OpenShift Dedicated 4

Cluster administration

Configuring OpenShift Dedicated clusters
OpenShift Dedicated 4 Cluster administration

Configuring OpenShift Dedicated clusters
Abstract

This document provides information about configuring OpenShift Dedicated clusters.
# Table of Contents

## CHAPTER 1. MANAGING ADMINISTRATION ROLES AND USERS

1.1. UNDERSTANDING ADMINISTRATION ROLES .......................................................... 3
  1.1.1. The cluster-admin role 3
  1.1.2. The dedicated-admin role 3
1.2. MANAGING OPENSHIFT DEDICATED ADMINISTRATORS .................................. 3
  1.2.1. Adding a user 3
  1.2.2. Removing a user 4

## CHAPTER 2. CONFIGURING PRIVATE CONNECTIONS

2.1. CONFIGURING PRIVATE CONNECTIONS FOR AWS .......................................... 5
  2.1.1. Understanding AWS cloud infrastructure access 5
  2.1.2. Configuring AWS infrastructure access 5
  2.1.3. Configuring AWS VPC peering 7
  2.1.4. Configuring an AWS VPN 8
  2.1.5. Configuring AWS Direct Connect 9
2.2. CONFIGURING A PRIVATE CLUSTER .................................................................. 10
  2.2.1. Enabling a private cluster during cluster creation 10
  2.2.2. Enabling an existing cluster to be private 11
  2.2.3. Enabling an existing private cluster to be public 11

## CHAPTER 3. NODES

3.1. ABOUT MACHINE POOLS .................................................................................. 13
  3.1.1. Machines 13
  3.1.2. Machine sets 13
  3.1.3. Machine pools 13
  3.1.4. Machine pools in multiple zone clusters 13
  3.1.5. Additional resources 14
3.2. MANAGING COMPUTE NODES ......................................................................... 14
  3.2.1. Creating a machine pool 14
  3.2.2. Deleting a machine pool 16
  3.2.3. Scaling compute nodes manually 17
  3.2.4. Node labels 17
    3.2.4.1. Adding node labels to a machine pool 17
  3.2.5. Adding taints to a machine pool 18
  3.2.6. Additional resources 19
3.3. ABOUT AUTOSCALING NODES ON A CLUSTER ............................................. 19
  3.3.1. Enabling autoscaling nodes on a cluster 20
    Enabling autoscaling nodes in an existing cluster using Red Hat OpenShift Cluster Manager 20
  3.3.2. Disabling autoscaling nodes on a cluster 20
    Disabling autoscaling nodes in an existing cluster using Red Hat OpenShift Cluster Manager 20
  3.3.3. About the cluster autoscaler 21
  3.3.4. Additional resources 22

## CHAPTER 4. LOGGING

4.1. ACCESSING THE SERVICE LOGS FOR OPENSHIFT DEDICATED CLUSTERS .... 23
  4.1.1. Viewing the service logs by using OpenShift Cluster Manager 23
  4.1.2. Adding cluster notification contacts 23
CHAPTER 1. MANAGING ADMINISTRATION ROLES AND USERS

1.1. UNDERSTANDING ADMINISTRATION ROLES

1.1.1. The cluster-admin role

As an administrator of an OpenShift Dedicated cluster with Customer Cloud Subscriptions (CCS), you have access to the cluster-admin role. The user who created the cluster can add the cluster-admin user role to an account to have the maximum administrator privileges. These privileges are not automatically assigned to your user account when you create the cluster. While logged in to an account with the cluster-admin role, users have mostly unrestricted access to control and configure the cluster. There are some configurations that are blocked with webhooks to prevent destabilizing the cluster, or because they are managed in OpenShift Cluster Manager Hybrid Cloud Console and any in-cluster changes would be overwritten. Usage of the cluster-admin role is subject to the restrictions listed in your Appendix 4 agreement with Red Hat. As a best practice, limit the number of cluster-admin users to as few as possible.

1.1.2. The dedicated-admin role

As an administrator of an OpenShift Dedicated cluster, your account has additional permissions and access to all user-created projects in your organization’s cluster. While logged in to an account with the dedicated-admin role, the developer CLI commands (under the oc command) allow you increased visibility and management capabilities over objects across projects, while the administrator CLI commands (under the oc adm command) allow you to complete additional operations.

NOTE

While your account does have these increased permissions, the actual cluster maintenance and host configuration is still performed by the OpenShift Operations Team.

1.2. MANAGING OPENSIGHT DEDICATED ADMINISTRATORS

Administrator roles are managed using a cluster-admin or dedicated-admin group on the cluster. Existing members of this group can edit membership through OpenShift Cluster Manager Hybrid Cloud Console.

1.2.1. Adding a user

Procedure

1. Navigate to the Cluster Details page and Access Control tab.

2. Select the Cluster Roles and Access tab and click Add user.

3. Enter the user name and select the group.

4. Click Add user.
NOTE

Adding a user to the `cluster-admin` group can take several minutes to complete.

1.2.2. Removing a user

**Procedure**

1. Navigate to the **Cluster Details** page and **Access Control** tab.

2. Click the Options menu to the right of the user and group combination and click **Delete**.
CHAPTER 2. CONFIGURING PRIVATE CONNECTIONS

2.1. CONFIGURING PRIVATE CONNECTIONS FOR AWS

2.1.1. Understanding AWS cloud infrastructure access

NOTE

AWS cloud infrastructure access does not apply to the Customer Cloud Subscription (CCS) infrastructure type that is chosen when you create a cluster because CCS clusters are deployed onto your account.

Amazon Web Services (AWS) infrastructure access permits Customer Portal Organization Administrators and cluster owners to enable AWS Identity and Access Management (IAM) users to have federated access to the AWS Management Console for their OpenShift Dedicated cluster. AWS access can be granted for customer AWS users, and private cluster access can be implemented to suit the needs of your OpenShift Dedicated environment.

1. Get started with configuring AWS infrastructure access for your OpenShift Dedicated cluster. By creating an AWS user and account and providing that user with access to the OpenShift Dedicated AWS account.

2. After you have access to the OpenShift Dedicated AWS account, use one or more of the following methods to establish a private connection to your cluster:

- Configuring AWS VPC peering: Enable VPC peering to route network traffic between two private IP addresses.
- Configuring AWS VPN: Establish a Virtual Private Network to securely connect your private network to your Amazon Virtual Private Cloud.
- Configuring AWS Direct Connect: Configure AWS Direct Connect to establish a dedicated network connection between your private network and an AWS Direct Connect location.

After configuring your cloud infrastructure access, learn more about Configuring a private cluster.

2.1.2. Configuring AWS infrastructure access

Amazon Web Services (AWS) infrastructure access allows Customer Portal Organization Administrators and cluster owners to enable AWS Identity and Access Management (IAM) users to have federated access to the AWS Management Console for their OpenShift Dedicated cluster. Administrators can select between Network Management or Read-only access options.

Prerequisites

- An AWS account with IAM permissions.

Procedure

1. Log in to your AWS account. If necessary, you can create a new AWS account by following the AWS documentation.

2. Create an IAM user with STS:AllowAssumeRole permissions within the AWS account.
a. Open the IAM dashboard of the AWS Management Console.

b. In the Policies section, click Create Policy.

c. Select the JSON tab and replace the existing text with the following:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "sts:AssumeRole",
         "Resource": "*"
      }
   ]
}
```

d. Click Next: Tags.

e. Optional: Add tags. Click Next: Review

f. Provide an appropriate name and description, then click Create Policy.

g. In the Users section, click Add user.

h. Provide an appropriate user name.

i. Select AWS Management Console access as the AWS access type.

j. Adjust the password requirements as necessary for your organization, then click Next: Permissions.

k. Click the Attach existing policies directly option. Search for and check the policy created in previous steps.

   **NOTE**

   It is not recommended to set a permissions boundary.

l. Click Next: Tags, then click Next: Review. Confirm the configuration is correct.

m. Click Create user, a success page appears.

n. Gather the IAM user’s Amazon Resource Name (ARN). The ARN will have the following format: `arn:aws:iam::000111222333:user/username`. Click Close.

3. Open OpenShift Cluster Manager Hybrid Cloud Console in your browser and select the cluster you want to allow AWS infrastructure access.

4. Select the Access control tab, and scroll to the AWS Infrastructure Access section.

5. Paste the AWS IAM ARN and select Network Management or Read-only permissions, then click Grant role.

6. Copy the AWS OSD console URL to your clipboard.
7. Sign in to your AWS account with your Account ID or alias, IAM user name, and password.

8. In a new browser tab, paste the AWS OSD Console URL that will be used to route to the AWS Switch Role page.

9. Your account number and role will be filled in already. Choose a display name if necessary, then click **Switch Role**.

**Verification**

- You now see **VPC** under **Recently visited services**.

### 2.1.3. Configuring AWS VPC peering

A Virtual Private Cloud (VPC) peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IPv4 addresses or IPv6 addresses. You can configure an Amazon Web Services (AWS) VPC containing an OpenShift Dedicated cluster to peer with another AWS VPC network.

**WARNING**

Private clusters cannot be fully deleted by Red Hat OpenShift Cluster Manager if the VPC the cluster is installed in is peered.

AWS supports inter-region VPC peering between all commercial regions excluding China.

**Prerequisites**

- Gather the following information about the Customer VPC that is required to initiate the peering request:
  - Customer AWS account number
  - Customer VPC ID
  - Customer VPC Region
  - Customer VPC CIDR

- Check the CIDR block used by the OpenShift Dedicated Cluster VPC. If it overlaps or matches the CIDR block for the Customer VPC, then peering between these two VPCs is not possible; see the Amazon VPC **Unsupported VPC peering configurations** documentation for details. If the CIDR blocks do not overlap, you can proceed with the procedure.

**Procedure**

1. **Initiate the VPC peering request**.

2. **Accept the VPC peering request**.
3. Update your Route tables for the VPC peering connection.

Additional resources

- For more information and troubleshooting help, see the AWS VPC guide.

2.1.4. Configuring an AWS VPN

You can configure an Amazon Web Services (AWS) OpenShift Dedicated cluster to use a customer’s on-site hardware Virtual Private Network (VPN) device. By default, instances that you launch into an AWS Virtual Private Cloud (VPC) cannot communicate with your own (remote) network. You can enable access to your remote network from your VPC by creating an AWS Site-to-Site VPN connection, and configuring routing to pass traffic through the connection.

NOTE

AWS VPN does not currently provide a managed option to apply NAT to VPN traffic. See the AWS Knowledge Center for more details.

Routing all traffic, for example 0.0.0.0/0, through a private connection is not supported. This requires deleting the internet gateway, which disables SRE management traffic.

Prerequisites

- Hardware VPN gateway device model and software version, for example Cisco ASA running version 8.3. See the AWS documentation to confirm whether your gateway device is supported by AWS.
- Public, static IP address for the VPN gateway device.
- BGP or static routing: if BGP, the ASN is required. If static routing, you must configure at least one static route.
- Optional: IP and port/protocol of a reachable service to test the VPN connection.

Procedure

1. Create a customer gateway to configure the VPN connection.
2. If you do not already have a Virtual Private Gateway attached to the intended VPC, create and attach a Virtual Private Gateway.
3. Configure routing and enable VPN route propagation.
4. Update your security group.
5. Establish the Site-to-Site VPN connection.

NOTE

Note the VPC subnet information, which you must add to your configuration as the remote network.

Additional resources
For more information and troubleshooting help, see the AWS VPN guide.

2.1.5. Configuring AWS Direct Connect

Amazon Web Services (AWS) Direct Connect requires a hosted Virtual Interface (VIF) connected to a Direct Connect Gateway (DXGateway), which is in turn associated to a Virtual Gateway (VGW) or a Transit Gateway in order to access a remote Virtual Private Cloud (VPC) in the same or another account.

If you do not have an existing DXGateway, the typical process involves creating the hosted VIF, with the DXGateway and VGW being created in your AWS account.

If you have an existing DXGateway connected to one or more existing VGWs, the process involves your AWS account sending an Association Proposal to the DXGateway owner. The DXGateway owner must ensure that the proposed CIDR will not conflict with any other VGWs they have associated.

Prerequisites

- Confirm the CIDR range of the OpenShift Dedicated VPC will not conflict with any other VGWs you have associated.

- Gather the following information:
  - The Direct Connect Gateway ID.
  - The AWS Account ID associated with the virtual interface.
  - The BGP ASN assigned for the DXGateway. Optional: the Amazon default ASN may also be used.

Procedure

1. **Create a VIF** or **view your existing VIFs** to determine the type of direct connection you need to create.

2. Create your gateway.
   
   a. If the Direct Connect VIF type is **Private**, **create a virtual private gateway**.
   
   b. If the Direct Connect VIF is **Public**, **create a Direct Connect gateway**.

3. If you have an existing gateway you want to use, **create an association proposal** and send the proposal to the DXGateway owner for approval.

**WARNING**

When connecting to an existing DXGateway, you are responsible for the costs.

Additional resources
For more information and troubleshooting help, see the AWS Direct Connect guide.

2.2. CONFIGURING A PRIVATE CLUSTER

An OpenShift Dedicated cluster can be made private so that internal applications can be hosted inside a corporate network. In addition, private clusters can be configured to have only internal API endpoints for increased security.

OpenShift Dedicated administrators can choose between public and private cluster configuration from within OpenShift Cluster Manager. Privacy settings can be configured during cluster creation or after a cluster is established.

2.2.1. Enabling a private cluster during cluster creation

You can enable private cluster settings when creating a new cluster.

Prerequisites

- The following private connections must be configured to allow private access:
  - VPC Peering
  - Cloud VPN
  - DirectConnect (AWS only)
  - TransitGateway (AWS only)
  - Cloud Interconnect (GCP only)

Procedure

1. Log in to OpenShift Cluster Manager Hybrid Cloud Console.
2. Click Create cluster → OpenShift Dedicated → Create cluster.
3. Configure your cluster details.
4. When selecting your preferred network configuration, select Advanced.
5. Select Private.

WARNING

When set to Private, you cannot access your cluster unless you have configured the private connections in your cloud provider as outlined in the prerequisites.

6. Click Create cluster. The cluster creation process begins and takes about 30-40 minutes to complete.
2.2.2. Enabling an existing cluster to be private

After a cluster has been created, you can later enable the cluster to be private.

Prerequisites

- The following private connections must be configured to allow private access:
  - VPC Peering
  - Cloud VPN
  - DirectConnect (AWS only)
  - TransitGateway (AWS only)
  - Cloud Interconnect (GCP only)

Procedure

1. Log in to OpenShift Cluster Manager Hybrid Cloud Console.
2. Select the public cluster you would like to make private.
3. On the Networking tab, select Make API private under Control Plane API endpoint.

WARNING

When set to Private, you cannot access your cluster unless you have configured the private connections in your cloud provider as outlined in the prerequisites.

4. Click Change settings.

NOTE

Transitioning your cluster between private and public can take several minutes to complete.

2.2.3. Enabling an existing private cluster to be public

After a private cluster has been created, you can later enable the cluster to be public.

Procedure
1. Log in to OpenShift Cluster Manager Hybrid Cloud Console.

2. Select the private cluster you would like to make public.

3. On the Networking tab, deselect Make API private under Control Plane API endpoint.

4. Click Change settings.

NOTE

Transitioning your cluster between private and public can take several minutes to complete.
CHAPTER 3. NODES

3.1. ABOUT MACHINE POOLS

OpenShift Dedicated uses machine pools as an elastic, dynamic provisioning method on top of your cloud infrastructure.

The primary resources are machines, machine sets, and machine pools.

**IMPORTANT**

As of the OpenShift Dedicated versions 4.8.35, 4.9.26, 4.10.6, the OpenShift Dedicated default per-pod pid limit is **4096**. If you want to enable this PID limit, you must upgrade your OpenShift Dedicated clusters to these versions or later. OpenShift Dedicated clusters with prior versions use a default PID limit of **1024**.

You cannot configure the per-pod PID limit on any OpenShift Dedicated cluster.

3.1.1. Machines

A machine is a fundamental unit that describes the host for a worker node.

3.1.2. Machine sets

MachineSet resources are groups of compute machines. If you need more machines or must scale them down, change the number of replicas in the machine pool to which the compute machine sets belong.

3.1.3. Machine pools

Machine pools are a higher level construct to compute machine sets.

A machine pool creates compute machine sets that are all clones of the same configuration across availability zones. Machine pools perform all of the host node provisioning management actions on a worker node. If you need more machines or must scale them down, change the number of replicas in the machine pool to meet your compute needs. You can manually configure scaling or set autoscaling.

By default, a cluster is created with one machine pool. You can add additional machine pools to an existing cluster, modify the default machine pool, and delete machine pools.

Multiple machine pools can exist on a single cluster, and they can each have different types or different size nodes.

3.1.4. Machine pools in multiple zone clusters

When you create a machine pool in a multiple availability zone (Multi-AZ) cluster, that one machine pool has 3 zones. The machine pool, in turn, creates a total of 3 compute machine sets - one for each zone in the cluster. Each of those compute machine sets manages one or more machines in its respective availability zone.

If you create a new Multi-AZ cluster, the machine pools are replicated to those zones automatically. If you add a machine pool to an existing Multi-AZ, the new pool is automatically created in those zones. Similarly, deleting a machine pool will delete it from all zones. Due to this multiplicative effect, using machine pools in Multi-AZ cluster can consume more of your project’s quota for a specific region when creating machine pools.
3.1.5. Additional resources

- About autoscaling

3.2. MANAGING COMPUTE NODES

This document describes how to manage compute (also known as worker) nodes with OpenShift Dedicated.

The majority of changes for compute nodes are configured on machine pools. A machine pool is a group of compute nodes in a cluster that have the same configuration, providing ease of management.

You can edit machine pool configuration options such as scaling, adding node labels, and adding taints.

3.2.1. Creating a machine pool

A default machine pool is created when you install an OpenShift Dedicated cluster. After installation, you can create additional machine pools for your cluster by using OpenShift Cluster Manager.

**IMPORTANT**

The compute (also known as worker) node instance types, autoscaling options, and node counts that are available to you depend on your OpenShift Dedicated subscriptions, resource quotas and deployment scenario. For more information, contact your sales representative or Red Hat support.

**Prerequisites**

- You created an OpenShift Dedicated cluster.

**Procedure**

1. Navigate to OpenShift Cluster Manager Hybrid Cloud Console and select your cluster.

2. Under the Machine pools tab, click Add machine pool.

3. Add a Machine pool name.

4. Select a Worker node instance type from the drop-down menu. The instance type defines the vCPU and memory allocation for each compute node in the machine pool.

**NOTE**

You cannot change the instance type for a machine pool after the pool is created.

5. Optional: Configure autoscaling for the machine pool:

   a. Select Enable autoscaling to automatically scale the number of machines in your machine pool to meet the deployment needs.
b. Set the minimum and maximum node count limits for autoscaling. The cluster autoscaler does not reduce or increase the machine pool node count beyond the limits that you specify.

- If you deployed your cluster using a single availability zone, set the **Minimum and maximum node count.** This defines the minimum and maximum compute node limits in the availability zone.

- If you deployed your cluster using multiple availability zones, set the **Minimum nodes per zone** and **Maximum nodes per zone.** This defines the minimum and maximum compute node limits per zone.

**NOTE**

Alternatively, you can set your autoscaling preferences for the machine pool after the machine pool is created.

6. If you did not enable autoscaling, select a compute node count:

- If you deployed your cluster using a single availability zone, select a **Worker node count** from the drop-down menu. This defines the number of compute nodes to provision to the machine pool for the zone.

- If you deployed your cluster using multiple availability zones, select a **Worker node count (per zone)** from the drop-down menu. This defines the number of compute nodes to provision to the machine pool per zone.

7. Optional: Add node labels and taints for your machine pool:

   a. Expand the **Edit node labels and taints** menu.

   b. Under **Node labels**, add **Key** and **Value** entries for your node labels.

   c. Under **Taints**, add **Key** and **Value** entries for your taints.

   d. For each taint, select an **Effect** from the drop-down menu. Available options include **NoSchedule**, **PreferNoSchedule**, and **NoExecute**.

**NOTE**

Alternatively, you can add the node labels and taints after you create the machine pool.

8. Optional: If you deployed OpenShift Dedicated on AWS using the Customer Cloud Subscription (CCS) model, use Amazon EC2 Spot Instances if you want to configure your machine pool to deploy machines as non-guaranteed AWS Spot Instances:

   a. Select **Use Amazon EC2 Spot Instances**.
b. Leave **Use On-Demand instance price** selected to use the on-demand instance price. Alternatively, select **Set maximum price** to define a maximum hourly price for a Spot Instance.

For more information about Amazon EC2 Spot Instances, see the [AWS documentation](https://aws.amazon.com/documentation/ec2/)

**IMPORTANT**

Your Amazon EC2 Spot Instances might be interrupted at any time. Use Amazon EC2 Spot Instances only for workloads that can tolerate interruptions.

**NOTE**

If you select **Use Amazon EC2 Spot Instances** for a machine pool, you cannot disable the option after the machine pool is created.

9. Click **Add machine pool** to create the machine pool.

**Verification**

- Verify that the machine pool is visible on the **Machine pools** page and the configuration is as expected.

### 3.2.2. Deleting a machine pool

You can delete a machine pool in the event that your workload requirements have changed and your current machine pools no longer meet your needs. You can delete machine pools using the Openshift Cluster Manager.

**Prerequisites**

- You have created an OpenShift Dedicated cluster.

- The cluster is in the ready state.

- You have an existing machine pool without any taints and with at least two instances for a single-AZ cluster or three instances for a multi-AZ cluster.

**Procedure**

1. From **OpenShift Cluster Manager Hybrid Cloud Console**, navigate to the **Clusters** page and select the cluster that contains the machine pool that you want to delete.

2. On the selected cluster, select the **Machine pools** tab.

3. Under the **Machine pools** tab, click the options menu for the machine pool that you want to delete.

4. Click **Delete**.

The selected machine pool is deleted.
3.2.3. Scaling compute nodes manually

If you have not enabled autoscaling for your machine pool, you can manually scale the number of compute (also known as worker) nodes in the pool to meet your deployment needs.

You must scale each machine pool separately.

Prerequisites

- You created an OpenShift Dedicated cluster.
- You have an existing machine pool.

Procedure

1. Navigate to OpenShift Cluster Manager Hybrid Cloud Console and select your cluster.

2. Under the Machine pools tab, click the options menu for the machine pool that you want to scale.

3. Select Scale.

4. Specify the node count:
   - If you deployed your cluster using a single availability zone, specify the Node count in the drop-down menu.
   - If you deployed your cluster using multiple availability zones, specify the Node count per zone in the drop-down menu.

   **NOTE**
   
   Your subscription determines the number of nodes that you can select.

5. Click Apply to scale the machine pool.

Verification

- Under the Machine pools tab, verify that the Node count for your machine pool is as expected.

3.2.4. Node labels

A label is a key-value pair applied to a Node object. You can use labels to organize sets of objects and control the scheduling of pods.

You can add labels during cluster creation or after. Labels can be modified or updated at any time.

Additional resources

- For more information about labels, see Kubernetes Labels and Selectors overview.

3.2.4.1. Adding node labels to a machine pool
Add or edit labels for compute (also known as worker) nodes at any time to manage the nodes in a manner that is relevant to you. For example, you can assign types of workloads to specific nodes.

Labels are assigned as key-value pairs. Each key must be unique to the object it is assigned to.

**Prerequisites**

- You created an OpenShift Dedicated cluster.
- You have an existing machine pool.

**Procedure**

1. Navigate to OpenShift Cluster Manager Hybrid Cloud Console and select your cluster.
2. Under the Machine pools tab, click the options menu for the machine pool that you want to add a label to.
3. Select Edit labels.
4. If you have existing labels in the machine pool that you want to remove, select x next to the label to delete it.
5. Add a label using the format `<key>=<value>` and press enter. For example, add `app=database` and then press enter. If the format is correct, the key value pair is then highlighted.
6. Repeat the previous step if you want to add additional labels.
7. Click Save to apply the labels to the machine pool.

**Verification**

1. Under the Machine pools tab, select > next to your machine pool to expand the view.
2. Verify that your labels are listed under Labels in the expanded view.

### 3.2.5. Adding taints to a machine pool

You can add taints for compute (also known as worker) nodes in a machine pool to control which pods are scheduled to them. When you apply a taint to a machine pool, the scheduler cannot place a pod on the nodes in the pool unless the pod specification includes a toleration for the taint.

**NOTE**

A cluster must have at least one machine pool that does not contain any taints.

**Prerequisites**

- You created an OpenShift Dedicated cluster.
- You have an existing machine pool that does not contain any taints and contains at least two instances.
Procedure

1. Navigate to OpenShift Cluster Manager Hybrid Cloud Console and select your cluster.

2. Under the Machine pools tab, click the options menu for the machine pool that you want to add a taint to.

3. Select Edit taints.

4. Add Key and Value entries for your taint.

5. Select an Effect for your taint from the drop-down menu. Available options include NoSchedule, PreferNoSchedule, and NoExecute.

6. Select Add taint if you want to add more taints to the machine pool.

7. Click Save to apply the taints to the machine pool.

Verification

1. Under the Machine pools tab, select > next to your machine pool to expand the view.

2. Verify that your taints are listed under Taints in the expanded view.

3.2.6. Additional resources

- About machine pools
- Enabling autoscaling
- Disabling autoscaling
- OpenShift Dedicated service definition

3.3. ABOUT AUTOSCALING NODES ON A CLUSTER

IMPORTANT

Autoscaling is available only on clusters that were purchased through the Red Hat Marketplace.

The autoscaler option can be configured to automatically scale the number of machines in a cluster.

The cluster autoscaler increases the size of the cluster when there are pods that failed to schedule on any of the current nodes due to insufficient resources or when another node is necessary to meet deployment needs. The cluster autoscaler does not increase the cluster resources beyond the limits that you specify.

Additionally, the cluster autoscaler decreases the size of the cluster when some nodes are consistently not needed for a significant period, such as when it has low resource use and all of its important pods can fit on other nodes.

When you enable autoscaling, you must also set a minimum and maximum number of worker nodes.
NOTE
Only cluster owners and organization admins can scale or delete a cluster.

3.3.1. Enabling autoscaling nodes on a cluster
You can enable autoscaling on worker nodes to increase or decrease the number of nodes available by editing the machine pool definition for an existing cluster.

Enabling autoscaling nodes in an existing cluster using Red Hat OpenShift Cluster Manager
Enable autoscaling for worker nodes in the machine pool definition from OpenShift Cluster Manager console.

Procedure
1. From OpenShift Cluster Manager Hybrid Cloud Console, navigate to the Clusters page and select the cluster that you want to enable autoscaling for.
2. On the selected cluster, select the Machine pools tab.
3. Click the Options menu at the end of the machine pool that you want to enable autoscaling for and select Scale.
4. On the Edit node count dialog, select the Enable autoscaling checkbox.
5. Select Apply to save these changes and enable autoscaling for the cluster.

3.3.2. Disabling autoscaling nodes on a cluster
You can disable autoscaling on worker nodes to increase or decrease the number of nodes available by editing the machine pool definition for an existing cluster.

You can disable autoscaling on a cluster using OpenShift Cluster Manager console.

Disabling autoscaling nodes in an existing cluster using Red Hat OpenShift Cluster Manager
Disable autoscaling for worker nodes in the machine pool definition from OpenShift Cluster Manager console.

Procedure
1. From OpenShift Cluster Manager Hybrid Cloud Console, navigate to the Clusters page and select the cluster with autoscaling that must be disabled.
2. On the selected cluster, select the Machine pools tab.
3. Click the Options menu at the end of the machine pool with autoscaling and select Scale.
4. On the "Edit node count" dialog, deselect the Enable autoscaling checkbox.
5. Select Apply to save these changes and disable autoscaling from the cluster.
Applying autoscaling to an OpenShift Dedicated cluster involves deploying a cluster autoscaler and then deploying machine autoscalers for each machine type in your cluster.

**IMPORTANT**

You can configure the cluster autoscaler only in clusters where the Machine API is operational.

### 3.3.3. About the cluster autoscaler

The cluster autoscaler adjusts the size of an OpenShift Dedicated cluster to meet its current deployment needs. It uses declarative, Kubernetes-style arguments to provide infrastructure management that does not rely on objects of a specific cloud provider. The cluster autoscaler has a cluster scope, and is not associated with a particular namespace.

The cluster autoscaler increases the size of the cluster when there are pods that fail to schedule on any of the current worker nodes due to insufficient resources or when another node is necessary to meet deployment needs. The cluster autoscaler does not increase the cluster resources beyond the limits that you specify.

The cluster autoscaler computes the total memory and CPU on all nodes the cluster, even though it does not manage the control plane nodes. These values are not single-machine oriented. They are an aggregation of all the resources in the entire cluster. For example, if you set the maximum memory resource limit, the cluster autoscaler includes all the nodes in the cluster when calculating the current memory usage. That calculation is then used to determine if the cluster autoscaler has the capacity to add more worker resources.

**IMPORTANT**

Ensure that the `maxNodesTotal` value in the `ClusterAutoscaler` resource definition that you create is large enough to account for the total possible number of machines in your cluster. This value must encompass the number of control plane machines and the possible number of compute machines that you might scale to.

Every 10 seconds, the cluster autoscaler checks which nodes are unnecessary in the cluster and removes them. The cluster autoscaler considers a node for removal if the following conditions apply:

- The node utilization is less than the `node utilization level` threshold for the cluster. The node utilization level is the sum of the requested resources divided by the allocated resources for the node. If you do not specify a value in the `ClusterAutoscaler` custom resource, the cluster autoscaler uses a default value of 0.5, which corresponds to 50% utilization.
- The cluster autoscaler can move all pods running on the node to the other nodes. The Kubernetes scheduler is responsible for scheduling pods on the nodes.
- The cluster autoscaler does not have scale down disabled annotation.

If the following types of pods are present on a node, the cluster autoscaler will not remove the node:

- Pods with restrictive pod disruption budgets (PDBs).
- Kube-system pods that do not run on the node by default.
- Kube-system pods that do not have a PDB or have a PDB that is too restrictive.
- Pods that are not backed by a controller object such as a deployment, replica set, or stateful set.
• Pods with local storage.

• Pods that cannot be moved elsewhere because of a lack of resources, incompatible node selectors or affinity, matching anti-affinity, and so on.

• Unless they also have a "cluster-autoscaler.kubernetes.io/safe-to-evict": "true" annotation, pods that have a "cluster-autoscaler.kubernetes.io/safe-to-evict": "false" annotation.

For example, you set the maximum CPU limit to 64 cores and configure the cluster autoscaler to only create machines that have 8 cores each. If your cluster starts with 30 cores, the cluster autoscaler can add up to 4 more nodes with 32 cores, for a total of 62.

If you configure the cluster autoscaler, additional usage restrictions apply:

• Do not modify the nodes that are in autoscaled node groups directly. All nodes within the same node group have the same capacity and labels and run the same system pods.

• Specify requests for your pods.

• If you have to prevent pods from being deleted too quickly, configure appropriate PDBs.

• Confirm that your cloud provider quota is large enough to support the maximum node pools that you configure.

• Do not run additional node group autoscalers, especially the ones offered by your cloud provider.

The horizontal pod autoscaler (HPA) and the cluster autoscaler modify cluster resources in different ways. The HPA changes the deployment’s or replica set’s number of replicas based on the current CPU load. If the load increases, the HPA creates new replicas, regardless of the amount of resources available to the cluster. If there are not enough resources, the cluster autoscaler adds resources so that the HPA-created pods can run. If the load decreases, the HPA stops some replicas. If this action causes some nodes to be underutilized or completely empty, the cluster autoscaler deletes the unnecessary nodes.

The cluster autoscaler takes pod priorities into account. The Pod Priority and Preemption feature enables scheduling pods based on priorities if the cluster does not have enough resources, but the cluster autoscaler ensures that the cluster has resources to run all pods. To honor the intention of both features, the cluster autoscaler includes a priority cutoff function. You can use this cutoff to schedule “best-effort” pods, which do not cause the cluster autoscaler to increase resources but instead run only when spare resources are available.

Pods with priority lower than the cutoff value do not cause the cluster to scale up or prevent the cluster from scaling down. No new nodes are added to run the pods, and nodes running these pods might be deleted to free resources.

Cluster autoscaling is supported for the platforms that have machine API available on it.

CHAPTER 4. LOGGING

4.1. ACCESSING THE SERVICE LOGS FOR OPENSHIFT DEDICATED CLUSTERS

You can view the service logs for your OpenShift Dedicated clusters by using Red Hat OpenShift Cluster Manager. The service logs detail cluster events such as load balancer quota updates and scheduled maintenance upgrades. The logs also show cluster resource changes such as the addition or deletion of users, groups, and identity providers.

Additionally, you can add notification contacts for an OpenShift Dedicated cluster. Subscribed users receive emails about cluster events that require customer action, known cluster incidents, upgrade maintenance, and other topics.

4.1.1. Viewing the service logs by using OpenShift Cluster Manager

You can view the service logs for an OpenShift Dedicated cluster by using Red Hat OpenShift Cluster Manager.

Prerequisites

- You have installed an OpenShift Dedicated cluster.

Procedure

1. Navigate to OpenShift Cluster Manager Hybrid Cloud Console and select your cluster.
2. In the Overview page for your cluster, view the service logs in the Cluster history section.
3. Optional: Filter the cluster service logs by Description or Severity from the drop-down menu. You can filter further by entering a specific item in the search bar.
4. Optional: Click Download history to download the service logs for your cluster in JSON or CSV format.

4.1.2. Adding cluster notification contacts

You can add notification contacts for your OpenShift Dedicated cluster. When an event occurs that triggers a cluster notification email, subscribed users are notified.

Procedure

1. Navigate to OpenShift Cluster Manager Hybrid Cloud Console and select your cluster.
2. On the Support tab, under the Notification contacts heading, click Add notification contact.
3. Enter the Red Hat username or email of the contact you want to add.

NOTE

The username or email address must relate to a user account in the Red Hat organization where the cluster is deployed.
4. Click **Add contact**.

**Verification**

- You see a confirmation message when you have successfully added the contact. The user appears under the **Notification contacts** heading on the **Support** tab.
