are added to the security group.

- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota.
  
  If you are using RHOSP version 15 or earlier, or the **ovn-octavia driver**, each load balancer has a security group with the user project.

- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment’s size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them.
  
  If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
- Use **openvswitch** firewall driver if ML2/OVS Neutron driver is used instead of **ovs-hybrid**.

12.3.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

**Procedure**

- Increase the quotas for a project by running the following command:
12.3.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the trunks extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to openvswitch instead of ovs_hybrid so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

12.3.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)’s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

**NOTE**

The following steps only capture the key pieces required during the deployment of RHOSP when dealing with Octavia. It is also important to note that registry methods vary.

This example uses the local registry method.

**Procedure**

1. If you are using the local registry, create a template to upload the images to the registry. For example:

   ```bash
   (undercloud) $ openstack overcloud container image prepare \
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
   --namespace=registry.access.redhat.com/rhosp13 \
   --push-destination=<local-ip-from-undercloud.conf>:8787 \
   --prefix=openstack- \
   --tag-from-label {version}-{product-version} \
   --output-env-file=/home/stack/templates/overcloud_images.yaml \
   --output-images-file /home/stack/local_registry_images.yaml
   ...
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
   ```
NOTE
The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from `registry.redhat.io` to the Undercloud node:

```bash
(undercloud) $ sudo openstack overcloud container image upload \
--config-file /home/stack/local_registry_images.yaml \
--verbose
```

This may take some time depending on the speed of your network and Undercloud disk.

4. Since an Octavia load balancer is used to access the OpenShift Container Platform API, you must increase their listeners’ default timeouts for the connections. The default timeout is 50 seconds. Increase the timeout to 20 minutes by passing the following file to the Overcloud deploy command:

```bash
(undercloud) $ cat octavia_timeouts.yaml
```

```yaml
parameter_defaults:
  OctaviaTimeoutClientData: 1200000
  OctaviaTimeoutMemberData: 1200000
```

NOTE
This is not needed for RHOSP 13.0.13+

5. Install or update your Overcloud environment with Octavia:

```bash
$ openstack overcloud deploy --templates \ 
  -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \ 
  -e octavia_timeouts.yaml
```

NOTE
This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see installation of Octavia using Director.

NOTE
When leveraging Kuryr SDN, the Overcloud installation requires the Neutron `trunk` extension. This is available by default on director deployments. Use the `openvswitch` firewall instead of the default `ovs-hybrid` when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.
6. In RHOSP versions earlier than 13.0.13, add the project ID to the `octavia.conf` configuration file after you create the project.

- To enforce network policies across services, like when traffic goes through the Octavia load balancer, you must ensure Octavia creates the Amphora VM security groups on the user project.
  This change ensures that required load balancer security groups belong to that project, and that they can be updated to enforce services isolation.

  **NOTE**

  This task is unnecessary in RHOSP version 13.0.13 or later.

  Octavia implements a new ACL API that restricts access to the load balancers VIP.

a. Get the project ID

   ```bash
   $ openstack project show <project>
   ```

   **Example output**

   ```
   +-------------+----------------------------------+
   | Field       | Value                            |
   +-------------+----------------------------------+
   | description |                                  |
   | domain_id   | default                          |
   | enabled     | True                             |
   | id          | PROJECT_ID                       |
   | is_domain   | False                            |
   | name        | *<project>*                      |
   | parent_id   | default                          |
   | tags        | []                               |
   +-------------+----------------------------------+
   ```

b. Add the project ID to `octavia.conf` for the controllers.

   i. Source the `stackrc` file:

   ```bash
   $ source stackrc  # Undercloud credentials
   ```

   ii. List the Overcloud controllers:

   ```bash
   $ openstack server list
   ```

   **Example output**

   ```
   +--------------------------------------+--------------+--------+-----------------------+-------
   | ID                                   | Name         | Status | Networks              |
   | Image                                | Flavor       |
   +--------------------------------------+--------------+--------+-----------------------+-------+
   ```
iii. SSH into the controller(s).

```
$ ssh heat-admin@192.168.24.8
```

c. Restart the Octavia worker so the new configuration loads.

```
controller-0$ sudo docker restart octavia_worker
```

**NOTE**

Depending on your RHOSP environment, Octavia might not support UDP listeners. If you use Kuryr SDN on RHOSP version 13.0.13 or earlier, UDP services are not supported. RHOSP version 16 or later support UDP.

### 12.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```
$ openstack loadbalancer provider list
```

**Example output**

```
+---------+-------------------------------------------------+
| name    | description                                     |
+---------+-------------------------------------------------+
| amphora | The Octavia Amphora driver.                     |
| octavia | Deprecated alias of the Octavia Amphora driver. |
| ovn     | Octavia OVN driver.                             |
+---------+-------------------------------------------------+
```

Beginning with RHOSP version 16, the Octavia OVN provider driver (**ovn**) is supported on OpenShift Container Platform on RHOSP deployments.
**ovn** is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If **ovn** is enabled, however, Kuryr uses it.

If Kuryr uses **ovn** instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

You can configure your cluster to use the Octavia OVN driver after your RHOSP cloud is upgraded from version 13 to version 16.

### 12.3.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

**RHOSP general limitations**

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.
- Clusters that use the OVN Octavia provider driver support **Service** objects for which the **.spec.selector** property is unspecified only if the **.subsets.addresses** property of the **Endpoints** object includes the subnet of the nodes or pods.
- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.

**RHOSP version limitations**

Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources. Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.
- Octavia RHOSP versions before 13.0.13 do not support UDP listeners. Therefore, OpenShift Container Platform UDP services are not supported.
- Octavia RHOSP versions before 13.0.13 cannot listen to multiple protocols on the same port. Services that expose the same port to different protocols, like TCP and UDP, are not supported.

**RHOSP environment limitations**

There are limitations when using Kuryr SDN that depend on your deployment environment.
Because of Octavia’s lack of support for the UDP protocol and multiple listeners, if the RHOSP version is earlier than 13.0.13, Kuryr forces pods to use TCP for DNS resolution.

In Go versions 1.12 and earlier, applications that are compiled with CGO support disabled use UDP only. In this case, the native Go resolver does not recognize the `use-vc` option in `resolv.conf`, which controls whether TCP is forced for DNS resolution. As a result, UDP is still used for DNS resolution, which fails.

To ensure that TCP forcing is allowed, compile applications either with the environment variable `CGO_ENABLED` set to 1, i.e. `CGO_ENABLED=1`, or ensure that the variable is absent.

In Go versions 1.13 and later, TCP is used automatically if DNS resolution using UDP fails.

**NOTE**

musl-based containers, including Alpine-based containers, do not support the `use-vc` option.

**RHOSP upgrade limitations**

As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a load balancer failover.
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

**IMPORTANT**

If OpenShift Container Platform detects a new Octavia version that supports UDP load balancing, it recreates the DNS service automatically. The service recreation ensures that the service default supports UDP load balancing.

The recreation causes the DNS service approximately one minute of downtime.

**12.3.3.5. Control plane and compute machines**

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space
TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

12.3.3.6. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

12.3.4. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to obtain the images that are necessary to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.3.5. Enabling Swift on RHOSP

Swift is operated by a user account with the swiftoperator role. Add the role to an account before you run the installation program.
IMPORTANT

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On Ceph RGW, the account in url option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the swiftoperator role to the account that will access Swift:

   ```
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

Your RHOSP deployment can now use Swift for the image registry.

12.3.6. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

Example output

```
+--------------------------------------+----------------+-------------+
| ID                                   | Name           | Router Type |
+--------------------------------------+----------------+-------------+
| 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
```
A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

**IMPORTANT**

If the external network’s CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the `install-config.yaml` file before you start the installation process.

The default network ranges are:

<table>
<thead>
<tr>
<th>Network</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>machineNetwork</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td>serviceNetwork</td>
<td>172.30.0.0/16</td>
</tr>
<tr>
<td>clusterNetwork</td>
<td>10.128.0.0/14</td>
</tr>
</tbody>
</table>

**WARNING**

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

**NOTE**

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

12.3.7. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

**IMPORTANT**

Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.
If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

```yaml
clouds:
    shiftstack:
        auth:
            project_name: shiftstack
            username: shiftstack_user
            password: XXX
            user_domain_name: Default
            project_domain_name: Default
    dev-env:
        region_name: RegionOne
        auth:
            username: 'devuser'
            password: XXX
            project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   a. Copy the certificate authority file to your machine.
   b. Add the machine to the certificate authority trust bundle:
      ```
      $ sudo cp ca.crt.pem /etc/pki/ca-trust/source/anchors/
      ```
   c. Update the trust bundle:
      ```
      $ sudo update-ca-trust extract
      ```
   d. Add the cacerts key to the clouds.yaml file. The value must be an absolute, non-root-accessible path to the CA certificate:
      ```
      clouds:
          shiftstack:
              ... 
              cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
      ```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the ca-cert.pem key in the cloud-provider-config keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the clouds.yaml file in one of the following locations:
   a. The value of the OS_CLIENT_CONFIG_FILE environment variable
b. The current directory

c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for `clouds.yaml` in that order.

### 12.3.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

#### Procedure

1. Access the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

    **IMPORTANT**

    The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

    **IMPORTANT**

    Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. From the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 12.3.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP), Red Hat OpenStack Platform (RHOSP).
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your bastion host.

- Have the `imageContentSources` values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir=<installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `gcp` as the platform to target.

   iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

   iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

   v. Select the region to deploy the cluster to.

   vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
vii. Select **openstack** as the platform to target.

viii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

ix. Specify the floating IP address to use for external access to the OpenShift API.

x. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

xi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

xii. Enter a name for your cluster. The name must be 14 or fewer characters long.

xiii. Paste the pull secret that you obtained from the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site.

2. In the **install-config.yaml** file, set the value of **platform.openstack.clusterOSImage** to the image location or name. For example:

   ```yaml
   platform:
     openstack:
       clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?
       sha256=f1ebbdbeb8a11f2e55ca19522c16c86f667f9ac8e4e0c1f0a812b068b16f7265d
   ```

3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

   a. Update the **pullSecret** value to contain the authentication information for your registry:

      ```yaml
      pullSecret: '{"auths": {"<bastion_host_name>:5000": {"auth": "<credentials>", "email": "you@example.com"}}}'}
      ```

      For **<bastion_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

   b. Add the **additionalTrustBundle** parameter and value.

      ```yaml
      additionalTrustBundle: |
      -----BEGIN CERTIFICATE-----
      ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
network: <existing_vpc>
controlPlaneSubnet: <control_plane_subnet>
computeSubnet: <compute_subnet>

For platform.gcp.network, specify the name for the existing Google VPC. For platform.gcp.controlPlaneSubnet and platform.gcp.computeSubnet, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

d. Add the image content resources, which look like this excerpt:

imageContentSources:
  - mirrors:
    - <bastion_host_name>:5000/<repo_name>/release
      source: quay.example.com/openshift-release-dev/ocp-release
    - mirrors:
      - <bastion_host_name>:5000/<repo_name>/release
        source: registry.example.com/ocp/release

To complete these values, use the imageContentSources that you recorded during mirror registry creation.

4. Make any other modifications to the install-config.yaml file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

5. Back up the install-config.yaml file so that you can use it to install multiple clusters.

   IMPORTANT

   The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

12.3.9.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the ec2.<region>.amazonaws.com, elasticloadbalancing.<region>.amazonaws.com, and s3.<region>.amazonaws.com endpoints to your VPC endpoint. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:@<ip>:<port> ¹
  httpsProxy: https://<username>:@<ip>:<port> ²
  noProxy: example.com ³
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpProxy value.

² A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then httpProxy is used for both HTTP and HTTPS connections. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an httpsProxy value.

³ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

⁴ If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless
the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

12.3.10. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the install-config.yaml file.

IMPORTANT

The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.3.10.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 12.9. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>
The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the `baseDomain` and `metadata.name` parameter values that uses the `<metadata.name>`, `<baseDomain>` format.

A fully-qualified domain or subdomain name, such as `example.com`.

Kubernetes resource `ObjectMeta`, from which only the `name` parameter is consumed.

The name of the cluster. DNS records for the cluster are all subdomains of `{{.metadata.name}}. {{.baseDomain}}`. String of lowercase letters, hyphens (`-`), and periods (`.`), such as `dev`. The string must be 14 characters or fewer long.

The configuration for the specific platform upon which to perform the installation: `aws`, `baremetal`, `azure`, `openstack`, `ovirt`, `vsphere`. For additional information about `platform.<platform>` parameters, consult the table for your specific platform that follows.

Get a pull secret from https://cloud.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```
**12.3.10.2. Network configuration parameters**

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 12.10. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong> You cannot modify parameters specified</td>
<td></td>
</tr>
<tr>
<td></td>
<td>by the <code>networking</code> object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network</td>
<td>Either <code>OpenShiftSDN</code> or <code>OVNKubernetes</code>.</td>
</tr>
<tr>
<td></td>
<td>Interface (CNI) plug-in to install.</td>
<td>The default value is <code>OpenShiftSDN</code>.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <code>10.128.0.0/14</code> with a host</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>prefix of <code>/23</code>.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the</td>
<td>- cidr: <code>10.128.0.0/14</code></td>
</tr>
<tr>
<td></td>
<td>blocks must not overlap.</td>
<td>hostPrefix: <code>23</code></td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>.</td>
<td>An IP address block in Classless Inter-</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td>Domain Routing (CIDR) notation. The prefix</td>
</tr>
<tr>
<td></td>
<td></td>
<td>length for an IPv4 block is between 0 and</td>
</tr>
<tr>
<td></td>
<td></td>
<td>32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>individual node. For example, if <code>hostPrefix</code></td>
<td>The default value is <code>23</code>.</td>
</tr>
<tr>
<td></td>
<td>is set to <code>23</code> then each node is assigned a /23</td>
<td></td>
</tr>
<tr>
<td></td>
<td>subnet out of the given <code>cidr</code>. A <code>hostPrefix</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>value of <code>23</code> provides 510 (2^(32 - 23) - 2) pod</td>
<td></td>
</tr>
<tr>
<td></td>
<td>IP addresses.</td>
<td></td>
</tr>
</tbody>
</table>
The IP address block for services. The default value is 172.30.0.0/16.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

An array with an IP address block in CIDR format. For example:

```
networking:
  serviceNetwork:
    - 172.30.0.0/16
```

The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.

An array of objects. For example:

```
networking:
  machineNetwork:
    - cidr: 10.0.0.0/16
```

Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

An IP network block in CIDR notation. For example, 10.0.0.0/16.

**NOTE**
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

### 12.3.10.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 12.11. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hypertexting, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.</td>
<td></td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
</tbody>
</table>
### 12.3.10.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

```yaml
sshKey:
  - key1
  - key2
  - key3
```
### Parameter Description Values

**controlPlane.platform.openstack.rootVolume.size**  
For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.  
Integer, for example **30**.

**controlPlane.platform.openstack.rootVolume.type**  
For control plane machines, the root volume’s type.  
String, for example **performance**.

**platform.openstack.cloud**  
The name of the RHOSP cloud to use from the list of clouds in the `clouds.yaml` file.  
String, for example **MyCloud**.

**platform.openstack.externalNetwork**  
The RHOSP external network name to be used for installation.  
String, for example **external**.

**platform.openstack.computeFlavor**  
The RHOSP flavor to use for control plane and compute machines.  
This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the **type** key in the `platform.openstack.defaultMachinePlatform` property. You can also set a flavor value for each machine pool individually.  
String, for example **m1.xlarge**.

### 12.3.10.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

**Table 12.13. Optional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>

<tr>
<td>platform.openstack.ingressFloatingIP</td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.apiFloatingIP</td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.externalDNS</td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;].</td>
</tr>
</tbody>
</table>
The UUID of a RHOSP subnet that the cluster's nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.

The first item in `networking.machinesSubnet` must match the value of `machinesSubnet`.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

A UUID as a string. For example, `fa806b2f-ac49-4bce-b9db-124bc64209bf`.

### 12.3.10.6. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

**Table 12.14. Additional GCP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>

<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryption Key.kmsKey.projectID</code></td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

### 12.3.10.7. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:
- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.

- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.

- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

12.3.10.8. Sample customized install-config.yaml file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OpenShift SDN, you must modify the `install-config.yaml` file to include `Kuryr` as the desired `networking.networkType` and proceed with the default OpenShift Container Platform SDN installation steps. This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: mlarge
      replicas: 3
metadata:
  name: example
  networking:
   clusterNetwork:
```

```yaml```
The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `serviceNetwork` property. The larger range is required to prevent IP address conflicts.

Both `trunkSupport` and `octaviaSupport` are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

12.3.10.9. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the Internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

12.3.10.9.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The **RHOSP networking service (Neutron) is enabled** and accessible through the RHOSP networking API.
- The RHOSP networking service has the **port security and allowed address pairs extensions enabled**.
The provider network can be shared with other tenants.

**TIP**

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

**TIP**

To create a network for a project that is named "openshift," enter the following command:

```bash
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command:

```bash
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is `169.254.169.254` by default.
  - Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:
    ```bash
    $ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
    ```

- Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

### 12.3.10.9.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on a Red Hat OpenStack Platform (RHOSP) provider network.

**Prerequisites**

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

**Procedure**
1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIP` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIP` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

... 
```yaml
platform:
  openstack:
    apiVIP: 192.0.2.13
    ingressVIP: 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
(...)
networking:
  machineNetwork:
    - cidr: 192.0.2.0/24
```

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.

**TIP**

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).
12.3.11. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH into the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH into your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.
NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the ssh-agent:

```bash
$ ssh-add <path>/<file_name>
```

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

```bash
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

3. Verify that the credentials were applied.

```bash
$ gcloud auth list
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

12.3.12. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.
12.3.12.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>

   **NOTE**

   If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

4. Add the FIPs to the install-config.yaml file as the values of the following parameters:

   - `platform.openstack.ingressFloatingIP`
   - `platform.openstack.apiFloatingIP`

   If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the install-config.yaml file.

   **TIP**

   You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.3.12.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the install-config.yaml file, do not define the following parameters:

   - `platform.openstack.ingressFloatingIP`
   - `platform.openstack.apiFloatingIP`

   If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork`
blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

12.3.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:

   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCP_CREDENTIALS_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir=<installation_directory> \
   --log-level=info
   ```

   For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
To view different installation details, specify warn, debug, or error instead of info.

NOTE
If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

Example output

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

NOTE
The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.

IMPORTANT
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

IMPORTANT
You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.

- If you assigned the Owner role to your service account, you can remove that role and replace it with the Viewer role.

- If you included the Service Account Key Admin role, you can remove it.
12.3.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster’s version:

   $ oc get clusterversion

4. View your Operators’ status:

   $ oc get clusteroperator

5. View all running pods in the cluster:

   $ oc get pods -A

12.3.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   `$ oc whoami`

   **Example output**

   `system:admin`

### 12.3.16. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

### 12.4. INSTALLING A CLUSTER ON OPENSTACK THAT SUPPORTS SR-IOV-CONNECTED COMPUTE MACHINES

In OpenShift Container Platform version 4.8, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that can use compute machines with single-root I/O virtualization (SR-IOV) technology.

#### 12.4.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
  - Verify that OpenShift Container Platform 4.8 is compatible with your RHOSP version by using the “Supported platforms for OpenShift clusters” section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- Verify that your network configuration does not rely on a provider network. Provider networks are not supported.
- Have a storage service installed in RHOSP, like block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.
- Have metadata service enabled in RHOSP

#### 12.4.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

<table>
<thead>
<tr>
<th>Table 12.15. Recommended resources for a default OpenShift Container Platform cluster on RHOSP</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table 12.15. Recommended resources for a default OpenShift Container Platform cluster on RHOSP</strong></td>
</tr>
</tbody>
</table>

1691
### Resource | Value
---|---
Floating IP addresses | 3
Ports | 15
Routers | 1
Subnets | 1
RAM | 112 GB
vCPUs | 28
Volume storage | 275 GB
Instances | 7
Security groups | 3
Security group rules | 60

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

#### 12.4.2.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

Additionally, for clusters that use single-root input/output virtualization (SR-IOV), RHOSP compute nodes require a flavor that supports huge pages.

**IMPORTANT**

SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

**Additional resources**

- For more information about configuring performant RHOSP compute nodes, see Configuring Compute nodes for performance.

**12.4.2.2. Bootstrap machine**

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**12.4.3. Internet and Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.8, you require access to the Internet to obtain the images that are necessary to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.4.4. Enabling Swift on RHOSP

Swift is operated by a user account with the `swiftoperator` role. Add the role to an account before you run the installation program.

**IMPORTANT**

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

**Prerequisites**

• You have a RHOSP administrator account on the target environment.

• The Swift service is installed.

• On Ceph RGW, the `account in url` option is enabled.

**Procedure**

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the `swiftoperator` role to the account that will access Swift:

   ```
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

   Your RHOSP deployment can now use Swift for the image registry.

12.4.5. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).
Prerequisites

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```bash
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   Example output

   ```
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

   **NOTE**

   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

12.4.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the `clouds.yaml` file:

   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

     **IMPORTANT**

     Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

     ```yaml
     clouds:
     shiftstack:
     auth:
     project_name: shiftstack
     ```
If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

a. Copy the certificate authority file to your machine.

b. Add the machine to the certificate authority trust bundle:

   ```
   $ sudo cp ca.crt.pem /etc/pki/ca-trust/source/anchors/
   ```

c. Update the trust bundle:

   ```
   $ sudo update-ca-trust extract
   ```

d. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```
   clouds:
   shiftstack:
   ...
   cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
   ```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

   ```
   $ oc edit configmap -n openshift-config cloud-provider-config
   ```

3. Place the `clouds.yaml` file in one of the following locations:

   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable

   b. The current directory

   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

   The installation program searches for `clouds.yaml` in that order.

12.4.7. Obtaining the installation program
Before you install OpenShift Container Platform, download the installation file on the mirror host.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. From the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

**12.4.8. Creating the installation configuration file**

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your bastion host.

- Have the **imageContentSources** values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.
Procedure

1. Create the **install-config.yaml** file.
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir=<installation_directory>  
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**
   
   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:
      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**
      
      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `gcp` as the platform to target.

      iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

      iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

      v. Select the region to deploy the cluster to.

      vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

      vii. Enter a descriptive name for your cluster.

      viii. Paste the pull secret that you obtained from the Pull Secret page on the Red Hat OpenShift Cluster Manager site.

2. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:
For `<bastion_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```
additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Define the network and subnets for the VPC to install the cluster in under the parent `platform.gcp` field:

```
network: <existing_vpc>
controlPlaneSubnet: <control_plane_subnet>
computeSubnet: <compute_subnet>
```

For `platform.gcp.network`, specify the name for the existing Google VPC. For `platform.gcp.controlPlaneSubnet` and `platform.gcp.computeSubnet`, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

d. Add the image content resources, which look like this excerpt:

```
imageContentSources:
  - mirrors:
    - <bastion_host_name>:5000/<repo_name>/release
      source: quay.example.com/openshift-release-dev/ocp-release
    - mirrors:
      - <bastion_host_name>:5000/<repo_name>/release
        source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

3. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.
12.4.8.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:  
     httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
     noProxy: example.com  # 3
   additionalTrustBundle: |  # 4
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   ...
   
   A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an `httpProxy` value.
A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then httpProxy is used for both HTTP and HTTPS connections. If you use an

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

12.4.9. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

NOTE
After installation, you cannot modify these parameters in the install-config.yaml file.

IMPORTANT
The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.4.9.1. Required configuration parameters
Required installation configuration parameters are described in the following table:

### Table 12.16. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
12.4.9.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.17. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from <a href="https://cloud.redhat.com/openshift/install/pull-secret">https://cloud.redhat.com/openshift/install/pull-secret</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td><code>{  &quot;auths&quot;:{  &quot;cloud.openshift.com&quot;:{    &quot;auth&quot;:&quot;b3Blb=&quot;,    &quot;email&quot;:&quot;you@example.com&quot;  },  &quot;quay.io&quot;:{    &quot;auth&quot;:&quot;b3Blb=&quot;,    &quot;email&quot;:&quot;you@example.com&quot;  }  }  }</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td><code>networking:</code>&lt;br&gt;<code>serviceNetwork:</code>&lt;br&gt;<code>- 172.30.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>networking:</code>&lt;br&gt;<code>machineNetwork:</code>&lt;br&gt;<code>- cidr: 10.0.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NOTE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set the <code>networking.machineNetwork</code> to match the CIDR that the preferred NIC resides in.</td>
</tr>
</tbody>
</table>

12.4.9.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 12.18. Optional parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>additionalTrustBundle</strong></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute</strong></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute.hyperthreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td><strong>compute.name</strong></td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
<tr>
<td><strong>compute.platform</strong></td>
<td>Required if you use <strong>compute</strong>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td><strong>aws</strong>, <strong>azure</strong>, <strong>gcp</strong>, <strong>openstack</strong>, <strong>ovirt</strong>, <strong>vsphere</strong>, or <strong>{}</strong></td>
</tr>
<tr>
<td><strong>compute.replicas</strong></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>

<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><strong>publish</strong></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to Internal. The default value is External.</td>
</tr>
</tbody>
</table>
The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 12.4.9.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.gcp.network</td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.gcp.type</td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td>platform.gcp.zones</td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAML sequence.</td>
</tr>
<tr>
<td>platform.gcp.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.computeSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.name</td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.location</td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.name</td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.location</td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

12.4.9.5. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.
Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

12.4.9.6. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an `inventory.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `inventory.yaml` file, edit the flavors for machines:
   a. If you want to use bare-metal control plane machines, change the value of
If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.

b. Change the value of `os_flavor_worker` to a bare metal flavor.

### An example bare metal inventory.yaml file

```yaml
all:
  hosts:
    localhost:
      ansible_connection: local
      ansible_python_interpreter: "{{ansible_playbook_python}}"

# User-provided values
os_subnet_range: '10.0.0.0/16'
os_flavor_master: 'my-bare-metal-flavor'
os_flavor_worker: 'my-bare-metal-flavor'
os_image_rhcos: 'rhcos'
os_external_network: 'external'
...
```

1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

2. Change this value to a bare metal flavor to use for compute machines.

Use the updated `inventory.yaml` file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

**NOTE**

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

### 12.4.9.7. Sample customized install-config.yaml file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.
12.4.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"

3. Verify that the credentials were applied.

   $ gcloud auth list

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

12.4.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

12.4.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   api.<cluster_name>.<base_domain>. IN A <API_FIP>

   *apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
NOTE

If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

4. Add the FIPs to the install-config.yaml file as the values of the following parameters:

- platform.openstack.ingressFloatingIP
- platform.openstack.apiFloatingIP

If you use these values, you must also enter an external network as the value of the platform.openstack.externalNetwork parameter in the install-config.yaml file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.4.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the file, do not define the following

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

12.4.12. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports single root I/O virtualization (SR-IOV), you can provision SR-IOV networks that compute machines run on.

NOTE

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.
Prerequisites

- Your cluster supports SR-IOV.

NOTE
If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.

- You created radio and uplink provider networks as part of your RHOSP deployment. The names radio and uplink are used in all example commands to represent these networks.

Procedure

1. On a command line, create a radio RHOSP network:

   $ openstack network create radio --provider-physical-network radio --provider-network-type flat --external

2. Create an uplink RHOSP network:

   $ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external

3. Create a subnet for the radio network:

   $ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio

4. Create a subnet for the uplink network:

   $ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink

12.4.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure
1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCloud_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir=<installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   **Example output**

   ```
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s
   ```

   **NOTE**

   The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kublet certificates. See the documentation for `Recovering from expired control plane certificates` for more information.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
   
   - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
   
   - If you included the **Service Account Key Admin** role, you can remove it.

12.4.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```bash
   $ oc get nodes
   ```

3. View your cluster's version:

   ```bash
   $ oc get clusterversion
   ```

4. View your Operators' status:

   ```bash
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:
12.4.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

   The cluster is operational. Before you can add SR-IOV compute machines though, you must perform additional tasks.

12.4.16. Preparing a cluster that runs on RHOSP for SR-IOV

Before you use single root I/O virtualization (SR-IOV) on a cluster that runs on Red Hat OpenStack Platform (RHOSP), make the RHOSP metadata service mountable as a drive and enable the No-IOMMU Operator for the virtual function I/O (VFIO) driver.

12.4.16.1. Enabling the RHOSP metadata service as a mountable drive

You can apply a machine config to your machine pool that makes the Red Hat OpenStack Platform (RHOSP) metadata service available as a mountable drive.

The following machine config enables the display of RHOSP network UUIDs from within the SR-IOV Network Operator. This configuration simplifies the association of SR-IOV resources to cluster SR-IOV resources.

Procedure

```
1. Create a machine config file from the following template:

**A mountable metadata service machine config file**

```yaml
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 20-mount-config
labels:
  machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    systemd:
      units:
      - name: create-mountpoint-var-config.service
        enabled: true
        contents:
        [Unit]
        Description=Create mountpoint /var/config
        Before=kubelet.service
        [Service]
        ExecStart=/bin/mkdir -p /var/config
        [Install]
        WantedBy=var-config.mount
      - name: var-config.mount
        enabled: true
        contents:
        [Unit]
        Before=local-fs.target
        [Mount]
        Where=/var/config
        What=/dev/disk/by-label/config-2
        [Install]
        WantedBy=local-fs.target
```

You can substitute a name of your choice.

2. From a command line, apply the machine config:

```
$ oc apply -f <machine_config_file_name>.yaml
```

### 12.4.16.2. Enabling the No-IOMMU feature for the RHOSP VFIO driver

You can apply a machine config to your machine pool that enables the No-IOMMU feature for the Red Hat OpenStack Platform (RHOSP) virtual function I/O (VFIO) driver. The RHOSP vfio-pci driver requires this feature.

**Procedure**
1. Create a machine config file from the following template:

**A No-IOMMU VFIO machine config file**

```yaml
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 99-vfio-noiommu
labels:
  machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      files:
        - path: /etc/modprobe.d/vfio-noiommu.conf
          mode: 0644
          contents:
            source: data;base64,b3B0aW9ucyB2ZmlvIGVuYWJsZV91bnNhZmVfbm9pb21tdV9tb2RIPI
```

You can substitute a name of your choice.

2. From a command line, apply the machine config:

```bash
$ oc apply -f <machine_config_file_name>.yaml
```

The cluster is installed and prepared for SR-IOV configuration. Complete the post-installation SR-IOV tasks that are listed in the "Next steps" section.

### 12.4.17. Next steps

- To complete SR-IOV configuration for your cluster:
  - Install the Performance Addon Operator.
  - Configure the Performance Addon Operator with huge pages support.
  - Install the SR-IOV Operator.
  - Configure your SR-IOV network device.
  - Add an SR-IOV compute machine set.

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.

- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.

- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.
12.5. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.8, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

12.5.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.8 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine from which you run the installation program, you have:
  - A single directory in which you can keep the files you create during the installation process
  - Python 3

12.5.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to obtain the images that are necessary to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.5.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 12.20. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the swiftoperator role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.
NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 12.5.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 12.5.3.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

### 12.5.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules’ repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.
Procedure

1. On a command line, add the repositories:
   a. Register with Red Hat Subscription Manager:
      $ sudo subscription-manager register # If not done already
   b. Pull the latest subscription data:
      $ sudo subscription-manager attach --pool={$YOUR_POOLID} # If not done already
   c. Disable the current repositories:
      $ sudo subscription-manager repos --disable=* # If not done already
   d. Add the required repositories:
      $ sudo subscription-manager repos \ 
        --enable=rhel-8-for-x86_64-baseos-rpms \ 
        --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \ 
        --enable=ansible-2.9-for-rhel-8-x86_64-rpms \ 
        --enable=rhel-8-for-x86_64-appstream-rpms

2. Install the modules:
   $ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr

3. Ensure that the python command points to python3:
   $ sudo alternatives --set python /usr/bin/python3

12.5.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

  $ xargs -n 1 curl -O <<<'
  https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/bootstrap.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/common.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/compute-nodes.yaml'
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 12.5.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   `$ tar xvf openshift-install-linux.tar.gz`

5. From the Pull Secret page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

12.5.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①

   ① Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   $ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   **NOTE**

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      **Example output**

      Agent pid 31874

      If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

      1. Add your SSH private key to the ssh-agent:

         $ ssh-add <path>/<file_name> ①
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"

3. Verify that the credentials were applied.

   $ gcloud auth list

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

12.5.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

2. Under Version, select the most recent release of OpenShift Container Platform 4.8 for Red Hat Enterprise Linux (RHEL) 8.

   IMPORTANT

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW).

4. Decompress the image.
NOTE

You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like `.gz` or `.tgz`. To find out if or how the file is compressed, in a command line, enter:

```bash
$ file <name_of_downloaded_file>
```

5. From the image that you downloaded, create an image that is named `rhcos` in your cluster by using the RHOSP CLI:

```bash
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-
$[RHCOS_VERSION]-openstack.qcow2 rhcos
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either `.raw` or `.qcow2` formats. If you use Ceph, you must use the `.raw` format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

12.5.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```bash
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   Example output

   ```bash
   +---------------------------------------------------+--------------+------------------+
   | ID | Name | Router Type |
   +---------------------------------------------------+--------------+------------------+
   ```
A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

NOTE
If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

12.5.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

12.5.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   ```
   $ openstack floating ip create --description "bootstrap machine" <external_network>
   ```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```
NOTE

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:

   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.5.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `inventory.yaml` file, do not define the following variables:

   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

If you cannot provide an external network, you can also leave `os_external_network` blank. If you do not provide a value for `os_external_network`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the `wait-for` command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.
NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

\[
\text{api.<cluster_name>..<base_domain>. IN A <api_port_IP>}
\]

\[
\text{*.apps.<cluster_name>..<base_domain>. IN A <ingress_port_IP>}
\]

If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

12.5.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, login information, and authorization service URLs.

Procedure

1. Create the `clouds.yaml` file:

   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

     **IMPORTANT**

     Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

     ```yaml
     clouds:
     shiftstack:
         auth:
             project_name: shiftstack
             username: shiftstack_user
             password: XXX
             user_domain_name: Default
             project_domain_name: Default
     dev-env:
         region_name: RegionOne
         auth:
             username: 'devuser'
             password: XXX
             project_name: 'devonly'
     
     2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

        a. Copy the certificate authority file to your machine.
b. Add the machine to the certificate authority trust bundle:

   $ sudo cp ca.crt.pem /etc/pki/ca-trust/source/anchors/

c. Update the trust bundle:

   $ sudo update-ca-trust extract

d. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```yaml
   clouds:
     shiftstack:
     ...
     cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
   ```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

   $ oc edit configmap -n openshift-config cloud-provider-config

3. Place the `clouds.yaml` file in one of the following locations:

   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable

   b. The current directory

   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

   The installation program searches for `clouds.yaml` in that order.

12.5.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP). Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your bastion host.

- Have the `imageContentSources` values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following
1. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir=<installation_directory>
```

For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `gcp` as the platform to target.

iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

v. Select the region to deploy the cluster to.

vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

vii. Select `openstack` as the platform to target.

viii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

ix. Specify the floating IP address to use for external access to the OpenShift API.

x. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

xi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
Enter a name for your cluster. The name must be 14 or fewer characters long.

Paste the pull secret that you obtained from the Pull Secret page on the Red Hat OpenShift Cluster Manager site.

2. In the install-config.yaml file, set the value of platform.openstack.clusterOSImage to the image location or name. For example:

```yaml
platform:
  openstack:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-
                  openstack.x86_64.qcow2.gz?
    sha256=ffe8bbd68e8a12a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
```

3. Edit the install-config.yaml file to provide the additional information that is required for an installation in a restricted network.

a. Update the pullSecret value to contain the authentication information for your registry:

```yaml
pullSecret: \{"auths":\{"<bastion_host_name>:5000":\{"auth": \"<credentials\\\",\"email":
    \"you@example.com\"\\}\}\}
```

For `<bastion_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the additionalTrustBundle parameter and value.

```yaml
additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file `install-config.yaml` in the directory that you specified.

12.5.13. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

   **NOTE**

   After installation, you cannot modify these parameters in the `install-config.yaml` file.

   **IMPORTANT**

   The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

12.5.13.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>
The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the `baseDomain` and `metadata.name` parameter values that uses the `<metadata.name>.<baseDomain>` format.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseDomain</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
<td></td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
### 12.5.13.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from <code>https://cloud.redhat.com/openshift/install/pull-secret</code> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auths&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;cloud.openshift.com&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>},</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;quay.io&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

**Table 12.22. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NOTE</td>
</tr>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- hostPrefix: 23</td>
</tr>
</tbody>
</table>

The default value is `10.128.0.0/14` with a host prefix of `/23`. If you specify multiple IP address blocks, the blocks must not overlap.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 ((2^{32} - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16. NOTE Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.</td>
</tr>
</tbody>
</table>

12.5.13.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 12.23. Optional parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <code>hypertreading</code>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is <code>3</code>, which is the default value.</td>
</tr>
</tbody>
</table>
The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><code>false</code> or <code>true</code></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to <code>Internal</code>. The default value is <code>External</code>.</td>
</tr>
</tbody>
</table>
**sshKey**

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 12.5.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 12.24. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example <strong>30</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example <strong>performance</strong>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.size</code></td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example <strong>30</strong>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.type</code></td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example <strong>performance</strong>.</td>
</tr>
<tr>
<td><code>platform.openstack.cloud</code></td>
<td>The name of the RHOSP cloud to use from the list of clouds in the <code>clouds.yaml</code> file.</td>
<td>String, for example <strong>MyCloud</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>platform.openstack.externalNetwork</td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td>platform.openstack.computeFlavor</td>
<td>The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.</td>
<td>String, for example m1.xlarge.</td>
</tr>
</tbody>
</table>

### 12.5.13.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

**Table 12.25. Optional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.additionalNetworkIDs</td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>compute.platform.openstack.additionalSecurityGroupIDs</td>
<td>Additional security groups that are associated with compute machines.</td>

<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.rootVolume.zones</td>
<td>For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImageProperties</td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;].</td>
</tr>
<tr>
<td></td>
<td>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td></td>
</tr>
<tr>
<td>platform.openstack.defaultMachinePlatform</td>
<td>The default machine pool platform configuration.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;type&quot;: &quot;ml.large&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;rootVolume&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;size&quot;: 30,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;type&quot;: &quot;performance&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td>platform.openstack.ingressFloatingIP</td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.openstack.apiFloatingIP</td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
</tbody>
</table>
### Parameter | Description | Values
---|---|---
**platform.openstack.externalDNS** | IP addresses for external DNS servers that cluster instances use for DNS resolution. | A list of IP addresses as strings. For example, ["8.8.8.8", "192.168.1.12"].

**platform.openstack.machinesSubnet** | The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet. The first item in `networking.machineNetwork` must match the value of `machinesSubnet`. If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP. | A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.

---

### 12.5.13.6. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

#### Table 12.26. Additional GCP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform.gcp.network</strong></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><strong>platform.gcp.type</strong></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><strong>platform.gcp.zones</strong></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><strong>platform.gcp.controlPlaneSubnet</strong></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><strong>platform.gcp.computeSubnet</strong></td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>controlPlane.platfor m.gcp.osDisk.encryptionKey.kmsKey.name</code></td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td><code>controlPlane.platfor m.gcp.osDisk.encryptionKey.kmsKey.keyRing</code></td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><code>controlPlane.platfor m.gcp.osDisk.encryptionKey.kmsKey.location</code></td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>controlPlane.platfor m.gcp.osDisk.encryptionKey.kmsKey.projectID</code></td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryptionKey.kmsKey.name</code></td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryptionKey.kmsKey.keyRing</code></td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryptionKey.kmsKey.location</code></td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryptionKey.kmsKey.projectID</code></td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

12.5.13.7. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.
This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

### 12.5.13.8. Sample customized install-config.yaml file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.
12.5.13.9. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:

   - To set the value by using a script, run:

     ```
     $ python -c 'import yaml; path = "install-config.yaml"; data = yaml.safe_load(open(path)); data["networking"]["machineNetwork"] = [{"cidr": "192.168.0.0/18"}]; open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```

     Insert a value that matches your intended Neutron subnet, e.g. `192.0.2.0/24`.

   - To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.
12.5.13.10. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

**Prerequisites**

- You have the *install-config.yaml* file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains *install-config.yaml*.

2. From that directory, either run a script to edit the *install-config.yaml* file or update the file manually:

   - To set the value by using a script, run:
     ```python
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["compute"][0]["replicas"] = 0;
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     
   - To set the value manually, open the file and set the value of *compute.<first entry>.replicas* to 0.

12.5.13.11. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the Internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

**NOTE**

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

### 12.5.13.11.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The **RHOSP networking service (Neutron) is enabled** and accessible through the RHOSP networking API.
- The RHOSP networking service has the **port security and allowed address pairs extensions** enabled.
The provider network can be shared with other tenants.

**TIP**

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

**TIP**

- **To create a network for a project that is named "openshift," enter the following command**
  
  ```
  $ openstack network create --project openshift
  ```

- **To create a subnet for a project that is named "openshift," enter the following command**
  
  ```
  $ openstack subnet create --project openshift
  ```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is `169.254.169.254` by default.
  
  Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

  ```
  $ openstack subnet create --dhcp --host-route destination=169.254.169.254/32,gateway=192.0.2.2 ...
  ```

- **Optional:** To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

### 12.5.13.11.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

**Prerequisites**

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".
1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIP` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIP` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...  
platform:
  openstack:
    apiVIP: 192.0.2.13
    ingressVIP: 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
  (...)
networking:
  machineNetwork:
    - cidr: 192.0.2.0/24
```

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.

**TIP**

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).
12.5.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir=<installation_directory>  
   ```

   **Example output**

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:
Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   $ rm -f openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   
   Because you create and manage these resources yourself, you do not have to initialize them.
   
   - You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

5. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   
   c. Save and exit the file.

6. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
   name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
     id: mycluster-100419-private-zone
     publicZone: 2
     id: example.openshift.com
   status: {}
   ```

   Remove this section completely.

   If you do so, you must add ingress DNS records manually in a later step.

7. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir=<installation_directory> 1
   
   1 For `<installation_directory>`, specify the same installation directory.
Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `/<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   │   └── kubeconfig
│   └── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

8. Export the metadata file's `infraID` key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

**TIP**

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

### 12.5.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

**Prerequisites**

- You have the bootstrap Ignition file that the installer program generates, `bootstrap.ign`.
- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files.
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

**Procedure**

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the host name and, if available, CA certificate file when it runs:

```python
import base64
import json
import os
```
with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()
files.append(
    
    'path': '/etc/hostname',
    'mode': 420,
    'contents': {
        'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
    }
)

ca_cert_path = os.environ.get('OS_CACERT', '')
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

files.append(
    
    'path': '/opt/openshift/tls/cloud-ca-cert.pem',
    'mode': 420,
    'contents': {
        'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64
    }
)

ignition['storage']['files'] = files;

with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)

2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

   $ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>

3. Get the image's details:

   $ openstack image show <image_name>

   Make a note of the file value; it follows the pattern v2/images/<image_ID>/file.

   NOTE

   Verify that the image you created is active.

4. Retrieve the image service's public address:
5. Combine the public address with the image file value and save the result as the storage location. The location follows the pattern 

6. Generate an auth token and save the token ID:

```bash
$ openstack token issue -c id -f value
```

7. Insert the following content into a file called $INFRA_ID-bootstrap-ignition.json and edit the placeholders to match your own values:

```json
{
    "ignition": {
        "config": {
            "merge": [{
                "source": "<storage_url>" ①,
                "httpHeaders": [{
                    "name": "X-Auth-Token" ②,
                    "value": "<token_ID>" ③
                }]
            }]
        },
        "security": {
            "tls": {
                "certificateAuthorities": [{
                    "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>" ④
                }]
            },
            "version": "3.2.0"
        }
    }
}
```

① Replace the value of ignition.config.merge.source with the bootstrap Ignition file storage URL.

② Set name in httpHeaders to "X-Auth-Token".

③ Set value in httpHeaders to your token’s ID.

④ If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.
WARNING

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

12.5.16. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

NOTE

As with the bootstrap Ignition configuration, you must explicitly define a host name for each control plane machine.

Prerequisites

- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

  ```bash
  $ for index in $(seq 0 2); do
     MASTER_HOSTNAME="$INFRA_ID-master-$index"
     python -c "import base64, json, sys;
     ignition = json.load(sys.stdin);
     storage = ignition.get('storage', {});
     files = storage.get('files', []);
     files.append({
         'path': '/etc/hostname',
         'mode': 420,
         'contents': 
             { 'source':
                 'data:text/plain;charset=utf-8;base64,' +
                 base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(),
                 'verification': {}},
         'filesystem': 'root'});
     storage['files'] = files;
     json.dump(ignition, sys.stdout)
  " <master.ign >"$INFRA_ID-master-$index-ignition.json"
  done
  
  You now have three control plane Ignition files: `<INFRA_ID>-master-0-ignition.json`, `<INFRA_ID>-master-1-ignition.json`, and `<INFRA_ID>-master-2-ignition.json`.

12.5.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.
Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the `inventory.yaml` playbook:

   **Example external network value in the inventory.yaml Ansible playbook**

   ```yaml
   ...
   # The public network providing connectivity to the cluster. If not
   # provided, the cluster external connectivity must be provided in another
   # way.

   # Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
   os_external_network: 'external'
   ...
   ```

   **IMPORTANT**

   If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

   **Example FIP values in the inventory.yaml Ansible playbook**

   ```yaml
   ...
   # OpenShift API floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the Control Plane to
   # serve the OpenShift API.
   os_api_fip: '203.0.113.23'

   # OpenShift Ingress floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the worker nodes to serve
   # the applications.
   os_ingress_fip: '203.0.113.19'

   # If this value is non-empty, the corresponding floating IP will be
   # attached to the bootstrap machine. This is needed for collecting logs
   # in case of install failure.
   os_bootstrap_fip: '203.0.113.20'
   ```
**IMPORTANT**

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform post-installation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See “Enabling access to the environment” for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml security-groups.yaml
   ```

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml network.yaml
   ```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

   ```bash
   $ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
   ```

   Optionally, you can use the `inventory.yaml` file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

### 12.5.17.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP **Bare Metal service (Ironic)** is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a **RHOSP flavor**.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.

You created an `inventory.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `inventory.yaml` file, edit the flavors for machines:
   
a. If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.

b. Change the value of `os_flavor_worker` to a bare metal flavor.

**An example bare metal inventory.yaml file**

```yaml
all:
  hosts:
    localhost:
      ansible_connection: local
      ansible_python_interpreter: "{{ansible_playbook_python}}"

# User-provided values
os_subnet_range: '10.0.0.0/16'
os_flavor_master: 'my-bare-metal-flavor'
os_flavor_worker: 'my-bare-metal-flavor'
os_image_rhcos: 'rhcos'
os_external_network: 'external'
...

1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

2. Change this value to a bare metal flavor to use for compute machines.

Use the updated `inventory.yaml` file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

**NOTE**

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

**12.5.18. Creating the bootstrap machine on RHOSP**

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.
Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `bootstrap.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `bootstrap.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml bootstrap.yaml
   ```

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

   ```bash
   $ openstack console log show "$INFRA_ID-bootstrap"
   ```

12.5.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
- The `inventory.yaml`, `common.yaml`, and `control-plane.yaml` Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. If the control plane Ignition config files aren't already in your working directory, copy them into it.

3. On a command line, run the `control-plane.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml control-plane.yaml
   ```
4. Run the following command to monitor the bootstrapping process:

```
$ openshift-install wait-for bootstrap-complete
```

You will see messages that confirm that the control plane machines are running and have joined the cluster:

```
INFO API v1.14.6+f9b5405 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

**12.5.20. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```

   Example output

   `system:admin`

**12.5.21. Deleting bootstrap resources from RHOSP**

Delete the bootstrap resources that you no longer need.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

```
1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `down-bootstrap.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml
   ```

   The bootstrap port, server, and floating IP address are deleted.

   **WARNING**

   If you did not disable the bootstrap Ignition file URL earlier, do so now.

12.5.22. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `compute-nodes.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml compute-nodes.yaml
   ```

   **Next steps**
12.5.23. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>NotReady</td>
<td>worker</td>
<td>76s</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>NotReady</td>
<td>worker</td>
<td>70s</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.
3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>  
  
  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
  ```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>  
  ``

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template="{{range $.items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

  ```bash
  $ oc get nodes
  ``

**Example output**

```plaintext
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  73m  v1.21.0
master-1  Ready     master  73m  v1.21.0
master-2  Ready     master  74m  v1.21.0
worker-0  Ready     worker  11m  v1.21.0
worker-1  Ready     worker  11m  v1.21.0
```

Additional information

- For more information on CSRs, see Certificate Signing Requests.

### 12.5.24. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

**Prerequisites**

- You have the installation program (*openshift-install*)

**Procedure**

- On a command line, enter:
$ openshift-install --log-level debug wait-for install-complete

The program outputs the console URL, as well as the administrator’s login information.

12.5.25. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.6. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.8, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

12.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.8 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine from which you run the installation program, you have:
  - A single directory in which you can keep the files you create during the installation process
  - Python 3

12.6.2. About Kuryr SDN

Kuryr is a container network interface (CNI) plug-in solution that uses the Neutron and Octavia Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container
Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the openshift-kuryr namespace:

- **kuryr-controller** - a single service instance installed on a master node. This is modeled in OpenShift Container Platform as a Deployment object.

- **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a DaemonSet object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The ovn-octavia Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

### 12.6.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster’s minimum requirements:

<table>
<thead>
<tr>
<th>Table 12.27. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource</td>
</tr>
<tr>
<td>---------</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3 - plus the expected number of Services of LoadBalancer type</td>
</tr>
<tr>
<td>Ports</td>
<td>1500 - 1 needed per Pod</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>Networks</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>250 - 1 needed per Service and per NetworkPolicy</td>
</tr>
<tr>
<td>Security group rules</td>
<td>1000</td>
</tr>
<tr>
<td>Load balancers</td>
<td>100 - 1 needed per Service</td>
</tr>
<tr>
<td>Load balancer listeners</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
<tr>
<td>Load balancer pools</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**IMPORTANT**

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:
The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods' booting time.

Each network policy is mapped into an RHOSP security group, and depending on the NetworkPolicy spec, one or more rules are added to the security group.

Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota. If you are using RHOSP version 15 or earlier, or the ovn-octavia driver, each load balancer has a security group with the user project.

The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment’s size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them. If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
- Use openvswitch firewall driver if ML2/OVS Neutron driver is used instead of ovs-hybrid.

12.6.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

**Procedure**

- Increase the quotas for a project by running the following command:

  ```
  $ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
  ```

12.6.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the trunks extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to openvswitch instead of ovs_hybrid so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

12.6.3.3. Configuring Octavia
Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)'s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

**NOTE**

The following steps only capture the key pieces required during the deployment of RHOSP when dealing with Octavia. It is also important to note that registry methods vary.

This example uses the local registry method.

**Procedure**

1. If you are using the local registry, create a template to upload the images to the registry. For example:

   ```bash
   (undercloud) $ openstack overcloud container image prepare \
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
   --namespace=registry.access.redhat.com/rhosp13 \
   --push-destination=<local-ip-from-undercloud.conf>:8787 \
   --prefix=openstack- \
   --tag-from-label {version}-{product-version} \
   --output-env-file=/home/stack/templates/overcloud_images.yaml \
   --output-images-file /home/stack/local_registry_images.yaml
   ...
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
     push_destination: <local-ip-from-undercloud.conf>:8787
   ```

2. Verify that the `local_registry_images.yaml` file contains the Octavia images. For example:

   ```yaml
   ...
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
     push_destination: <local-ip-from-undercloud.conf>:8787
   ```

   **NOTE**

   The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from `registry.redhat.io` to the Undercloud node:

   ```bash
   (undercloud) $ sudo openstack overcloud container image upload \
   --config-file /home/stack/local_registry_images.yaml \
   --verbose
   ```

   This may take some time depending on the speed of your network and Undercloud disk.
4. Since an Octavia load balancer is used to access the OpenShift Container Platform API, you must increase their listeners’ default timeouts for the connections. The default timeout is 50 seconds. Increase the timeout to 20 minutes by passing the following file to the Overcloud deploy command:

(undercloud) $ cat octavia_timeouts.yaml
parameter_defaults:
  OctaviaTimeoutClientData: 1200000
  OctaviaTimeoutMemberData: 1200000

**NOTE**
This is not needed for RHOSP 13.0.13+.

5. Install or update your Overcloud environment with Octavia:

$ openstack overcloud deploy --templates
  -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml
  -e octavia_timeouts.yaml

**NOTE**
This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see installation of Octavia using Director.

**NOTE**
When leveraging Kuryr SDN, the Overcloud installation requires the Neutron trunk extension. This is available by default on director deployments. Use the opensvswitch firewall instead of the default ovsv-hybrid when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

6. In RHOSP versions earlier than 13.0.13, add the project ID to the octavia.conf configuration file after you create the project.

- To enforce network policies across services, like when traffic goes through the Octavia load balancer, you must ensure Octavia creates the Amphora VM security groups on the user project.
  This change ensures that required load balancer security groups belong to that project, and that they can be updated to enforce services isolation.

**NOTE**
This task is unnecessary in RHOSP version 13.0.13 or later.

Octavia implements a new ACL API that restricts access to the load balancers VIP.

a. Get the project ID
b. Add the project ID to `octavia.conf` for the controllers.

i. Source the `stackrc` file:

```
$ source stackrc  # Undercloud credentials
```

ii. List the Overcloud controllers:

```
$ openstack server list
```

Example output

```
+--------------------------------------+--------------+--------+-----------------------+-------|
| ID                                   | Name         | Status | Networks              |-------|
| Image          | Flavor       |        |                        |-------|
| 6bef8e73-2ba5-4860-a0b1-3937f8ca7e01 | controller-0 | ACTIVE | ctlplane=192.168.24.8   | overcloud-full | controller |
| dda3173a-ab26-47f8-a2dc-8473b4a67ab9 | compute-0    | ACTIVE | ctlplane=192.168.24.6   | overcloud-full | compute   |
```

iii. SSH into the controller(s).

```
$ ssh heat-admin@192.168.24.8
```

iv. Edit the `octavia.conf` file to add the project into the list of projects where Amphora security groups are on the user’s account.
# List of project IDs that are allowed to have Load balancer security groups belonging to them.

```
amp_secgroup_allowed_projects = PROJECT_ID
```

c. Restart the Octavia worker so the new configuration loads.

```bash
controller-0$ sudo docker restart octavia_worker
```

**NOTE**

Depending on your RHOSP environment, Octavia might not support UDP listeners. If you use Kuryr SDN on RHOSP version 13.0.13 or earlier, UDP services are not supported. RHOSP version 16 or later support UDP.

### 12.6.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```bash
$ openstack loadbalancer provider list
```

**Example output**

```
+---------+-------------------------------------------------+
| name    | description                                     |
+---------+-------------------------------------------------+
| amphora | The Octavia Amphora driver.                     |
| octavia | Deprecated alias of the Octavia Amphora driver. |
| ovn     | Octavia OVN driver.                             |
+---------+-------------------------------------------------+
```

Beginning with RHOSP version 16, the Octavia OVN provider driver (`ovn`) is supported on OpenShift Container Platform on RHOSP deployments.

`ovn` is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If `ovn` is enabled, however, Kuryr uses it.

If Kuryr uses `ovn` instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

### 12.6.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.
RHOSP general limitations
Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.

- Clusters that use the OVN Octavia provider driver support **Service** objects for which the .spec.selector property is unspecified only if the .subsets.addresses property of the **Endpoints** object includes the subnet of the nodes or pods.

- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.

RHOSP version limitations
Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources.

- Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.

- Octavia RHOSP versions before 13.0.13 do not support UDP listeners. Therefore, OpenShift Container Platform UDP services are not supported.

- Octavia RHOSP versions before 13.0.13 cannot listen to multiple protocols on the same port. Services that expose the same port to different protocols, like TCP and UDP, are not supported.

RHOSP environment limitations
There are limitations when using Kuryr SDN that depend on your deployment environment.

Because of Octavia’s lack of support for the UDP protocol and multiple listeners, if the RHOSP version is earlier than 13.0.13, Kuryr forces pods to use TCP for DNS resolution.

In Go versions 1.12 and earlier, applications that are compiled with CGO support disabled use UDP only. In this case, the native Go resolver does not recognize the **use-vc** option in **resolv.conf**, which controls whether TCP is forced for DNS resolution. As a result, UDP is still used for DNS resolution, which fails.

To ensure that TCP forcing is allowed, compile applications either with the environment variable **CGO_ENABLED** set to 1, i.e. **CGO_ENABLED=1**, or ensure that the variable is absent.

In Go versions 1.13 and later, TCP is used automatically if DNS resolution using UDP fails.

**NOTE**

musl-based containers, including Alpine-based containers, do not support the **use-vc** option.

RHOSP upgrade limitations
As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.
You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a load balancer failover.
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

**IMPORTANT**

If OpenShift Container Platform detects a new Octavia version that supports UDP load balancing, it recreates the DNS service automatically. The service recreation ensures that the service default supports UDP load balancing.

The recreation causes the DNS service approximately one minute of downtime.

### 12.6.3.5. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 12.6.3.6. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

### 12.6.4. Internet and Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.8, you require access to the Internet to obtain the images that are necessary to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 12.6.5. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

**NOTE**

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

**Prerequisites**

- Python 3 is installed on your machine.

**Procedure**

1. On a command line, add the repositories:
   
   a. Register with Red Hat Subscription Manager:
      
      ```
      $ sudo subscription-manager register # If not done already
      
      $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
      ```
c. Disable the current repositories:

```bash
$ sudo subscription-manager repos --disable=* # If not done already
```

d. Add the required repositories:

```bash
$ sudo subscription-manager repos \
    --enable=rhel-8-for-x86_64-baseos-rpms \
    --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
    --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
    --enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```bash
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
```

3. Ensure that the `python` command points to `python3`:

```bash
$ sudo alternatives --set python /usr/bin/python3
```

### 12.6.6. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

**Prerequisites**

- The curl command-line tool is available on your machine.

**Procedure**

- To download the playbooks to your working directory, run the following script from a command line:

```bash
$ xargs -n 1 curl -O <<< ' 
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/bootstrap.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/common.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/compute-nodes.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/control-plane.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/inventory.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/network.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/security-groups.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/downbootstrap.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.8/uapi/openstack/down-
```
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 12.6.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.
1. IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

2. IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. From the Pull Secret page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

12.6.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

3. IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an
existing key pair, ensure your public key is in the your ~/.ssh directory.

NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   $ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE
   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

   Example output

      Agent pid 31874

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

   1. Add your SSH private key to the ssh-agent:

      $ ssh-add <path>/<file_name> 1

      1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

      Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.
3. Verify that the credentials were applied.

   $ gcloud auth list

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 12.6.9. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

**Prerequisites**

- The RHOSP CLI is installed.

**Procedure**

2. Under Version, select the most recent release of OpenShift Container Platform 4.8 for Red Hat Enterprise Linux (RHEL) 8.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW).

4. Decompress the image.

   **NOTE**

   You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

   $ file <name_of_downloaded_file>

5. From the image that you downloaded, create an image that is named rhcos in your cluster by using the RHOSP CLI:
After you upload the image to RHOSP, it is usable in the installation process.

12.6.10. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```bash
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   **Example output**

   ```
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

   **NOTE**

   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.
12.6.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

12.6.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```sh
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```sh
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   ```sh
   $ openstack floating ip create --description "bootstrap machine" <external_network>
   ```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

   **NOTE**

   If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:

   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

   If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.
TIP
You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.6.11.2. Completing installation without floating IP addresses
You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the inventory.yaml file, do not define the following variables:

- os_api_fip
- os_bootstrap_fip
- os_ingress_fip

If you cannot provide an external network, you can also leave os_external_network blank. If you do not provide a value for os_external_network, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the wait-for command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE
You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>

If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

12.6.12. Defining parameters for the installation program
The OpenShift Container Platform installation program relies on a file that is called clouds.yaml. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure
1. Create the clouds.yaml file:
   - If your RHOSP distribution includes the Horizon web UI, generate a clouds.yaml file in it.
IMPORTANT

Remember to add a password to the auth field. You can also keep secrets in a separate file from clouds.yaml.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
  dev-env:
    region_name: RegionOne
    auth:
      username: 'devuser'
      password: XXX
      project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   a. Copy the certificate authority file to your machine.
   b. Add the machine to the certificate authority trust bundle:
      ```bash
      $ sudo cp ca.crt.pem /etc/pki/ca-trust/source/anchors/
      ```
   c. Update the trust bundle:
      ```bash
      $ sudo update-ca-trust extract
      ```
   d. Add the cacerts key to the clouds.yaml file. The value must be an absolute, non-root-accessible path to the CA certificate:
      ```yaml
      clouds:
        shiftstack:
          ... 
        cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
      ```
TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:

    a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
    b. The current directory
    c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
    d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

   The installation program searches for `clouds.yaml` in that order.

12.6.13. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP). Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your bastion host.

- Have the `imageContentSources` values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create the `install-config.yaml` file.

    a. Change to the directory that contains the installation program and run the following command:

    ```
    $ ./openshift-install create install-config --dir=<installation_directory> 1
    ```

    1 For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select gcp as the platform to target.

iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

v. Select the region to deploy the cluster to.

vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

vii. Select openstack as the platform to target.

viii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

ix. Specify the floating IP address to use for external access to the OpenShift API.

x. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

xi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

xii. Enter a name for your cluster. The name must be 14 or fewer characters long.

xiii. Paste the pull secret that you obtained from the Pull Secret page on the Red Hat OpenShift Cluster Manager site.

2. In the install-config.yaml file, set the value of platform.openstack.clusterOSImage to the image location or name. For example:

```yaml
platform:
```
3. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: "{"auths":{"<bastion_host_name>:5000": {"auth": "<credentials>", "email": "you@example.com"}}}
   
   For `<bastion_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.
   
   b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle:
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
   
   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.
   
   c. Define the network and subnets for the VPC to install the cluster in under the parent `platform.gcp` field:

   ```yaml
   network: `<existing_vpc>`
   controlPlaneSubnet: `<control_plane_subnet>`
   computeSubnet: `<compute_subnet>`
   
   For `platform.gcp.network`, specify the name for the existing Google VPC. For `platform.gcp.controlPlaneSubnet` and `platform.gcp.computeSubnet`, specify the existing subnets to deploy the control plane machines and compute machines, respectively.
   
   d. Add the image content resources, which look like this excerpt:

   ```yaml
   imageContentSources:
   - mirrors:
     - `<bastion_host_name>:5000/<repo_name>/release
       source: quay.example.com/openshift-release-dev/ocp-release
     - mirrors:
       - `<bastion_host_name>:5000/<repo_name>/release
         source: registry.example.com/ocp/release
   
   To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.
4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   IMPORTANT

   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file `install-config.yaml` in the directory that you specified.

### 12.6.14. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

   **NOTE**

   After installation, you cannot modify these parameters in the `install-config.yaml` file.

   **IMPORTANT**

   The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 12.6.14.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

#### Table 12.28. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;. &lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.   String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
<td></td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from <a href="https://cloud.redhat.com/openshift/install/pull-secret">https://cloud.redhat.com/openshift/install/pull-secret</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>{&quot;auths&quot;:{ &quot;cloud.openshift.com&quot;:{&quot;auth&quot;:&quot;b3Blb=&quot;,&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;},&quot;quay.io&quot;:{&quot;auth&quot;:&quot;b3Blb=&quot;,&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;}}} }</td>
<td>}</td>
</tr>
</tbody>
</table>
12.6.14.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.29. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 ($2^{32} - 2$) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
</tbody>
</table>
networking.serviceNetwork

The IP address block for services. The default value is 172.30.0.0/16.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

An array with an IP address block in CIDR format. For example:

```
networking:
  serviceNetwork:
    - 172.30.0.0/16
```

networking.machineNetwork

The IP address blocks for machines.

If you specify multiple IP address blocks, the blocks must not overlap.

An array of objects. For example:

```
networking:
  machineNetwork:
    - cidr: 10.0.0.0/16
```

networking.machineNetwork.cidr

Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

An IP network block in CIDR notation. For example, 10.0.0.0/16.

**NOTE**

Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

### 12.6.14.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 12.30. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute.hyperthreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><strong>compute.name</strong></td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>

<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td>platform.openstack.ingressFloatingIP</td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example <strong>128.0.0.1</strong>.</td>
</tr>
<tr>
<td>platform.openstack.apiFloatingIP</td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example <strong>128.0.0.1</strong>.</td>
</tr>
<tr>
<td>platform.openstack.externalDNS</td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;]].</td>
</tr>
</tbody>
</table>
The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.

The first item in `networking.machineNetwork` must match the value of `machinesSubnet`.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

A UUID as a string. For example, `fa806b2f-ac49-4bce-b9db-124bc64209bf`.

### 12.6.14.6. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

#### Table 12.33. Additional GCP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>

<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.location</code></td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</code></td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td><code>compute.platform.gcp.osDisk.encryptionKey.kmsKey.name</code></td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td><code>compute.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</code></td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><code>compute.platform.gcp.osDisk.encryptionKey.kmsKey.location</code></td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>compute.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</code></td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

**12.6.14.7. Custom subnets in RHOSP deployments**

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:
• The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.

• The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.

• The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

• If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

• If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

• You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

12.6.14.8. Sample customized install-config.yaml file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OpenShift SDN, you must modify the `install-config.yaml` file to include Kuryr as the desired `networking.networkType` and proceed with the default OpenShift Container Platform SDN installation steps. This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: mlarge
      replicas: 3
metadata:
  name: example
  networking:
    clusterNetwork:
```

CHAPTER 12. INSTALLING ON OPENSTACK

1811
The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `serviceNetwork` property. The larger range is required to prevent IP address conflicts.

Both `trunkSupport` and `octaviaSupport` are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the Internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

**NOTE**

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

### 12.6.14.9.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The **RHOSP networking service (Neutron) is enabled** and accessible through the RHOSP networking API.
- The RHOSP networking service has the **port security and allowed address pairs extensions enabled**.
The provider network can be shared with other tenants.

**TIP**

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

**TIP**

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is `169.254.169.254` by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

12.6.14.9.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on a Red Hat OpenStack Platform (RHOSP) provider network. Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".
1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIP` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIP` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```yaml
...  
platform:  
  openstack:  
    apiVIP: 192.0.2.13  
    ingressVIP: 192.0.2.23  
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf  
    (...)  
  networking:  
    machineNetwork:  
      - cidr: 192.0.2.0/24
```

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.

**TIP**

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](Understanding multiple networks).
12.6.14.10. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```
     $ python -c 'import yaml; path = "install-config.yaml"; data = yaml.safe_load(open(path)); data["networking"]['machineNetwork'] = ["cidr": "192.168.0.0/18"]; open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```
     Insert a value that matches your intended Neutron subnet, e.g. `192.0.2.0/24`.
   - To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.

12.6.14.11. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```
     $ python -c 'import yaml; path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["networking"]['machineNetwork'] = object("cidr": "192.168.0.0/18");
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```
To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to 0.

12.6.14.12. Modifying the network type

By default, the installation program selects the OpenShiftSDN network type. To use Kuryr instead, change the value in the installation configuration file that the program generated.

**Prerequisites**

- You have the file `install-config.yaml` that was generated by the OpenShift Container Platform installation program

**Procedure**

1. In a command prompt, browse to the directory that contains `install-config.yaml`.
2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```python
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["networking"]['networkType'] = "Kuryr";
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```
   - To set the value manually, open the file and set `networking.networkType` to "Kuryr".

12.6.15. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.
Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir=<installation_directory>
   ```

   **Example output**

   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift

   1 For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.

5. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   ```bash
   OpenShift Container Platform 4.8 Installing
   ```

   1818
a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

c. Save and exit the file.

6. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
     name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
       id: mycluster-100419-private-zone
     publicZone: 2
       id: example.openshift.com
   status: {}
   
   1 2 Remove this section completely.
   
   If you do so, you must add ingress DNS records manually in a later step.

7. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir=<installation_directory>
   
   1 For `<installation_directory>`, specify the same installation directory.
   
   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadm-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   ├── kubeadm-password
   │   │   └── bootstrap.ign
   │   ├── kubeconfig
   │   │   └── master.ign
   │   └── metadata.json
   │       └── worker.ign
   
   8. Export the metadata file’s `infraID` key as an environment variable:

   ```bash
   $ export INFRA_ID=$(jq -r .infraID metadata.json)
   ```
TIP

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

12.6.16. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, `bootstrap.ign`.
- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the host name and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()

files.append(
    {
        'path': '/etc/hostname',
        'mode': 420,
        'contents': {
            'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
        }
    }
)

ca_cert_path = os.environ.get('OS_CACERT', '')
if ca_cert_path:
```
2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

   ```bash
   $ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
   
   $ openstack image show <image_name>
   ``

   Make a note of the `file` value; it follows the pattern `v2/images/<image_ID>/file`.

   **NOTE**

   Verify that the image you created is active.

3. Get the image's details:

   ```bash
   $ openstack catalog show image
   ``

4. Retrieve the image service's public address:

   ```bash
   $ openstack catalog show image
   ```

5. Combine the public address with the image `file` value and save the result as the storage location. The location follows the pattern `<image_service_public_URL>/v2/images/<image_ID>/file`.

6. Generate an auth token and save the token ID:

   ```bash
   $ openstack token issue -c id -f value
   ```

7. Insert the following content into a file called `$INFRA_ID-bootstrap-ignition.json` and edit the placeholders to match your own values:

   ```json
   {
     "ignition": {
       "config": {
         "merge": {
           "source": "<storage_url>",
           ...
         }
       }
     }
   }
   ```
Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.

Set `name` in `httpHeaders` to "X-Auth-Token".

Set `value` in `httpHeaders` to your token’s ID.

If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

**WARNING**

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

### 12.6.17. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

**NOTE**

As with the bootstrap Ignition configuration, you must explicitly define a host name for each control plane machine.

**Prerequisites**
• The infrastructure ID from the installation program’s metadata file is set as an environment variable ($INFRA_ID).
  
  • If the variable is not set, see “Creating the Kubernetes manifest and Ignition config files”.

Procedure

• On a command line, run the following Python script:

```
$ for index in $(seq 0 2); do
  MASTER_HOSTNAME="$INFRA_ID-master-$index"
  python -c "import base64, json, sys;
  ignition = json.load(sys.stdin);
  storage = ignition.get('storage', {});
  files = storage.get('files', []);
  files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
    'data:text/plain;charset=utf-8;base64,' +
    base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
    'filesystem': 'root');
  storage['files'] = files;
  ignition['storage'] = storage
  json.dump(ignition, sys.stdout)"
  <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: <INFRA_ID>-master-0-ignition.json, <INFRA_ID>-master-1-ignition.json, and <INFRA_ID>-master-2-ignition.json.

12.6.18. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

• Python 3 is installed on your machine.

• You downloaded the modules in "Downloading playbook dependencies".

• You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the `inventory.yaml` playbook:

   **Example external network value in the `inventory.yaml` Ansible playbook**

   ```yaml
   ...
   # The public network providing connectivity to the cluster. If not
   # provided, the cluster external connectivity must be provided in another
   # way.
   ...
   # Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
   os_external_network: "external"
   ...
   ```
IMPORTANT

If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

   Example FIP values in the `inventory.yaml` Ansible playbook

   ```
   ...
   # OpenShift API floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the Control Plane to
   # serve the OpenShift API.
   os_api_fip: '203.0.113.23'

   # OpenShift Ingress floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the worker nodes to serve
   # the applications.
   os_ingress_fip: '203.0.113.19'

   # If this value is non-empty, the corresponding floating IP will be
   # attached to the bootstrap machine. This is needed for collecting logs
   # in case of install failure.
   os_bootstrap_fip: '203.0.113.20'
   ```

   IMPORTANT

   If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform post-installation network configuration.

   If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

   See “Enabling access to the environment” for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml security-groups.yaml
   ```

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml network.yaml
   ```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

   ```bash
   $ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
   ```
12.6.19. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `bootstrap.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `bootstrap.yaml` playbook:

   ```
   $ ansible-playbook -i inventory.yaml bootstrap.yaml
   ```

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

   ```
   $ openstack console log show "$INFRA_ID-bootstrap"
   ```

12.6.20. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
- The `inventory.yaml`, `common.yaml`, and `control-plane.yaml` Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. If the control plane Ignition config files aren’t already in your working directory, copy them into it.
3. On a command line, run the `control-plane.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml control-plane.yaml
   ```

4. Run the following command to monitor the bootstrapping process:

   ```bash
   $ openshift-install wait-for bootstrap-complete
   ```

   You will see messages that confirm that the control plane machines are running and have joined the cluster:

   ```
   INFO API v1.14.6+f9b5405 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   ...
   INFO It is now safe to remove the bootstrap resources
   ```

12.6.21. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   system:admin

12.6.22. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

**Prerequisites**
You downloaded the modules in "Downloading playbook dependencies".

You downloaded the playbooks in "Downloading the installation playbooks".

The inventory.yaml, common.yaml, and down-bootstrap.yaml Ansible playbooks are in a common directory.

The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the down-bootstrap.yaml playbook:

   ```
   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml
   ```

   The bootstrap port, server, and floating IP address are deleted.

**WARNING**

If you did not disable the bootstrap Ignition file URL earlier, do so now.

**12.6.23. Creating compute machines on RHOSP**

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".

- You downloaded the playbooks in "Downloading the installation playbooks".

- The inventory.yaml, common.yaml, and compute-nodes.yaml Ansible playbooks are in a common directory.

- The metadata.json file that the installation program created is in the same directory as the Ansible playbooks.

- The control plane is active.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the playbook:

   ```
   $ ansible-playbook -i inventory.yaml compute-nodes.yaml
   ```
Next steps

- Approve the certificate signing requests for the machines.

12.6.24. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   Example output

   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.21.0
   master-1  Ready     master  63m  v1.21.0
   master-2  Ready     master  64m  v1.21.0
   worker-0  NotReady  worker  76s  v1.21.0
   worker-1  NotReady  worker  70s  v1.21.0

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

   Example output

   NAME        AGE     REQUESTOR                                                                   CONDITION
   csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending

   ...
In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

   **NOTE**

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec, oc rsh, and oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

   - To approve them individually, run the following command for each valid CSR:

     ```bash
     $ oc adm certificate approve <csr_name>
     ```

     * `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     ```bash
     $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{" \n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
     ```

     **NOTE**

     Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   ```

   **Example output**
5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:
     
     ```bash
     $ oc adm certificate approve <csr_name>
     
     **<csr_name>** is the name of a CSR from the list of current CSRs.
     ```

   - To approve all pending CSRs, run the following command:
     
     ```bash
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
     
     $ oc get nodes
     ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

   ```bash
   $ oc get nodes
   
   Example output
   
<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.21.0</td>
</tr>
</tbody>
</table>
   
   **NOTE**

   It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

   **Additional information**

   - For more information on CSRs, see [Certificate Signing Requests](#).

### 12.6.25. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

**Prerequisites**

- You have the installation program (**openshift-install**)
Procedure

- On a command line, enter:
  
  ```
  $ openshift-install --log-level debug wait-for install-complete
  ```

  The program outputs the console URL, as well as the administrator’s login information.

**12.6.26. Next steps**

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

**12.7. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN SR-IOV INFRASTRUCTURE**

In OpenShift Container Platform 4.8, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure and uses single-root input/output virtualization (SR-IOV) networks to run compute machines.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, such as Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

**12.7.1. Prerequisites**

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.8 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine where you run the installation program, you have:
  - A single directory in which you can keep the files you create during the installation process
  - Python 3
12.7.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to obtain the images that are necessary to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

12.7.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

**Table 12.34. Recommended resources for a default OpenShift Container Platform cluster on RHOSP**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Resource</td>
<td>Value</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 12.7.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

Additionally, for clusters that use single-root input/output virtualization (SR-IOV), RHOSP compute nodes require a flavor that supports huge pages.
IMPORTANT

SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

Additional resources

- For more information about configuring performant RHOSP compute nodes, see Configuring Compute nodes for performance.

12.7.3.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

12.7.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:
   a. Register with Red Hat Subscription Manager:
      
      $ sudo subscription-manager register # If not done already
   b. Pull the latest subscription data:
      
      $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
   c. Disable the current repositories:
      
      $ sudo subscription-manager repos --disable=* # If not done already
d. Add the required repositories:

```
$ sudo subscription-manager repos \
   --enable=rhel-8-for-x86_64-baseos-rpms \
   --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
   --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
   --enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
```

3. Ensure that the `python` command points to `python3`:

```
$ sudo alternatives --set python /usr/bin/python3
```

### 12.7.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

#### Prerequisites

- The `curl` command-line tool is available on your machine.

#### Procedure

- To download the playbooks to your working directory, run the following script from a command line:

```
$ xargs -n 1 curl -O <<< '  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/bootstrap.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/common.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/compute-nodes.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/control-plane.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/inventory.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/network.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/security-groups.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/downbootstrap.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/downcompute-nodes.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/downcontrol-plane.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/download-balancers.yaml  
    https://raw.githubusercontent.com/openshift/installer/release-4.8/upi/openstack/down
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 12.7.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
1. **IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. From the [Pull Secret](https://example.com) page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 12.7.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

1. **IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

1. **NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   ```
   $ eval "$(ssh-agent -s)"
   ```

   Example output

   Agent pid 31874

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   Example output

   Agent pid 31874

   1. Add your SSH private key to the ssh-agent:

   ```
   $ ssh-add <path>/<file_name>
   ```

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

   ```
   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
   ```
3. Verify that the credentials were applied.

```bash
$ gcloud auth list
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 12.7.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

**Prerequisites**

- The RHOSP CLI is installed.

**Procedure**

1. Log in to the Red Hat Customer Portal’s [Product Downloads page](https://www.redhat.com/).

2. Under **Version**, select the most recent release of OpenShift Container Platform 4.8 for Red Hat Enterprise Linux (RHEL) 8.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the *Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)*.

4. Decompress the image.

   **NOTE**

   You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like `.gz` or `.tgz`. To find out if or how the file is compressed, in a command line, enter:

   ```bash
   $ file <name_of_downloaded_file>
   ```

5. From the image that you downloaded, create an image that is named `rhcos` in your cluster by using the RHOSP CLI:

   ```bash
   $ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-
   ${RHCOS_VERSION}-openstack.qcow2 rhcos
   ```
IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either `.raw` or `.qcow2` formats. If you use Ceph, you must use the `.raw` format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

12.7.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the ‘External’ network:

   `$ openstack network list --long -c ID -c Name -c "Router Type"
   
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

   NOTE

   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

12.7.10. Enabling access to the environment
At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

12.7.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   `$ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>`

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   `$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>`

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   `$ openstack floating ip create --description "bootstrap machine" <external_network>`

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

   **NOTE**

   If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:

   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

   If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.
You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.7.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the inventory.yaml file, do not define the following variables:

- os_api_fip
- os_bootstrap_fip
- os_ingress_fip

If you cannot provide an external network, you can also leave os_external_network blank. If you do not provide a value for os_external_network, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the wait-for command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>

If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

12.7.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called clouds.yaml. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the clouds.yaml file:
   - If your RHOSP distribution includes the Horizon web UI, generate a clouds.yaml file in it.
IMPORTANT

Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
  dev-env:
    region_name: RegionOne
    auth:
      username: 'devuser'
      password: XXX
      project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

   a. Copy the certificate authority file to your machine.

   b. Add the machine to the certificate authority trust bundle:

   ```bash
   $ sudo cp ca.crt.pem /etc/pki/ca-trust/source/anchors/
   ```

   c. Update the trust bundle:

   ```bash
   $ sudo update-ca-trust extract
   ```

   d. Add the `cacert` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```yaml
cclouds:
  shiftstack:
    ...
  cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```
TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```bash
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:
   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`
   The installation program searches for `clouds.yaml` in that order.

12.7.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP). Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your bastion host.
- Have the `imageContentSources` values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

```bash
$ ./openshift-install create install-config --dir=<installation_directory>
```

1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

d. Select **gcp** as the platform to target.

e. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

f. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

g. Select the region to deploy the cluster to.

h. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

i. Select **openstack** as the platform to target.

j. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

k. Specify the floating IP address to use for external access to the OpenShift API.

l. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

m. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

n. Enter a name for your cluster. The name must be 14 or fewer characters long.

o. Paste the pull secret that you obtained from the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site.

2. In the `install-config.yaml` file, set the value of `platform.openstack.clusterOSImage` to the image location or name. For example:

```yaml
platform:
```
3. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

   a. Update the **pullSecret** value to contain the authentication information for your registry:

   ```yaml
   pullSecret: {"auths":{"<bastion_host_name>:5000": {"auth": "<credentials>", "email": "you@example.com"}}}
   ```

   For **<bastion_host_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

   b. Add the **additionalTrustBundle** parameter and value.

   ```yaml
   additionalTrustBundle:
     -----BEGIN CERTIFICATE-----
     ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
     -----END CERTIFICATE-----
   ```

   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

   c. Define the network and subnets for the VPC to install the cluster in under the parent **platform.gcp** field:

   ```yaml
   network: <existing_vpc>
   controlPlaneSubnet: <control_plane_subnet>
   computeSubnet: <compute_subnet>
   ```

   For **platform.gcp.network**, specify the name for the existing Google VPC. For **platform.gcp.controlPlaneSubnet** and **platform.gcp.computeSubnet**, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

   d. Add the image content resources, which look like this excerpt:

   ```yaml
   imageContentSources:
   - mirrors:
     - <bastion_host_name>:5000/<repo_name>/release
       source: quay.example.com/openshift-release-dev/ocp-release
     - mirrors:
       - <bastion_host_name>:5000/<repo_name>/release
         source: registry.example.com/ocp/release
   ```

   To complete these values, use the **imageContentSources** that you recorded during mirror registry creation.
4. Make any other modifications to the install-config.yaml file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

5. Back up the install-config.yaml file so that you can use it to install multiple clusters.

   **IMPORTANT**
   
   The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file install-config.yaml in the directory that you specified.

### 12.7.13. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

   **NOTE**
   
   After installation, you cannot modify these parameters in the install-config.yaml file.

   **IMPORTANT**
   
   The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

#### 12.7.13.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from <a href="https://cloud.redhat.com/openshift/install/pull-secret">https://cloud.redhat.com/openshift/install/pull-secret</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{</td>
</tr>
</tbody>
</table>
|               | }                                                                                                                                                                                                           |   | "auths":{
|               |   "cloud.openshift.com":{
|               |     "auth":"b3Blb=",
|               |     "email":"you@example.com"
|               |   },
|               |   "quay.io":{

|               |     "email":"you@example.com"
|               |   }
|               | }                                                                                                                                                                                                           |
12.7.13.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 12.36. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the <strong>networking</strong> object after installation.</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
</tbody>
</table>
|                               | The default value is 10.128.0.0/14 with a host prefix of /23.               | networking:
|                               | If you specify multiple IP address blocks, the blocks must not overlap.     |   | clusterNetwork:
|                               | cidr: 10.128.0.0/14                                                        |     | - cidr: 10.128.0.0/14
|                               | hostPrefix: 23                                                             |   | hostPrefix: 23 |
| networking.clusterNetwork.cidr| Required if you use networking.clusterNetwork. An IP address block.       | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. |
|                               | An IPv4 network.                                                           |                                                                       |
| networking.clusterNetwork.hostPrefix | The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses. | A subnet prefix. The default value is 23. |
### networking.serviceNetwork
The IP address block for services. The default value is **172.30.0.0/16**.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

- **networking**: An array with an IP address block in CIDR format. For example:
  - `networking:
    serviceNetwork:
    - 172.30.0.0/16`

### networking.machineNetwork
The IP address blocks for machines.

- **networking**: An array of objects. For example:
  - `networking:
    machineNetwork:
    - cidr: 10.0.0.0/16`

### networking.machineNetwork.cidr
Required if you use **networking.machineNetwork**. An IP address block. The default value is **10.0.0.0/16** for all platforms other than libvirt. For libvirt, the default value is **192.168.126.0/24**.

- **networking**: An IP network block in CIDR notation. For example, **10.0.0.0/16**.

  **NOTE**
  Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

### 12.7.13.3. Optional configuration parameters
Optional installation configuration parameters are described in the following table:

#### Table 12.37. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <strong>MachinePool</strong> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool” table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <code>hypertreading</code>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><code>Enabled</code> or <code>Disabled</code></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td><code>master</code></td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is <code>3</code>, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.</td>
<td></td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>imageContentSources.source</code></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><code>imageContentSources.mirrors</code></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><code>publish</code></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to <code>Internal</code>. The default value is <code>External</code>.</td>
</tr>
<tr>
<td><code>sshKey</code></td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: <code>&lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</code></td>
</tr>
</tbody>
</table>

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

### 12.7.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 12.38. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.size</code></td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.type</code></td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><code>platform.openstack.cloud</code></td>
<td>The name of the RHOSP cloud to use from the list of clouds in the <code>clouds.yaml</code> file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td><code>platform.openstack.externalNetwork</code></td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td><code>platform.openstack.computeFlavor</code></td>
<td>The RHOSP flavor to use for control plane and compute machines.</td>
<td>String, for example m1.xlarge.</td>
</tr>
</tbody>
</table>

**12.7.13.5. Optional RHOSP configuration parameters**

Optional RHOSP configuration parameters are described in the following table:

**Table 12.39. Optional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>controlPlane.plat</code></td>
<td><code>form.openstack.rootVolume.size</code></td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>controlPlane.plat</code></td>
<td><code>form.openstack.rootVolume.type</code></td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><code>platform.openstack.cloud</code></td>
<td>The name of the RHOSP cloud to use from the list of clouds in the <code>clouds.yaml</code> file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td><code>platform.openstack.externalNetwork</code></td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td><code>platform.openstack.computeFlavor</code></td>
<td>The RHOSP flavor to use for control plane and compute machines.</td>
<td>String, for example m1.xlarge.</td>
</tr>
</tbody>
</table>

This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the `type` key in the `platform.openstack.defaultMachinePlatform` property. You can also set a flavor value for each machine pool individually.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.zones</code></td>
<td>For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>

<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>controlPlane.platfrom.openstack.zones</strong></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><strong>controlPlane.platfrom.openstack.rootVolume.zones</strong></td>
<td>For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><strong>platform.openstack.clusterOSImage</strong></td>
<td>The location from which the installer downloads the RHCS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffeebd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffeebd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.openstack.clusterOSIImageProperties</td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image. You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi. You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;]].</td>
</tr>
</tbody>
</table>
| platform.openstack.defaultMachinePlatform | The default machine pool platform configuration. | {  
|                                |                                                                              | "type": "ml.large",  
|                                |                                                                              |  "rootVolume": {  
|                                |                                                                              |      "size": 30,  
|                                |                                                                              |      "type": "performance"  
|                                |                                                                              | }  
|                                |                                                                              | }  
| platform.openstack.ingressFloatingIP | An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property. | An IP address, for example 128.0.0.1. |
| platform.openstack.apiFloatingIP | An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property. | An IP address, for example 128.0.0.1. |
| platform.openstack.externalDNS | IP addresses for external DNS servers that cluster instances use for DNS resolution. | A list of IP addresses as strings. For example, \["8.8.8.8", "192.168.1.12"]\]. |
The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.

The first item in `networking.machineNetwork` must match the value of `machinesSubnet`.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

**A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.**

---

### 12.7.13.6. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

**Table 12.40. Additional GCP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.gcp.network</code></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.gcp.type</code></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><code>platform.gcp.zones</code></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as us-central1-a, in a YAML sequence.</td>
</tr>
<tr>
<td><code>platform.gcp.controlPlaneSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>platform.gcp.computeSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.name</code></td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</strong></td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.location</strong></td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</strong></td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td><strong>compute.platform.gcp.osDisk.encryptionKey.kmsKey.name</strong></td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td><strong>compute.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</strong></td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><strong>compute.platform.gcp.osDisk.encryptionKey.kmsKey.location</strong></td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><strong>compute.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</strong></td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

12.7.13.7. Sample customized install-config.yaml file for RHOSP

This sample install-config.yaml demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your install-config.yaml file by using the installation program.
Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file. This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:
If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

**12.7.13.9. Setting a custom subnet for machines**

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

**Prerequisites**

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["networking"]["machineNetwork"] = [{"cidr": "192.168.0.0/18"];
     open(path, "w").write(yaml.dump(data, default_flow_style=False))
     ```
   - Insert a value that matches your intended Neutron subnet, e.g. `192.0.2.0/24`.

- To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.

**12.7.13.10. Emptying compute machine pools**

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.
Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.
2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["compute"][0]["replicas"] = 0;
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```
   - To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to 0.

12.7.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:
1. For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.
   - You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

5. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

6. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   ```
Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

7. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir=<installation_directory>  
```

For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

8. Export the metadata file’s `infraID` key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

**TIP**

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

### 12.7.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.
Prerequisites

- You have the bootstrap Ignition file that the installer program generates, `bootstrap.ign`.
- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the host name and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()
files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {
    'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
}})

ca_cert_path = os.environ.get('OS_CACERT', '')
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()
    files.append({'path': '/opt/openshift/tls/cloud-ca-cert.pem', 'mode': 420, 'contents': {
        'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64
    }})

ignition['storage']['files'] = files;
```
2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```bash
with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)
```

$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>

3. Get the image's details:

```bash
$ openstack image show <image_name>
```

Make a note of the file value; it follows the pattern v2/images/<image_ID>/file.

**NOTE**

Verify that the image you created is active.

4. Retrieve the image service's public address:

```bash
$ openstack catalog show image
```

5. Combine the public address with the image file value and save the result as the storage location. The location follows the pattern <image_service_public_URL>/v2/images/<image_ID>/file.

6. Generate an auth token and save the token ID:

```bash
$ openstack token issue -c id -f value
```

7. Insert the following content into a file called $INFRA_ID-bootstrap-ignition.json and edit the placeholders to match your own values:

```json
{
    "ignition": {
        "config": {
            "merge": [{
                "source": "<storage_url>" 1
            },
            "httpHeaders": [{
                "name": "X-Auth-Token", 2
                "value": "<token_ID>" 3
            }]
        }
    },
    "security": {
        "tls": {
            "certificateAuthorities": [{
                "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>" 4
            }]
        }
    }
}
```
Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.

Set `name` in `httpHeaders` to "X-Auth-Token".

Set `value` in `httpHeaders` to your token’s ID.

If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

---

**WARNING**

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

---

**12.7.16. Creating control plane Ignition config files on RHOSP**

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

**NOTE**

As with the bootstrap Ignition configuration, you must explicitly define a host name for each control plane machine.

**Prerequisites**

- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

**Procedure**

- On a command line, run the following Python script:

  ```bash
  $ for index in $(seq 0 2); do
  MASTER_HOSTNAME="$INFRA_ID-master-$index"
  python -c "import base64, json, sys;
  ignition = json.load(sys.stdin);
  storage = ignition.get('storage', {});
  ```
You now have three control plane Ignition files: `<INFRA_ID>-master-0-ignition.json`, `<INFRA_ID>-master-1-ignition.json`, and `<INFRA_ID>-master-2-ignition.json`.

### 12.7.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

#### Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

#### Procedure

1. Optional: Add an external network value to the `inventory.yaml` playbook:
   
   **Example external network value in the inventory.yaml Ansible playbook**
   
   ```yaml
   ...
   
   # The public network providing connectivity to the cluster. If not
   # provided, the cluster external connectivity must be provided in another
   # way.
   
   # Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
   os_external_network: 'external'
   ...
   ```

   **IMPORTANT**

   If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

   **Example FIP values in the inventory.yaml Ansible playbook**
   
   ```yaml
   ...
   ```
IMPORTANT

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform post-installation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

   $ ansible-playbook -i inventory.yaml security-groups.yaml

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

   $ ansible-playbook -i inventory.yaml network.yaml

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

   $ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"

Optionally, you can use the `inventory.yaml` file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

12.7.17.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.
NOTE

Be sure that your install-config.yaml file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

Prerequisites

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an inventory.yaml file as part of the OpenShift Container Platform installation process.

Procedure

1. In the inventory.yaml file, edit the flavors for machines:
   a. If you want to use bare-metal control plane machines, change the value of os_flavor_master to a bare metal flavor.
   b. Change the value of os_flavor_worker to a bare metal flavor.

An example bare metal inventory.yaml file

```yaml
all:
  hosts:
    localhost:
      ansible_connection: local
      ansible_python_interpreter: "{{ansible_playbook_python}}"

# User-provided values
os_subnet_range: '10.0.0.0/16'
1
os_flavor_master: 'my-bare-metal-flavor'
2
os_flavor_worker: 'my-bare-metal-flavor'
os_image_rhcos: 'rhcos'
1
os_external_network: 'external'

...```

1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
2. Change this value to a bare metal flavor to use for compute machines.
Use the updated `inventory.yaml` file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

**NOTE**

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
/openshift-install wait-for install-complete --log-level debug
```

### 12.7.18. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `bootstrap.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the `bootstrap.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml bootstrap.yaml
```
3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

```
$ openstack console log show "$INFRA_ID-bootstrap"
```

### 12.7.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
The infrastructure ID from the installation program's metadata file is set as an environment variable (\$INFRA_ID).

The inventory.yaml, common.yaml, and control-plane.yaml Ansible playbooks are in a common directory.

You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. If the control plane Ignition config files aren't already in your working directory, copy them into it.

3. On a command line, run the control-plane.yaml playbook:

   $ ansible-playbook -i inventory.yaml control-plane.yaml

4. Run the following command to monitor the bootstrapping process:

   $ openshift-install wait-for bootstrap-complete

   You will see messages that confirm that the control plane machines are running and have joined the cluster:

   INFO API v1.14.6+f9b5405 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   ...
   INFO It is now safe to remove the bootstrap resources

12.7.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadm credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.
2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```

**Example output**

```
system:admin
```

### 12.7.21. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `down-bootstrap.yaml` Ansible playbooks are in a common directory.
- The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the `down-bootstrap.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml down-bootstrap.yaml
```

The bootstrap port, server, and floating IP address are deleted.

**WARNING**

If you did not disable the bootstrap Ignition file URL earlier, do so now.

### 12.7.22. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports single root I/O virtualization (SR-IOV), you can provision SR-IOV networks that compute machines run on.

**NOTE**

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.
Prerequisites

- Your cluster supports SR-IOV.

**NOTE**

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.

- You created radio and uplink provider networks as part of your RHOSP deployment. The names radio and uplink are used in all example commands to represent these networks.

Procedure

1. On a command line, create a radio RHOSP network:
   
   ```
   $ openstack network create radio --provider-physical-network radio --provider-network-type flat --external
   ```

2. Create an uplink RHOSP network:

   ```
   $ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
   ```

3. Create a subnet for the radio network:

   ```
   $ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio
   ```

4. Create a subnet for the uplink network:

   ```
   $ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink
   ```

12.7.23. Creating compute machines that run on SR-IOV networks

After standing up the control plane, create compute machines that run on the SR-IOV networks that you created in "Creating SR-IOV networks for compute machines".

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `metadata.yaml` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.
- You created radio and uplink SR-IOV networks as described in "Creating SR-IOV networks for compute machines".
Procedure

1. On a command line, change the working directory to the location of the `inventory.yaml` and `common.yaml` files.

2. Add the `radio` and `uplink` networks to the end of the `inventory.yaml` file by using the `additionalNetworks` parameter:

   ```yaml
   ....
   # If this value is non-empty, the corresponding floating IP will be
   # attached to the bootstrap machine. This is needed for collecting logs
   # in case of install failure.
   os_bootstrap_fip: '203.0.113.20'

   additionalNetworks:
   - id: radio
     count: 4
     type: direct
     port_security_enabled: no
   - id: uplink
     count: 4
     type: direct
     port_security_enabled: no
   ```

   The `count` parameter defines the number of SR-IOV virtual functions (VFs) to attach to each worker node. In this case, each network has four VFs.

3. Replace the content of the `compute-nodes.yaml` file with the following text:

   ```yaml
   Example 12.1. compute-nodes.yaml

   - import_playbook: common.yaml

   - hosts: all
     gather_facts: no

   vars:
     worker_list: []
     port_name_list: []
     nic_list: []

   tasks:
   # Create the SDN/primary port for each worker node
   - name: 'Create the Compute ports'
     os_port:
       name: "{{ item.1 }}-{{ item.0 }}"
       network: "{{ os_network }}"
       security_groups:
         - "{{ os_sg_worker }}"
       allowed_address_pairs:
         - ip_address: "{{ os_ingressVIP }}"
       with_indexed_items: "{{ [os_port_worker] * os_compute_nodes_number }}"
       register: ports

   # Tag each SDN/primary port with cluster name
   - name: 'Set Compute ports tag'
   ```
command:
  cmd: "openstack port set --tag {{ cluster_id_tag }} {{ item.1 }}-{{ item.0 }}"
with_indexed_items: "{{ [os_port_worker] * os_compute_nodes_number }}"

- name: 'List the Compute Trunks'
  command:
    cmd: "openstack network trunk list"
  when: os_networking_type == "Kuryr"
  register: compute_trunks

- name: 'Create the Compute trunks'
  command:
    cmd: "openstack network trunk create --parent-port {{ item.1.id }} {{ os_compute_trunk_name }}-{{ item.0 }}"
  with_indexed_items: "{{ ports.results }}"
  when:
    - os_networking_type == "Kuryr"
    - "os_compute_trunk_name|string not in compute_trunks.stdout"

- name: ‘Call additional-port processing’
  include_tasks: additional-ports.yaml

# Create additional ports in OpenStack
- name: 'Create additionalNetworks ports'
  os_port:
    name: "{{ item.0 }}-{{ item.1.name }}"
    vnic_type: "{{ item.1.type }}"
    network: "{{ item.1.uuid }}"
    port_security_enabled: "{{ item.1.port_security_enabled|default(omit) }}"
    no_security_groups: "{{ 'true' if item.1.security_groups is not defined else omit }}"
    security_groups: "{{ item.1.security_groups | default(omit) }}"
  with_nested:
    - "{{ worker_list }}"
    - "{{ port_name_list }}"

# Tag the ports with the cluster info
- name: 'Set additionalNetworks ports tag'
  command:
    cmd: "openstack port set --tag {{ cluster_id_tag }} {{ item.0 }}-{{ item.1.name }}"
  with_nested:
    - "{{ worker_list }}"
    - "{{ port_name_list }}"

# Build the nic list to use for server create
- name: Build nic list
  set_fact:
    nic_list: "{{ nic_list | default([]) + [ item.name ] }}"
  with_items:
    - "{{ port_name_list }}"

# Create the servers
- name: 'Create the Compute servers'
  vars:
    worker_nics: "{{ [ item.1 ] | product(nic_list) | map('join','-') | map('regex_replace', '(.*)', 'port-name=\1') | list }}"
  os_server:
    name: "{{ item.1 }}"
image: "{{ os_image_rhcos }}"
flavor: "{{ os_flavor_worker }}"
auto_ip: no
userdata: "{{ lookup('file', 'worker.ign') | string }}"
security_groups: []
nics: "{{ ['port-name=' + os_port_worker + '-' + item.0|string } + worker_nics }}"
config_drive: yes
with_indexed_items: "{{ worker_list }}"

# Build a list of worker nodes with indexes
- name: 'Build worker list'
  set_fact:
    worker_list: "{{ worker_list | default([]) + [ item.1 + '-' + item.0 | string ] }}"
  with_indexed_items: "{{ [ os_compute_server_name ] * os_compute_nodes_number }}"

# Ensure that each network specified in additionalNetworks exists
- name: 'Verify additionalNetworks'
  os_networks_info:
    name: "{{ item.id }}"
  with_items: "{{ additionalNetworks }}"
  register: network_info

# Expand additionalNetworks by the count parameter in each network definition
- name: 'Build port and port index list for additionalNetworks'
  set_fact:
    port_list:
      net_name': item.1.id,
      'uuid': network_info.results[item.0].openstack_networks[0].id,
      'type': item.1.type|default('normal'),
      'security_groups': item.1.security_groups|default(omit),
      'port_security_enabled': item.1.port_security_enabled|default(omit)
    index_list: "{{ index_list | default([]) + range(item.1.count|default(1)) | list }}"
  with_indexed_items: "{{ additionalNetworks }}"

# Calculate and save the name of the port
# The format of the name is cluster_name-worker-workerID-networkUUID(partial)-count
# i.e. fdp-nz995-worker-1-99bcd111-1
- name: 'Calculate port name'
  set_fact:
    port_name_list: "{{ port_name_list | default([]) + [ item.1 | combine( {name' : item.1.uuid | regex_search('([^-]+)') + '-' + index_list[item.0]|string } ) ] }}"
  with_indexed_items: "{{ port_list }}"
  when: port_list is defined

4. Insert the following content into a local file that is called additional-ports.yaml:

Example 12.2. additional-ports.yaml

```yaml
# Build a list of worker nodes with indexes
- name: 'Build worker list'
  set_fact:
    worker_list: "{{ worker_list | default([]) + [ item.1 + '-' + item.0 | string ] }}"
  with_indexed_items: "{{ [ os_compute_server_name ] * os_compute_nodes_number }}"

# Ensure that each network specified in additionalNetworks exists
- name: 'Verify additionalNetworks'
  os_networks_info:
    name: "{{ item.id }}"
  with_items: "{{ additionalNetworks }}"
  register: network_info

# Expand additionalNetworks by the count parameter in each network definition
- name: 'Build port and port index list for additionalNetworks'
  set_fact:
    port_list:
      net_name': item.1.id,
      'uuid': network_info.results[item.0].openstack_networks[0].id,
      'type': item.1.type|default('normal'),
      'security_groups': item.1.security_groups|default(omit),
      'port_security_enabled': item.1.port_security_enabled|default(omit)
    index_list: "{{ index_list | default([]) + range(item.1.count|default(1)) | list }}"
  with_indexed_items: "{{ additionalNetworks }}"

# Calculate and save the name of the port
# The format of the name is cluster_name-worker-workerID-networkUUID(partial)-count
# i.e. fdp-nz995-worker-1-99bcd111-1
- name: 'Calculate port name'
  set_fact:
    port_name_list: "{{ port_name_list | default([]) + [ item.1 | combine( {name': item.1.uuid | regex_search('([^-]+)') + '-' + index_list[item.0]|string } ) ] }}"
  with_indexed_items: "{{ port_list }}"
  when: port_list is defined
```

5. On a command line, run the `compute-nodes.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml compute-nodes.yaml
```

1878
12.7.24. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.21.0
   master-1  Ready     master  63m  v1.21.0
   master-2  Ready     master  64m  v1.21.0
   worker-0  NotReady  worker  76s  v1.21.0
   worker-1  NotReady  worker  70s  v1.21.0
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the *Pending* or *Approved* status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**

   ```
   NAME        AGE     REQUESTOR                                      CONDITION
   csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper  Pending
   csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper  Pending
   ...
   ```

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in *Pending* status, approve the CSRs for your cluster machines:
NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  $ oc adm certificate approve <csr_name> 1

  1 <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57tv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>...</td>
</tr>
</tbody>
</table>
CHAPTER 12. INSTALLING ON OPENSTACK

5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
6. After all client and server CSRs have been approved, the machines have the Ready status.
Verify this by running the following command:
$ oc get nodes

Example output
NAME
master-0
master-1
master-2
worker-0
worker-1

STATUS ROLES AGE VERSION
Ready master 73m v1.21.0
Ready master 73m v1.21.0
Ready master 74m v1.21.0
Ready worker 11m v1.21.0
Ready worker 11m v1.21.0

NOTE
It can take a few minutes after approval of the server CSRs for the machines to
transition to the Ready status.
Additional information
For more information on CSRs, see Certificate Signing Requests .

12.7.25. Verifying a successful installation
Verify that the OpenShift Container Platform installation is complete.
Prerequisites
You have the installation program (openshift-install)
Procedure
On a command line, enter:
$ openshift-install --log-level debug wait-for install-complete
The program outputs the console URL, as well as the administrator’s login information.

1881


The cluster is operational. Before you can configure it for SR-IOV networks though, you must perform additional tasks.

12.7.26. Preparing a cluster that runs on RHOSP for SR-IOV

Before you use single root I/O virtualization (SR-IOV) on a cluster that runs on Red Hat OpenStack Platform (RHOSP), make the RHOSP metadata service mountable as a drive and enable the No-IOMMU Operator for the virtual function I/O (VFIO) driver.

12.7.26.1. Enabling the RHOSP metadata service as a mountable drive

You can apply a machine config to your machine pool that makes the Red Hat OpenStack Platform (RHOSP) metadata service available as a mountable drive.

The following machine config enables the display of RHOSP network UUIDs from within the SR-IOV Network Operator. This configuration simplifies the association of SR-IOV resources to cluster SR-IOV resources.

Procedure

1. Create a machine config file from the following template:

A mountable metadata service machine config file

```yaml
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 20-mount-config
labels:
  machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    systemd:
      units:
        - name: create-mountpoint-var-config.service
          enabled: true
          contents: |
          [Unit]
          Description=Create mountpoint /var/config
          Before=kubelet.service
          [Service]
          ExecStart=/bin/mkdir -p /var/config
          [Install]
          WantedBy=var-config.mount
          - name: var-config.mount
            enabled: true
            contents: |
            [Unit]
            Before=local-fs.target
            [Mount]
```
1. You can substitute a name of your choice.

2. From a command line, apply the machine config:

   ```
   $ oc apply -f <machine_config_file_name>.yaml
   ```

### 12.7.26.2. Enabling the No-IOMMU feature for the RHOSP VFIO driver

You can apply a machine config to your machine pool that enables the No-IOMMU feature for the Red Hat OpenStack Platform (RHOSP) virtual function I/O (VFIO) driver. The RHOSP vfio-pci driver requires this feature.

#### Procedure

1. Create a machine config file from the following template:

   **A No-IOMMU VFIO machine config file**

   ```yaml
   kind: MachineConfig
   apiVersion: machineconfiguration.openshift.io/v1
   metadata:
     name: 99-vfio-noiommu
     labels:
       machineconfiguration.openshift.io/role: worker
   spec:
     config:
       ignition:
         version: 3.2.0
       storage:
         files:
           - path: /etc/modprobe.d/vfio-noiommu.conf
             mode: 0644
             contents:
               source:
                 data: base64,b3B0aW9ucyB2ZmlvIGVuYWJsZV91bnNhZmVfbm9pb21tdV9tb2RIPETEK
   ```

   You can substitute a name of your choice.

2. From a command line, apply the machine config:

   ```
   $ oc apply -f <machine_config_file_name>.yaml
   ```

#### NOTE

After you apply the machine config to the machine pool, you can watch the machine config pool status to see when the machines are available.
The cluster is installed and prepared for SR-IOV configuration. You must now perform the SR-IOV configuration tasks in “Next steps”.

12.7.27. Additional resources

- See Performance Addon Operator for low latency nodes for information about configuring your deployment for real-time running and low latency.

12.7.28. Next steps

- To complete SR-IOV configuration for your cluster:
  - Install the Performance Addon Operator.
  - Configure the Performance Addon Operator with huge pages support.
  - Install the SR-IOV Operator.
  - Configure your SR-IOV network device.

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.

- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.

- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.8. INSTALLING A CLUSTER ON OPENSTACK IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.8, you can install a cluster on Red Hat OpenStack Platform (RHOSP) in a restricted network by creating an internal mirror of the installation release content.

12.8.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You read the documentation on selecting a cluster installation method and preparing it for users.

- You verified that OpenShift Container Platform 4.8 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

- You created a registry on your mirror host and obtained the imageContentSources data for your version of OpenShift Container Platform.
IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have the metadata service enabled in RHOSP.

12.8.2. About installations in restricted networks

In OpenShift Container Platform 4.8, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

12.8.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

12.8.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 12.41. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
</tbody>
</table>
An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 12.8.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 12.8.3.2. Bootstrap machine
During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

### 12.8.4. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to obtain the images that are necessary to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 12.8.5. Enabling Swift on RHOSP

Swift is operated by a user account with the swiftoperator role. Add the role to an account before you run the installation program.
IMPORTANT

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On Ceph RGW, the account in url option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the swiftoperator role to the account that will access Swift:

   $ openstack role add --user <user> --project <project> swiftoperator

Your RHOSP deployment can now use Swift for the image registry.

12.8.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called clouds.yaml. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the clouds.yaml file:

   - If your RHOSP distribution includes the Horizon web UI, generate a clouds.yaml file in it.

     IMPORTANT

     Remember to add a password to the auth field. You can also keep secrets in a separate file from clouds.yaml.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

     clouds:
     shiftstack:
       auth:
       project_name: shiftstack
2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   
a. Copy the certificate authority file to your machine.

   b. Add the machine to the certificate authority trust bundle:

      ```bash
      $ sudo cp ca.crt.pem /etc/pki/ca-trust/source/anchors/
      ```

   c. Update the trust bundle:

      ```bash
      $ sudo update-ca-trust extract
      ```

   d. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

      ```yaml
      clouds:
        shiftstack:
          ...  
        cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
      ```

   **TIP**

   After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

   ```bash
   $ oc edit configmap -n openshift-config cloud-provider-config
   ```

3. Place the `clouds.yaml` file in one of the following locations:

   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable

   b. The current directory

   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

   The installation program searches for `clouds.yaml` in that order.

**12.8.7. Creating the RHCOS image for restricted network installations**
Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network Red Hat OpenStack Platform (RHOSP) environment.

Prerequisites

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

Procedure

2. Under Version, select the most recent release of OpenShift Container Platform 4.8 for RHEL 8.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW) image.

4. Decompress the image.

   **NOTE**
   You must decompress the image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

   $ file <name_of_downloaded_file>

5. Upload the image that you decompressed to a location that is accessible from the bastion server, like Glance. For example:

   $ openstack image create --file rhcos-44.81.202003110027-0-openstack.x86_64.qcow2 --disk-format qcow2 rhcos-$(RHCOS_VERSION)

   **IMPORTANT**
   Depending on your RHOSP environment, you might be able to upload the image in either .raw or .qcow2 formats. If you use Ceph, you must use the .raw format.
The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

12.8.8. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP). Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your bastion host.
- Have the `imageContentSources` values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir=<installation_directory>
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   IMPORTANT

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.
NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select gcp as the platform to target.

iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

v. Select the region to deploy the cluster to.

vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

vii. Select openstack as the platform to target.

viii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

ix. Specify the floating IP address to use for external access to the OpenShift API.

x. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

xi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

xii. Enter a name for your cluster. The name must be 14 or fewer characters long.

xiii. Paste the pull secret that you obtained from the Pull Secret page on the Red Hat OpenShift Cluster Manager site.

2. In the install-config.yaml file, set the value of platform.openstack.clusterOSImage to the image location or name. For example:

   ```yaml
   platform:
     openstack:
       clusterOSImage: http://mirror.example.com/images/rhcos-43.81.20191231630.0-openstack.x86_64.qcow2.gz?
       sha256=f3ebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
   ```

3. Edit the install-config.yaml file to provide the additional information that is required for an installation in a restricted network.

   a. Update the pullSecret value to contain the authentication information for your registry:

   ```yaml
   pullSecret: {"auths":{"<bastion_host_name>:5000": {"auth": "<credentials>","email": "you@example.com"}}}
   ```
For `<bastion_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```bash
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Define the network and subnets for the VPC to install the cluster in under the parent `platform.gcp` field:

```
network: <existing_vpc>
controlPlaneSubnet: <control_plane_subnet>
computeSubnet: <compute_subnet>
```

For `platform.gcp.network`, specify the name for the existing Google VPC. For `platform.gcp.controlPlaneSubnet` and `platform.gcp.computeSubnet`, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

d. Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - <bastion_host_name>:5000/<repo_name>/release
    source: quay.example.com/openshift-release-dev/ocp-release
  - mirrors:
  - <bastion_host_name>:5000/<repo_name>/release
    source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 12.8.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s
platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 12.8.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws**, **baremetal**, **azure**, **openstack**, **ovirt**, **vsphere**.

For additional information about `platform.<platform>` parameters, consult the table for your specific platform that follows.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform</strong></td>
<td>The configuration for the specific platform upon which to perform the installation: <strong>aws</strong>, <strong>baremetal</strong>, <strong>azure</strong>, <strong>openstack</strong>, <strong>ovirt</strong>, <strong>vsphere</strong>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>pullSecret</strong></td>
<td>Get a pull secret from <a href="https://cloud.redhat.com/openshift/install/pull-secret">https://cloud.redhat.com/openshift/install/pull-secret</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td><code>{  &quot;auths&quot;:{  &quot;cloud.openshift.com&quot;:{  &quot;auth&quot;:&quot;b3Blb=&quot;,  &quot;email&quot;:&quot;you@example.com&quot;  },  &quot;quay.io&quot;:{  &quot;auth&quot;:&quot;b3Blb=&quot;,  &quot;email&quot;:&quot;you@example.com&quot;  }} }</code></td>
</tr>
</tbody>
</table>

### 12.8.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 12.43. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <code>OpenShiftSDN</code> or <code>OVNKubernetes</code>. The default value is <code>OpenShiftSDN</code>.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <code>10.128.0.0/14</code> with a host prefix of <code>/23</code>.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 (2^((32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>The default value is 23.</td>
<td>The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <code>172.30.0.0/16</code>.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
</tbody>
</table>
### networking.machine Network

The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.

- **Values**: An array of objects. For example:
  ```
  networking:
    machineNetwork:
      - cidr: 10.0.0.0/16
  ```

### networking.machine Network.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

- **Values**: An IP network block in CIDR notation. For example, `10.0.0.0/16`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

#### 12.8.8.13. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>additionalTrustBundle</code></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>compute</code></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td></td>
<td>dynamically tries to determine the capabilities of the provided credentials,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td></td>
</tr>
</tbody>
</table>
Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**
If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Sources and repositories for the release-image content.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Specifying one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

To deploy a private cluster, which cannot be accessed from the internet, set `publish` to `Internal`. The default value is `External`.

The SSH key or keys to authenticate access your cluster machines.

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 12.8.8.1.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 12.45. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.size</code></td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.type</code></td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.openstack.cloud</td>
<td>The name of the RHOSP cloud to use from the list of clouds in the <code>clouds.yaml</code> file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td>platform.openstack.externalNetwork</td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td>platform.openstack.computeFlavor</td>
<td>The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the <code>platform.openstack.defaultMachinePlatform</code> property. You can also set a flavor value for each machine pool individually.</td>
<td>String, for example m1.xlarge.</td>
</tr>
</tbody>
</table>

12.8.8.15. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 12.46. Optional RHOSP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.additionalNetworkIDs</td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>compute.platform.openstack.additionalSecurityGroupIDs</td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>compute.platform.openstack.zones</strong></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><strong>compute.platform.openstack.rootVolume.zones</strong></td>
<td>For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.additionalNetworkIDs</strong></td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.additionalSecurityGroupIDs</strong></td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
</tbody>
</table>
**Parameter** | **Description** | **Values**
--- | --- | ---
**controlPlane.platform.openstack.zones** | RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property. | A list of strings. For example, ["zone-1", "zone-2"].

**controlPlane.platform.openstack.rootVolume.zones** | For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone. | A list of strings, for example ["zone-1", "zone-2"].

**platform.openstack.clusterOSImage** | The location from which the installer downloads the RH COS image. You must set this parameter to perform an installation in a restricted network. | An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d. The value can also be the name of an existing Glance image, for example my-rhcos.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.openstack.clusterOSImageProperties</td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;].</td>
</tr>
<tr>
<td></td>
<td>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td></td>
</tr>
<tr>
<td>platform.openstack.defaultMachinePlatform</td>
<td>The default machine pool platform configuration.</td>
<td>{</td>
</tr>
</tbody>
</table>
|                                                                          |                                                                                                                                                                                                              |   "type": "ml.large",
|                                                                          |                                                                                                                                                                                                              |   "rootVolume": {
|                                                                          |                                                                                                                                                                                                              |     "size": 30,
|                                                                          |                                                                                                                                                                                                              |     "type": "performance"
|                                                                          |                                                                                                                                                                                                              | }                                                                                                                                                                                                    |
| platform.openstack.ingressFloatingIP                                     | An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.                                                 | An IP address, for example 128.0.0.1.                                                                                                                                                               |
| platform.openstack.apiFloatingIP                                        | An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.                                             | An IP address, for example 128.0.0.1.                                                                                                                                                               |
| platform.openstack.externalDNS                                          | IP addresses for external DNS servers that cluster instances use for DNS resolution.                                                                                                                                                 | A list of IP addresses as strings. For example, ["8.8.8.8", "192.168.1.12"].                                                                                                                |
The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.

The first item in `networking.machineNetwork` must match the value of `machinesSubnet`.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

---

### 12.8.8.1.6. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.gcp.network</code></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.gcp.type</code></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><code>platform.gcp.zones</code></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>platform.gcp.controlPlaneSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>platform.gcp.computeSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.name</code></td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.location</td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.name</td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.location</td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td>compute.platform.gcp.osDisk.encryptionKey.kmsKey.projectID</td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

12.8.8.2. Sample customized install-config.yaml file for restricted OpenStack installations

This sample install-config.yaml demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your install-config.yaml file by using the installation program.
12.8.9. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the

```
~/.ssh/authorized_keys
```

list for the `core` user on each node, which enables password-less authentication.
After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `/openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>  # 1
   ```

   1 Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.
a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the **ssh-agent**:

```bash
$ ssh-add <path>/<file_name>
```

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

2. Set the **GOOGLE_APPLICATION_CREDENTIALS** environment variable to the full path to your service account private key file.

```bash
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

3. Verify that the credentials were applied.

```bash
$ gcloud auth list
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 12.8.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

#### 12.8.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.
Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>

   **NOTE**

   If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

4. Add the FIPs to the install-config.yaml file as the values of the following parameters:

   - platform.openstack.ingressFloatingIP
   - platform.openstack.apiFloatingIP

   If you use these values, you must also enter an external network as the value of the platform.openstack.externalNetwork parameter in the install-config.yaml file.

   **TIP**

   You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

12.8.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the install-config.yaml file, do not define the following parameters:

   - platform.openstack.ingressFloatingIP
   - platform.openstack.apiFloatingIP

   If you cannot provide an external network, you can also leave platform.openstack.externalNetwork blank. If you do not provide a value for platform.openstack.externalNetwork, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.
If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```bash
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 12.8.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCloud_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir=<installation_directory> \
   --log-level=info
   ```

1. For `<installation_directory>`, specify the
2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.  

---

**CHAPTER 12. INSTALLING ON OPENSTACK**

1913
NOTE
If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

NOTE
The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

IMPORTANT
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

IMPORTANT
You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
   - If you assigned the Owner role to your service account, you can remove that role and replace it with the Viewer role.
   - If you included the Service Account Key Admin role, you can remove it.

12.8.12. Verifying cluster status
You can verify your OpenShift Container Platform cluster’s status during or after installation.
Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster’s version:

   $ oc get clusterversion

4. View your Operators’ status:

   $ oc get clusteroperator

5. View all running pods in the cluster:

   $ oc get pods -A

12.8.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:
12.8.14. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json \\n  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

Next steps

- Customize your cluster.

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.

- If necessary, you can opt out of remote health reporting.

- Configure image streams for the Cluster Samples Operator and the must-gather tool.

- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.

- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

12.9. UNINSTALLING A CLUSTER ON OPENSTACK

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP).

12.9.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.
NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access. For example, some Google Cloud resources require IAM permissions in shared VPC host projects, or there might be unused health checks that must be deleted.

Prerequisites

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```bash
   $ ./openshift-install destroy cluster \
   --dir=<installation_directory> --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

12.10. UNINSTALLING A CLUSTER ON RHOSP FROM YOUR OWN INFRASTRUCTURE

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP) on user-provisioned infrastructure.

12.10.1. Downloading playbook dependencies

The Ansible playbooks that simplify the removal process on user-provisioned infrastructure require several Python modules. On the machine where you will run the process, add the modules’ repositories and then download them.

**NOTE**

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.
Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:
   a. Register with Red Hat Subscription Manager:
      
      ```
      $ sudo subscription-manager register # If not done already
      ```
   b. Pull the latest subscription data:
      
      ```
      $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
      ```
   c. Disable the current repositories:
      
      ```
      $ sudo subscription-manager repos --disable=* # If not done already
      ```
   d. Add the required repositories:
      
      ```
      $ sudo subscription-manager repos \
        --enable=rhel-8-for-x86_64-baseos-rpms \ 
        --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \ 
        --enable=ansible-2.9-for-rhel-8-x86_64-rpms \ 
        --enable=rhel-8-for-x86_64-appstream-rpms
      ```

2. Install the modules:

   ```
   $ sudo yum install python3-openstackclient ansible python3-openstacksdk
   ```

3. Ensure that the `python` command points to `python3`:

   ```
   $ sudo alternatives --set python /usr/bin/python3
   ```

12.10.2. Removing a cluster from RHOSP that uses your own infrastructure

You can remove an OpenShift Container Platform cluster on Red Hat OpenStack Platform (RHOSP) that uses your own infrastructure. To complete the removal process quickly, run several Ansible playbooks.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies."
- You have the playbooks that you used to install the cluster.
- You modified the playbooks that are prefixed with `down-` to reflect any changes that you made to their corresponding installation playbooks. For example, changes to the `bootstrap.yaml` file are reflected in the `down-bootstrap.yaml` file.
All of the playbooks are in a common directory.

Procedure

1. On a command line, run the playbooks that you downloaded:

   ```
   $ ansible-playbook -i inventory.yaml \
   down-bootstrap.yaml \
   down-control-plane.yaml \
   down-compute-nodes.yaml \
   down-load-balancers.yaml \
   down-network.yaml \
   down-security-groups.yaml
   ```

2. Remove any DNS record changes you made for the OpenShift Container Platform installation.

   OpenShift Container Platform is removed from your infrastructure.
CHAPTER 13. INSTALLING ON RHV

13.1. PREPARING TO INSTALL ON RHV

13.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

13.1.2. Choosing a method to install OpenShift Container Platform on RHV

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See Installation process for more information about installer-provisioned and user-provisioned installation processes.

13.1.2.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on Red Hat Virtualization (RHV) virtual machines that are provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- **Installing a cluster quickly on RHV** You can quickly install OpenShift Container Platform on RHV virtual machines that the OpenShift Container Platform installation program provisions.
- **Installing a cluster on RHV with customizations** You can install a customized OpenShift Container Platform cluster on installer-provisioned guests on RHV. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available post-installation.

13.1.2.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on RHV virtual machines that you provision, by using one of the following methods:

- **Installing a cluster on RHV with user-provisioned infrastructure** You can install OpenShift Container Platform on RHV virtual machines that you provision. You can use the provided Ansible playbooks to assist with the installation.
- **Installing a cluster on RHV in a restricted network** You can install OpenShift Container Platform on RHV in a restricted or disconnected network by creating an internal mirror of the installation release content. You can use this method to install a user-provisioned cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

13.2. INSTALLING A CLUSTER QUICKLY ON RHV

OpenShift Container Platform 4.8 Installing
You can quickly install a default, non-customized, OpenShift Container Platform cluster on a Red Hat Virtualization (RHV) cluster, similar to the one shown in the following diagram.

The installation program uses installer-provisioned infrastructure to automate creating and deploying the cluster.

To install a default cluster, you prepare the environment, run the installation program and answer its prompts. Then, the installation program creates the OpenShift Container Platform cluster.

For an alternative to installing a default cluster, see Installing a cluster with customizations.

**NOTE**

This installation program is available for Linux and macOS only.

### 13.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

### 13.2.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The
Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 13.2.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.8 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

**Requirements**

- The RHV version is 4.4.

- The RHV environment has one data center whose state is Up.
The RHV data center contains an RHV cluster.

The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:

- Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
- 112 GiB RAM or more, including:
  - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
  - 16 GiB or more for each of the three control plane machines which provide the control plane.
  - 16 GiB or more for each of the three compute machines, which run the application workloads.

The RHV storage domain must meet these etcd backend performance requirements.

For affinity group support: Three or more hosts in the RHV cluster. If necessary, you can disable affinity groups. For details, see Example: Removing all affinity groups for a non-production lab setup in Installing a cluster on RHV with customizations.

In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.

To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.

The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.

A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:

- **DiskOperator**
- **DiskCreator**
- **UserTemplateBasedVm**
- **TemplateOwner**
- **TemplateCreator**
- **ClusterAdmin** on the target cluster
WARNING

Apply the principle of least privilege: Avoid using an administrator account with SuperUser privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary ovirt-config.yaml file that might be compromised.

Additional resources

- Example: Removing all affinity groups for a non-production lab setup.

13.2.4. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

IMPORTANT

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

Procedure

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.8.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version.
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
   c. Click the name of that data center.
   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.
   e. Record the Domain Name for use later on.
   f. Confirm Free Space has at least 230 GiB.
g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.

h. In the data center details, click the Clusters tab.

i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.

a. In the RHV Administration Portal, click Compute > Clusters.

b. Click the cluster where you plan to install OpenShift Container Platform.

c. In the cluster details, click the Hosts tab.

d. Inspect the hosts and confirm they have a combined total of at least 28 Logical CPU Cores available exclusively for the OpenShift Container Platform cluster.

e. Record the number of available Logical CPU Cores for use later on.

f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.

g. Confirm that, all together, the hosts have 112 GiB of Max free Memory for scheduling new virtual machines distributed to meet the requirements for each of the following OpenShift Container Platform machines:

- 16 GiB required for the bootstrap machine
- 16 GiB required for each of the three control plane machines
- 16 GiB for each of the three compute machines

h. Record the amount of Max free Memory for scheduling new virtual machines for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

```bash
$ curl -k -u <username>@<profile>:<password> https://<engine-fqdn>/ovirt-engine/api
```

1 For `<username>`, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the Profile dropdown list. For `<password>`, specify the password for that user name.

2 For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

For example:

```bash
$ curl -k -u ocpadmin@internal:pw123 https://rhv-env.virtlab.example.com/ovirt-engine/api
```
13.2.5. Preparing the network environment on RHV

Configure two static IP addresses for the OpenShift Container Platform cluster and create DNS entries using these addresses.

Procedure

1. Reserve two static IP addresses
   a. On the network where you plan to install OpenShift Container Platform, identify two static IP addresses that are outside the DHCP lease pool.
   b. Connect to a host on this network and verify that each of the IP addresses is not in use. For example, use Address Resolution Protocol (ARP) to check that none of the IP addresses have entries:

   ```
   $ arp 10.35.1.19
   ```

   Example output

   ```
   10.35.1.19 (10.35.1.19) -- no entry
   ```
   c. Reserve two static IP addresses following the standard practices for your network environment.
   d. Record these IP addresses for future reference.

2. Create DNS entries for the OpenShift Container Platform REST API and apps domain names using this format:

   ```
   api.<cluster-name>.<base-domain>   <ip-address>  
   *.apps.<cluster-name>.<base-domain>   <ip-address>
   ```

   For `<cluster-name>`, `<base-domain>`, and `<ip-address>`, specify the cluster name, base domain, and static IP address of your OpenShift Container Platform API.

   Specify the cluster name, base domain, and static IP address of your OpenShift Container Platform apps for Ingress and the load balancer.

   For example:

   ```
   api.my-cluster.virtlab.example.com 10.35.1.19
   *.apps.my-cluster.virtlab.example.com 10.35.1.20
   ```

13.2.6. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in insecure mode.
WARNING

Installing in insecure mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.

Procedure

1. Create a file named ~/.ovirt/ovirt-config.yaml.

2. Add the following content to ovirt-config.yaml:

   ```yaml
   ovirt_url: https://ovirt.example.com/ovirt-engine/api
   ovirt_fqdn: ovirt.example.com
   ovirt_pem_url: ""
   ovirt_username: ocpadmin@internal
   ovirt_password: super-secret-password
   ovirt_insecure: true
   ```

3. Run the installer.

13.2.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```
Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   
   For example, run the following to view the ~/.ssh/id_rsa.pub public key:
   ```

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   **NOTE**

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   
   **Example output**

   Agent pid 31874
   ```

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

   1. Add your SSH private key to the ssh-agent:

   ```
   $ ssh-add <path>/<file_name>  
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
2. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

   ```
   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
   ```

3. Verify that the credentials were applied.

   ```
   $ gcloud auth list
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 13.2.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. From the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site, download your
installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

13.2.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Open the `ovirt-imageio` port to the Engine from the machine running the installer. By default, the port is `54322`.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCLOUD_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir=<installation_directory> \
   --log-level=info
   ```

   **1** For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.
Respond to the installation program prompts.

a. Optional: For **SSH Public Key**, select a password-less public key, such as
   ~/.ssh/id_rsa.pub. This key authenticates connections with the new OpenShift Container
   Platform cluster.

   **NOTE**
   For production OpenShift Container Platform clusters on which you want to
   perform installation debugging or disaster recovery, select an SSH key that
   your ssh-agent process uses.

b. For **Platform**, select ovirt.

c. For **Engine FQDN[:PORT]**, enter the fully qualified domain name (FQDN) of the RHV
   environment.
   For example:
   
   rhv-env.virtlab.example.com:443

d. The installer automatically generates a CA certificate. For **Would you like to use the
   above certificate to connect to the Engine?**, answer y or N. If you answer N, you must
   install OpenShift Container Platform in insecure mode.

e. For **Engine username**, enter the user name and profile of the RHV administrator using this
   format:

   `<username>@<profile>`

   For `<username>`, specify the user name of an RHV administrator. For `<profile>`,
   specify the login profile, which you can get by going to the RHV Administration Portal
   login page and reviewing the Profile dropdown list. For example: **admin@internal**.

f. For **Engine password**, enter the RHV admin password.

g. For **Cluster**, select the RHV cluster for installing OpenShift Container Platform.

h. For **Storage domain**, select the storage domain for installing OpenShift Container
   Platform.

i. For **Network**, select a virtual network that has access to the RHV Manager REST API.

j. For **Internal API Virtual IP**, enter the static IP address you set aside for the cluster’s REST
   API.

k. For **Ingress virtual IP**, enter the static IP address you reserved for the wildcard apps
   domain.

l. For **Base Domain**, enter the base domain of the OpenShift Container Platform cluster. If
   this cluster is exposed to the outside world, this must be a valid domain recognized by DNS
   infrastructure. For example, enter: **virtlab.example.com**

m. For **Cluster Name**, enter the name of the cluster. For example, **my-cluster**. Use cluster
   name from the externally registered/resolvable DNS entries you created for the OpenShift
Container Platform REST API and apps domain names. The installation program also gives this name to the cluster in the RHV environment.

n. For **Pull Secret**, copy the pull secret from the `pull-secret.txt` file you downloaded earlier and paste it here. You can also get a copy of the same pull secret from the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

**Example output**

```
... info Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for **Recovering from expired control plane certificates** for more information.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
- If you assigned the Owner role to your service account, you can remove that role and replace it with the Viewer role.

- If you included the Service Account Key Admin role, you can remove it.

**IMPORTANT**

You have completed the steps required to install the cluster. The remaining steps show you how to verify the cluster and troubleshoot the installation.
CHAPTER 14. INSTALLING THE OPENSHIFT CLI BY DOWNLOADING THE BINARY

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.8. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the Command line interface section, select Linux from the drop-down menu and click Download command-line tools.
4. Unpack the archive:
   ```
   $ tar xvzf <file>
   
   $ echo $PATH
   ```
5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:
   ```
   $ echo $PATH
   ```

After you install the CLI, it is available using the oc command:

```
$ oc <command>
```
After you install the CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

1. Navigate to the [Infrastructure Provider](#) page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the **Command line interface** section, select **MacOS** from the drop-down menu and click **Download command-line tools**.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.
   
   To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the CLI, it is available using the `oc` command:

```
$ oc <command>
```

To learn more, see [Getting started with the OpenShift CLI](#).
CHAPTER 15. LOGGING IN TO THE CLUSTER BY USING THE CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

15.1. VERIFYING CLUSTER STATUS

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s `kubeconfig` file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```bash
   $ oc get nodes
   ```
3. View your cluster’s version:
   
   `$ oc get clusterversion`

4. View your Operators’ status:
   
   `$ oc get clusteroperator`

5. View all running pods in the cluster:
   
   `$ oc get pods -A`

**Troubleshooting**

If the installation fails, the installation program times out and displays an error message. To learn more, see [Troubleshooting installation issues](#).

### 15.2. ACCESSING THE OPENSShift CONTAINER PLATFORM WEB CONSOLE ON RHV

After the OpenShift Container Platform cluster initializes, you can log into the OpenShift Container Platform web console.

**Procedure**

1. Optional: In the Red Hat Virtualization (RHV) Administration Portal, open **Compute → Cluster**.

2. Verify that the installation program creates the virtual machines.

3. Return to the command line where the installation program is running. When the installation program finishes, it displays the user name and temporary password for logging into the OpenShift Container Platform web console.

4. In a browser, open the URL of the OpenShift Container Platform web console. The URL uses this format:

   `console-openshift-console.apps.<clustername>.<basedomain>`

   For `<clustername>.<basedomain>`, specify the cluster name and base domain.

   For example:

   `console-openshift-console.apps.my-cluster.virtlab.example.com`

### 15.3. TROUBLESHOOTING COMMON ISSUES WITH INSTALLING ON RED HAT VIRTUALIZATION (RHV)

Here are some common issues you might encounter, along with proposed causes and solutions.

#### 15.3.1. CPU load increases and nodes go into a Not Ready state
Symptom: CPU load increases significantly and nodes start going into a Not Ready state.

Cause: The storage domain latency might be too high, especially for control plane nodes (also known as the master nodes).

Solution:
Make the nodes ready again by restarting the kubelet service:

```bash
$ systemctl restart kubelet
```

Inspect the OpenShift Container Platform metrics service, which automatically gathers and reports on some valuable data such as the etcd disk sync duration. If the cluster is operational, use this data to help determine whether storage latency or throughput is the root issue. If so, consider using a storage resource that has lower latency and higher throughput.

To get raw metrics, enter the following command as kubeadmin or user with cluster-admin privileges:

```bash
```

To learn more, see Exploring Application Endpoints for the purposes of Debugging with OpenShift 4.x

15.3.2. Trouble connecting the OpenShift Container Platform cluster API

- **Symptom:** The installation program completes but the OpenShift Container Platform cluster API is not available. The bootstrap virtual machine remains up after the bootstrap process is complete. When you enter the following command, the response will time out.

  ```bash
  $ oc login -u kubeadmin -p *** <apiurl>
  
  ```

- **Cause:** The bootstrap VM was not deleted by the installation program and has not released the cluster’s API IP address.

- **Solution:** Use the `wait-for` subcommand to be notified when the bootstrap process is complete:

  ```bash
  $ ./openshift-install wait-for bootstrap-complete
  
  When the bootstrap process is complete, delete the bootstrap virtual machine:

  ```bash
  $ ./openshift-install destroy bootstrap
  
15.4. POST-INSTALLATION TASKS

After the OpenShift Container Platform cluster initializes, you can perform the following tasks.

- Optional: After deployment, add or replace SSH keys using the Machine Config Operator (MCO) in OpenShift Container Platform.

- Optional: Remove the `kubeadmin` user. Instead, use the authentication provider to create a user with cluster-admin privileges.

15.5. INSTALLING A CLUSTER ON RHV WITH CUSTOMIZATIONS
You can customize and install an OpenShift Container Platform cluster on Red Hat Virtualization (RHV), similar to the one shown in the following diagram.

The installation program uses installer-provisioned infrastructure to automate creating and deploying the cluster.

To install a customized cluster, you prepare the environment and perform the following steps:

1. Create an installation configuration file, the `install-config.yaml` file, by running the installation program and answering its prompts.
2. Inspect and modify parameters in the `install-config.yaml` file.
3. Make a working copy of the `install-config.yaml` file.
4. Run the installation program with a copy of the `install-config.yaml` file.

Then, the installation program creates the OpenShift Container Platform cluster.

For an alternative to installing a customized cluster, see Installing a default cluster.

**NOTE**

This installation program is available for Linux and macOS only.

**15.5.1. Prerequisites**
You reviewed details about the OpenShift Container Platform installation and update processes.

You read the documentation on selecting a cluster installation method and preparing it for users.

If you use a firewall, you configured it to allow the sites that your cluster requires access to.

15.5.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

15.5.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.8 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating
the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

Requirements

- The RHV version is 4.4.
- The RHV environment has one data center whose state is **Up**.
- The RHV data center contains an RHV cluster.
- The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
  - Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
  - 112 GiB RAM or more, including:
    - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
    - 16 GiB or more for each of the three control plane machines which provide the control plane.
    - 16 GiB or more for each of the three compute machines, which run the application workloads.
- The RHV storage domain must meet these etcd backend performance requirements.
- For affinity group support:
  One physical machine per worker or control plane. Workers and control planes can be on the same physical machine. For example, if you have three workers and three control planes, you need three physical machines. If you have four workers and three control planes, you need four physical machines.
  - For hard anti-affinity (default): A minimum of three physical machines. For more than three worker nodes, one physical machine per worker or control plane. Workers and control planes can be on the same physical machine.
  - For custom affinity groups: Ensure that the resources are appropriate for the affinity group rules that you define.
- In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.
- To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.
- The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.
A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:

- **DiskOperator**
- **DiskCreator**
- **UserTemplateBasedVm**
- **TemplateOwner**
- **TemplateCreator**
- **ClusterAdmin** on the target cluster

**WARNING**

Apply the principle of least privilege: Avoid using an administrator account with **SuperUser** privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary `ovirt-config.yaml` file that might be compromised.

### 15.5.4. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

**IMPORTANT**

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

**Procedure**

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.8.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select **About**.
   b. In the window that opens, make a note of the **RHV Software Version**
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see [Support Matrix for OpenShift Container Platform on RHV](#).

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click **Compute → Data Centers**.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
c. Click the name of that data center.

d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.

e. Record the Domain Name for use later on.

f. Confirm Free Space has at least 230 GiB.

g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.

h. In the data center details, click the Clusters tab.

i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.

a. In the RHV Administration Portal, click Compute > Clusters.

b. Click the cluster where you plan to install OpenShift Container Platform.

c. In the cluster details, click the Hosts tab.

d. Inspect the hosts and confirm they have a combined total of at least 28 Logical CPU Cores available exclusively for the OpenShift Container Platform cluster.

e. Record the number of available Logical CPU Cores for use later on.

f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.

g. Confirm that, all together, the hosts have 112 GiB of Max free Memory for scheduling new virtual machines distributed to meet the requirements for each of the following OpenShift Container Platform machines:

   - 16 GiB required for the bootstrap machine
   - 16 GiB required for each of the three control plane machines
   - 16 GiB for each of the three compute machines

h. Record the amount of Max free Memory for scheduling new virtual machines for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

   ```bash
   $ curl -k -u <username>@<profile>:<password> "https://<engine-fqdn>/ovirt-engine/api"
   ```

   For `<username>` specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the Profile dropdown list. For `<password>`, specify the password for that user.
For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

For example:

```
$ curl -k -u ocpadmin@internal:pw123 \  
https://rhv-env.virtlab.example.com/ovirt-engine/api
```

### 15.5.5. Preparing the network environment on RHV

Configure two static IP addresses for the OpenShift Container Platform cluster and create DNS entries using these addresses.

**Procedure**

1. Reserve two static IP addresses
   
   a. On the network where you plan to install OpenShift Container Platform, identify two static IP addresses that are outside the DHCP lease pool.

   b. Connect to a host on this network and verify that each of the IP addresses is not in use. For example, use Address Resolution Protocol (ARP) to check that none of the IP addresses have entries:

   ```
   $ arp 10.35.1.19
   ```

   **Example output**

   ```
   10.35.1.19 (10.35.1.19) -- no entry
   ```

   c. Reserve two static IP addresses following the standard practices for your network environment.

   d. Record these IP addresses for future reference.

2. Create DNS entries for the OpenShift Container Platform REST API and apps domain names using this format:

   ```
   api.<cluster-name>.<base-domain>   <ip-address>  
   *.apps.<cluster-name>.<base-domain>   <ip-address>
   ```

   **For `<cluster-name>`, `<base-domain>`, and `<ip-address>`**, specify the cluster name, base domain, and static IP address of your OpenShift Container Platform API.

   **Specify the cluster name, base domain, and static IP address of your OpenShift Container Platform apps for Ingress and the load balancer.**

   **For example:**

   ```
   api.my-cluster.virtlab.example.com 10.35.1.19
   *.apps.my-cluster.virtlab.example.com 10.35.1.20
   ```
15.5.6. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in insecure mode.

WARNING

Installing in insecure mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.

Procedure

1. Create a file named ~/.ovirt.ovirt-config.yaml.

2. Add the following content to ovirt-config.yaml:

   ```yaml
   ovirt_url: https://ovirt.example.com/ovirt-engine/api
   ovirt_fqdn: ovirt.example.com
   ovirt_pem_url: ""
   ovirt_username: ocpadmin@internal
   ovirt_password: super-secret-password
   ovirt_insecure: true
   ```

3. Run the installer.

15.5.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The .openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name> 1

1 Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   $ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE
   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

      If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

      1. Add your SSH private key to the ssh-agent:

         $ ssh-add <path>/<file_name> 1
Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

2. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

```
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

3. Verify that the credentials were applied.

```
$ gcloud auth list
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

15.5.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.
4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```shell
$ tar xvf openshift-install-linux.tar.gz
```

5. From the Pull Secret page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 15.5.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP). Red Hat Virtualization (RHV).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```shell
   $ ./openshift-install create install-config --dir=<installation_directory>  
   ```

   i. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   i. Select `gcp` as the platform to target.

   ii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

   iii. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

   iv. Select the region to deploy the cluster to.
v. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

b. Respond to the installation program prompts.

   i. For **SSH Public Key**, select a password-less public key, such as ~/.ssh/id_rsa.pub. This key authenticates connections with the new OpenShift Container Platform cluster.

   ![NOTE]
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, select an SSH key that your ssh-agent process uses.

   ii. For **Platform**, select ovirt.

   iii. For **Enter oVirt’s API endpoint URL**, enter the URL of the RHV API using this format:

   ```
   https://<engine-fqdn>/ovirt-engine/api
   ```

   For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

   For example:

   ```
   $ curl -k -u ocpadmin@internal:pw123 \\
   https://rhv-env.virtlab.example.com/ovirt-engine/api
   ```

   iv. For **Is the oVirt CA trusted locally?**, enter Yes, because you have already set up a CA certificate. Otherwise, enter No.

   v. For **oVirt’s CA bundle**, if you entered Yes for the preceding question, copy the certificate content from /etc/pki/ca-trust/source/anchors/ca.pem and paste it here. Then, press Enter twice. Otherwise, if you entered No for the preceding question, this question does not appear.

   vi. For **oVirt engine username**, enter the user name and profile of the RHV administrator using this format:

   ```
   <username>@<profile>
   ```

   For `<username>`, specify the user name of an RHV administrator. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the Profile dropdown list. Together, the user name and profile should look similar to this example:

   ```
   ocpadmin@internal
   ```

   vii. For **oVirt engine password**, enter the RHV admin password.

   viii. For **oVirt cluster**, select the cluster for installing OpenShift Container Platform.
ix. For **oVirt storage domain**, select the storage domain for installing OpenShift Container Platform.

x. For **oVirt network**, select a virtual network that has access to the RHV Manager REST API.

xi. For **Internal API Virtual IP**, enter the static IP address you set aside for the cluster’s REST API.

xii. For **Ingress virtual IP**, enter the static IP address you reserved for the wildcard apps domain.

xiii. For **Base Domain**, enter the base domain of the OpenShift Container Platform cluster. If this cluster is exposed to the outside world, this must be a valid domain recognized by DNS infrastructure. For example, enter: `virtlab.example.com`

xiv. For **Cluster Name**, enter the name of the cluster. For example, `my-cluster`. Use cluster name from the externally registered/resolvable DNS entries you created for the OpenShift Container Platform REST API and apps domain names. The installation program also gives this name to the cluster in the RHV environment.

xv. For **Pull Secret**, copy the pull secret from the `pull-secret.txt` file you downloaded earlier and paste it here. You can also get a copy of the same pull secret from the Pull Secret page on the Red Hat OpenShift Cluster Manager site.

2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.

**NOTE**

If you have any intermediate CA certificates on the engine, verify that the certificates appear in the `ovirt-config.yaml` file and the `install-config.yaml` file. If they do not appear, add them as follows:

1. In the `~/.ovirt/ovirt-config.yaml` file:

   ```yaml
   [ovirt_ca_bundle]: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA>
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   <INTERMEDIATE_CA>
   -----END CERTIFICATE-----
   ```

2. In the `install-config.yaml` file:

   ```yaml
   [additionalTrustBundle]: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA>
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   <INTERMEDIATE_CA>
   -----END CERTIFICATE-----
   ```

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.
IMPORTANT

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

15.5.9.1. Example install-config.yaml files for Red Hat Virtualization (RHV)

You can customize the OpenShift Container Platform cluster the installation program creates by changing the parameters and parameter values in the `install-config.yaml` file.

The following examples are specific to installing OpenShift Container Platform on RHV.

`install-config.yaml` is located in `<installation_directory>`, which you specified when you ran the following command.

```bash
$ ./openshift-install create install-config --dir=<installation_directory>
```

**NOTE**

- These example files are provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

- Changing the `install-config.yaml` file can increase the resources your cluster requires. Verify that your RHV environment has those additional resources. Otherwise, the installation or cluster will fail.

Example default `install-config.yaml` file

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - architecture: amd64
    hyperthreading: Enabled
    name: worker
    platform: {}
    replicas: 3
controlPlane:
  architecture: amd64
  hyperthreading: Enabled
  name: master
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: my-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
```
Example minimal `install-config.yaml` file

```yaml
apiVersion: v1
baseDomain: example.com
metadata:
  name: test-cluster
platform:
  ovirt:
    api_vip: 10.46.8.230
    ingress_vip: 10.46.8.232
    ovirt_cluster_id: dba5f69f-e89c-4891-b768-e2ba0815b76b
    ovirt_storage_domain_id: ed7b0f4e-0e96-492a-8ff-279213ee1468
    ovirt_network_name: ovirtmgmt
    vnicProfileID: 3fa86930-0be5-4052-b667-b79f0a729692
    pullSecret: '{"auths": ...}'
    sshKey: ssh-ed12345 AAAA...
```

Example Custom machine pools in `install-config.yaml` file

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
platform:
  ovirt:
    cpu:
      cores: 4
      sockets: 2
      memoryMB: 65536
    osDisk:
      sizeGB: 100
      vmType: server
      replicas: 3
      compute:
        - name: worker
          platform:
            ovirt:
              cpu:
                cores: 4
                sockets: 4
                memoryMB: 65536
                osDisk:
                  sizeGB: 200
                  vmType: server
```
Example non-enforcing affinity group
It is recommended to add a non-enforcing affinity group to distribute the control plane and workers, if possible, to use as much of the cluster as possible.

Example removing all affinity groups for a non-production lab setup
For non-production lab setups, you must remove all affinity groups to concentrate the OpenShift replicas:

```
platform:
  ovirt:
    affinityGroups:
      - description: AffinityGroup to place each compute machine on a separate host
        enforcing: true
        name: compute
        priority: 3
      - description: AffinityGroup to place each control plane machine on a separate host
        enforcing: true
        name: controlplane
        priority: 5
      - description: AffinityGroup to place worker nodes and control plane nodes on separate hosts
        enforcing: false
        name: openshift
        priority: 5
  compute:
    - architecture: amd64
      hyperthreading: Enabled
      name: worker
  controlPlane:
    architecture: amd64
    hyperthreading: Enabled
    name: master
```

Example removing all affinity groups for a non-production lab setup
For non-production lab setups, you must remove all affinity groups to concentrate the OpenShift Container Platform cluster on the few hosts you have.

```yaml
platform:
  ovirt:
    affinityGroups: []
compute:
- architecture: amd64
  hyperthreading: Enabled
  name: worker
  platform:
    ovirt:
      affinityGroupsNames: []
replicas: 3
controlPlane:
  architecture: amd64
  hyperthreading: Enabled
  name: master
  platform:
    ovirt:
      affinityGroupsNames: []
replicas: 3
```

15.5.9.2. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

15.5.9.2.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 15.1. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform</td>
<td></td>
<td></td>

      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 15.5.9.2.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 15.2. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>networking.type</strong></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td><strong>networking.clusterNetwork</strong></td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
</tbody>
</table>

The default value is **10.128.0.0/14** with a host prefix of /23.

If you specify multiple IP address blocks, the blocks must not overlap.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 ($2^{32 - 23} - 2$) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example: <code>networking: serviceNetwork: - 172.30.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: <code>networking: machineNetwork: - cidr: 10.0.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16. <strong>NOTE</strong> Set the <code>networking.machineNetwork</code> to match the CIDR that the preferred NIC resides in.</td>
</tr>
</tbody>
</table>

### 15.5.9.2.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 15.3. Optional parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>additionalTrustBundle</strong></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute</strong></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute.hyperthreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td><strong>compute.name</strong></td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
<tr>
<td><strong>compute.platform</strong></td>
<td>Required if you use <strong>compute</strong>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <strong>controlPlane.platform</strong> parameter value.</td>
<td><strong>aws, azure, gcp, openstack, ovirt, vsphere</strong>, or <strong>{}</strong></td>
</tr>
</tbody>
</table>
### Parameter Table

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>controlPlane.hypertreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or <code>hypertreading</code>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
</tr>
<tr>
<td><code>controlPlane.name</code></td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td><code>controlPlane.platform</code></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td><code>controlPlane.replicas</code></td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”)</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fips</code></td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled).</td>
<td><code>false</code> or <code>true</code></td>
</tr>
<tr>
<td><code>imageContentSources</code></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><code>imageContentSources.source</code></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><code>imageContentSources.mirrors</code></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><code>publish</code></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to <code>Internal</code>. The default value is <code>External</code>.</td>
</tr>
</tbody>
</table>
The SSH key or keys to authenticate access your cluster machines.

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

## 15.5.9.2.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

**Table 15.4. Additional GCP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.gcp.network</td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.gcp.type</td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td>platform.gcp.zones</td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as us-central1-a, in a YAML sequence.</td>
</tr>
<tr>
<td>platform.gcp.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.computeSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.name</td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>controlPlane.platfor m.gcp.osDisk.encryptionKey.kmsKey.keyRing</code></td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><code>controlPlane.platfor m.gcp.osDisk.encryptionKey.kmsKey.location</code></td>
<td>For control plane machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>controlPlane.platfor m.gcp.osDisk.encryptionKey.kmsKey.projectID</code></td>
<td>For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryption Key.kmsKey.name</code></td>
<td>The name of the customer managed encryption key to be used for compute machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryption Key.kmsKey.keyRing</code></td>
<td>For compute machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryption Key.kmsKey.location</code></td>
<td>For compute machines, the GCP location in which the key ring exists. For more information on KMS locations, see Google’s documentation on Cloud KMS locations.</td>
<td>The GCP location for the key ring.</td>
</tr>
<tr>
<td><code>compute.platform.gc p.osDisk.encryption Key.kmsKey.projectID</code></td>
<td>For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set.</td>
<td>The GCP project ID.</td>
</tr>
</tbody>
</table>

#### 15.5.9.2.5. Additional Red Hat Virtualization (RHV) configuration parameters

Additional RHV configuration parameters are described in the following table:

**Table 15.5. Additional Red Hat Virtualization (RHV) parameters for clusters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.ovirt.ovirt_cluster_id</code></td>
<td>Required. The Cluster where the VMs will be created.</td>
<td>String. For example: [example value]</td>
</tr>
<tr>
<td><code>platform.ovirt.ovirt_storage_domain_id</code></td>
<td>Required. The Storage Domain ID where the VM disks will be created.</td>
<td>String. For example: [example value]</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.ovirt.ovirt_network_name</td>
<td>Required. The network name where the VM nics will be created.</td>
<td>String. For example: <code>ocpcluster</code></td>
</tr>
<tr>
<td>platform.ovirt.vnicProfileID</td>
<td>Required. The vNIC profile ID of the VM network interfaces. This can be inferred if the cluster network has a single profile.</td>
<td>String. For example: <code>3fa86930-0be5-4052-b667-b79f0a729692</code></td>
</tr>
<tr>
<td>platform.ovirt.api_vip</td>
<td>Required. An IP address on the machine network that will be assigned to the API virtual IP (VIP). You can access the OpenShift API at this endpoint.</td>
<td>String. Example: <code>10.46.8.230</code></td>
</tr>
<tr>
<td>platform.ovirt.ingress_vip</td>
<td>Required. An IP address on the machine network that will be assigned to the Ingress virtual IP (VIP).</td>
<td>String. Example: <code>10.46.8.232</code></td>
</tr>
<tr>
<td>platform.ovirt.affinityGroups</td>
<td>Optional. A list of affinity groups to create during the installation process.</td>
<td>List of objects.</td>
</tr>
<tr>
<td>platform.ovirt.affinityGroups.description</td>
<td>Required if you include <code>platform.ovirt.affinityGroups</code>. A description of the affinity group.</td>
<td>String. Example: AffinityGroup for spreading each compute machine to a different host</td>
</tr>
<tr>
<td>platform.ovirt.affinityGroups.enforcing</td>
<td>Required if you include <code>platform.ovirt.affinityGroups</code>. When set to <code>true</code>, RHV does not provision any machines if not enough hardware nodes are available. When set to <code>false</code>, RHV does provision machines even if not enough hardware nodes are available, resulting in multiple virtual machines being hosted on the same physical machine.</td>
<td>String. Example: <code>true</code></td>
</tr>
<tr>
<td>platform.ovirt.affinityGroups.name</td>
<td>Required if you include <code>platform.ovirt.affinityGroups</code>. The name of the affinity group.</td>
<td>String. Example: <code>compute</code></td>
</tr>
</tbody>
</table>
**platform.ovirt.affinityGroups.priority**

Required if you include `platform.ovirt.affinityGroups`. The priority given to an affinity group when `platform.ovirt.affinityGroups.enforcing = false`. RHV applies affinity groups in the order of priority, where a greater number takes precedence over a lesser one. If multiple affinity groups have the same priority, the order in which they are applied is not guaranteed.

Integer. Example: 3

### 15.5.9.2.6. Additional RHV parameters for machine pools

Additional RHV configuration parameters for machine pools are described in the following table:

**Table 15.6. Additional RHV parameters for machine pools**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.cpu</code></td>
<td>Optional. Defines the CPU of the VM.</td>
<td>Object</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.cpu.cores</code></td>
<td>Required if you use <code>&lt;machine-pool&gt;.platform.ovirt.cpu</code>. The number of cores. Total virtual CPUs (vCPUs) is cores * sockets.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.cpusockets</code></td>
<td>Required if you use <code>&lt;machine-pool&gt;.platform.ovirt.cpu</code>. The number of sockets per core. Total virtual CPUs (vCPUs) is cores * sockets.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.memoryMB</code></td>
<td>Optional. Memory of the VM in MiB.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.instanceTypeID</code></td>
<td>Optional. An instance type UUID, such as <code>00000009-0009-0009-0009-0000000000f1</code>, which you can get from the <code>https://&lt;engine-fqdn&gt;/ovirt-engine/api/instancetypes</code> endpoint.</td>
<td>String of UUID</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.osDisk</code></td>
<td>Optional. Defines the first and bootable disk of the VM.</td>
<td>String</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.osDisk.sizeGB</code></td>
<td>Required if you use <code>&lt;machine-pool&gt;.platform.ovirt.osDisk</code>. Size of the disk in GiB.</td>
<td>Number</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.vmType</code></td>
<td>Optional. The VM workload type, such as <code>high-performance</code>, <code>server</code>, or <code>desktop</code>. By default, master nodes use <code>high-performance</code>, and worker nodes use <code>server</code>. For details, see Explanation of Settings in the New Virtual Machine and Edit Virtual Machine Windows and Configuring High Performance Virtual Machines, Templates, and Pools in the Virtual Machine Management Guide.</td>
<td>String</td>
</tr>
</tbody>
</table>

**NOTE**

`high_performance` improves performance on the VM, but there are limitations. For example, you cannot access the VM with a graphical console. For more information see Configuring High Performance Virtual Machines, Templates, and Pools in the Virtual Machine Management Guide.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;machine-pool</code>.platform.ovirt.affinityGroupsNames`</td>
<td>Optional. A list of affinity group names that should be applied to the virtual machines. The affinity groups must exist in RHV, or be created during installation as described in <em>Additional RHV parameters for clusters</em> in this topic. This entry can be empty.</td>
<td>String</td>
</tr>
</tbody>
</table>

**Example with two affinity groups**

This example defines two affinity groups, named `compute` and `clusterWideNonEnforcing`:

```yaml
<machine-pool>:
  platform:
    ovirt:
      affinityGroupNames:
        - compute
        - clusterWideNonEnforcing
```

This example defines no affinity groups:

```yaml
<machine-pool>:
  platform:
    ovirt:
      affinityGroupNames: []
```

**NOTE**

You can replace `<machine-pool>` with `controlPlane` or `compute`.

### 15.5.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Open the `ovirt-imageio` port to the Engine from the machine running the installer. By default, the port is 54322.

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**
1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   - The GOOGLE_CREDENTIALS, GOOGLE_CLOUD_KEYFILE_JSON, or GCLOUD_KEYFILE_JSON environment variables
   - The ~/.gcp/osServiceAccount.json file
   - The gcloud cli default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir=<installation_directory> \
   --log-level=info
   ```

   - For <installation_directory>, specify the location of your customized ./install-config.yaml file.
   - To view different installation details, specify warn, debug, or error instead of info.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

   **Example output**

   ```
   "INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export
   KUBECONFIG=\"/home/myuser/install_dir/auth/kubeconfig\"'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s
   ```

   **NOTE**

   The cluster access and credential information also outputs to <installation_directory>/openshift_install.log when an installation succeeds.
IMPORTANT

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.

   - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
   
   - If you included the **Service Account Key Admin** role, you can remove it.

IMPORTANT

You have completed the steps required to install the cluster. The remaining steps show you how to verify the cluster and troubleshoot the installation.

15.5.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.8. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

Procedure

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the **Command line interface** section, select **Linux** from the drop-down menu and click **Download command-line tools**.

4. Unpack the archive:

   ```bash
   $ tar xvzf <file>
   ```
Place the **oc** binary in a directory that is on your **PATH**. To check your **PATH**, execute the following command:

```
$ echo $PATH
```

After you install the CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the **Command line interface** section, select **Windows** from the drop-down menu and click **Download command-line tools**.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

```
C:> path
```

After you install the CLI, it is available using the **oc** command:

```
C:> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

1. Navigate to the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the **Command line interface** section, select **MacOS** from the drop-down menu and click **Download command-line tools**.
4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the CLI, it is available using the **oc** command:
15.5.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
   
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```
   
   Example output
   
   ```python
   system:admin
   ```
   
   To learn more, see [Getting started with the OpenShift CLI](#).

15.5.13. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
   
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:
$ oc get nodes

3. View your cluster’s version:

$ oc get clusterversion

4. View your Operators’ status:

$ oc get clusteroperator

5. View all running pods in the cluster:

$ oc get pods -A

Troubleshooting

If the installation fails, the installation program times out and displays an error message. To learn more, see Troubleshooting installation issues.

15.5.14. Accessing the OpenShift Container Platform web console on RHV

After the OpenShift Container Platform cluster initializes, you can log into the OpenShift Container Platform web console.

Procedure

2. Verify that the installation program creates the virtual machines.

3. Return to the command line where the installation program is running. When the installation program finishes, it displays the user name and temporary password for logging into the OpenShift Container Platform web console.

4. In a browser, open the URL of the OpenShift Container Platform web console. The URL uses this format:

    console-openshift-console.apps.<clusternam>e.<basedomain>

For <clusternam>e.<basedomain>, specify the cluster name and base domain.

For example:

    console-openshift-console.apps.my-cluster.virtlab.example.com

15.5.15. Troubleshooting common issues with installing on Red Hat Virtualization (RHV)

Here are some common issues you might encounter, along with proposed causes and solutions.

15.5.15.1. CPU load increases and nodes go into a Not Ready state
• **Symptom:** CPU load increases significantly and nodes start going into a Not Ready state.

• **Cause:** The storage domain latency might be too high, especially for control plane nodes (also known as the master nodes).

• **Solution:**
  Make the nodes ready again by restarting the kubelet service:

  $ systemctl restart kubelet

  Inspect the OpenShift Container Platform metrics service, which automatically gathers and reports on some valuable data such as the etcd disk sync duration. If the cluster is operational, use this data to help determine whether storage latency or throughput is the root issue. If so, consider using a storage resource that has lower latency and higher throughput.

  To get raw metrics, enter the following command as kubeadmin or user with cluster-admin privileges:

  To learn more, see Exploring Application Endpoints for the purposes of Debugging with OpenShift 4.x

15.5.15.2. Trouble connecting the OpenShift Container Platform cluster API

• **Symptom:** The installation program completes but the OpenShift Container Platform cluster API is not available. The bootstrap virtual machine remains up after the bootstrap process is complete. When you enter the following command, the response will time out.

  $ oc login -u kubeadmin -p *** <apiurl>

• **Cause:** The bootstrap VM was not deleted by the installation program and has not released the cluster’s API IP address.

• **Solution:** Use the wait-for subcommand to be notified when the bootstrap process is complete:

  $ ./openshift-install wait-for bootstrap-complete

  When the bootstrap process is complete, delete the bootstrap virtual machine:

  $ ./openshift-install destroy bootstrap

15.5.16. Post-installation tasks

After the OpenShift Container Platform cluster initializes, you can perform the following tasks.

• Optional: After deployment, add or replace SSH keys using the Machine Config Operator (MCO) in OpenShift Container Platform.

• Optional: Remove the kubeadmin user. Instead, use the authentication provider to create a user with cluster-admin privileges.

15.5.17. Next steps
15.6. INSTALLING A CLUSTER ON RHV WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.8, you can install a customized OpenShift Container Platform cluster on Red Hat Virtualization (RHV) and other infrastructure that you provide. The OpenShift Container Platform documentation uses the term *user-provisioned infrastructure* to refer to this infrastructure type.

The following diagram shows an example of a potential OpenShift Container Platform cluster running on a RHV cluster.

15.6.1. Prerequisites

The following items are required to install an OpenShift Container Platform cluster on a RHV environment.

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on RHV.

15.6.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

15.6.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.8 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.
Requirements

- The RHV version is 4.4.
- The RHV environment has one data center whose state is **Up**.
- The RHV data center contains an RHV cluster.
- The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
  - Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
  - 112 GiB RAM or more, including:
    - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
    - 16 GiB or more for each of the three control plane machines which provide the control plane.
    - 16 GiB or more for each of the three compute machines, which run the application workloads.
- The RHV storage domain must meet these etcd backend performance requirements.
- In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.
- To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.
- The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.
- A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:
  - **DiskOperator**
  - **DiskCreator**
  - **UserTemplateBasedVm**
  - **TemplateOwner**
  - **TemplateCreator**
  - **ClusterAdmin** on the target cluster
15.6.4. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

**IMPORTANT**

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

**Procedure**

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.8.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version.
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
   c. Click the name of that data center.
   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.
   e. Record the Domain Name for use later on.
   f. Confirm Free Space has at least 230 GiB.
   g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.
   h. In the data center details, click the Clusters tab.
1. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.
   a. In the RHV Administration Portal, click **Compute > Clusters**.
   b. Click the cluster where you plan to install OpenShift Container Platform.
   c. In the cluster details, click the **Hosts** tab.
   d. Inspect the hosts and confirm they have a combined total of at least 28 **Logical CPU Cores** available exclusively for the OpenShift Container Platform cluster.
   e. Record the number of available **Logical CPU Cores** for use later on.
   f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.
   g. Confirm that, all together, the hosts have 112 GiB of **Max free Memory for scheduling new virtual machines** distributed to meet the requirements for each of the following OpenShift Container Platform machines:
      - 16 GiB required for the bootstrap machine
      - 16 GiB required for each of the three control plane machines
      - 16 GiB for each of the three compute machines
   h. Record the amount of **Max free Memory for scheduling new virtual machines** for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

   ```
   $ curl -k -u <username>@<profile>:<password> \ 
   https://<engine-fqdn>/ovirt-engine/api
   ```

   **For** `<username>`, **specify the user name of an RHV account** with privileges to create and manage an OpenShift Container Platform cluster on RHV. **For** `<profile>`, **specify the login profile**, which you can get by going to the RHV Administration Portal login page and reviewing the **Profile** dropdown list. **For** `<password>`, **specify the password for that user name**.

   **For** `<engine-fqdn>`, **specify the fully qualified domain name** of the RHV environment.

   For example:

   ```
   $ curl -k -u ocpadmin@internal:pw123 \
   https://rhv-env.virtlab.example.com/ovirt-engine/api
   ```

15.6.5. Network infrastructure configuration for installing OpenShift Container Platform on Red Hat Virtualization (RHV)
Before installing OpenShift Container Platform, configure your network environment to meet the following requirements.

When they boot, virtual machines must have IP addresses get the Ignition config files. Consider configuring DHCP to provide persistent IP addresses and hostnames to the cluster machines.

**Firewall**

Configure your firewall so your cluster has access to required sites.

**Network connectivity**

Configure your network to enable the following connections:

- Grant every machine access to every other machine on ports **30000-32767**. This provides connectivity to OpenShift Container Platform components.
- Grant every machine access to reserved ports **10250-10259** and **9000-9999**.
- Grant every machine access on ports **2379-2380**. This provides access to etcd, peers, and metrics on the control plane.
- Grant every machine access to the Kubernetes API on port **6443**.

**Load balancers**

Configure one or two (preferred) layer-4 load balancers:

- Provide load balancing for ports **6443** and **22623** on the control plane and bootstrap machines. Port **6443** provides access to the Kubernetes API server and must be reachable both internally and externally. Port **22623** must be accessible to nodes within the cluster.
- Provide load balancing for port **443** and **80** for machines that run the Ingress router, which are usually worker nodes in the default configuration. Both ports must be accessible from within and outside the cluster.

**DNS**

Configure infrastructure-provided DNS to allow the correct resolution of the main components and services. If you use only one load balancer, these DNS records can point to the same IP address.

- Create DNS records for **api.<cluster_name>.<base_domain>** (internal and external resolution) and **api-int.<cluster_name>.<base_domain>** (internal resolution) that point to the load balancer for the control plane machines.
- Create a DNS record for ***.apps.<cluster_name>.<base_domain>** that points to the load balancer for the Ingress router. For example, ports **443** and **80** of the compute machines.

**15.6.6. Setting up the installation machine**

To run the binary **openshift-install** installation program and Ansible scripts, set up the RHV Manager or an Red Hat Enterprise Linux (RHEL) computer with network access to the RHV environment and the REST API on the RHV Manager/oVirt Engine.

**Procedure**

1. Update or install Python3 and Ansible. For example:
# dnf update python3 ansible

2. Install the `python3-ovirt-engine-sdk4` package to get the Python Software Development Kit.

3. Install the `ovirt.image-template` Ansible role. On RHV Manager and other Red Hat Enterprise Linux (RHEL) machines, this role is distributed as the `ovirt-ansible-image-template` package. For example, enter:
   
   # dnf install ovirt-ansible-image-template

4. Install the `ovirt.vm-infra` Ansible role. On RHV Manager and other RHEL machines, this role is distributed as the `ovirt-ansible-vm-infra` package.
   
   # dnf install ovirt-ansible-vm-infra

5. Create an environment variable and assign an absolute or relative path to it. For example, enter:
   
   $ export ASSETS_DIR=./wrk

### NOTE

The installation program uses this variable to create a directory where it saves important installation-related files. Later, the installation process reuses this variable to locate those asset files. Avoid deleting this assets directory; it is required for uninstalling the cluster.

### 15.6.7. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in **insecure** mode.

![WARNING]

**WARNING**

Installing in **insecure** mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.

### Procedure

1. Create a file named `~/.ovirt/ovirt-config.yaml`.

2. Add the following content to `ovirt-config.yaml`:

   ```yaml
   ovirt_url: https://ovirt.example.com/ovirt-engine/api
   ```
15.6.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:
$ cat <path>/<file_name>.pub

For example, run the following to view the ~/.ssh/id_rsa.pub public key:

$ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

   $ eval "$(ssh-agent -s)"

   Example output

   Agent pid 31874

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>  

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"

3. Verify that the credentials were applied.

   $ gcloud auth list

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.
15.6.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. From the **Pull Secret** page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

15.6.10. Downloading the Ansible playbooks

Download the Ansible playbooks for installing OpenShift Container Platform version 4.8 on RHV.

**Procedure**

1. On your installation machine, run the following commands:

   ```
   $ mkdir playbooks
   $ cd playbooks
   $ curl -L -X GET https://api.github.com/repos/openshift/installer/contents/upi/ovirt
   ```
After you download these Ansible playbooks, you must also create the environment variable for the assets directory and customize the `inventory.yml` file before you create an installation configuration file by running the installation program.

15.6.11. The `inventory.yml` file

You use the `inventory.yml` file to define and create elements of the OpenShift Container Platform cluster you are installing. This includes elements such as the Red Hat Enterprise Linux CoreOS (RHCOS) image, virtual machine templates, bootstrap machine, control plane nodes, and worker nodes. You also use `inventory.yml` to destroy the cluster.

The following `inventory.yml` example shows you the parameters and their default values. The quantities and numbers in these default values meet the requirements for running a production OpenShift Container Platform cluster in a RHV environment.

Example `inventory.yml` file

```yaml
---
all:
vars:

ovirt_cluster: "Default"

ocp:
  assets_dir: "{{ lookup('env', 'ASSETS_DIR') }}"
  ovirt_config_path: "{{ lookup('env', 'HOME') }}/.ovirt/ovirt-config.yaml"

# ---
# {op-system} section
# ---
rhcos:
  image_url: "https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/latest/latest/rhcos-openstack.x86_64.qcow2.gz"
  local_cmp_image_path: "/tmp/rhcos.qcow2.gz"
  local_image_path: "/tmp/rhcos.qcow2"

# ---
# Profiles section
# ---
control_plane:
  cluster: "{{ ovirt_cluster }}"
  memory: 16GiB
  sockets: 4
  cores: 1
  template: rhcos_tpl
  operating_system: "rhcos_x64"
  type: high_performance
  graphical_console:
    headless_mode: false
```
protocol:
- spice
- vnc
disks:
- size: 120GiB

  ocp_type: master
  profile: "{{ control_plane }}"
- name: "{{ metadata.infraID }}-worker0"
  ocp_type: worker
  profile: "{{ compute }}"
IMPORTANT

Enter values for parameters whose descriptions begin with "Enter." Otherwise, you can use the default value or replace it with a new value.

General section

- **ovirt_cluster**: Enter the name of an existing RHV cluster in which to install the OpenShift Container Platform cluster.

- **ocp.assets_dir**: The path of a directory the *openshift-install* installation program creates to store the files that it generates.

- **ocp.ovirt_config_path**: The path of the *ovirt-config.yaml* file the installation program generates, for example, `./wrk/install-config.yaml`. This file contains the credentials required to interact with the REST API of the oVirt Engine/RHV Manager.

Red Hat Enterprise Linux CoreOS (RHCOS) section

- **image_url**: Enter the URL of the RHCOS image you specified for download.

- **local_cmp_image_path**: The path of a local download directory for the compressed RHCOS image.

- **local_image_path**: The path of a local directory for the extracted RHCOS image.

Profiles section

This section consists of two profiles:

- **control_plane**: The profile of the bootstrap and control plane nodes.

- **compute**: The profile of workers nodes in the compute plane.

These profiles have the following parameters. The default values of the parameters meet the minimum requirements for running a production cluster. You can increase or customize these values to meet your workload requirements.

- **cluster**: The value gets the cluster name from *ovirt_cluster* in the General Section.

- **memory**: The amount of memory, in GB, for the virtual machine.

- **sockets**: The number of sockets for the virtual machine.

- **cores**: The number of cores for the virtual machine.

- **template**: The name of the virtual machine template. If plan to install multiple clusters, and these clusters use templates that contain different specifications, prepend the template name with the ID of the cluster.
- **operating_system**: The type of guest operating system in the virtual machine. With oVirt/RHV version 4.4, this value must be `rhcos_x64` so the value of *Ignition script* can be passed to the VM.

- **type**: Enter `server` as the type of the virtual machine.

  **IMPORTANT**

  You must change the value of the `type` parameter from `high_performance` to `server`.

- **disks**: The disk specifications. The *control_plane* and *compute* nodes can have different storage domains.

- **size**: The minimum disk size.

- **name**: Enter the name of a disk connected to the target cluster in RHV.

- **interface**: Enter the interface type of the disk you specified.

- **storage_domain**: Enter the storage domain of the disk you specified.

- **nics**: Enter the `name` and `network` the virtual machines use. You can also specify the virtual network interface profile. By default, NICs obtain their MAC addresses from the oVirt/RHV MAC pool.

**Virtual machines section**

This final section, `vms`, defines the virtual machines you plan to create and deploy in the cluster. By default, it provides the minimum number of control plane and worker nodes for a production environment.

`vms` contains three required elements:

- **name**: The name of the virtual machine. In this case, `metadata.infraID` prepends the virtual machine name with the infrastructure ID from the `metadata.yml` file.

- **ocp_type**: The role of the virtual machine in the OCP cluster. Possible values are `bootstrap`, `master`, `worker`.

- **profile**: The name of the profile from which each virtual machine inherits specifications. Possible values in this example are `control_plane` or `compute`.

  You can override the value a virtual machine inherits from its profile. To do this, you add the name of the profile attribute to the virtual machine in `inventory.yml` and assign it an overriding value. To see an example of this, examine the `name: "{{ metadata.infraID }}-bootstrap"` virtual machine in the preceding `inventory.yml` example: It has a `type` attribute whose value, `server`, overrides the value of the `type` attribute this virtual machine would otherwise inherit from the `control_plane` profile.

**Metadata variables**

For virtual machines, `metadata.infraID` prepends the name of the virtual machine with the infrastructure ID from the `metadata.json` file you create when you build the Ignition files.

The playbooks use the following code to read `infraID` from the specific file located in the `ocp.assets_dir`. 

**1987**
15.6.12. Specifying the RHCOS image settings

Update the Red Hat Enterprise Linux CoreOS (RHCOS) image settings of the `inventory.yml` file. Later, when you run this file one of the playbooks, it downloads a compressed Red Hat Enterprise Linux CoreOS (RHCOS) image from the `image_url` URL to the `local_cmp_image_path` directory. The playbook then uncompresses the image to the `local_image_path` directory and uses it to create oVirt/RHV templates.

Procedure

1. Locate the RHCOS image download page for the version of OpenShift Container Platform you are installing, such as

   Index of /pub/openshift-v4/dependencies/rhcos/latest/latest

2. From that download page, copy the URL of an OpenStack qcow2 image, such as

   https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/latest/latest/rhcos-openstack.x86_64.qcow2.gz

3. Edit the `inventory.yml` playbook you downloaded earlier. In it, paste the URL as the value for `image_url`. For example:

   ```yaml
   rhcos:
     "https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/latest/latest/rhcos-openstack.x86_64.qcow2.gz"
   ```

15.6.13. Creating the install config file

You create an installation configuration file by running the installation program, `openshift-install`, and responding to its prompts with information you specified or gathered earlier.

When you finish responding to the prompts, the installation program creates an initial version of the `install-config.yaml` file in the assets directory you specified earlier, for example, `./wrk/install-config.yaml`

The installation program also creates a file, `$HOME/.ovirt/ovirt-config.yaml`, that contains all the connection parameters that are required to reach the oVirt Engine/RHV Manager and use its REST API.

**NOTE:** The installation process does not use values you supply for some parameters, such as **Internal API virtual IP** and **Ingress virtual IP**, because you have already configured them in your infrastructure DNS.

It also uses the values you supply for parameters in `inventory.yml`, like the ones for **oVirt cluster**, **oVirt storage**, and **oVirt network**. And uses a script to remove or replace these same values from `install-config.yaml` with the previously mentioned **virtual IPs**.

Procedure

---

- name: include metadata.json vars
  include_vars:
    file: "{{ ocp.assets_dir }}/metadata.json"
  name: metadata

...
1. Run the installation program:

   $ openshift-install create install-config --dir $ASSETS_DIR

2. Respond to the installation program’s prompts with information about your system.

   **Example output**

   > ? SSH Public Key /home/user/.ssh/id_dsa.pub
   > ? Platform <ovirt>
   > ? Enter ovirt-engine username <ocpadmin@internal>
   > ? Enter password <******>
   > ? oVirt cluster <cluster>
   > ? oVirt storage <storage>
   > ? oVirt network <net>
   > ? Internal API virtual IP <172.16.0.252>
   > ? Ingress virtual IP <172.16.0.251>
   > ? Base Domain <example.org>
   > ? Cluster Name <ocp4>
   > ? Pull Secret [? for help] <********>

   For **Internal API virtual IP** and **Ingress virtual IP**, supply the IP addresses you specified when you configured the DNS service.

   Together, the values you enter for the **oVirt cluster** and **Base Domain** prompts form the FQDN portion of URLs for the REST API and any applications you create, such as https://api.ocp4.example.org:6443/ and https://console-openshift-console.apps.ocp4.example.org.

   To get your pull secret, visit https://cloud.redhat.com/openshift/install/pull-secret.

### 15.6.14. Customizing install-config.yaml

Here, you use three Python scripts to override some of the installation program’s default behaviors:

- By default, the installation program uses the machine API to create nodes. To override this default behavior, you set the number of compute nodes to zero replicas. Later, you use Ansible playbooks to create the compute nodes.

- By default, the installation program sets the IP range of the machine network for nodes. To override this default behavior, you set the IP range to match your infrastructure.

- By default, the installation program sets the platform to **ovirt**. However, installing a cluster on user-provisioned infrastructure is more similar to installing a cluster on bare metal. Therefore, you delete the ovirt platform section from **install-config.yaml** and change the platform to **none**. Instead, you use **inventory.yml** to specify all of the required settings.

   **NOTE**

   These snippets work with Python 3 and Python 2.

**Procedure**

1. Set the number of compute nodes to zero replicas:

   ```text
   $ openshift-install create install-config --dir $ASSETS_DIR
   ```
2. Set the IP range of the machine network. For example, to set the range to **172.16.0.0/16**, enter:

```
$ python3 -c 'import os, yaml
path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
conf = yaml.safe_load(open(path))
conf["compute"][0]["replicas"] = 0
open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
```

3. Remove the ovirt section and change the platform to **none**:

```
$ python3 -c 'import os, yaml
path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
conf = yaml.safe_load(open(path))
platform = conf["platform"]
del platform["ovirt"]
platform["none"] = {}
open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
```

### 15.6.15. Generate manifest files

Use the installation program to generate a set of manifest files in the assets directory.

The command to generate the manifest files displays a warning message before it consumes the **install-config.yaml** file.

If you plan to reuse the **install-config.yaml** file, create a backup copy of it before you back it up before you generate the manifest files.

**Procedure**

1. Optional: Create a backup copy of the **install-config.yaml** file:

   ```
   $ cp install-config.yaml install-config.yaml.backup
   ```

2. Generate a set of manifests in your assets directory:

   ```
   $ openshift-install create manifests --dir $ASSETS_DIR
   ```

   This command displays the following messages.

**Example output**

```
INFO Consuming Install Config from target directory
WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings
```

The command generates the following manifest files:
15.6.16. Making control-plane nodes non-schedulable

Because you are manually creating and deploying the control plane machines, you must configure a manifest file to make the control plane nodes non-schedulable.

Procedure

1. To make the control plane nodes non-schedulable, enter:

```bash
$ python3 -c 'import os, yaml
path = "%s/manifests/cluster-scheduler-02-config.yml" % os.environ["ASSETS_DIR"]
'"`
15.6.17. Building the Ignition files

To build the Ignition files from the manifest files you just generated and modified, you run the installation program. This action creates a Red Hat Enterprise Linux CoreOS (RHCOS) machine, initramfs, which fetches the Ignition files and performs the configurations needed to create a node.

In addition to the Ignition files, the installation program generates the following:

- An auth directory that contains the admin credentials for connecting to the cluster with the oc and kubectl utilities.

- A metadata.json file that contains information such as the OpenShift Container Platform cluster name, cluster ID, and infrastructure ID for the current installation.

The Ansible playbooks for this installation process use the value of infraID as a prefix for the virtual machines they create. This prevents naming conflicts when there are multiple installations in the same oVirt/RHV cluster.

**NOTE**

Certificates in Ignition configuration files expire after 24 hours. Complete the cluster installation and keep the cluster running in a non-degraded state for 24 hours so that the first certificate rotation can finish.

**Procedure**

1. To build the Ignition files, enter:

   ```
   $ openshift-install create ignition-configs --dir $ASSETS_DIR
   ```

   **Example output**

   ```
   $ tree
   .
   ├── wrk
   │   └── auth
   │       ├── kubeadmin-password
   │       └── kubectx
   │           └── bootstrap.ign
   │                   └── master.ign
   │                           └── metadata.json
   │                               └── worker.ign
   ```

15.6.18. Creating templates and virtual machines

After confirming the variables in the inventory.yml, you run the first Ansible provisioning playbook, create-templates-and-vms.yml.

This playbook uses the connection parameters for the RHV Manager from $HOME/.ovirt/ovirt-config.yaml and reads metadata.json in the assets directory.
If a local Red Hat Enterprise Linux CoreOS (RHCOS) image is not already present, the playbook downloads one from the URL you specified for `image_url` in `inventory.yml`. It extracts the image and uploads it to RHV to create templates.

The playbook creates a template based on the `control_plane` and `compute` profiles in the `inventory.yml` file. If these profiles have different names, it creates two templates.

When the playbook finishes, the virtual machines it creates are stopped. You can get information from them to help configure other infrastructure elements. For example, you can get the virtual machines’ MAC addresses to configure DHCP to assign permanent IP addresses to the virtual machines.

**Procedure**

1. In `inventory.yml`, under the `control_plane` and `compute` variables, change both instances of `type: high_performance` to `type: server`.

2. Optional: If you plan to perform multiple installations to the same cluster, create different templates for each OCP installation. In the `inventory.yml` file, prepend the value of `template` with `infraID`. For example:

   ```yaml
   control_plane:
     cluster: "{{ ovirt_cluster }}"
     memory: 16GiB
     sockets: 4
     cores: 1
     template: "{{ metadata.infraID }}-rhcos_tpl"
     operating_system: "rhcos_x64"
   ...
   
   3. Create the templates and virtual machines:

   ```bash
   $ ansible-playbook -i inventory.yml create-templates-and-vms.yml
   ```

**15.6.19. Creating the bootstrap machine**

You create a bootstrap machine by running the `bootstrap.yml` playbook. This playbook starts the bootstrap virtual machine, and passes it the `bootstrap.ign` Ignition file from the assets directory. The bootstrap node configures itself so it can serve Ignition files to the control plane nodes.

To monitor the bootstrap process, you use the console in the RHV Administration Portal or connect to the virtual machine by using SSH.

**Procedure**

1. Create the bootstrap machine:

   ```bash
   $ ansible-playbook -i inventory.yml bootstrap.yml
   ```

2. Connect to the bootstrap machine using a console in the Administration Portal or SSH. Replace `<bootstrap_ip>` with the bootstrap node IP address. To use SSH, enter:

   ```bash
   $ ssh core@<bootstrap.ip>
   ```
3. Collect **bootkube.service** journald unit logs for the release image service from the bootstrap node:

```bash
$ journalctl -b -f -u release-image.service -u bootkube.service
```

**NOTE**

The **bootkube.service** log on the bootstrap node outputs **etcd connection refused** errors, indicating that the bootstrap server is unable to connect to etcd on control plane nodes (also known as the master nodes). After etcd has started on each control plane node and the nodes have joined the cluster, the errors should stop.

### 15.6.20. Creating the control plane nodes

You create the control plane nodes by running the **masters.yml** playbook. This playbook passes the **master.ign** Ignition file to each of the virtual machines. The Ignition file contains a directive for the control plane node to get the Ignition from a URL such as **https://api-int.ocp4.example.org:22623/config/master**. The port number in this URL is managed by the load balancer, and is accessible only inside the cluster.

**Procedure**

1. Create the control plane nodes:

   ```bash
   $ ansible-playbook -i inventory.yml masters.yml
   ```

2. While the playbook creates your control plane, monitor the bootstrapping process:

   ```bash
   $ openshift-install wait-for bootstrap-complete --dir $ASSETS_DIR
   ```

**Example output**

```
INFO API v1.18.3+b74c5ed up
INFO Waiting up to 40m0s for bootstrapping to complete...
```

3. When all the pods on the control plane nodes and etcd are up and running, the installation program displays the following output.

**Example output**

```
INFO It is now safe to remove the bootstrap resources
```

### 15.6.21. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=$ASSETS_DIR/auth/kubeconfig
   ```
The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:
   
   ```bash
   $ oc get nodes
   ```

3. View your cluster’s version:
   
   ```bash
   $ oc get clusterversion
   ```

4. View your Operators’ status:
   
   ```bash
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:
   
   ```bash
   $ oc get pods -A
   ```

### 15.6.22. Removing the bootstrap machine

After the **wait-for** command shows that the bootstrap process is complete, you must remove the bootstrap virtual machine to free up compute, memory, and storage resources. Also, remove settings for the bootstrap machine from the load balancer directives.

**Procedure**

1. To remove the bootstrap machine from the cluster, enter:
   
   ```bash
   $ ansible-playbook -i inventory.yml retire-bootstrap.yml
   ```

2. Remove settings for the bootstrap machine from the load balancer directives.

### 15.6.23. Creating the worker nodes and completing the installation

Creating worker nodes is similar to creating control plane nodes. However, worker nodes workers do not automatically join the cluster. To add them to the cluster, you review and approve the workers’ pending CSRs (Certificate Signing Requests).

After approving the first requests, you continue approving CSR until all of the worker nodes are approved. When you complete this process, the worker nodes become **Ready** and can have pods scheduled to run on them.

Finally, monitor the command line to see when the installation process completes.

**Procedure**

1. Create the worker nodes:
   
   ```bash
   $ ansible-playbook -i inventory.yml workers.yml
   ```

2. To list all of the CSRs, enter:
   
   ```bash
   ```
Eventually, this command displays one CSR per node. For example:

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-2lnxd</td>
<td>63m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master0.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hff4q</td>
<td>64m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hfn96</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master2.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-m724n</td>
<td>6m2s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-p4dz2</td>
<td>60m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-t9vfj</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master1.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-tggr</td>
<td>61m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-wcbrf</td>
<td>7m6s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
</tbody>
</table>

3. To filter the list and see only pending CSRs, enter:

```
$ watch "oc get csr -A | grep pending -i"
```

This command refreshes the output every two seconds and displays only pending CSRs. For example:

Example output

```
Every 2.0s: oc get csr -A | grep pending -i

csr-m724n 10m kubernetes.io/kube-apiserver-client-kubelet system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
csr-wcbrf 11m kubernetes.io/kube-apiserver-client-kubelet system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
```

4. Inspect each pending request. For example:

Example output

```
$ oc describe csr csr-m724n
```

Example output

```
Name: csr-m724n
Labels: <none>
```
5. If the CSR information is correct, approve the request:

   $ oc adm certificate approve csr-m724n

6. Wait for the installation process to finish:

   $ openshift-install wait-for install-complete --dir $ASSETS_DIR --log-level debug

When the installation completes, the command line displays the URL of the OpenShift Container Platform web console and the administrator user name and password.

## 15.7. INSTALLING A CLUSTER ON RHV IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.8, you can install a customized OpenShift Container Platform cluster on Red Hat Virtualization (RHV) in a restricted network by creating an internal mirror of the installation release content.

### 15.7.1. Prerequisites

The following items are required to install an OpenShift Container Platform cluster on a RHV environment.

- You reviewed details about the [OpenShift Container Platform installation and update processes](https://docs.openshift.com/4.8/install/image/mirror.html).
- You read the documentation on [selecting a cluster installation method and preparing it for users](https://docs.openshift.com/4.8/install/configure/rhv.html).
- You have a supported combination of versions in the [Support Matrix for OpenShift Container Platform on RHV](https://access.redhat.com/articles/65946).
- You created a registry on your mirror host and obtained the `imageContentSources` data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned **persistent storage** for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

15.7.2. About installations in restricted networks

In OpenShift Container Platform 4.8, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

15.7.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

15.7.3. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the **Red Hat OpenShift Cluster Manager (OCM)**.

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use **subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the **Red Hat OpenShift Cluster Manager** page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access **Quay.io** to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

15.7.4. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.8 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

Requirements

- The RHV version is 4.4.
- The RHV environment has one data center whose state is Up.
- The RHV data center contains an RHV cluster.
- The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
  - Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
  - 112 GiB RAM or more, including:
    - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
    - 16 GiB or more for each of the three control plane machines which provide the control plane.
    - 16 GiB or more for each of the three compute machines, which run the application workloads.
- The RHV storage domain must meet these etcd backend performance requirements.
- In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.

- To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.

- The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.

- A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:
  - DiskOperator
  - DiskCreator
  - UserTemplateBasedVm
  - TemplateOwner
  - TemplateCreator
  - ClusterAdmin on the target cluster

WARNING
Apply the principle of least privilege: Avoid using an administrator account with SuperUser privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary ovirt-config.yaml file that might be compromised.

15.7.5. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

IMPORTANT
These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

Procedure

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.8.
a. In the RHV Administration Portal, click the help icon in the upper-right corner and select About.

b. In the window that opens, make a note of the RHV Software Version.

c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.

2. Inspect the data center, cluster, and storage.

   a. In the RHV Administration Portal, click Compute → Data Centers.

   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.

   c. Click the name of that data center.

   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.

   e. Record the Domain Name for use later on.

   f. Confirm Free Space has at least 230 GiB.

   g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.

   h. In the data center details, click the Clusters tab.

   i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.

   a. In the RHV Administration Portal, click Compute > Clusters.

   b. Click the cluster where you plan to install OpenShift Container Platform.

   c. In the cluster details, click the Hosts tab.

   d. Inspect the hosts and confirm they have a combined total of at least 28 Logical CPU Cores available exclusively for the OpenShift Container Platform cluster.

   e. Record the number of available Logical CPU Cores for use later on.

   f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.

   g. Confirm that, all together, the hosts have 112 GiB of Max free Memory for scheduling new virtual machines distributed to meet the requirements for each of the following OpenShift Container Platform machines:

      • 16 GiB required for the bootstrap machine

      • 16 GiB required for each of the three control plane machines

      • 16 GiB for each of the three compute machines
h. Record the amount of **Max free Memory for scheduling new virtual machines** for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

```
$ curl -k -u <username>@<profile>:<password> \ 1
  https://<engine-fqdn>/ovirt-engine/api 2
```

1 For `<username>`, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the **Profile** dropdown list. For `<password>`, specify the password for that user name.

2 For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

For example:

```
$ curl -k -u ocpadmin@internal:pw123 \ 1
  https://rhv-env.virtlab.example.com/ovirt-engine/api 2
```

15.7.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in *initramfs* during boot to fetch their Ignition config files.

15.7.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as `localhost` or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

15.7.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have Internet access to pull images for platform containers and provide telemetry data to Red Hat.
Table 15.7. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>

15.7.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>,<cluster_name>,<base_domain>`.  

Table 15.10. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on `Validating DNS resolution for user-provisioned infrastructure` for detailed validation steps.

### 15.7.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

#### Example 15.1. Sample DNS zone database

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
```
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.
Example 15.2. Sample DNS zone database for reverse records

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

1. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
2. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
3. Provides reverse DNS resolution for the bootstrap machine.
4. Provides reverse DNS resolution for the control plane machines.
5. Provides reverse DNS resolution for the control plane machines.
6. Provides reverse DNS resolution for the compute machines.
7. Provides reverse DNS resolution for the compute machines.
8. Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

15.7.7.2. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

- A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**NOTE**

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

### Table 15.11. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.
TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

15.7.7.2.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 15.3. Sample API and application ingress load balancer configuration

```
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
```
OpenShift Container Platform 4.8 Installing

```
dafemon
defaults
  mode        http
  log         global
  option      dontlognull
  option      http-server-close
  option      redispatch
  retries     3
  timeout     http-request 10s
  timeout     queue 1m
  timeout     connect 10s
  timeout     client 1m
  timeout     server 1m
  timeout     http-keep-alive 10s
  timeout     check 10s
  maxconn     3000
frontend stats
  bind *:1936
  mode        http
  log         global
  maxconn     10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster
  stats auth admin:ocp4
  stats uri /stats
listen api-server-6443  
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623  
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443  
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80  
  bind *:80
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:80 check inter 1s
  server worker1 worker1.ocp4.example.com:80 check inter 1s
```
In the example, the cluster name is **ocp4**.

Port **6443** handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port **22623** handles the machine config server traffic and points to the control plane machines.

Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443, 22623, 443,** and **80** by running **netstat -nltpu** on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy_connect_any=1**.

### 15.7.8. Setting up the installation machine

To run the binary **openshift-install** installation program and Ansible scripts, set up the RHV Manager or an Red Hat Enterprise Linux (RHEL) computer with network access to the RHV environment and the REST API on the RHV Manager/oVirt Engine.

**Procedure**

1. Update or install Python3 and Ansible. For example:

   ```bash
   # dnf update python3 ansible
   ```

2. Install the **python3-ovirt-engine-sdk4** package to get the Python Software Development Kit.

3. Install the **ovirt.image-template** Ansible role. On RHV Manager and other Red Hat Enterprise Linux (RHEL) machines, this role is distributed as the **ovirt-ansible-image-template** package. For example, enter:

   ```bash
   # dnf install ovirt-ansible-image-template
   ```
4. Install the `ovirt.vm-infra` Ansible role. On RHV Manager and other RHEL machines, this role is distributed as the `ovirt-ansible-vm-infra` package.

```
# dnf install ovirt-ansible-vm-infra
```

5. Create an environment variable and assign an absolute or relative path to it. For example, enter:

```
$ export ASSETS_DIR=./wrk
```

**NOTE**

The installation program uses this variable to create a directory where it saves important installation-related files. Later, the installation process reuses this variable to locate those asset files. Avoid deleting this assets directory; it is required for uninstalling the cluster.

### 15.7.9. Setting up the CA certificate for RHV

Download the CA certificate from the Red Hat Virtualization (RHV) Manager and set it up on the installation machine.

You can download the certificate from a webpage on the RHV Manager or by using a `curl` command. Later, you provide the certificate to the installation program.

**Procedure**

1. Use either of these two methods to download the CA certificate:
   
   - Go to the Manager’s webpage, `https://<engine-fqdn>/ovirt-engine/`. Then, under *Downloads*, click the *CA Certificate* link.
   
   - Run the following command:

     ```
     ```

     For `<engine-fqdn>`, specify the fully qualified domain name of the RHV Manager, such as `rhv-env.virtlab.example.com`

2. Configure the CA file to grant rootless user access to the Manager. Set the CA file permissions to have an octal value of 0644 (symbolic value: `-rw-r--r--`):

   ```
   $ sudo chmod 0644 /tmp/ca.pem
   ```

3. For Linux, copy the CA certificate to the directory for server certificates. Use `-p` to preserve the permissions:

   ```
   $ sudo cp -p /tmp/ca.pem /etc/pki/ca-trust/source/anchors/ca.pem
   ```

4. Add the certificate to the certificate manager for your operating system:
For macOS, double-click the certificate file and use the Keychain Access utility to add the file to the System keychain.

For Linux, update the CA trust:

```
$ sudo update-ca-trust
```

**NOTE**
If you use your own certificate authority, make sure the system trusts it.

### Additional Resources

To learn more, see Authentication and Security in the RHV documentation.

#### 15.7.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**
Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   $ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

   Example output

      Agent pid 31874

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> 

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

      Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the GOOGLE_APPLICATION_CREDENTIALS environment variable to the full path to your service account private key file.

   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
CHAPTER 15. LOGGING IN TO THE CLUSTER BY USING THE CLI

3. Verify that the credentials were applied.
$ gcloud auth list
Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation
program.

15.7.11. Downloading the Ansible playbooks
Download the Ansible playbooks for installing OpenShift Container Platform version 4.8 on RHV.
Procedure
1. On your installation machine, run the following commands:
$ mkdir playbooks
$ cd playbooks
$ curl -L -X GET https://api.github.com/repos/openshift/installer/contents/upi/ovirt\?
ref\=$release-{product-version} |
grep 'download_url.*\.yml' |
awk '{ print $2 }' | sed -r 's/("|",)//g' |
xargs -n 1 curl -O
Next steps
After you download these Ansible playbooks, you must also create the environment variable for
the assets directory and customize the inventory.yml file before you create an installation
configuration file by running the installation program.

15.7.12. The inventory.yml file
You use the inventory.yml file to define and create elements of the OpenShift Container Platform
cluster you are installing. This includes elements such as the Red Hat Enterprise Linux CoreOS (RHCOS)
image, virtual machine templates, bootstrap machine, control plane nodes, and worker nodes. You also
use inventory.yml to destroy the cluster.
The following inventory.yml example shows you the parameters and their default values. The quantities
and numbers in these default values meet the requirements for running a production OpenShift
Container Platform cluster in a RHV environment.

Example inventory.yml file
--all:
vars:
ovirt_cluster: "Default"
ocp:
assets_dir: "{{ lookup('env', 'ASSETS_DIR') }}"
ovirt_config_path: "{{ lookup('env', 'HOME') }}/.ovirt/ovirt-config.yaml"

Enter values for parameters whose descriptions begin with "Enter." Otherwise, you can use the default value or replace it with a new value.

General section

- **ovirt_cluster**: Enter the name of an existing RHV cluster in which to install the OpenShift Container Platform cluster.
- **ocp.assets_dir**: The path of a directory the openshift-install installation program creates to store the files that it generates.
- **ocp.ovirt_config_path**: The path of the ovirt-config.yaml file the installation program generates, for example, /wrk/install-config.yaml. This file contains the credentials required to interact with the REST API of the oVirt Engine/RHV Manager.

Red Hat Enterprise Linux CoreOS (RHCOS) section

- **image_url**: Enter the URL of the RHCOS image you specified for download.
- **local_cmp_image_path**: The path of a local download directory for the compressed RHCOS image.
- **local_image_path**: The path of a local directory for the extracted RHCOS image.
Profiles section

This section consists of two profiles:

- **control_plane**: The profile of the bootstrap and control plane nodes.
- **compute**: The profile of workers nodes in the compute plane.

These profiles have the following parameters. The default values of the parameters meet the minimum requirements for running a production cluster. You can increase or customize these values to meet your workload requirements.

- **cluster**: The value gets the cluster name from `ovirt_cluster` in the General Section.
- **memory**: The amount of memory, in GB, for the virtual machine.
- **sockets**: The number of sockets for the virtual machine.
- **cores**: The number of cores for the virtual machine.
- **template**: The name of the virtual machine template. If plan to install multiple clusters, and these clusters use templates that contain different specifications, prepend the template name with the ID of the cluster.
- **operating_system**: The type of guest operating system in the virtual machine. With oVirt/RHV version 4.4, this value must be `rhcos_x64` so the value of Ignition script can be passed to the VM.
- **type**: Enter `server` as the type of the virtual machine.

Important

```
You must change the value of the type parameter from high_performance to server.
```

- **disks**: The disk specifications. The `control_plane` and `compute` nodes can have different storage domains.
- **size**: The minimum disk size.
- **name**: Enter the name of a disk connected to the target cluster in RHV.
- **interface**: Enter the interface type of the disk you specified.
- **storage_domain**: Enter the storage domain of the disk you specified.
- **nics**: Enter the **name** and **network** the virtual machines use. You can also specify the virtual network interface profile. By default, NICs obtain their MAC addresses from the oVirt/RHV MAC pool.

Virtual machines section

This final section, `vms`, defines the virtual machines you plan to create and deploy in the cluster. By default, it provides the minimum number of control plane and worker nodes for a production environment.

`vms` contains three required elements:
• **name**: The name of the virtual machine. In this case, `metadata.infraID` prepends the virtual machine name with the infrastructure ID from the `metadata.yml` file.

• **ocp_type**: The role of the virtual machine in the OCP cluster. Possible values are **bootstrap**, **master**, **worker**.

• **profile**: The name of the profile from which each virtual machine inherits specifications. Possible values in this example are **control_plane** or **compute**.

You can override the value a virtual machine inherits from its profile. To do this, you add the name of the profile attribute to the virtual machine in `inventory.yml` and assign it an overriding value. To see an example of this, examine the name: `{{ metadata.infraID }}-bootstrap` virtual machine in the preceding `inventory.yml` example: It has a **type** attribute whose value, **server**, overrides the value of the **type** attribute this virtual machine would otherwise inherit from the **control_plane** profile.

### Metadata variables

For virtual machines, `metadata.infraID` prepends the name of the virtual machine with the infrastructure ID from the `metadata.json` file you create when you build the Ignition files.

The playbooks use the following code to read `infraID` from the specific file located in the `ocp.assets_dir`.

```yaml
...
- name: include metadata.json vars
  include_vars:
    file: "{{ ocp.assets_dir }}/metadata.json"
    name: metadata
...
```

### 15.7.13. Specifying the RHCOS image settings

Update the Red Hat Enterprise Linux CoreOS (RHCOS) image settings of the `inventory.yml` file. Later, when you run this file one of the playbooks, it downloads a compressed Red Hat Enterprise Linux CoreOS (RHCOS) image from the `image_url` URL to the `local_cmp_image_path` directory. The playbook then uncompresses the image to the `local_image_path` directory and uses it to create oVirt/RHV templates.

**Procedure**

1. Locate the RHCOS image download page for the version of OpenShift Container Platform you are installing, such as [Index of /pub/openshift-v4/dependencies/rhcos/latest/latest](https://index.of/pub/openshift-v4/dependencies/rhcos/latest/latest).

2. From that download page, copy the URL of an OpenStack qcow2 image, such as [https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/latest/latest/rhcos-openstack.x86_64.qcow2.gz](https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/latest/latest/rhcos-openstack.x86_64.qcow2.gz).

3. Edit the `inventory.yml` playbook you downloaded earlier. In it, paste the URL as the value for `image_url`. For example:

   ```yaml
   rhcos:
     "https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/latest/latest/rhcos-openstack.x86_64.qcow2.gz"
   ```
15.7.14. Creating the install config file

You create an installation configuration file by running the installation program, `openshift-install`, and responding to its prompts with information you specified or gathered earlier.

When you finish responding to the prompts, the installation program creates an initial version of the `install-config.yaml` file in the assets directory you specified earlier, for example, `./wrk/install-config.yaml`

The installation program also creates a file, `~/ovirt/ovirt-config.yaml`, that contains all the connection parameters that are required to reach the oVirt Engine/RHV Manager and use its REST API.

**NOTE:** The installation process does not use values you supply for some parameters, such as **Internal API virtual IP** and **Ingress virtual IP**, because you have already configured them in your infrastructure DNS.

It also uses the values you supply for parameters in `inventory.yml`, like the ones for **oVirt cluster**, **oVirt storage**, and **oVirt network**. And uses a script to remove or replace these same values from `install-config.yaml` with the previously mentioned **virtual IPs**.

**Procedure**

1. Run the installation program:

   ```bash
   $ openshift-install create install-config --dir $ASSETS_DIR
   ```

2. Respond to the installation program’s prompts with information about your system.

   **Example output**

   ```
   ? SSH Public Key /home/user/.ssh/id_dsa.pub
   ? Platform <ovirt>
   ? Enter ovirt-engine username <ocpadmin@internal>
   ? Enter password <******>
   ? oVirt cluster <cluster>
   ? oVirt storage <storage>
   ? oVirt network <net>
   ? Internal API virtual IP <172.16.0.252>
   ? Ingress virtual IP <172.16.0.251>
   ? Base Domain <example.org>
   ? Cluster Name <ocp4>
   ? Pull Secret [? for help] <******>
   ```

   For **Internal API virtual IP** and **Ingress virtual IP**, supply the IP addresses you specified when you configured the DNS service.

   Together, the values you enter for the **oVirt cluster** and **Base Domain** prompts form the FQDN portion of URLs for the REST API and any applications you create, such as `https://api.ocp4.example.org:6443` and `https://console-openshift-console.apps.ocp4.example.org`.

   To get your pull secret, visit `https://cloud.redhat.com/openshift/install/pull-secret`.

15.7.15. Sample install-config.yaml file for RHV
You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    - hostPrefix: 23
  hostPrefix: 23
networkType: OpenShiftSDN
serviceNetwork: 172.30.0.0/16
platform:
  none: {}
  fips: false
  pullSecret: '{"auths": ...}'
  sshKey: 'ssh-ed25519 AAAA...'
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, - , and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

**IMPORTANT**

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml**, ensure that your capacity planning accounts for the dramatically decreased machine performance.
You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{28} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to none. You cannot provide additional platform configuration variables for RHV infrastructure.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret that you obtained from the Red Hat OpenShift Cluster Manager site. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
15.7.15.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   ...
   ```

   **1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must not specify an `httpProxy` value.
A proxy URL to use for creating HTTPS connections outside the cluster. If this field is not specified, then `httpProxy` is used for both HTTP and HTTPS connections. If you use an A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle. If you use an MITM transparent proxy network that does not require additional proxy configuration but requires additional CAs, you must provide the MITM CA certificate.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster` Proxy object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

15.7.16. Customizing `install-config.yaml`

Here, you use three Python scripts to override some of the installation program’s default behaviors:

- By default, the installation program uses the machine API to create nodes. To override this default behavior, you set the number of compute nodes to zero replicas. Later, you use Ansible playbooks to create the compute nodes.

- By default, the installation program sets the IP range of the machine network for nodes. To override this default behavior, you set the IP range to match your infrastructure.

- By default, the installation program sets the platform to `ovirt`. However, installing a cluster on user-provisioned infrastructure is more similar to installing a cluster on bare metal. Therefore, you delete the ovirt platform section from `install-config.yaml` and change the platform to `none`. Instead, you use `inventory.yml` to specify all of the required settings.

**NOTE**

These snippets work with Python 3 and Python 2.
Procedure

1. Set the number of compute nodes to zero replicas:

   ```
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["compute"][0]["replicas"] = 0
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
   ```

2. Set the IP range of the machine network. For example, to set the range to 172.16.0.0/16, enter:

   ```
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["networking"]["machineNetwork"][0]["cidr"] = "172.16.0.0/16"
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
   ```

3. Remove the ovirt section and change the platform to none:

   ```
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   platform = conf["platform"]
   del platform["ovirt"]
   platform["none"] = {}
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
   ```

15.7.17. Generate manifest files

Use the installation program to generate a set of manifest files in the assets directory.

The command to generate the manifest files displays a warning message before it consumes the install-config.yaml file.

If you plan to reuse the install-config.yaml file, create a backup copy of it before you back it up before you generate the manifest files.

Procedure

1. Optional: Create a backup copy of the install-config.yaml file:

   ```
   $ cp install-config.yaml install-config.yaml.backup
   ```

2. Generate a set of manifests in your assets directory:

   ```
   $ openshift-install create manifests --dir $ASSETS_DIR
   ```

   This command displays the following messages.

   **Example output**
INFO Consuming Install Config from target directory
WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings

The command generates the following manifest files:

Example output

```
$ tree
  .

  │                                                                                       └── openshift
  │                                                                                           └── 99_kubeadmin-password-secret.yaml
  │                                                                                               └── 99_openshift-cluster-api_master-user-data-secret.yaml
  │                                                                                                       └── 99_openshift-cluster-api_worker-user-data-secret.yaml
  │                                                                                                           └── 99_openshift-machineconfig_99-master-ssh.yaml
  │                                                                                                               └── 99_openshift-machineconfig_99-worker-ssh.yaml
  │                                                                                                                   └── openshift-install-manifests.yaml
  └── openshift
```

Next steps

- Make control plane nodes non-schedulable.

15.7.18. Making control-plane nodes non-schedulable

Because you are manually creating and deploying the control plane machines, you must configure a manifest file to make the control plane nodes non-schedulable.

Procedure
Procedure

1. To make the control plane nodes non-schedulable, enter:

```python
$ python3 -c 'import os, yaml
path = "%s/manifests/cluster-scheduler-02-config.yml" % os.environ["ASSETS_DIR"]
data = yaml.safe_load(open(path))
data["spec"]["mastersSchedulable"] = False
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

15.7.19. Building the Ignition files

To build the Ignition files from the manifest files you just generated and modified, you run the installation program. This action creates a Red Hat Enterprise Linux CoreOS (RHCOS) machine, `initramfs`, which fetches the Ignition files and performs the configurations needed to create a node.

In addition to the Ignition files, the installation program generates the following:

- An `auth` directory that contains the admin credentials for connecting to the cluster with the `oc` and `kubectl` utilities.

- A `metadata.json` file that contains information such as the OpenShift Container Platform cluster name, cluster ID, and infrastructure ID for the current installation.

The Ansible playbooks for this installation process use the value of `infraID` as a prefix for the virtual machines they create. This prevents naming conflicts when there are multiple installations in the same oVirt/RHV cluster.

**NOTE**

Certificates in Ignition configuration files expire after 24 hours. Complete the cluster installation and keep the cluster running in a non-degraded state for 24 hours so that the first certificate rotation can finish.

Procedure

1. To build the Ignition files, enter:

   ```bash
   $ openshift-install create ignition-configs --dir $ASSETS_DIR
   ```

Example output

```bash
$ tree
.
  └── wrk
    ├── auth
    │   └── kubeadmin-password
    │   └── kubeconfig
    └── bootstrap.ign
      └── master.ign
        └── metadata.json
            └── worker.ign
```

15.7.20. Creating templates and virtual machines
After confirming the variables in the `inventory.yml`, you run the first Ansible provisioning playbook, `create-templates-and-vms.yml`.

This playbook uses the connection parameters for the RHV Manager from `$HOME/.ovirt/ovirt-config.yaml` and reads `metadata.json` in the assets directory.

If a local Red Hat Enterprise Linux CoreOS (RHCOS) image is not already present, the playbook downloads one from the URL you specified for `image_url` in `inventory.yml`. It extracts the image and uploads it to RHV to create templates.

The playbook creates a template based on the `control_plane` and `compute` profiles in the `inventory.yml` file. If these profiles have different names, it creates two templates.

When the playbook finishes, the virtual machines it creates are stopped. You can get information from them to help configure other infrastructure elements. For example, you can get the virtual machines’ MAC addresses to configure DHCP to assign permanent IP addresses to the virtual machines.

Procedure

1. In `inventory.yml`, under the `control_plane` and `compute` variables, change both instances of `type: high_performance` to `type: server`.

2. Optional: If you plan to perform multiple installations to the same cluster, create different templates for each OCP installation. In the `inventory.yml` file, prepend the value of `template` with `infraID`. For example:

   ```yaml
   control_plane:
     cluster: "{{ ovirt_cluster }}"
     memory: 16GiB
     sockets: 4
     cores: 1
     template: "{{ metadata.infraID }}-rhcos_tpl"
     operating_system: "rhcos_x64"
   ...
   
   $ ansible-playbook -i inventory.yml bootstrap.yml
   
15.7.21. Creating the bootstrap machine

You create a bootstrap machine by running the `bootstrap.yml` playbook. This playbook starts the bootstrap virtual machine, and passes it the `bootstrap.ign` Ignition file from the assets directory. The bootstrap node configures itself so it can serve Ignition files to the control plane nodes.

To monitor the bootstrap process, you use the console in the RHV Administration Portal or connect to the virtual machine by using SSH.

Procedure

1. Create the bootstrap machine:

   ```bash
   $ ansible-playbook -i inventory.yml bootstrap.yml
   ```
2. Connect to the bootstrap machine using a console in the Administration Portal or SSH. Replace `<bootstrap_ip>` with the bootstrap node IP address. To use SSH, enter:

```
$ ssh core@<bootstrap.ip>
```

3. Collect `bootkube.service` journald unit logs for the release image service from the bootstrap node:

```
[core@ocp4-lk6b4-bootstrap ~]$ journalctl -b -f -u release-image.service -u bootkube.service
```

**NOTE**

The `bootkube.service` log on the bootstrap node outputs etcd `connection refused` errors, indicating that the bootstrap server is unable to connect to etcd on control plane nodes (also known as the master nodes). After etcd has started on each control plane node and the nodes have joined the cluster, the errors should stop.

### 15.7.22. Creating the control plane nodes

You create the control plane nodes by running the `masters.yml` playbook. This playbook passes the `master.ign` Ignition file to each of the virtual machines. The Ignition file contains a directive for the control plane node to get the Ignition from a URL such as `https://api-int.ocp4.example.org:22623/config/master`. The port number in this URL is managed by the load balancer, and is accessible only inside the cluster.

**Procedure**

1. Create the control plane nodes:

```
$ ansible-playbook -i inventory.yml masters.yml
```

2. While the playbook creates your control plane, monitor the bootstrapping process:

```
$ openshift-install wait-for bootstrap-complete --dir $ASSETS_DIR
```

**Example output**

```
INFO API v1.18.3+b74c5ed up
INFO Waiting up to 40m0s for bootstrapping to complete...
```

3. When all the pods on the control plane nodes and etcd are up and running, the installation program displays the following output.

**Example output**

```
INFO It is now safe to remove the bootstrap resources
```

### 15.7.23. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.
Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=$ASSETS_DIR/auth/kubeconfig

   The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster’s version:

   $ oc get clusterversion

4. View your Operators’ status:

   $ oc get clusteroperator

5. View all running pods in the cluster:

   $ oc get pods -A

15.7.24. Removing the bootstrap machine

After the **wait-for** command shows that the bootstrap process is complete, you must remove the bootstrap virtual machine to free up compute, memory, and storage resources. Also, remove settings for the bootstrap machine from the load balancer directives.

Procedure

1. To remove the bootstrap machine from the cluster, enter:

   $ ansible-playbook -i inventory.yml retire-bootstrap.yml

2. Remove settings for the bootstrap machine from the load balancer directives.

15.7.25. Creating the worker nodes and completing the installation

Creating worker nodes is similar to creating control plane nodes. However, worker nodes workers do not automatically join the cluster. To add them to the cluster, you review and approve the workers’ pending CSRs (Certificate Signing Requests).

After approving the first requests, you continue approving CSR until all of the worker nodes are approved. When you complete this process, the worker nodes become **Ready** and can have pods scheduled to run on them.

Finally, monitor the command line to see when the installation process completes.

Procedure
1. Create the worker nodes:

   $ ansible-playbook -i inventory.yml workers.yml

2. To list all of the CSRs, enter:

   $ oc get csr -A

   Eventually, this command displays one CSR per node. For example:

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-2lnxd</td>
<td>63m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master0.ocp4.example.org</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hff4q</td>
<td>64m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hsn96</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master2.ocp4.example.org</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-m724n</td>
<td>6m2s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Pending</td>
</tr>
<tr>
<td>csr-p4dz2</td>
<td>60m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-t9vfj</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master1.ocp4.example.org</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-tggtr</td>
<td>61m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-wcbrf</td>
<td>7m6s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Pending</td>
</tr>
</tbody>
</table>

3. To filter the list and see only pending CSRs, enter:

   $ watch "oc get csr -A | grep pending -i"

   This command refreshes the output every two seconds and displays only pending CSRs. For example:

   **Example output**

   Every 2.0s: oc get csr -A | grep pending -i

   csr-m724n 10m kubernetes.io/kube-apiserver-client-kubelet
   system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
   csr-wcbrf 11m kubernetes.io/kube-apiserver-client-kubelet
   system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending

4. Inspect each pending request. For example:

   **Example output**
Example output

Name: csr-m724n
Labels: <none>
Annotations: <none>
CreationTimestamp: Sun, 19 Jul 2020 15:59:37 +0200
Signer: kubernetes.io/kube-apiserver-client-kubelet
Status: Pending
Subject:
  Common Name: system:node:ocp4-lk6b4-worker1.ocp4.example.org
  Serial Number:
  Organization: system:nodes
Events: <none>

5. If the CSR information is correct, approve the request:

   $ oc adm certificate approve csr-m724n

6. Wait for the installation process to finish:

   $ openshift-install wait-for install-complete --dir $ASSETS_DIR --log-level debug

When the installation completes, the command line displays the URL of the OpenShift Container Platform web console and the administrator user name and password.

15.7.26. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  $ oc patch OperatorHub cluster --type json \
  -p '["op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

15.8. UNINSTALLING A CLUSTER ON RHV

You can remove an OpenShift Container Platform cluster from Red Hat Virtualization (RHV).
15.8.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access. For example, some Google Cloud resources require IAM permissions in shared VPC host projects, or there might be unused health checks that must be deleted.

**Prerequisites**

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

**Procedure**

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```bash
   $ ./openshift-install destroy cluster --dir=<installation_directory> --log-level=info
   ``

   - For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   - To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

15.8.2. Removing a cluster that uses user-provisioned infrastructure

When you are finished using the cluster, you can remove a cluster that uses user-provisioned infrastructure from your cloud.

**Prerequisites**

- Have the original playbook files, assets directory and files, and `$ASSETS_DIR` environment variable that you used to you install the cluster. Typically, you can achieve this by using the same computer you used when you installed the cluster.

**Procedure**

1. To remove the cluster, enter:

   $ ansible-playbook -i inventory.yml
   retire-bootstrap.yml
   retire-masters.yml
   retire-workers.yml

2. Remove any configurations you added to DNS, load balancers, and any other infrastructure for this cluster.
CHAPTER 16. INSTALLING ON VSPHERE

16.1. PREPARING TO INSTALL ON VSPHERE

16.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall and plan to use Telemetry, you configured the firewall to allow the sites required by your cluster.

16.1.2. Choosing a method to install OpenShift Container Platform on vSphere

You can install OpenShift Container Platform on vSphere by using installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provide. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See the Installation process for more information about installer-provisioned and user-provisioned installation processes.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

16.1.2.1. Installer-provisioned infrastructure installation of OpenShift Container Platform on vSphere

Installer-provisioned infrastructure allows the installation program to pre-configure and automate the provisioning of resources required by OpenShift Container Platform.

- **Installing a cluster on vSphere** You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure installation with no customization.

- **Installing a cluster on vSphere with customizations** You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure installation with the default customization options.

- **Installing a cluster on vSphere with network customizations** You can install OpenShift Container Platform on installer-provisioned vSphere infrastructure, with network customizations. You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.

- **Installing a cluster on vSphere in a restricted network** You can install a cluster on VMware
vSphere infrastructure in a restricted network by creating an internal mirror of the installation release content. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the Internet.

16.1.2.2. User-provisioned infrastructure installation of OpenShift Container Platform on vSphere

User-provisioned infrastructure requires the user to provision all resources required by OpenShift Container Platform.

- **Installing a cluster on vSphere with user-provisioned infrastructure** You can install OpenShift Container Platform on VMware vSphere infrastructure that you provision.

- **Installing a cluster on vSphere with network customizations with user-provisioned infrastructure**: You can install OpenShift Container Platform on VMware vSphere infrastructure that you provision with customized network configuration options.

- **Installing a cluster on vSphere in a restricted network with user-provisioned infrastructure** OpenShift Container Platform can be installed on VMware vSphere infrastructure that you provision in a restricted network.

16.1.3. Uninstalling an installer-provisioned infrastructure installation of OpenShift Container Platform on vSphere

- **Uninstalling a cluster on vSphere that uses installer-provisioned infrastructure** You can remove a cluster that you deployed on VMware vSphere infrastructure that used installer-provisioned infrastructure.

16.2. INSTALLING A CLUSTER ON VSPHERE

In OpenShift Container Platform version 4.8, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure.

16.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You read the documentation on selecting a cluster installation method and preparing it for users.

- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

16.2.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of
updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 16.2.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 16.1. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>
If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.

### 16.2.4. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 16.1. Roles and privileges required for installation**

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>vSphere object for role</td>
<td>When required</td>
<td>Required privileges</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------</td>
<td>------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>vSphere vCenter</td>
<td>Always</td>
<td>Cns.SearchableInventoryService.Tagging.AttachTag</td>
</tr>
<tr>
<td></td>
<td></td>
<td>InventoryService.Tagging.CreateCategory</td>
</tr>
<tr>
<td></td>
<td></td>
<td>InventoryService.Tagging.CreateTag</td>
</tr>
<tr>
<td></td>
<td></td>
<td>InventoryService.Tagging.DeleteCategory</td>
</tr>
<tr>
<td></td>
<td></td>
<td>InventoryService.Tagging.DeleteTag</td>
</tr>
<tr>
<td></td>
<td></td>
<td>InventoryService.Tagging.EditCategory</td>
</tr>
<tr>
<td></td>
<td></td>
<td>InventoryService.Tagging.EditTag</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Sessions.ValidateSession</td>
</tr>
<tr>
<td></td>
<td></td>
<td>StorageProfile.View</td>
</tr>
<tr>
<td>vSphere vCenter Cluster</td>
<td>Always</td>
<td>Host.Config.StorageResource.AssignVMToPool</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VApp.AssignResourcePool</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VApp.Import</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Config.AddNewDisk</td>
</tr>
<tr>
<td>vSphere Datastore</td>
<td>Always</td>
<td>Datastore.AllocateSpace</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Datastore.Browse</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Datastore.FileManagement</td>
</tr>
<tr>
<td>vSphere Port Group</td>
<td>Always</td>
<td>Network.Assign</td>
</tr>
</tbody>
</table>

**CHAPTER 16. INSTALLING ON VSPHERE**
<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere object for role</td>
<td>When required</td>
<td>Required privileges</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 16.2. Required permissions and propagation settings

<table>
<thead>
<tr>
<th>vSphere object</th>

<tr>
<td>vSphere vCenter Virtual Machine Folder</td>
<td>Existing</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td></td>
<td>folder</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**Cluster resources**
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**Required IP Addresses**
An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.
### Table 16.2. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;..&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;..&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

#### 16.2.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N '' -f /path/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

```
$ cat /path/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add /path/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`
Example output

- Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

2. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

```bash
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

3. Verify that the credentials were applied.

```bash
$ gcloud auth list
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**16.2.6. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:
5. From the Pull Secret page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

16.2.7. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

**Procedure**

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The <vCenter>/certs/download.zip file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   ├── lin
   │   └── 108f4d17.0
   │       └── 108f4d17.r1
   │           └── 7e757f6a.0
   │               └── 8e4f8471.0
   │                   └── 8e4f8471.r0
   │   └── mac
   │       └── 108f4d17.0
   │           └── 108f4d17.r1
   │               └── 7e757f6a.0
   │                   └── 8e4f8471.0
   │                       └── 8e4f8471.r0
   └── win
       └── 108f4d17.0.crt
           └── 108f4d17.r1.crl
               └── 7e757f6a.0.crt
                   └── 8e4f8471.0.crt
                       └── 8e4f8471.r0.crl
   3 directories, 15 files
   ```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```
16.2.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCloud_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The gcloud cli default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```shell
   $ ./openshift-install create cluster --dir=<installation_directory> \  
   --log-level=info
   ```

   **1**
   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **2**
   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

Provide values at the prompts:

a. Optional: Select an SSH key to use to access your cluster machines.
NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

b. Select `gcp` as the platform to target.

c. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

d. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

e. Select the region to deploy the cluster to.

f. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

g. Select `vsphere` as the platform to target.

h. Specify the name of your vCenter instance.

i. Specify the user name and password for the vCenter account that has the required permissions to create the cluster. The installation program connects to your vCenter instance.

j. Select the datacenter in your vCenter instance to connect to.

k. Select the default vCenter datastore to use.

l. Select the vCenter cluster to install the OpenShift Container Platform cluster in.

m. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

n. Enter the virtual IP address that you configured for control plane API access.

o. Enter the virtual IP address that you configured for cluster ingress.

p. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

q. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured. If you provide a name that is longer than 6 characters, only the first 6 characters will be used in the infrastructure ID that is generated from the cluster name.

r. Paste the pull secret that you obtained from the `Pull Secret` page on the Red Hat OpenShift Cluster Manager site.

NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.
When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

**Example output**

```none
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.

   - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
   - If you included the **Service Account Key Admin** role, you can remove it.

### 16.2.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.8. Download and install the new version of **oc**.
Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the Command line interface section, select Linux from the drop-down menu and click Download command-line tools.
4. Unpack the archive:
   ```bash
   $ tar xzvf <file>
   ``
5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:
   ```bash
   $ echo $PATH
   ``

After you install the CLI, it is available using the oc command:

```bash
$ oc <command>
```

Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.
2. Select your infrastructure provider, and, if applicable, your installation type.
3. In the Command line interface section, select Windows from the drop-down menu and click Download command-line tools.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:
   ```cmd
   C:\> path
   ```

After you install the CLI, it is available using the oc command:

```cmd
C:\> oc <command>
```

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

$ tar xvzf <file>

```bash
$ echo $PATH
```

```cmd
C:\> path
```
1. Navigate to the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site.

2. Select your infrastructure provider, and, if applicable, your installation type.

3. In the Command line interface section, select MacOS from the drop-down menu and click Download command-line tools.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your PATH.
   
   To check your PATH, open a terminal and execute the following command:

   ```bash
   $ echo $PATH
   ```

   After you install the CLI, it is available using the **oc** command:

   ```bash
   $ oc <command>
   ```

16.2.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```bash
   system:admin
   ```

16.2.11. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.
16.2.11.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

16.2.11.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

16.2.11.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have "100Gi" capacity.
IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   NOTE
   
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry
   
   NOTE
   
   If the storage type is `emptyDir`, the replica number cannot be greater than 1.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
     claim: 1
   
   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```bash
   $ oc get clusteroperator image-registry
   
   16.2.11.2.2. Configuring block registry storage for VMware vSphere
   
   To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.
IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only **1 replica**:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   **1**. A unique name that represents the **PersistentVolumeClaim** object.

   **2**. The access mode of the PersistentVolumeClaim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.

   **3**. The size of the PersistentVolumeClaim.

   b. Create the **PersistentVolumeClaim** object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   ```

3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

   ```yaml
   storage:
     pvc:
       claim: 1
   ```

**Example output**

1. Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.
creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 16.2.12. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See **Snapshot Limitations** for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 16.2.13. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

### 16.3. INSTALLING A CLUSTER ON VSPHERE WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.8, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

#### 16.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
NOTE

Be sure to also review this site list if you are configuring a proxy.

16.3.2. Internet and Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.8, you require access to the Internet to install your cluster. The Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, also requires Internet access. If your cluster is connected to the Internet, Telemetry runs automatically, and your cluster is registered to the Red Hat OpenShift Cluster Manager (OCM).

Once you confirm that your Red Hat OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually using OCM, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

You must have Internet access to:

- Access the Red Hat OpenShift Cluster Manager page to download the installation program and perform subscription management. If the cluster has Internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

16.3.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 16.3. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>

</tr>
</tbody>
</table>
| Networking (NSX-T)         | vSphere 6.5U3 or vSphere 6.7U2 and later | vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.

Storage with in-tree drivers | vSphere 6.5 and later | This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

### 16.3.4. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 16.3. Roles and privileges required for installation**

<table>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](https://vdocs.vmware.com/vcenter-documentation/latest/vsphere/permissions-and-user-management-tasks.pdf) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**Cluster resources**
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**Required IP Addresses**
An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>_<cluster_name>._<base_domain>..`
Table 16.4. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td><code>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

16.3.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  # Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
```

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

```bash
$ cat <path>/<file_name>.pub
```

For example, run the following to view the ~/.ssh/id_rsa.pub public key:

```bash
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

**NOTE**

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

1. Add your SSH private key to the ssh-agent:

```bash
$ ssh-add <path>/<file_name>  # Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa
```
Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

2. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

```
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

3. Verify that the credentials were applied.

```
$ gcloud auth list
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

16.3.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the Red Hat OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:
5. From the Pull Secret page on the Red Hat OpenShift Cluster Manager site, download your installation pull secret. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

16.3.7. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The <vCenter>/certs/download.zip file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

```
certs
  └── lin
      ├── 108f4d17.0
      │     └── 108f4d17.r1
      │     └── 7e757f6a.0
      │     └── 8e4f8471.0
      │     └── 8e4f8471.r0
      └── mac
          ├── 108f4d17.0
          │     └── 108f4d17.r1
          │     └── 7e757f6a.0
          │     └── 8e4f8471.0
          │     └── 8e4f8471.r0
          └── win
              ├── 108f4d17.0.crt
              │     └── 108f4d17.r1.crt
              │     └── 7e757f6a.0.crt
              │     └── 8e4f8471.0.crt
              │     └── 8e4f8471.r0.crt
```

3 directories, 15 files

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
# update-ca-trust extract
```
16.3.8. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP). VMware vSphere.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the install-config.yaml file.
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir=<installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

      ii. Select gcp as the platform to target.

      iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

      iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

      v. Select the region to deploy the cluster to.
vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

vii. Select vsphere as the platform to target.

viii. Specify the name of your vCenter instance.

ix. Specify the user name and password for the vCenter account that has the required permissions to create the cluster. The installation program connects to your vCenter instance.

x. Select the datacenter in your vCenter instance to connect to.

xi. Select the default vCenter datastore to use.

xii. Select the vCenter cluster to install the OpenShift Container Platform cluster in.

xiii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

xiv. Enter the virtual IP address that you configured for control plane API access.

xv. Enter the virtual IP address that you configured for cluster ingress.

xvi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xvii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xviii. Paste the pull secret that you obtained from the Pull Secret page on the Red Hat OpenShift Cluster Manager site.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the “Installation configuration parameters” section.
NOTE
If you have any intermediate CA certificates on the engine, verify that the certificates appear in the `ovirt-config.yaml` file and the `install-config.yaml` file. If they do not appear, add them as follows:

1. In the `~/.ovirt/ovirt-config.yaml` file:

   ```yaml
   [ovirt_ca_bundle]: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA>
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   <INTERMEDIATE_CA>
   -----END CERTIFICATE-----
   
   [additionalTrustBundle]: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA>
   -----END CERTIFICATE-----
   -----BEGIN CERTIFICATE-----
   <INTERMEDIATE_CA>
   -----END CERTIFICATE-----
   
2. In the `install-config.yaml` file:

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT
The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

16.3.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

NOTE
After installation, you cannot modify these parameters in the `install-config.yaml` file.

IMPORTANT
The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

16.3.8.1.1. Required configuration parameters
Required installation configuration parameters are described in the following table:

**Table 16.5. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>, <code>{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as <code>dev</code>.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
Get a pull secret from https://cloud.redhat.com/openshift/install/pull-secret to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

16.3.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 16.6. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The default value is <strong>OpenShiftSDN</strong>.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
</tbody>
</table>
|                         | The default value is **10.128.0.0/14** with a host prefix of /23. | `networking:
|                         | If you specify multiple IP address blocks, the blocks must not overlap. |  clusterNetwork:
|                         |                                            | - cidr: **10.128.0.0/14**  
<p>|                         |                                            | hostPrefix: <strong>23</strong>       |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>networking.clusterNetwork.cidr</code></td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in CIDR notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td><code>networking.clusterNetwork.hostPrefix</code></td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td><code>networking.serviceNetwork</code></td>
<td>The IP address block for services. The default value is <code>172.30.0.0/16</code>.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td><code>networking:</code></td>
</tr>
<tr>
<td><code>networking.machinNetwork</code></td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td><code>networking.machinNetwork.cidr</code></td>
<td>Required if you use <code>networking.machinNetwork</code>. An IP address block.</td>
<td>An IP network block in CIDR notation. For example, <code>10.0.0.0/16</code>.</td>
</tr>
<tr>
<td></td>
<td>The default value is <code>10.0.0.0/16</code> for all platforms other than libvirt. For libvirt, the default value is <code>192.168.126.0/24</code>.</td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td>Set the <code>networking.machinNetwork</code> to match the CIDR that the preferred NIC resides in.</td>
<td></td>
</tr>
</tbody>
</table>

**16.3.8.13. Optional configuration parameters**

Optional installation configuration parameters are described in the following table:

**Table 16.7. Optional parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><code>Enabled</code> or <code>Disabled</code></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>

<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;').</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.</td>
<td></td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set publish to Internal. The default value is External.</td>
</tr>
</tbody>
</table>
| sshKey | The SSH key or keys to authenticate access your cluster machines. | One or more keys. For example: 

sskKey:
<key1>
<key2>
<key3> |

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your *ssh-agent* process uses.

### 16.3.8.1.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

#### Table 16.8. Additional GCP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform.gcp.network</strong></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><strong>platform.gcp.type</strong></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><strong>platform.gcp.zones</strong></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as us-central1-a, in a YAML sequence.</td>
</tr>
<tr>
<td><strong>platform.gcp.controlPlaneSubnet</strong></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><strong>platform.gcp.computeSubnet</strong></td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.name</strong></td>
<td>The name of the customer managed encryption key to be used for control plane machine disk encryption.</td>
<td>The encryption key name.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.gcp.osDisk.encryptionKey.kmsKey.keyRing</strong></td>
<td>For control plane machines, the name of the KMS key ring to which the KMS key belongs.</td>
<td>The KMS key ring name.</td>

### 16.3.8.15. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.vsphere.password</td>
<td>The password for the vCenter username.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.datacenter</td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.defaultDatastore</td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.folder</td>
<td><strong>Optional.</strong> The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, /&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;.</td>
</tr>
<tr>
<td>platform.vsphere.network</td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.cluster</td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.apiVIP</td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.ingressVIP</td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
</tbody>
</table>

### 16.3.8.1.6 Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

**Table 16.10. Optional VMware vSphere machine pool parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
<th>2080</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
<td></td>
</tr>
</tbody>
</table>

2080
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.osDisk.diskSizeGB</code></td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.cpus</code></td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.coresPerSocket</code></td>
<td>The number of cores per socket in a virtual machine. The number of virtual CPUs (vCPUs) on the virtual machine is <code>platform.vsphere.cpus/platform.vsphere.coresPerSocket</code>. The default value is 1.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.memoryMB</code></td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

16.3.8.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com  
compute:  
  - hyperthreading: Enabled  
    name: worker  
    replicas: 3  
    platform:  
      vsphere:  
        cpus: 2  
        coresPerSocket: 2  
        memoryMB: 8196  
        osDisk:  
          diskSizeGB: 120  
controlPlane:  
  hyperthreading: Enabled  
  name: master  
  replicas: 3  
  platform:  
    vsphere:  
      cpus: 4  
      coresPerSocket: 2  
      memoryMB: 16384  
      osDisk:  
        diskSizeGB: 120  
metadata:  
  name: cluster  
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

16.3.9. Deploying the cluster
You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites
1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCGLOUD_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```shell
   $ ./openshift-install create cluster --dir=<installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   **Example output**

   ```shell
   ... 
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export 
   KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift- 
   console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj- 
   Wt5AL"
   INFO Time elapsed: 36m22s
   ```

   **NOTE**
