Abstract

This guide provides the information to install and configure 3scale API Management.

Table of Contents

PREFACE	5
MAKING OPEN SOURCE MORE INCLUSIVE	6
CHAPTER 1. REGISTRY SERVICE ACCOUNTS FOR 3SCALE	7
1.1. CREATING A REGISTRY SERVICE ACCOUNT	7
1.2. CONFIGURING CONTAINER REGISTRY AUTHENTICATION	7
1.3. MODIFYING A REGISTRY SERVICE ACCOUNT	8
1.4. ADDITIONAL RESOURCES	9
CHAPTER 2. INSTALLING 3SCALE ON OPENSIFT	10
2.1. SYSTEM REQUIREMENTS FOR INSTALLING 3SCALE ON OPENSIFT	10
2.1.1. Environment requirements	10
2.1.2. Hardware requirements	11
2.2. INSTALLING THE 3SCALE OPERATOR ON OPENSIFT	12
2.2.1. Creating a new OpenShift project	12
2.2.2. Installing and configuring the 3scale operator using the OLM	13
2.2.2.1. Restrictions in disconnected environments	14
2.2.3. Upgrading the 3scale operator using the OLM	15
2.2.3.1. Configuring automated application of micro releases	16
2.3. INSTALLING THE APICAST OPERATOR ON OPENSIFT	17
2.4. DEPLOYING 3SCALE USING THE OPERATOR	17
2.4.1. Deploying the APIManager custom resource	18
2.4.2. Getting the Admin Portal URL	19
2.4.3. Getting the APIManager Admin Portal and Master Admin Portal credentials	19
2.4.4. External databases for 3scale using the operator	20
2.5. DEPLOYMENT CONFIGURATION OPTIONS FOR 3SCALE ON OPENSIFT USING THE OPERATOR	21
2.5.1. Configuring proxy parameters for embedded APIcast	21
2.5.2. Injecting custom environments with the 3scale operator	24
2.5.3. Injecting custom policies with the 3scale operator	25
2.5.4. Configuring OpenTracing with the 3scale operator	27
2.5.5. Enabling TLS at the pod level with the 3scale operator	29
2.5.6. Proof of concept for evaluation deployment	30
2.5.6.1. Default deployment configuration	30
2.5.6.2. Evaluation installation	30
2.5.7. External databases installation	31
2.5.7.1. Backend Redis secret	32
2.5.7.2. System Redis secret	32
2.5.7.3. System database secret	33
2.5.7.4. Zync database secret	34
2.5.7.5. APIManager custom resources to deploy 3scale	34
2.5.8. Enabling pod affinity in the 3scale operator	35
2.5.8.1. Customizing node affinity and tolerations at component level	35
2.5.9. Multiple clusters in multiple availability zones	37
2.5.9.1. Prerequisites for multiple clusters installations	37
2.5.9.2. Active-passive clusters on the same region with shared databases	38
2.5.9.3. Configuring and installing shared databases	38
2.5.9.4. Manual failover shared databases	39
2.5.9.5. Active-passive clusters on different regions with synced databases	40
2.5.9.6. Configuring and installing synced databases	41
2.5.9.7. Manual failover synced databases	41
2.5.10. Amazon Simple Storage Service 3scale Filestorage installation	42

2.5.10.1. Amazon S3 secret	42
2.5.11. PostgreSQL installation	43
2.5.12. Configuring SMTP variables (optional)	43
2.5.13. Customizing compute resource requirements at component level	45
2.5.13.1. Default APIManager components compute resources	46
2.5.13.1.1. CPU and memory units	46
2.5.14. Customizing node affinity and tolerations at component level	47
2.5.15. Reconciliation	48
2.5.15.1. Resources	48
2.5.15.2. Backend replicas	48
2.5.15.3. APICast replicas	49
2.5.15.4. System replicas	49
2.5.15.5. Zync replicas	49
2.6. INSTALLING 3SCALE WITH THE OPERATOR USING ORACLE AS THE SYSTEM DATABASE	49
2.6.1. Preparing the Oracle Database	50
2.6.2. Building a custom system container image	51
2.6.3. Installing 3scale with Oracle using the operator	53
2.7. TROUBLESHOOTING COMMON 3SCALE INSTALLATION ISSUES	53
2.7.1. Previous deployment leaving dirty persistent volume claims	54
2.7.2. Wrong or missing credentials of the authenticated image registry	54
2.7.3. Incorrectly pulling from the Docker registry	56
2.7.4. Permission issues for MySQL when persistent volumes are mounted locally	56
2.7.5. Unable to upload logo or images	57
2.7.6. Test calls not working on OpenShift	57
2.7.7. APICast on a different project from 3scale failing to deploy	57
2.8. ADDITIONAL RESOURCES	58
CHAPTER 3. INSTALLING APICAST	59
3.1. APICAST DEPLOYMENT OPTIONS	59
3.2. APICAST ENVIRONMENTS	59
3.3. CONFIGURING THE INTEGRATION SETTINGS	60
3.4. CONFIGURING YOUR PRODUCT	60
3.4.1. Declaring the API backend	60
3.4.2. Configuring the authentication settings	61
3.4.3. Configuring the API test call	62
3.5. DEPLOYING APICAST ON THE DOCKER CONTAINERIZED ENVIRONMENT	63
3.5.1. Installing the Docker containerized environment	63
3.5.2. Running the Docker containerized environment gateway	64
3.5.2.1. The docker command options	65
3.5.2.2. Testing APICast	65
3.5.3. Additional resources	65
3.5.4. Deploying APICast on Podman	65
3.5.4.1. Installing the Podman container environment	66
3.5.4.2. Running the Podman environment	66
3.5.4.2.1. Testing APICast with Podman	67
3.5.4.3. The podman command options	67
3.5.4.4. Additional resources	67
3.6. DEPLOYING AN APICAST GATEWAY SELF-MANAGED SOLUTION USING THE OPERATOR	67
3.6.1. APICast deployment and configuration options	68
3.6.1.1. Providing a 3scale system endpoint	68
3.6.1.1.1. Verifying the APICast gateway is running and available	69
3.6.1.1.2. Exposing APICast externally via a Kubernetes Ingress	70
3.6.1.2. Providing a configuration secret	70

3.6.1.2.1. Verifying APIcast gateway is running and available	72
3.6.1.3. Injecting custom environments with the APIcast operator	72
3.6.1.4. Injecting custom policies with the APIcast operator	73
3.6.1.5. Configuring OpenTracing with the APIcast operator	75
3.7. ADDITIONAL RESOURCES	76
CHAPTER 4. EXTERNAL REDIS DATABASE CONFIGURATION FOR HIGH AVAILABILITY SUPPORT IN 3SCALE	77
4.1. SETTING UP REDIS FOR ZERO DOWNTIME	77
4.2. CONFIGURING BACK-END COMPONENTS FOR 3SCALE	78
4.2.1. Creating backend-redis and system-redis secrets	78
4.2.2. Deploying a fresh installation of 3scale for HA	78
4.2.3. Migrating a non-HA deployment of 3scale to HA	79
4.2.3.1. Using Redis Enterprise	80
4.2.3.2. Using Redis Sentinel	80
4.3. REDIS DATABASE SHARDING AND REPLICATION	81
4.4. ADDITIONAL INFORMATION	82
CHAPTER 5. CONFIGURING AN EXTERNAL MYSQL DATABASE	84
5.1. EXTERNAL MYSQL DATABASE LIMITATIONS	84
5.2. EXTERNALIZING THE MYSQL DATABASE	85
5.3. ROLLING BACK	88
5.4. ADDITIONAL INFORMATION	88

PREFACE

This guide will help you to install and configure 3scale

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our [CTO Chris Wright's message](#).

CHAPTER 1. REGISTRY SERVICE ACCOUNTS FOR 3SCALE

To use container images from **registry.redhat.io** in a shared environment with Red Hat 3scale API Management 2.13, you must use a *Registry Service Account* instead of an individual user's *Customer Portal* credentials.

IMPORTANT

Before deploying 3scale on OpenShift via the operator, follow the steps outlined in this chapter, as the deployment uses registry authentication.

To create and modify a registry service account, perform the steps outlined in the following sections:

- [Creating a registry service account](#)
- [Configuring container registry authentication](#)
- [Modifying a registry service account](#)

1.1. CREATING A REGISTRY SERVICE ACCOUNT

To create a registry service account, follow the procedure below.

Procedure

1. Navigate to the [Registry Service Accounts](#) page and log in.
2. Click **New Service Account**
3. Fill in the form on the *Create a New Registry Service Account* page.
 - a. Add a name for the *service account*.
Note: You will see a fixed-length, randomly generated numerical string before the form field.
 - b. Enter a *Description*.
 - c. Click **Create**.
4. Navigate back to your *Service Accounts*.
5. Click the *Service Account* you created.
6. Make a note of the username, including the prefix string, for example **12345678|username**, and your password. This username and password will be used to log in to **registry.redhat.io**.

NOTE

There are tabs available on the *Token Information* page that show you how to use the authentication token. For example, the *Token Information* tab shows the username in the format **12345678|username** and the password string below it.

1.2. CONFIGURING CONTAINER REGISTRY AUTHENTICATION

As a 3scale administrator, configure authentication with **registry.redhat.io** before you deploy 3scale on OpenShift.

Prerequisites

- A Red Hat OpenShift Container Platform (OCP) account with administrator credentials.
- OpenShift **oc** client tool is installed. For more details, see the [OpenShift CLI documentation](#).

Procedure

1. Log into your OpenShift cluster as administrator:

```
$ oc login -u <admin_username>
```

2. Open the project in which you want to deploy 3scale:

```
$ oc project your-openshift-project
```

3. Create a **docker-registry** secret using your Red Hat Customer Portal account, replacing **threescale-registry-auth** with the secret to create:

```
$ oc create secret docker-registry threescale-registry-auth \  
  --docker-server=registry.redhat.io \  
  --docker-username="customer_portal_username" \  
  --docker-password="customer_portal_password" \  
  --docker-email="email_address"
```

You will see the following output:

```
secret/threescale-registry-auth created
```

4. Link the secret to your service account to use the secret for pulling images. The service account name must match the name that the OpenShift pod uses. This example uses the **default** service account:

```
$ oc secrets link default threescale-registry-auth --for=pull
```

5. Link the secret to the **builder** service account to use the secret for pushing and pulling build images:

```
$ oc secrets link builder threescale-registry-auth
```

Additional resources

For more details on authenticating with Red Hat for container images:

- [Red Hat container image authentication](#)
- [Red Hat registry service accounts](#)

1.3. MODIFYING A REGISTRY SERVICE ACCOUNT

You can edit or delete service accounts from the *Registry Service Account* page, by using the pop-up menu to the right of each authentication token in the table.

WARNING

The regeneration or removal of *service accounts* will impact systems that are using the token to authenticate and retrieve content from **registry.redhat.io**.

A description for each function is as follows:

- **Regenerate token:** Allows an authorized user to reset the password associated with the *Service Account*.
Note: You cannot modify the username for the *Service Account*.
- **Update Description:** Allows an authorized user to update the description for the *Service Account*.
- **Delete Account:** Allows an authorized user to remove the *Service Account*.

1.4. ADDITIONAL RESOURCES

- [Red Hat Container Registry Authentication](#)
- [Authentication enabled Red Hat registry](#)

CHAPTER 2. INSTALLING 3SCALE ON OPENSIFT

This section walks you through steps to deploy Red Hat 3scale API Management 2.13 on OpenShift.

The 3scale solution for on-premises deployment is composed of:

- Two API gateways: embedded APIcast
- One 3scale Admin Portal and Developer Portal with persistent storage

NOTE

- When deploying 3scale, you must first configure registry authentication to the Red Hat container registry. See [Configuring container registry authentication](#).
- The 3scale Istio Adapter is available as an optional adapter that allows labeling a service running within the Red Hat OpenShift Service Mesh, and integrate that service with 3scale. Refer to [3scale adapter](#) documentation for more information.

Prerequisites

- You must configure 3scale servers for UTC (Coordinated Universal Time).
- Create user credentials using the step in [Creating a registry service account](#).

To install 3scale on OpenShift, perform the steps outlined in the following sections:

- [System requirements for installing 3scale on OpenShift](#)
- [Deploying 3scale using the operator](#)
- [External databases for 3scale using the operator](#)
- [Deployment configuration options for 3scale on OpenShift using the operator](#)
- [Installing 3scale with the operator using Oracle as the system database](#)
- [Troubleshooting common 3scale installation issues](#)

2.1. SYSTEM REQUIREMENTS FOR INSTALLING 3SCALE ON OPENSIFT

This section lists the system requirements for installing 3scale on OpenShift.

2.1.1. Environment requirements

Red Hat 3scale API Management requires an environment specified in [supported configurations](#).

**NOTE**

The requirements for persistent volumes vary between different deployment types. When deploying with external databases, persistent volumes are not necessary. For some deployment types, an Amazon S3 bucket can serve as a substitute for persistent volumes. If you use local file system storage, consider the specific deployment type and its associated requirements for persistent volumes.

Persistent volumes

- 3 RWO (ReadWriteOnce) persistent volumes for Redis and MySQL persistence
- 1 RWX (ReadWriteMany) persistent volume for Developer Portal content and System-app Assets

Configure the RWX persistent volume to be group writable. For a list of persistent volume types that support the required access modes, see the [OpenShift documentation](#).

**NOTE**

Network File System (NFS) is supported on 3scale for the RWX volume only.

For IBM Power (ppc64le) and IBM Z (s390x), provision local storage using the following:

Storage

- NFS

If you are using an Amazon Simple Storage Service (Amazon S3) bucket for content management system (CMS) storage:

Persistent volumes

- 3 RWO (ReadWriteOnce) persistent volumes for Redis and MySQL persistence

Storage

- 1 Amazon S3 bucket
- NFS

2.1.2. Hardware requirements

Hardware requirements depend on your usage needs. Red Hat recommends that you test and configure your environment to meet your specific requirements. The following are the recommendations when configuring your environment for 3scale on OpenShift:

- Compute optimized nodes for deployments on cloud environments (AWS c4.2xlarge or Azure Standard_F8).
- Very large installations may require a separate node (AWS M4 series or Azure Av2 series) for Redis if memory requirements exceed your current node's available RAM.
- Separate nodes between routing and compute tasks.

- Dedicated computing nodes for 3scale specific tasks.

Additional resources

- [Understanding persistent storage](#)

2.2. INSTALLING THE 3SCALE OPERATOR ON OPENSIFT

NOTE

3scale supports the last two general availability (GA) releases of OpenShift Container Platform (OCP). For more information, see the [Red Hat 3scale API Management Supported Configurations](#) page.

This documentation shows you how to:

- Create a new project.
- Deploy a Red Hat 3scale API Management instance.
- Install the 3scale operator through Operator Lifecycle Manager (OLM).
- Deploy the custom resources once the operator has been deployed.

Prerequisites

- Access to a supported version of an OpenShift Container Platform 4 cluster using an account with administrator privileges.
 - For more information about supported configurations, see the [Red Hat 3scale API Management Supported Configurations](#) page.

WARNING

Deploy the 3scale operator and custom resource definitions (CRDs) in a separate newly created, empty *project*. If you deploy them in an existing project containing infrastructure, it could alter or delete existing elements.

To install the 3scale operator on OpenShift, perform the steps outlined in the following sections:

- [Section 2.2.1, "Creating a new OpenShift project"](#)
- [Section 2.2.2, "Installing and configuring the 3scale operator using the OLM"](#)

2.2.1. Creating a new OpenShift project

This procedure explains how to create a new OpenShift project named **3scale-project**. Replace this project name with your own.

Procedure

To create a new OpenShift project:

- Indicate a valid name using alphanumeric characters and dashes. As an example, run the command below to create **3scale-project**:

```
$ oc new-project 3scale-project
```

This creates the new *OpenShift project* where the operator, the *APIManager* custom resource (CR), and the *Capabilities* custom resources will be installed. The operator manages the custom resources through OLM in that project.

2.2.2. Installing and configuring the 3scale operator using the OLM

Use Operator Lifecycle Manager (OLM) to install the 3scale operator on an OpenShift Container Platform (OCP) 4.6 cluster through the OperatorHub in the OCP console. You can install the 3scale operator using the following installation modes:

- Cluster-wide in which the operator is available in all namespaces on the cluster.
- A specific namespace on the cluster

NOTE

If you are using the OpenShift Container Platform on a restricted network or a disconnected cluster, the Operator Lifecycle Manager can no longer use the OperatorHub. Follow the instructions for setting up and using the OLM in the guide titled [Using Operator Lifecycle Manager on restricted networks](#).

Prerequisites

- You must install and deploy the 3scale operator in the project that you defined in [Creating a new OpenShift project](#).

Procedure

1. In the OpenShift Container Platform console, log in using an account with administrator privileges.

NOTE

The menu structure depends on the version of OpenShift you are using:

2. Click **Operators > OperatorHub**
3. In the **Filter by keyword** box, type *3scale operator* to find *Red Hat Integration - 3scale*.
4. Click *Red Hat Integration - 3scale*. Information about the operator is displayed.
5. Read the information about the operator and click **Install**. The *Install Operator* page opens.
6. On the **Install Operator** page, select the desired channel to update in the **Update channel** section.

7. In the *Installation mode* section, select where to install the operator.
 - a. **All namespaces on the cluster (default)**- The operator will be available in all namespaces on the cluster.
 - b. **A specific namespace on the cluster**- The operator will only be available in the specific single namespace on the cluster that you have selected.
8. Click **Install**.
9. After the installation is complete, the system displays a confirmation message indicating that the operator is ready for use.
10. Verify that the 3scale operator ClusterServiceVersion (CSV) is correctly installed. Also check if it reports that the installation of the operator has been successful:
 - Click **Operators > Installed Operators**
 - Click on the **Red Hat Integration - 3scale** operator.
 - In the **Details** tab, scroll down to the **Conditions** section, where the **Succeeded** condition should read **InstallSucceeded** under the **Reason** column.

Besides the indicated procedure, create a list of the allowed domains you intend to use in the 3scale Developer Portal while using OCP on restricted networks. Consider the following examples:

- Any link you intend to add to the Developer Portal.
- SSO integrations through third party SSO providers such as GitHub.
- Billing.
- Webhooks that trigger an external URL.

2.2.2.1. Restrictions in disconnected environments

The following list outlines current restrictions in a disconnected environment for 3scale 2.13:

- The GitHub login to the Developer Portal is not available.
- Support links are not operational.
- Links to external documentation are not operational.
- The validator for the OpenAPI Specification (OAS) in the Developer Portal is not operational, affecting links to external services.
- In the product *Overview* page in **ActiveDocs**, links to OAS are not operational.
 - It is also necessary to check the option *Skip swagger validations* when you create a new ActiveDocs specification.

Additional resources

- For troubleshooting information, see the [OpenShift Container Platform documentation](#).

- For more information about using the OLM on restricted networks, see [Using Operator Lifecycle Manager on restricted networks](#).
- For more information about preparing your installation on restricted networks, see [Mirroring images for a disconnected installation](#).
- For more information about supported configurations, see the [Red Hat 3scale API Management Supported Configurations](#) page.

2.2.3. Upgrading the 3scale operator using the OLM

To upgrade the 3scale operator from a single namespace to a cluster-wide installation in all namespaces on an operator-based deployment, you must remove the 3scale operator from the namespace and then reinstall the operator on the cluster.

Cluster administrators can delete installed operators from a selected namespace by using the web console. Uninstalling the operator does not uninstall an existing 3scale instance.

After the 3scale operator is uninstalled from the namespace, you can use OLM to install the operator in the cluster-wide mode.

Prerequisites

- 3scale administrator permissions or an OpenShift role that has delete permissions for the namespace.

Procedure

1. In the OpenShift Container Platform console, log in using an account with administrator privileges.

NOTE

The menu structure depends on the version of OpenShift you are using:

2. Click **Operators > OperatorHub**. The installed Operators page is displayed.
3. Enter *3scale* into the *Filter by name* to find the Operator and click on it.
4. On the *Operator Details* page, select **Uninstall Operator** from the **Actions** drop-down menu to remove it from a specific namespace.
5. An *Uninstall Operator?* dialog box is displayed, reminding you that:

Removing the operator will not remove any of its custom resource definitions or managed resources. If your operator has deployed applications on the cluster or configured off-cluster resources, these will continue to run and need to be cleaned up manually. This action removes the operator as well as the Operator deployments and pods, if any. Any operands and resources managed by the operator, including CRDs and CRs, are not removed. The web console enables dashboards and navigation items for some operators. To remove these after uninstalling the operator, you might need to manually delete the operator CRDs.

6. Select **Uninstall**. This operator stops running and no longer receives updates.

7. In the OpenShift Container Platform console click **Operators > OperatorHub**.
8. In the **Filter by keyword** box, type *3scale operator* to find *Red Hat Integration - 3scale*.
9. Click *Red Hat Integration - 3scale*. Information about the operator is displayed.
10. Click **Install**. The *Install Operator* page opens.
11. On the **Install Operator** page, select the desired channel to update in the **Update channel** section.
12. In the *Installation mode* section, select **All namespaces on the cluster (default)** The operator will be available in all namespaces on the cluster.
13. Click **Subscribe**. The *3scale operator* details page is displayed and you can see the *Subscription Overview*.
14. Confirm that the subscription **Upgrade Status** is displayed as **Up to date**.
15. Verify that the 3scale operator ClusterServiceVersion (CSV) is displayed.

Additional Resources

- For more information about installing the 3scale operator, see [Install and configure 3scale API Management](#).

2.2.3.1. Configuring automated application of micro releases

The 3scale operator's approval strategy must be set to *Automatic* to obtain micro release updates and have them be applied automatically. The following describes the differences between *Automatic* and *Manual* settings, and outlines the steps in a procedure to change from one to the other.

Automatic and manual:

- During installation, the *Automatic* setting is the selected option by default. Installation of new updates occur as they become available. You can change this during the install or at any time afterwards.
- If you select the *Manual* option during installation or at any time afterwards, you will receive updates when they are available. Next, you must approve the *Install Plan* and apply it yourself.

Procedure

1. Click **Operators > Installed Operators**
2. Click **3scale API Management** from the list of *Installed Operators*.
3. Click the **Subscription** tab. Under the *Subscription Details* heading, you will see the subheading *Approval*.
4. Click the link below *Approval*. The link is set to **Automatic** by default. A modal with the heading *Change Update Approval Strategy* will pop up.
5. Choose the option of your preference: *Automatic (default)* or *Manual*, and then click **Save**.

Additional resources

- See *Approval Strategy* under [Installing Operators in your namespace](#) .

2.3. INSTALLING THE APICAST OPERATOR ON OPENSIFT

This guide provides steps for installing the APICast operator through the OpenShift Container Platform (OCP) console.

Prerequisites

- OCP 4.x or later with administrator privileges.

Procedure

1. Create new project **operator-test** in **Projects > Create Project**
2. Click **Operators > OperatorHub**
3. In the **Filter by keyword** box, type *apicast operator* to find *Red Hat Integration - 3scale APICast gateway*.
4. Click *Red Hat Integration - 3scale APICast gateway* . Information about the APICast operator is displayed
5. Click *Install*. The *Create Operator Subscription* page opens.
6. Click *Subscribe* to accept all of the default selections on the *Create Operator Subscription* page.
 - a. The subscription upgrade status is shown as *Up to date*.
7. Click **Operators > Installed Operators** to verify that the APICast operator *ClusterServiceVersion (CSV)* status displays to *InstallSucceeded* in the **operator-test** project.

2.4. DEPLOYING 3SCALE USING THE OPERATOR

This section takes you through installing and deploying the 3scale solution via the 3scale operator, using the *APIManager* CR.

NOTE

- Wildcard routes have been [removed](#) since 3scale 2.6.
 - This functionality is handled by Zync in the background.
- When API providers are created, updated, or deleted, routes automatically reflect those changes.

Prerequisites

- [Configuring container registry authentication](#)
- To make sure you receive automatic updates of micro releases for 3scale, you must have enabled the automatic approval functionality in the 3scale operator. *Automatic* is the default approval setting. To change this at any time based on your specific needs, use the steps for [Configuring automated application of micro releases](#).

- Deploying 3scale using the operator first requires that you follow the steps in [Installing the 3scale Operator on OpenShift](#)
- OpenShift Container Platform 4
 - A user account with administrator privileges in the OpenShift cluster.
 - For more information about supported configurations, see the [Red Hat 3scale API Management Supported Configurations](#) page.

Follow these procedures to deploy 3scale using the operator:

- [Deploying the APIManager custom resource](#)
- [Getting the Admin Portal URL](#)
- [External databases for 3scale using the operator](#)

2.4.1. Deploying the *APIManager* custom resource

NOTE

If you decide to use Amazon Simple Storage Service (Amazon S3), see [Amazon Simple Storage Service 3scale FileStorage installation](#).

Deploying the *APIManager* CR will make the operator begin processing and will deploy a 3scale solution from it.

Procedure

1. Click **Operators > Installed Operators**
 - a. From the list of *Installed Operators*, click *Red Hat Integration - 3scale*.
2. Click the *API Manager* tab.
3. Click **Create APIManager**.
4. Clear the sample content and add the following *YAML* definitions to the editor, then click **Create**.
 - Before 3scale 2.8, you could configure the automatic addition of replicas by setting the **highAvailability** field to **true**. From 3scale 2.8, the addition of replicas is controlled through the *replicas* field in the *APIManager* CR as shown in the following example.

NOTE

The *wildcardDomain* parameter can be any desired name you wish to give that resolves to an IP address, which is a valid DNS domain.

- *APIManager* CR with minimum requirements:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
```

```

name: apimanager-sample
spec:
  wildcardDomain: example.com

```

- APIManager CR with replicas configured:

```

apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: apimanager-sample
spec:
  system:
    appSpec:
      replicas: 1
    sidekiqSpec:
      replicas: 1
  zync:
    appSpec:
      replicas: 1
    queSpec:
      replicas: 1
  backend:
    cronSpec:
      replicas: 1
    listenerSpec:
      replicas: 1
    workerSpec:
      replicas: 1
  apicast:
    productionSpec:
      replicas: 1
    stagingSpec:
      replicas: 1
  wildcardDomain: example.com

```

2.4.2. Getting the Admin Portal URL

When you deploy 3scale using the operator, a default tenant is created, with a fixed URL: **3scale-admin.`{wildcardDomain}`**

The 3scale Dashboard shows the new portal URL of the tenant. As an example, if the `<wildCardDomain>` is **3scale-project.example.com**, the Admin Portal URL is: **https://3scale-admin.3scale-project.example.com**.

The **wildcardDomain** is the `<wildCardDomain>` parameter you provided during installation. Open this unique URL in a browser using the this command:

```

xdg-open https://3scale-admin.3scale-project.example.com

```

Optionally, you can create new tenants on the *MASTER portal URL*: **master.`{wildcardDomain}`**.

2.4.3. Getting the APIManager Admin Portal and Master Admin Portal credentials

To log in to either the 3scale Admin Portal or Master Admin Portal after the operator-based deployment, you need the credentials for each separate portal. To get these credentials:

1. Run the following commands to get the Admin Portal credentials:

```
oc get secret system-seed -o json | jq -r .data.ADMIN_USER | base64 -d
oc get secret system-seed -o json | jq -r .data.ADMIN_PASSWORD | base64 -d
```

- a. Log in as the Admin Portal administrator to verify these credentials are working.

2. Run the following commands to get the Master Admin Portal credentials:

```
oc get secret system-seed -o json | jq -r .data.MASTER_USER | base64 -d
oc get secret system-seed -o json | jq -r .data.MASTER_PASSWORD | base64 -d
```

- a. Log in as the Master Admin Portal administrator to verify these credentials are working.

Additional resources

For more information about the *APIManager* fields, refer to the [Reference documentation](#).

2.4.4. External databases for 3scale using the operator

IMPORTANT

When you externalize databases from a Red Hat 3scale API Management deployment, this means to provide isolation from the application and resilience against service disruptions at the database level. The resilience to service disruptions depends on the service level agreements (SLAs) provided by the infrastructure or platform provider where you host the databases. This is not offered by 3scale. For more details on externalizing of databases offered by your chosen deployment, see the associated documentation.

When you use an external databases for 3scale using the operator, the aim is to provide uninterrupted uptime if, for example, one or more databases were to fail.

If you use external databases in your 3scale operator-based deployment, note the following:

- Configure and deploy 3scale critical databases externally. Critical databases include the system database, system redis, and backend redis components. Ensure that you deploy and configure these components in a way that makes them highly available.
- Specify the connection endpoints to those components for 3scale by creating their corresponding Kubernetes secrets before deploying 3scale.
 - See [External databases installation](#) for more information.
 - See [Enabling Pod Disruption Budgets](#) for more information about non-database deployment configurations.
- In the *APIManager* CR, set the **.spec.externalComponents** attribute to specify that system database, system redis, and backend redis are external:

```
externalComponents:
  backend:
```

```

redis: true
system:
  database: true
  redis: true
zync:
  database: true

```

Additionally, if you want the zync database to be highly available to avoid zync potentially losing queue jobs data on restart, note the following:

- Deploy and configure the zync database externally. Make sure you deploy and configure the database in a way that it is highly available.
- Specify the connection endpoint to the zync database for 3scale by creating its corresponding Kubernetes secret before deploying 3scale.
 - See [Zync database secret](#).
- Configure 3scale by setting the **.spec.externalComponents.zync.database** attribute in the **APIManager** CR to **true** to specify that the zync database is an external database.

2.5. DEPLOYMENT CONFIGURATION OPTIONS FOR 3SCALE ON OPENSIFT USING THE OPERATOR

This section provides information about the deployment configuration options for Red Hat 3scale API Management on OpenShift using the operator.

Prerequisites

- [Configuring container registry authentication](#)
- Deploying 3scale using the operator first requires that you follow the steps in [Installing the 3scale Operator on OpenShift](#)
- OpenShift Container Platform 4.x
 - A user account with administrator privileges in the OpenShift cluster.

2.5.1. Configuring proxy parameters for embedded APIcast

As a 3scale administrator, you can configure proxy parameters for embedded APIcast staging and production. This section provides reference information for specifying proxy parameters in an *APIManager* custom resource (CR). In other words, you are using the 3scale operator, an *APIManager* CR to deploy 3scale on OpenShift.

You can specify these parameters when you deploy an *APIManager* CR for the first time or you can update a deployed *APIManager* CR and the operator will reconcile the update. See [Deploying the APIManager custom resource](#).

There are four proxy-related configuration parameters for embedded APIcast:

- **allProxy**
- **httpProxy**
- **httpsProxy**

- **noProxy**

allProxy

The **allProxy** parameter specifies an HTTP or HTTPS proxy to be used for connecting to services when a request does not specify a protocol-specific proxy.

After you set up a proxy, configure APIcast by setting the **allProxy** parameter to the address of the proxy. Authentication is not supported for the proxy. In other words, APIcast does not send authenticated requests to the proxy.

The value of the **allProxy** parameter is a string, there is no default, and the parameter is not required. Use this format to set the **spec.apicast.productionSpec.allProxy** parameter or the **spec.apicast.stagingSpec.allProxy** parameter:

<scheme>://<host>:<port>

For example:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  apicast:
    productionSpec:
      allProxy: http://forward-proxy:80
    stagingSpec:
      allProxy: http://forward-proxy:81
```

httpProxy

The **httpProxy** parameter specifies an HTTP proxy to be used for connecting to HTTP services.

After you set up a proxy, configure APIcast by setting the **httpProxy** parameter to the address of the proxy. Authentication is not supported for the proxy. In other words, APIcast does not send authenticated requests to the proxy.

The value of the **httpProxy** parameter is a string, there is no default, and the parameter is not required. Use this format to set the **spec.apicast.productionSpec.httpProxy** parameter or the **spec.apicast.stagingSpec.httpProxy** parameter:

http://<host>:<port>

For example:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  apicast:
    productionSpec:
      httpProxy: http://forward-proxy:80
    stagingSpec:
      httpProxy: http://forward-proxy:81
```

httpsProxy

The **httpsProxy** parameter specifies an HTTPS proxy to be used for connecting to services.

After you set up a proxy, configure APIcast by setting the **httpsProxy** parameter to the address of the proxy. Authentication is not supported for the proxy. In other words, APIcast does not send authenticated requests to the proxy.

The value of the **httpsProxy** parameter is a string, there is no default, and the parameter is not required. Use this format to set the **spec.apicast.productionSpec.httpsProxy** parameter or the **spec.apicast.stagingSpec.httpsProxy** parameter:

https://<host>:<port>

For example:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  apicast:
    productionSpec:
      httpsProxy: https://forward-proxy:80
    stagingSpec:
      httpsProxy: https://forward-proxy:81
```

noProxy

The **noProxy** parameter specifies a comma-separated list of hostnames and domain names. When a request contains one of these names, APIcast does not proxy the request.

If you need to stop access to the proxy, for example during maintenance operations, set the **noProxy** parameter to an asterisk (*). This matches all hosts specified in all requests and effectively disables any proxies.

The value of the **noProxy** parameter is a string, there is no default, and the parameter is not required. Specify a comma-separated string to set the **spec.apicast.productionSpec.noProxy** parameter or the **spec.apicast.stagingSpec.noProxy** parameter. For example:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  apicast:
    productionSpec:
      noProxy: theStore,company.com,big.red.com
    stagingSpec:
      noProxy: foo,bar.com,.extra.dot.com
```

Additional resources

- [Custom resource definition for APIcast staging configuration in an APIManager custom resource](#)

- [Custom resource definition for APIcast production configuration in an APIManager custom resource](#)

2.5.2. Injecting custom environments with the 3scale operator

In a 3scale installation that uses embedded APIcast, you can use the 3scale operator to inject custom environments. Embedded APIcast is also referred to as managed or hosted APIcast. A custom environment defines behavior that APIcast applies to all upstream APIs that the gateway serves. To create a custom environment, define a global configuration in Lua code.

You can inject a custom environment before or after 3scale installation. After injecting a custom environment and after 3scale installation, you can remove a custom environment. The 3scale operator reconciles the changes.

Prerequisites

- The 3scale operator is installed.

Procedure

1. Write Lua code that defines the custom environment that you want to inject. For example, the following **env1.lua** file shows a custom logging policy that the 3scale operator loads for all services.

```
local cjson = require('cjson')
local PolicyChain = require('apicast.policy_chain')
local policy_chain = context.policy_chain

local logging_policy_config = cjson.decode([[
{
  "enable_access_logs": false,
  "custom_logging": "\"{{request}}\" to service {{service.id}} and {{service.name}}\"
}
]])

policy_chain:insert( PolicyChain.load_policy('logging', 'builtin', logging_policy_config), 1)

return {
  policy_chain = policy_chain,
  port = { metrics = 9421 },
}
```

2. Create a secret from the Lua file that defines the custom environment. For example:

```
$ oc create secret generic custom-env-1 --from-file=./env1.lua
```

A secret can contain multiple custom environments. Specify the **--from-file** option for each file that defines a custom environment. The operator loads each custom environment.

3. Define an *APIManager* custom resource (CR) that references the secret you just created. The following example shows only content relative to referencing the secret that defines the custom environment.

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
```

```

metadata:
  name: apimanager-apicast-custom-environment
spec:
  wildcardDomain: <desired-domain>
  apicast:
    productionSpec:
      customEnvironments:
        - secretRef:
            name: custom-env-1
    stagingSpec:
      customEnvironments:
        - secretRef:
            name: custom-env-1

```

An *APIManager* CR can reference multiple secrets that define custom environments. The operator loads each custom environment.

4. Create the *APIManager* CR that adds the custom environment. For example:

```
$ oc apply -f apimanager.yaml
```

Next steps

You cannot update the content of a secret that defines a custom environment. If you need to update the custom environment you can do either of the following:

- The recommended option is to create a secret with a different name and update the *APIManager* (CR) field, **customEnvironments[].secretRef.name**. The operator triggers a rolling update and loads the updated custom environment.
- Alternatively, you can update the existing secret, redeploy APIcast by setting **spec.apicast.productionSpec.replicas** or **spec.apicast.stagingSpec.replicas** to 0, and then redploy APIcast again by setting **spec.apicast.productionSpec.replicas** or **spec.apicast.stagingSpec.replicas** back to its previous value.

2.5.3. Injecting custom policies with the 3scale operator

In a 3scale installation that uses embedded APIcast, you can use the 3scale operator to inject custom policies. Embedded APIcast is also referred to as managed or hosted APIcast. Injecting a custom policy adds the policy code to APIcast. You can then use either of the following to add the custom policy to an API product's policy chain:

- 3scale API
- **Product** custom resource (CR)

To use the 3scale Admin Portal to add the custom policy to a product's policy chain, you must also register the custom policy's schema with a **CustomPolicyDefinition** CR. Custom policy registration is a requirement only when you want to use the Admin Portal to configure a product's policy chain.

You can inject a custom policy as part of or after 3scale installation. After injecting a custom policy and after 3scale installation, you can remove a custom policy by removing its specification from the *APIManager* CR. The 3scale operator reconciles the changes.

Prerequisites

- You are installing or you previously installed the 3scale operator.
- You have defined a custom policy as described in [Write your own policy](#). That is, you have already created, for example, the **my-policy.lua**, **apicast-policy.json**, and **init.lua** files that define a custom policy,

Procedure

1. Create a secret from the files that define one custom policy. For example:

```
$ oc create secret generic my-first-custom-policy-secret \
  --from-file=./apicast-policy.json \
  --from-file=./init.lua \
  --from-file=./my-first-custom-policy.lua
```

If you have more than one custom policy, create a secret for each custom policy. A secret can contain only one custom policy.

2. Define an *APIManager* CR that references each secret that contains a custom policy. You can specify the same secret for APIcast staging and APIcast production. The following example shows only content relative to referencing secrets that contain custom policies.

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: apimanager-apicast-custom-policy
spec:
  apicast:
    stagingSpec:
      customPolicies:
        - name: my-first-custom-policy
          version: "0.1"
          secretRef:
            name: my-first-custom-policy-secret
        - name: my-second-custom-policy
          version: "0.1"
          secretRef:
            name: my-second-custom-policy-secret
    productionSpec:
      customPolicies:
        - name: my-first-custom-policy
          version: "0.1"
          secretRef:
            name: my-first-custom-policy-secret
        - name: my-second-custom-policy
          version: "0.1"
          secretRef:
            name: my-second-custom-policy-secret
```

An *APIManager* CR can reference multiple secrets that define different custom policies. The operator loads each custom policy.

3. Create the *APIManager* CR that references the secrets that contain the custom policies. For example:

```
$ oc apply -f apimanager.yaml
```

Next steps

You cannot update the content of a secret that defines a custom policy. If you need to update the custom policy you can do either of the following:

- The recommended option is to create a secret with a different name and update the *APIManager* CR **customPolicies** section to refer to the new secret. The operator triggers a rolling update and loads the updated custom policy.
- Alternatively, you can update the existing secret, redeploy APIcast by setting **spec.apicast.productionSpec.replicas** or **spec.apicast.stagingSpec.replicas** to 0, and then redploy APIcast again by setting **spec.apicast.productionSpec.replicas** or **spec.apicast.stagingSpec.replicas** back to its previous value.

2.5.4. Configuring OpenTracing with the 3scale operator

In a 3scale installation that uses embedded APIcast, you can use the 3scale operator to configure OpenTracing. You can configure OpenTracing in the staging or production environments or both environments. By enabling OpenTracing, you get more insight and better observability on the APIcast instance.

Prerequisites

- The 3scale operator is installed or you are in the process of installing it.
- Prerequisites listed in [Configuring APIcast to use OpenTracing](#).
- [Jaeger is installed](#).

Procedure

1. Define a secret that contains your OpenTracing configuration details in **stringData.config**. This is the only valid value for the attribute that contains your OpenTracing configuration details. Any other specification prevents APIcast from receiving your OpenTracing configuration details. The following example shows a valid secret definition:

```
apiVersion: v1
kind: Secret
metadata:
  name: myjaeger
stringData:
  config: |-
    {
      "service_name": "apicast",
      "disabled": false,
      "sampler": {
        "type": "const",
        "param": 1
      },
      "reporter": {
        "queueSize": 100,
        "bufferFlushInterval": 10,
        "logSpans": false,
```

```

    "localAgentHostPort": "jaeger-all-in-one-inmemory-agent:6831"
  },
  "headers": {
    "jaegerDebugHeader": "debug-id",
    "jaegerBaggageHeader": "baggage",
    "TraceContextHeaderName": "uber-trace-id",
    "traceBaggageHeaderPrefix": "testctx-"
  },
  "baggage_restrictions": {
    "denyBaggageOnInitializationFailure": false,
    "hostPort": "127.0.0.1:5778",
    "refreshInterval": 60
  }
}
type: Opaque

```

2. Create the secret. For example, if you saved the previous secret definition in the **myjaeger.yaml** file, you would run the following command:

```
$ oc create -f myjaeger.yaml
```

3. Define an *APIManager* custom resource (CR) that specifies **OpenTracing** attributes. In the CR definition, set the **openTracing.tracingConfigSecretRef.name** attribute to the name of the secret that contains your OpenTracing configuration details. The following example shows only content relative to configuring OpenTracing.

```

apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: apimanager1
spec:
  apicast:
    stagingSpec:
      ...
      openTracing:
        enabled: true
        tracingLibrary: jaeger
        tracingConfigSecretRef:
          name: myjaeger
    productionSpec:
      ...
      openTracing:
        enabled: true
        tracingLibrary: jaeger
        tracingConfigSecretRef:
          name: myjaeger

```

4. Create the *APIManager* CR that configures OpenTracing. For example, if you saved the *APIManager* CR in the **apimanager1.yaml** file, you would run the following command:

```
$ oc apply -f apimanager1.yaml
```

Next steps

Depending on how OpenTracing is installed, you should see the traces in the Jaeger service user interface.

Additional resource

- [APIManager custom resource definition](#)

2.5.5. Enabling TLS at the pod level with the 3scale operator

3scale deploys two APICast instances, one for production and the other for staging. TLS can be enabled for only production or only staging, or for both instances.

Prerequisites

- A valid certificate for enabling TLS.

Procedure

1. Create a secret from your valid certificate, for example:

```
$ oc create secret tls mycertsecret --cert=server.crt --key=server.key
```

The configuration exposes secret references in the *APIManager* custom resource (CR). You create the secret and then reference the name of the secret in the *APIManager* CR as follows:

- Production: The *APIManager* CR exposes the certificate in the **.spec.apicast.productionSpec.httpsCertificateSecretRef** field.
- Staging: The *APIManager* CR exposes the certificate in the **.spec.apicast.stagingSpec.httpsCertificateSecretRef** field. Optionally, you can configure the following:
 - **httpsPort** indicates which port APICast should start listening on for HTTPS connections. If this clashes with the HTTP port APICast uses this port for HTTPS only.
 - **httpsVerifyDepth** defines the maximum length of the client certificate chain.

NOTE

Provide a valid certificate and reference from the *APIManager* CR. If the configuration can access **httpsPort** but not **httpsCertificateSecretRef**, APICast uses an embedded self-signed certificate. This is not recommended.

2. Click **Operators > Installed Operators**
3. From the list of **Installed Operators**, click **3scale Operator**.
4. Click the **API Manager** tab.
5. Click **Create APIManager**.
6. Add the following YAML definitions to the editor.
 - a. If enabling for *production*, configure the following YAML definitions:

```
spec:
  apicast:
    productionSpec:
      httpsPort: 8443
      httpsVerifyDepth: 1
      httpsCertificateSecretRef:
        name: mycertsecret
```

- b. If enabling for *staging*, configure the following YAML definitions:

```
spec:
  apicast:
    stagingSpec:
      httpsPort: 8443
      httpsVerifyDepth: 1
      httpsCertificateSecretRef:
        name: mycertsecret
```

7. Click **Create**.

2.5.6. Proof of concept for evaluation deployment

The following sections describe the configuration options applicable to the proof of concept for an evaluation deployment of 3scale. This deployment uses internal databases as default.

IMPORTANT

The configuration for external databases is the standard deployment option for production environments.

2.5.6.1. Default deployment configuration

- Containers will have [Kubernetes resource limits and requests](#) .
 - This ensures a minimum performance level.
 - It limits resources to allow external services and allocation of solutions.
- Deployment of internal databases.
- File storage will be based on Persistence Volumes (PV).
 - One will require read, write, execute (RWX) access mode.
 - OpenShift configured to provide them upon request.
- Deploy MySQL as the internal relational database.

The default configuration option is suitable for proof of concept (PoC) or evaluation by a customer.

One, many, or all of the default configuration options can be overridden with specific field values in the *APIManager* CR. The 3scale operator allows all available combinations.

2.5.6.2. Evaluation installation

For and evaluation installtion, containers will not have [kubernetes resource limits and requests](#) specified. For example:

- Small memory footprint
- Fast startup
- Runnable on laptop
- Suitable for presale/sales demos

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  wildcardDomain: lvh.me
  resourceRequirementsEnabled: false
```

Additional resources

- See [APIManager](#) CR for more information.

2.5.7. External databases installation

IMPORTANT

When you externalize databases from a Red Hat 3scale API Management deployment, this means to provide isolation from the application and resilience against service disruptions at the database level. The resilience to service disruptions depends on the service level agreements (SLAs) provided by the infrastructure or platform provider where you host the databases. This is not offered by 3scale. For more details on externalizing of databases offered by your chosen deployment, see the associated documentation.

An external databases installation is suitable for production where you want to provide uninterrupted uptime or where you plan to reuse your own databases.

IMPORTANT

When enabling the 3scale external databases installation mode, you can configure one or more of the following databases as external to 3scale:

- **backend-redis**
- **system-redis**
- **system-database** (**mysql**, **postgresql**, or **oracle**)
- **zync-database**

3scale 2.8 and above has been tested is supported with the following database versions:

Database	Version
Redis	5.0
MySQL	8.0
PostgreSQL	13

Before creating an *APIManager* CR to deploy 3scale, you must provide the following connection settings for the external databases by using OpenShift secrets.

2.5.7.1. Backend Redis secret

Deploy two external Redis instances and fill in the connection settings as shown in the following example:

```
apiVersion: v1
kind: Secret
metadata:
  name: backend-redis
stringData:
  REDIS_STORAGE_URL: "redis://backend-redis-storage"
  REDIS_STORAGE_SENTINEL_HOSTS: "redis://sentinel-0.example.com:26379,redis://sentinel-1.example.com:26379, redis://sentinel-2.example.com:26379"
  REDIS_STORAGE_SENTINEL_ROLE: "master"
  REDIS_QUEUES_URL: "redis://backend-redis-queues"
  REDIS_QUEUES_SENTINEL_HOSTS: "redis://sentinel-0.example.com:26379,redis://sentinel-1.example.com:26379, redis://sentinel-2.example.com:26379"
  REDIS_QUEUES_SENTINEL_ROLE: "master"
type: Opaque
```

The *Secret* name must be **backend-redis**.

2.5.7.2. System Redis secret

Deploy two external Redis instances and fill in the connection settings as shown in the following example:

```
apiVersion: v1
kind: Secret
metadata:
  name: system-redis
stringData:
  URL: "redis://system-redis"
  SENTINEL_HOSTS: "redis://sentinel-0.example.com:26379,redis://sentinel-1.example.com:26379, redis://sentinel-2.example.com:26379"
  SENTINEL_ROLE: "master"
  NAMESPACE: ""
type: Opaque
```

The *Secret* name must be **system-redis**.

2.5.7.3. System database secret

NOTE

- The *Secret* name must be **system-database**.

When you are deploying 3scale, you have three alternatives for your system database. Configure different attributes and values for each alternative's related secret.

- MySQL
- PostgreSQL
- Oracle Database

To deploy a MySQL, PostgreSQL, or an Oracle Database system database secret, fill in the connection settings as shown in the following examples:

MySQL system database secret

```
apiVersion: v1
kind: Secret
metadata:
  name: system-database
stringData:
  URL: "mysql2://{DB_USER}:{DB_PASSWORD}@{DB_HOST}:{DB_PORT}/{DB_NAME}"
type: Opaque
```

IMPORTANT

If you use MySQL 8.0 with 3scale 2.12, you must set the authentication plugin to **mysql_native_password**. Add the following to the MySQL configuration file:

```
[mysqld]
default_authentication_plugin=mysql_native_password
```

PostgreSQL system database secret

```
apiVersion: v1
kind: Secret
metadata:
  name: system-database
stringData:
  URL: "postgresql://{DB_USER}:{DB_PASSWORD}@{DB_HOST}:{DB_PORT}/{DB_NAME}"
type: Opaque
```

Oracle system database secret

```
apiVersion: v1
kind: Secret
metadata:
  name: system-database
```

```
stringData:
  URL: "oracle-enhanced://{DB_USER}:{DB_PASSWORD}@{DB_HOST}:{DB_PORT}/{DB_NAME}"
  ORACLE_SYSTEM_PASSWORD: "{SYSTEM_PASSWORD}"
type: Opaque
```

**NOTE**

- **{DB_USER}** and **{DB_PASSWORD}** are the username and password of the regular non-system user.
- **{DB_NAME}** is the Oracle Database [service name](#).

2.5.7.4. Zync database secret

In a zync database setup, when the **spec.externalComponents.zync.database** field is set to **true**, you must create a secret named **zync** before you deploy 3scale. In this secret, set the **DATABASE_URL** and **DATABASE_PASSWORD** fields to the values that point to your external zync database, for example:

```
apiVersion: v1
kind: Secret
metadata:
  name: zync
stringData:
  DATABASE_URL: postgresql://<zync-db-user>:<zync-db-password>@<zync-db-host>:<zync-db-
port>/zync_production
  ZYNC_DATABASE_PASSWORD: <zync-db-password>
type: Opaque
```

The zync database must be in high-availability mode.

2.5.7.5. APIManager custom resources to deploy 3scale**NOTE**

- When you enable external components, you must create a secret for each external component (**backend-redis**, **system-redis**, **system-database**, **zync**) before you deploy 3scale.
- For an external **system-database**, choose only one type of database to externalize.

Configuration of the *APIManager* custom resource (CR) depends on whether or not your choice of database is external to your 3scale deployment.

If your **backend-redis**, **system-redis**, or **system-database** will be external to 3scale, the *APIManager* CR you must populate the corresponding **externalComponents** object. For example:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  wildcardDomain: lvh.me
```

```
externalComponents:
  system:
    database: true
```

Additional resources

- [Backend redis secret](#)
- [System database secret](#)
- [APIManager ExternalComponentsSpec](#)
- [Zync secret](#)

2.5.8. Enabling pod affinity in the 3scale operator

You can enable pod affinities in the 3scale operator for every component. This ensures distribution of pod replicas from each **deploymentConfig** across different nodes of the cluster, so they will be evenly balanced across different availability zones (AZ).

2.5.8.1. Customizing node affinity and tolerations at component level

Customize kubernetes [affinity](#) and [tolerations](#) in your 3scale solution through the *APIManager* CR attributes. You can then customize to schedule different 3scale components onto kubernetes nodes.

For example, to set a custom node affinity for **backend-listener** and custom tolerations for **system-memcached**, do the following:

Custom affinity and tolerations

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  backend:
    listenerSpec:
      affinity:
        nodeAffinity:
          requiredDuringSchedulingIgnoredDuringExecution:
            nodeSelectorTerms:
              - matchExpressions:
                  - key: "kubernetes.io/hostname"
                    operator: In
                    values:
                      - ip-10-96-1-105
                  - key: "beta.kubernetes.io/arch"
                    operator: In
                    values:
                      - amd64
      system:
        memcachedTolerations:
          - key: key1
            value: value1
            operator: Equal
```

```

effect: NoSchedule
- key: key2
value: value2
operator: Equal
effect: NoSchedule

```

Add the following affinity block to **apicastProductionSpec** or to any non-database **deploymentConfig**. This adds a soft **podAntiAffinity** configuration using **preferredDuringSchedulingIgnoredDuringExecution**. The scheduler will try to run this set of **apicast-production** pods in different hosts from different AZs. If it is not possible, then allow them to run elsewhere:

Soft podAntiAffinity

```

affinity:
  podAntiAffinity:
    preferredDuringSchedulingIgnoredDuringExecution:
      - weight: 100
        podAffinityTerm:
          labelSelector:
            matchLabels:
              deploymentConfig: apicast-production
          topologyKey: kubernetes.io/hostname
      - weight: 99
        podAffinityTerm:
          labelSelector:
            matchLabels:
              deploymentConfig: apicast-production
          topologyKey: topology.kubernetes.io/zone

```

In the following example, a hard **podAntiAffinity** configuration is set using **requiredDuringSchedulingIgnoredDuringExecution**. Conditions must be met to schedule a pod onto a node. A risk exists, for example, that you will not be able to schedule new pods on a cluster with low free resources:

Hard podAntiAffinity

```

affinity:
  podAntiAffinity:
    requiredDuringSchedulingIgnoredDuringExecution:
      - weight: 100
        podAffinityTerm:
          labelSelector:
            matchLabels:
              deploymentConfig: apicast-production
          topologyKey: kubernetes.io/hostname
      - weight: 99
        podAffinityTerm:
          labelSelector:
            matchLabels:
              deploymentConfig: apicast-production
          topologyKey: topology.kubernetes.io/zone

```

Additional resources

See [APIManager CDR reference](#) for a full list of attributes related to affinity and tolerations.

2.5.9. Multiple clusters in multiple availability zones

NOTE

In case of failure, bringing a passive cluster into active mode disrupts the provision of the service until the procedure finishes. Due to this disruption, be sure to have a maintenance window.

This documentation focuses on deployment using Amazon Web Services (AWS). The same configuration options apply to other public cloud vendors where the provider's managed database services offer, for example, support for multiple availability zones and multiple regions.

When you want to install 3scale on several OpenShift clusters and high availability (HA) zones, there are options available which you can refer to here.

In multiple cluster installation options, clusters work in an active/passive configuration, with the failover procedure involving a few manual steps.

2.5.9.1. Prerequisites for multiple clusters installations

Use the following in 3scale installations that involve using several OpenShift clusters:

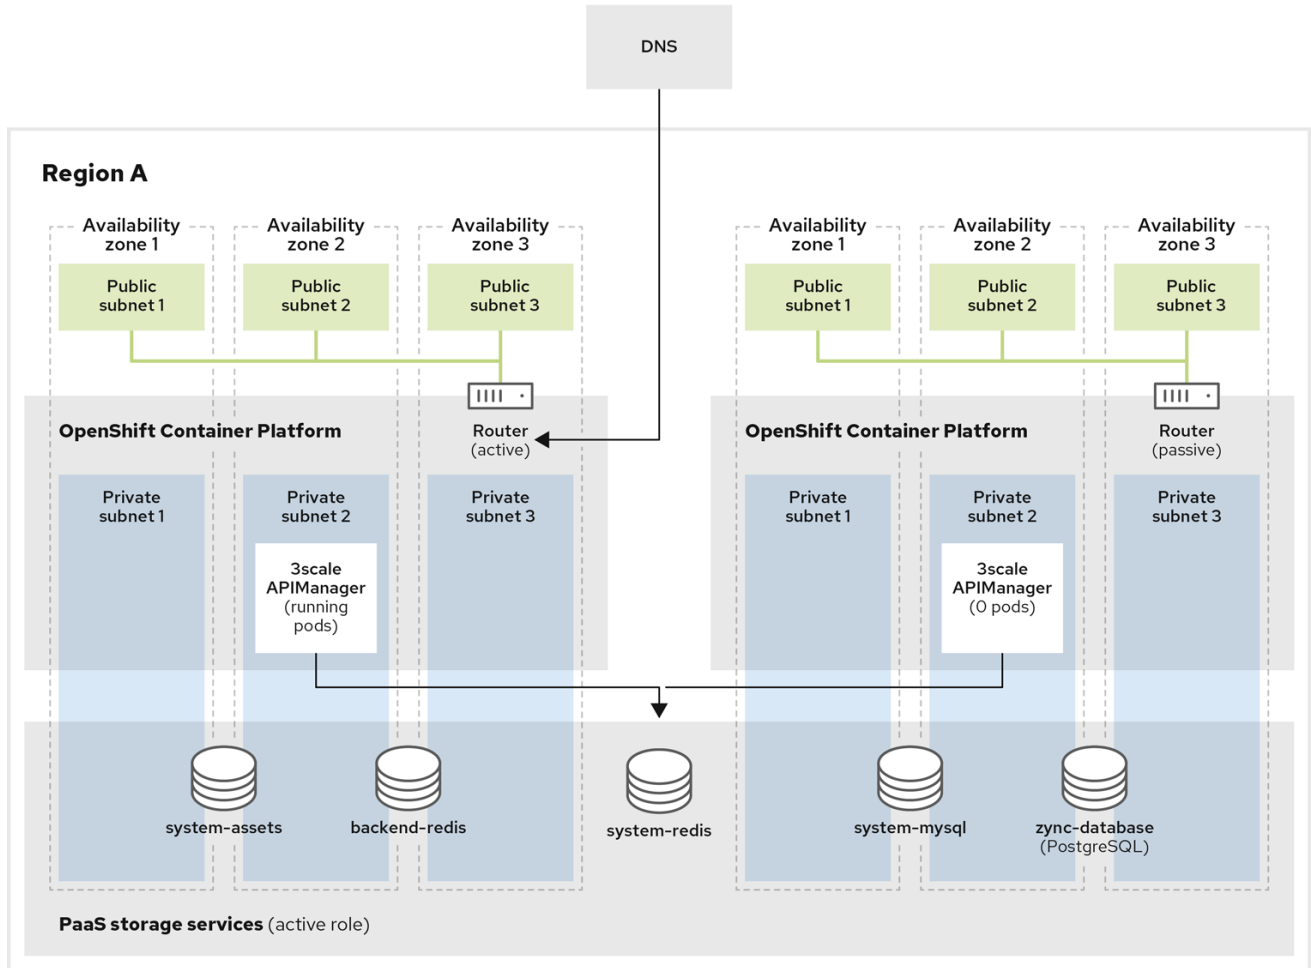

- Use pod affinities with both **kubernetes.io/hostname** and **topology.kubernetes.io/zone** rules in the *APIManager* custom resource (CR).
- Use pod disruption budgets in the *APIManager* CR.
- A 3scale installation over multiple clusters must use the same shared *wildcardDomain* attribute specifications in the *APIManager* CR. The use of a different domain for each cluster is not allowed in this installation mode, as the information stored in the database would be conflicting.
- You must manually deploy the secrets containing credentials, such as tokens and passwords, in all clusters with the same values. The 3scale operator creates them with secure random values on every cluster. In this case, you need to have the same credentials in both clusters. You will find the list of secrets and how to configure them in the 3scale operator documentation. The following is the list of secrets you must mirror in both clusters:
 - **backend-internal-api**
 - **system-app**
 - **system-events-hook**
 - **system-master-apicast**
 - **system-seed**

You must manually deploy secrets with the database connection strings for **backend-redis**, **system-redis**, **system-database** and **zync**. See [External databases installation](#).
 - Databases shared among clusters must use the same values on all clusters.
 - If each cluster have their own databases, they must use different values on each cluster.

2.5.9.2. Active-passive clusters on the same region with shared databases

This setup consists of having two or more clusters in the same region and deploying 3scale in active-passive mode. One cluster is active, receiving traffic, the others are in standby mode without receiving traffic, therefore passive, but prepared to assume the active role in case there is a failure in the active cluster.

In this installation option, only a single region is in use and databases will be shared among all clusters.

3scale_289_1122

2.5.9.3. Configuring and installing shared databases

Procedure

1. Create two or more OpenShift clusters in the same region using different availability zones (AZs). A minimum of three zones is recommended.
2. Create all required AWS ElastiCache (EC) instances with Amazon Relational Database Service (RDS) Multi-AZ enabled:
 - a. One AWS EC for Backend Redis database
 - b. One AWS EC for System Redis database
3. Create all required AWS RDS instances with Amazon RDS Multi-AZ enabled:

- a. One AWS RDS for the System database
 - b. One AWS RDS for Zync database
4. Configure a AWS S3 bucket for the system assets.
 5. Create a custom domain in AWS Route53 or your DNS provider and point it to the OpenShift router of the active cluster. This must coincide with the *wildcardDomain* attribute from *APIManager* custom resource (CR).
 6. Install 3scale in the passive cluster. The *APIManager* CR should be identical to the one used in the previous step. When all pods are running, change the *APIManager* to deploy 0 replicas for all the *backend*, *system*, *zync* and *APICAST* pods.
 - a. Set replicas to 0 to avoid consuming jobs from active database. Deployment will fail due to pod dependencies if each replica is set to 0 at first. For example, pods checking that others are running. First deploy as normal, then set replicas to 0 as shown in the *APIManager* spec example:

```
spec:
  apicast:
    stagingSpec:
      replicas: 0
    productionSpec:
      replicas: 0
  backend:
    listenerSpec:
      replicas: 0
    workerSpec:
      replicas: 0
    cronSpec:
      replicas: 0
  zync:
    appSpec:
      replicas: 0
    queSpec:
      replicas: 0
  system:
    appSpec:
      replicas: 0
    sidekiqSpec:
      replicas: 0
```

2.5.9.4. Manual failover shared databases

Procedure

1. In the active cluster, scale down the replicas of the *backend*, *system*, *zync*, and *APICAST* pods to 0.
 - a. This becomes the new passive cluster, so you ensure that the new passive cluster will not consume jobs from active databases. Downtime starts here.
2. In the passive cluster, edit the *APIManager* to scale up the replicas of the *backend*, *system*, *zync*, and *APICAST* pods that were set to 0, so it will become the active cluster.

3. In the new active cluster, recreate the OpenShift routes created by `zync`.
 - a. Run the `zync:resync:domains` command from the `system-master` container of the `system-app` pod:

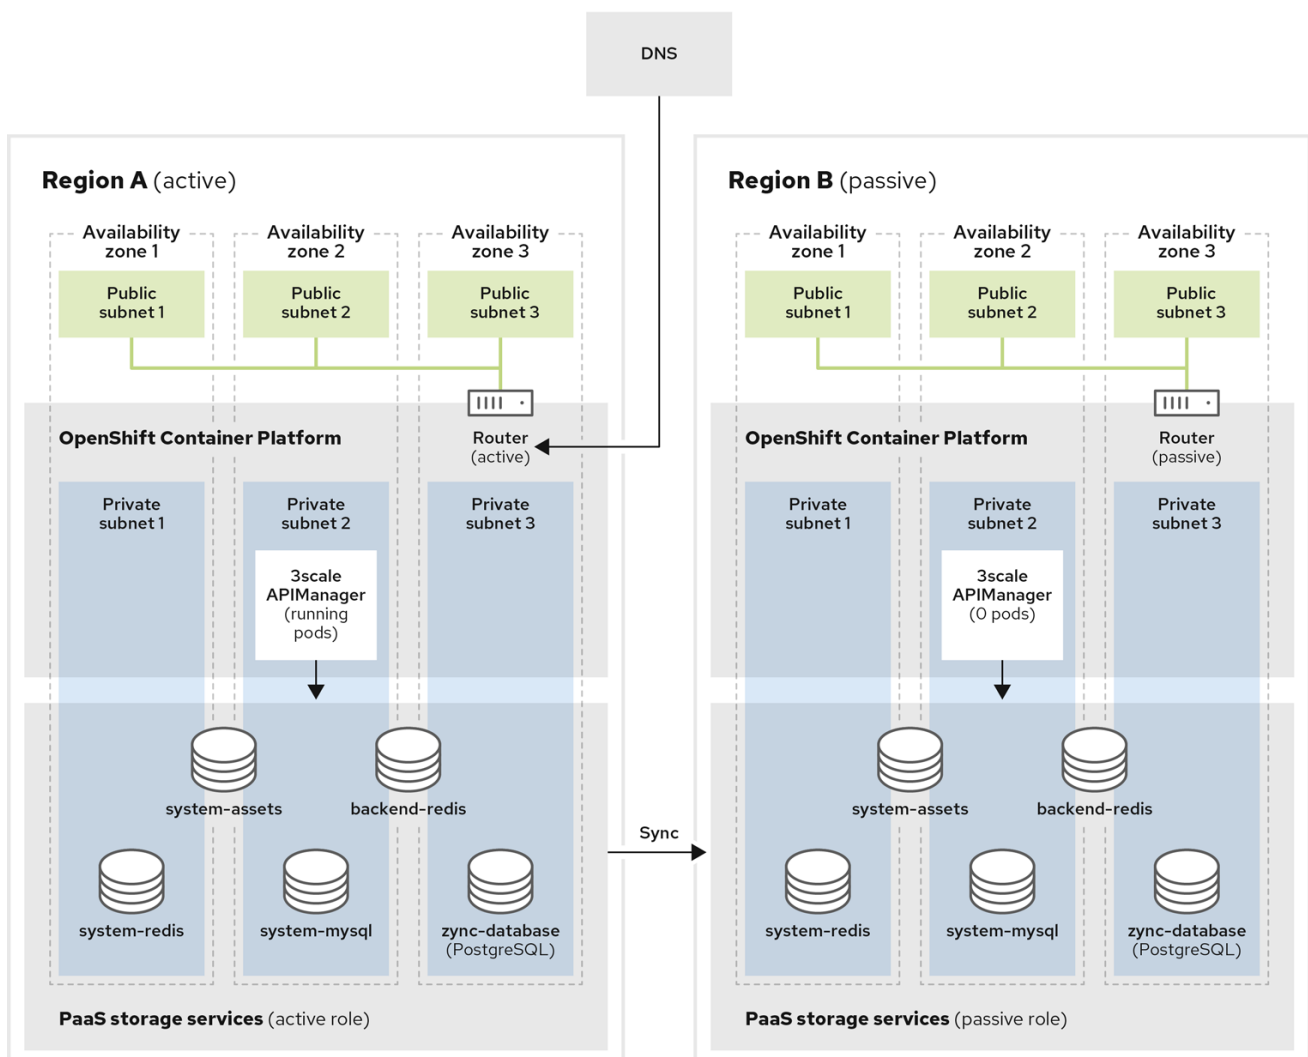

```
bundle exec rake zync:resync:domains
```

4. Point the custom domain created in AWS Route53 to the OpenShift router of the new active cluster.
 - a. The old passive cluster will start to receive traffic, and becomes the new active cluster.

2.5.9.5. Active-passive clusters on different regions with synced databases

This setup consists of having two or more clusters in different regions and deploying 3scale in active-passive mode. One cluster is active, receiving traffic, the others are in standby mode without receiving traffic, therefore passive, but prepared to assume the active role in case there is a failure in the active cluster.

To ensure good database access latency, each cluster has its own database instances. The databases from the active 3scale installation are replicated to the read-replica databases of the 3scale passive installations so the data is available and up to date in all regions for a possible failover.

3scale_289_1122

2.5.9.6. Configuring and installing synced databases

Procedure

1. Create two or more OpenShift clusters in different regions using different availability zones. A minimum of three zones is recommended.
2. Create all required AWS ElastiCache instances with Amazon RDS Multi-AZ enabled on every region:
 - a. Two AWS EC for Backend Redis database: one per region.
 - b. Two AWS EC for System Redis database: one per region.
 - c. Use the cross-region replication with the Global Datastore feature enabled, so the databases from passive regions are read-replicas from the master databases at the active region.
3. Create all required AWS RDS instances with Amazon RDS Multi-AZ enabled on every region:
 - a. Two AWS RDS for the System database.
 - b. Two AWS RDS for Zync database.
 - c. Use cross-region replication, so the databases from passive regions are read-replicas from the master databases at the active region.
4. Configure a AWS S3 bucket for the system assets on every region using cross-region replication.
5. Create a custom domain in AWS Route53 or your DNS provider and point it to the OpenShift Router of the active cluster. This must coincide with the *wildcardDomain* attribute from *APIManager* CR.
6. Install 3scale in the passive cluster. The *APIManager* CR should be identical to the one used in the previous step. When all pods are running, change the *APIManager* to deploy 0 replicas for all the **backend**, **system**, **zync**, and **APIcast** pods.
 - a. Set replicas to 0 to avoid consuming jobs from active database. Deployment will fail due to pod dependencies if each replica is set to 0 at first. For example, pods checking that others are running. First deploy as normal, then set replicas to 0.

2.5.9.7. Manual failover synced databases

Procedure

1. Do steps 1, 2 and 3 from [Manual Failover shared databases](#).
 - a. Every cluster has its own independent databases: read-replicas from the master at the active region.
 - b. You must manually execute a failover on every database to select the new master on the passive region, which then becomes the active region.
2. Manual failovers of the databases to execute are:
 - a. AWS RDS: *System* and *Zync*.

- b. AWS ElastiCaches: *Backend* and *System*.
3. Do step 4 from [Manual Failover shared databases](#).

2.5.10. Amazon Simple Storage Service 3scale *Filestorage* installation

Before creating *APIManager* custom resource (CR) to deploy 3scale, connection settings for the S3 service needs to be provided using an openshift secret.

2.5.10.1. Amazon S3 secret

The following examples show 3scale *FileStorage* using Amazon Simple Storage Service (Amazon S3) instead of persistent volume claim (PVC).

Before creating *APIManager* CR to deploy 3scale, connection settings for the S3 service needs to be provided using an openshift secret.

NOTE

AN AWS S3 compatible provider can be configured in the S3 secret with **AWS_HOSTNAME**, **AWS_PATH_STYLE**, and **AWS_PROTOCOL** optional keys. See the [S3 secret reference](#) for more details.

In the following example, *Secret* name can be anything, as it will be referenced in the *APIManager* CR.

```
apiVersion: v1
kind: Secret
metadata:
  creationTimestamp: null
  name: aws-auth
stringData:
  AWS_ACCESS_KEY_ID: 123456
  AWS_SECRET_ACCESS_KEY: 98765544
  AWS_BUCKET: mybucket.example.com
  AWS_REGION: eu-west-1
type: Opaque
```

NOTE

Amazon S3 region and Amazon S3 bucket settings are provided directly in the *APIManager* CR. The Amazon S3 secret name is provided directly in the *APIManager* CR.

Lastly, create the *APIManager* CR to deploy 3scale.

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  wildcardDomain: lvh.me
  system:
    fileStorage:
```

```
simpleStorageService:
  configurationSecretRef:
    name: aws-auth
```

Check [APIManager SystemS3Spec](#) for reference.

2.5.11. PostgreSQL installation

A MySQL internal relational database is the default deployment. This deployment configuration can be overridden to use PostgreSQL instead.

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  wildcardDomain: lvh.me
  system:
    database:
      postgresql: {}
```

Additional resources

- See [APIManager DatabaseSpec](#) for more information.

2.5.12. Configuring SMTP variables (optional)

3scale uses email to [send notifications](#) and [invite new users](#). If you intend to use these features, you must provide your own SMTP server and configure SMTP variables in the **system-smtp** secret.

Perform the following steps to configure the SMTP variables in the system-smtp secret.

Procedure

1. If you are not already logged in, log in to OpenShift:

```
$ oc login
```

2. Using the **oc patch** command, specify the secret type where **system-smtp** is the name of the secret, followed by the **-p** option, and write the new values in JSON for the following variables:

Table 2.1. system-smtp

Field	Description	Default value
address	This is the address (hostname or IP) of the remote mail server to use. If this is set to a value different than "", system will use the mail server to send mails related to events that happen in the API management solution.	""

Field	Description	Default value
port	This is the port of the remote mail server to use.	""
domain	Use domain if the mail server requires a HELO domain.	""
authentication	Use if the mail server requires authentication. Set the authentication types: plain to send the password in the clear, login to send password Base64 encoded, or cram_md5 to combine a challenge/response mechanism based on the HMAC-MD5 algorithm.	""
username	Use username if the mail server requires authentication and the authentication type requires it.	""
password	Use password if the mail server requires authentication and the authentication type requires it.	""
openssl.verify.mode	When using TLS, you can set how OpenSSL checks the certificate. This is useful if you need to validate a self-signed and/or a wildcard certificate. You can use the name of an OpenSSL verify constant: none or peer .	""
from_address	from address value for the no-reply mail.	""

Examples

```
$ oc patch secret system-smtp -p '{"stringData":{"address":"<your_address>"}}'
$ oc patch secret system-smtp -p '{"stringData":{"username":"<your_username>"}}'
$ oc patch secret system-smtp -p '{"stringData":{"password":"<your_password>"}}'
```

- After you have set the secret variables, redeploy the **system-app** and **system-sidekiq** pods:

```
$ oc rollout latest dc/system-app
$ oc rollout latest dc/system-sidekiq
```

4. Check the status of the rollout to ensure it has finished:

```
$ oc rollout status dc/system-app
$ oc rollout status dc/system-sidekiq
```

2.5.13. Customizing compute resource requirements at component level

Customize Kubernetes [Compute Resource Requirements](#) in your 3scale solution through the *APIManager* custom resource (CR) attributes. Do this to customize compute resource requirements, which is CPU and memory, assigned to a specific *APIManager* component.

The following example outlines how to customize compute resource requirements for the system-master's **system-provider** container, for the **backend-listener** and for the **zync-database**:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  backend:
    listenerSpec:
      resources:
        requests:
          memory: "150Mi"
          cpu: "300m"
        limits:
          memory: "500Mi"
          cpu: "1000m"
  system:
    appSpec:
      providerContainerResources:
        requests:
          memory: "111Mi"
          cpu: "222m"
        limits:
          memory: "333Mi"
          cpu: "444m"
  zync:
    databaseResources:
      requests:
        memory: "111Mi"
        cpu: "222m"
      limits:
        memory: "333Mi"
        cpu: "444m"
```

Additional resources

See [APIManager CRD reference](#) for more information about how to specify component-level CR requirements.

2.5.13.1. Default APIManager components compute resources

When you configure the *APIManager* **spec.resourceRequirementsEnabled** attribute as **true**, the default compute resources are set for the *APIManager* components.

The specific compute resources default values that are set for the *APIManager* components are shown in the following table.

2.5.13.1.1. CPU and memory units

The following list explains the units you will find mentioned in the compute resources default values table. For more information on CPU and memory units, see [Managing Resources for Containers](#).

Resource units explanation

- m - milliCPU or millicore
- Mi - mebibytes
- Gi - gibibyte
- G - gigabyte

Table 2.2. Compute resources default values

Component	CPU requests	CPU limits	Memory requests	Memory limits
system-app's system-master	50m	1000m	600Mi	800Mi
system-app's system-provider	50m	1000m	600Mi	800Mi
system-app's system-developer	50m	1000m	600Mi	800Mi
system-sidekiq	100m	1000m	500Mi	2Gi
system-sphinx	80m	1000m	250Mi	512Mi
system-redis	150m	500m	256Mi	32Gi
system-mysql	250m	No limit	512Mi	2Gi
system-postgresql	250m	No limit	512Mi	2Gi
backend-listener	500m	1000m	550Mi	700Mi
backend-worker	150m	1000m	50Mi	300Mi
backend-cron	50m	150m	40Mi	80Mi

Component	CPU requests	CPU limits	Memory requests	Memory limits
backend-redis	1000m	2000m	1024Mi	32Gi
apicast-production	500m	1000m	64Mi	128Mi
apicast-staging	50m	100m	64Mi	128Mi
zync	150m	1	250M	512Mi
zync-que	250m	1	250M	512Mi
zync-database	50m	250m	250M	2G

2.5.14. Customizing node affinity and tolerations at component level

Customize Kubernetes [Affinity](#) and [Tolerations](#) in your Red Hat 3scale API Management solution through the *APIManager* CR attributes to customize where and how the different 3scale components of an installation are scheduled onto Kubernetes Nodes.

The following example sets a custom node affinity for the backend. It also sets listener and custom tolerations for the **system-memcached**:

```

apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  backend:
    listenerSpec:
      affinity:
        nodeAffinity:
          requiredDuringSchedulingIgnoredDuringExecution:
            nodeSelectorTerms:
              - matchExpressions:
                  - key: "kubernetes.io/hostname"
                    operator: In
                    values:
                      - ip-10-96-1-105
                  - key: "beta.kubernetes.io/arch"
                    operator: In
                    values:
                      - amd64
    system:
      memcachedTolerations:
        - key: key1
          value: value1
          operator: Equal
          effect: NoSchedule
        - key: key2

```

```
value: value2
operator: Equal
effect: NoSchedule
```

Additional resources

See [APIManager CRD reference](#) for a full list of attributes related to affinity and tolerations.

2.5.15. Reconciliation

Once 3scale has been installed, the 3scale operator enables updating a given set of parameters from the custom resource (CR) to modify system configuration options. Modifications are made by *hot swapping*, that is, without stopping or shutting down the system.

Not all the parameters of the *APIManager* custom resource definitions (CRDs) are reconcilable.

The following is a list of reconcilable parameters:

- [Resources](#)
- [Backend replicas](#)
- [APIcast replicas](#)
- [System replicas](#)

2.5.15.1. Resources

Resource limits and requests for all 3scale components.

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  resourceRequirementsEnabled: true/false
```

2.5.15.2. Backend replicas

Backend components pod count.

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  backend:
    listenerSpec:
      replicas: X
    workerSpec:
      replicas: Y
    cronSpec:
      replicas: Z
```

2.5.15.3. APIcast replicas

APIcast staging and production components pod count.

```

apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  apicast:
    productionSpec:
      replicas: X
    stagingSpec:
      replicas: Z

```

2.5.15.4. System replicas

System app and system *sidekiq* components pod count

```

apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  system:
    appSpec:
      replicas: X
    sidekiqSpec:
      replicas: Z

```

2.5.15.5. Zync replicas

Zync app and que components pod count

```

apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  zync:
    appSpec:
      replicas: X
    queSpec:
      replicas: Z

```

2.6. INSTALLING 3SCALE WITH THE OPERATOR USING ORACLE AS THE SYSTEM DATABASE

As a Red Hat 3scale API Management administrator, you can install the 3scale with the operator using the Oracle Database. By default, 3scale 2.13 has a component called **system** that stores configuration data in a MySQL database. You can override the default database and store your information in an external Oracle Database.

NOTE

- The Oracle Database is not supported with OpenShift Container Platform (OCP) versions 4.2 and 4.3 when you are performing an operator-only installation of 3scale. For more information, refer to the [Red Hat 3scale API Management Supported Configurations](#) page.
- In this documentation **myregistry.example.com** is used as an example of the registry URL. Replace it with your registry URL.
- Disclaimer: *Links contained herein to external website(s) are provided for convenience only. Red Hat has not reviewed the links and is not responsible for the content or its availability. The inclusion of any link to an external website does not imply endorsement by Red Hat of the website or their entities, products or services. You agree that Red Hat is not responsible or liable for any loss or expenses that may result due to your use of (or reliance on) the external site or content.*

Prerequisites

- A container registry to push container images, accessible by the OCP cluster where 3scale installed.
- An [installation of the 3scale operator](#).
 - Do not install the *APIManager* CR, as it will be created in the following procedure.
- A [Registry service account for 3scale](#) .
- A supported version of the [Oracle Database](#) accessible from your OpenShift cluster.
- Access to the Oracle Database system user for installation procedures.

To install 3scale with the operator using Oracle as the system database, use the following steps:

- [Preparing the Oracle Database](#)
- [Building a custom system container image](#)
- [Installing 3scale with Oracle using the operator](#)

2.6.1. Preparing the Oracle Database

As a 3scale administrator, you must fully prepare the Oracle Database for your 3scale installation when you decide to use it as the default.

Procedure

1. Create a new database.
2. Apply the following settings:

```
ALTER SYSTEM SET max_string_size=extended SCOPE=SPFILE;
```

3. Create a regular non-system user before the Oracle Database installation with 3scale.
 - a. The password for a regular Oracle Database non-system user must be unique and not

the password that you specify must match the **system** password.

- b. The Oracle Database initialization script runs the following SQL command:

```
ALTER USER {DB_USER} IDENTIFIED BY {DB_PASSWORD}
```

- Make sure this SQL command executes correctly before starting the 3scale installation.
- **{DB_USER}** and **{DB_PASSWORD}** are the username and password of the regular non-system user.
- Your database configuration might prevent this command from completing successfully if the parameters **PASSWORD_REUSE_TIME** and **PASSWORD_REUSE_MAX** are set in a way that restricts reusing the same password.
- The Oracle Database **system** user executes commands with system privileges.
 - Some are detailed in this [GitHub repository](#).
 - The latest can be executed in the [Oracle Database initializer](#) when the tables are initialized in the database. There may be other commands executed not listed in these links.
- The **system** user is also required for upgrades when there are any schema migrations to run, so other commands not included in the previous links may be executed.

Additional resources

- For information on creating a new database, see the [Oracle Database 19c](#) documentation.

2.6.2. Building a custom system container image

Procedure

1. Download 3scale OpenShift templates from the [GitHub repository](#) and extract the archive:

```
tar -xzf 3scale-2.13.0-GA.tar.gz
```

2. From the *Instant Client Downloads* page, download:
 - A client: It can be either *basic-lite* or *basic*.
 - The *ODBC driver*.
 - The *SDK* for Oracle Database 19c.
 - For 3scale, use [Instant Client Downloads for Linux x86-64 \(64-bit\)](#)
 - For ppc64le and 3scale, use [Oracle Instant Client Downloads for Linux on Power Little Endian \(64-bit\)](#)
3. Check the [Red Hat 3scale API Management Supported Configurations](#) for the following Oracle software components:
 - Oracle Instant Client Package: Basic or Basic Light

- Oracle Instant Client Package: SDK
- Oracle Instant Client Package: ODBC

Table 2.3. Oracle 19c example packages for 3scale

Oracle 19c package name	Compressed file name
Basic	instantclient-basic-linux.x64-19.8.0.0.odbu.zip
Basic Light	instantclient-basclite-linux.x64-19.8.0.0.odbu.zip
SDK	instantclient-sdk-linux.x64-19.8.0.0.odbu.zip
ODBC	instantclient-odbc-linux.x64-19.8.0.0.odbu.zip

Table 2.4. Oracle 19c example packages for ppc64le and 3scale

Oracle 19c package name	Compressed file name
Basic	instantclient-basic-linux.leppc64.c64-19.3.0.0.odbu.zip
Basic Light	instantclient-basclite-linux.leppc64.c64-19.3.0.0.odbu.zip
SDK	instantclient-sdk-linux.leppc64.c64-19.3.0.0.odbu.zip
ODBC	instantclient-odbc-linux.leppc64.c64-19.3.0.0.odbu.zip

**NOTE**

If the client packages versions downloaded and stored locally do not match with the ones 3scale expects, 3scale will automatically download and use the appropriate ones in the following steps.

4. Place your Oracle Database Instant Client Package files into the **system-oracle-3scale-2.13.0-GA/oracle-client-files** directory.
5. Login to your **registry.redhat.io** account using the credentials you created in [Creating a Registry Service Account](#).

```
$ docker login registry.redhat.io
```

- Build the custom system Oracle-based image. The image tag must be a fixed image tag as in the following example:

```
$ docker build . --tag myregistry.example.com/system-oracle:2.13.0-1
```

- Push the system Oracle-based image to a container registry accessible by the OCP cluster. This container registry is where your 3scale solution is going to be installed:

```
$ docker push myregistry.example.com/system-oracle:2.13.0-1
```

2.6.3. Installing 3scale with Oracle using the operator

Procedure

- Set up the Oracle Database URL connection string and Oracle Database system password by creating the **system-database** secret with the corresponding fields. See, [External databases installation](#) for the Oracle Database.
- Install your 3scale solution by creating an *APIManager* CR. Follow the instructions in [Deploying 3scale using the operator](#).
 - The *APIManager* CR must specify the **.spec.system.image** field set to the system's Oracle-based image you previous built:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIManager
metadata:
  name: example-apimanager
spec:
  imagePullSecrets:
    - name: threescale-registry-auth
    - name: custom-registry-auth
  system:
    image: "myregistry.example.com/system-oracle:2.13.0-1"
  externalComponents:
    system:
      database: true
```

2.7. TROUBLESHOOTING COMMON 3SCALE INSTALLATION ISSUES

This section contains a list of common installation issues and provides guidance for their resolution.

- [Previous deployment leaving dirty persistent volume claims](#)
- [Wrong or missing credentials of the authenticated image registry](#)
- [Incorrectly pulling from the Docker registry](#)
- [Permission issues for MySQL when persistent volumes are mounted locally](#)
- [Unable to upload logo or images](#)
- [Test calls not working on OpenShift](#)

- [APIcast on a different project from 3scale failing to deploy](#)

2.7.1. Previous deployment leaving dirty persistent volume claims

Problem

A previous deployment attempt leaves a dirty Persistent Volume Claim (PVC) causing the MySQL container to fail to start.

Cause

Deleting a project in OpenShift does not clean the PVCs associated with it.

Solution

Procedure

1. Find the PVC containing the erroneous MySQL data with the **oc get pvc** command:

```
# oc get pvc
NAME                STATUS  VOLUME  CAPACITY  ACCESSMODES  AGE
backend-redis-storage Bound   vol003  100Gi    RWO,RWX      4d
mysql-storage       Bound   vol006  100Gi    RWO,RWX      4d
system-redis-storage Bound   vol008  100Gi    RWO,RWX      4d
system-storage      Bound   vol004  100Gi    RWO,RWX      4d
```

2. Stop the deployment of the system-mysql pod by clicking **cancel deployment** in the OpenShift UI.
3. Delete everything under the MySQL path to clean the volume.
4. Start a new **system-mysql** deployment.

2.7.2. Wrong or missing credentials of the authenticated image registry

Problem

Pods are not starting. ImageStreams show the following error:

```
! error: Import failed (InternalError): ...unauthorized: Please login to the Red Hat Registry
```

Cause

While installing 3scale on OpenShift 4.x, OpenShift fails to start pods because ImageStreams cannot pull the images they reference. This happens because the pods cannot authenticate against the registries they point to.

Solution

Procedure

1. Type the following command to verify the configuration of your container registry authentication:

```
$ oc get secret
```

```
Stopped:
  backend-listener
  backend-redis
  system-app
```

2. Type the following command to see the status of each pod:

```
$ oc get pods
NAME                                READY  STATUS   RESTARTS  AGE
3scale-operator-66cc6d857b-sxhgm    1/1    Running   0          17h
apicast-production-1-deploy         1/1    Running   0          17m
apicast-production-1-pxkqm         0/1    Pending   0          17m
apicast-staging-1-dbwcw            1/1    Running   0          17m
apicast-staging-1-deploy           0/1    Completed 0          17m
backend-cron-1-deploy               1/1    Running   0          17m
```

2.7.3. Incorrectly pulling from the Docker registry

Problem

The following error occurs during installation:

```
svc/system-redis - 1EX.AMP.LE.IP:6379
dc/system-redis deploys docker.io/rhsc/redis-32-rhel7:3.2-5.3
deployment #1 failed 13 minutes ago: config change
```

Cause

OpenShift searches for and pulls container images by issuing the **docker** command. This command refers to the **docker.io** Docker registry instead of the **registry.redhat.io** Red Hat Ecosystem Catalog.

This occurs when the system contains an unexpected version of the Docker containerized environment.

Solution

Procedure

Use the [appropriate version](#) of the Docker containerized environment.

2.7.4. Permission issues for MySQL when persistent volumes are mounted locally

Problem

The system-mysql pod crashes and does not deploy causing other systems dependant on it to fail deployment. The pod log displays the following error:

```
[ERROR] Cannot start server : on unix socket: Permission denied
[ERROR] Do you already have another mysql server running on socket: /var/lib/mysql/mysql.sock ?
[ERROR] Aborting
```

Cause

The MySQL process is started with inappropriate user permissions.

Solution

Procedure

1. The directories used for the persistent volumes MUST have the write permissions for the root group. Having read-write permissions for the root user is not enough as the MySQL service runs as a different user in the root group. Execute the following command as the root user:

```
chmod -R g+w /path/for/pvs
```

2. Execute the following command to prevent SELinux from blocking access:

```
chcon -Rt svirt_sandbox_file_t /path/for/pvs
```

2.7.5. Unable to upload logo or images

Problem

Unable to upload a logo - **system-app** logs display the following error:

```
Errno::EACCES (Permission denied @ dir_s_mkdir - /opt/system/public//system/provider-name/2
```

Cause

Persistent volumes are not writable by OpenShift.

Solution

Procedure

Ensure your persistent volume is writable by OpenShift. It should be owned by root group and be group writable.

2.7.6. Test calls not working on OpenShift

Problem

Test calls do not work after creation of a new service and routes on OpenShift. Direct calls via curl also fail, stating: **service not available**.

Cause

3scale requires HTTPS routes by default, and OpenShift routes are not secured.

Solution

Procedure

Ensure the **secure route** checkbox is clicked in your OpenShift router settings.

2.7.7. APIcast on a different project from 3scale failing to deploy

Problem

APIcast deploy fails (pod does not turn blue). You see the following error in the logs:

update acceptor rejected apicast-3: pods for deployment "apicast-3" took longer than 600 seconds to become ready

You see the following error in the pod:

```
Error synching pod, skipping: failed to "StartContainer" for "apicast" with RunContainerError: "GenerateRunContainerOptions: secrets \"apicast-configuration-url-secret\" not found"
```

Cause

The secret was not properly set up.

Solution

Procedure

When creating a secret with APIcast v3, specify **apicast-configuration-url-secret**:

```
oc create secret generic apicast-configuration-url-secret --from-literal=password=https://<ACCESS_TOKEN>@<TENANT_NAME>-admin.<WILDCARD_DOMAIN>
```

2.8. ADDITIONAL RESOURCES

- [External Components Specification](#)
- [System database](#)

CHAPTER 3. INSTALLING APICAST

APICast is an NGINX based API gateway used to integrate your internal and external API services with the Red Hat 3scale API Management Platform. APICast does load balancing by using round-robin.

In this guide you will learn about deployment options, environments provided, and how to get started.

Prerequisites

APICast is not a standalone API gateway. It needs connection to 3scale API Manager.

- A working 3scale [On-Premises](#) instance.

To install APICast, perform the steps outlined in the following sections:

- [APICast deployment options](#)
- [APICast environments](#)
- [Configuring the integration settings](#)
- [Configuring your product](#)
- [Deploying APICast on the Docker containerized environment](#)
- [Deploying an APICast gateway self-managed solution using the operator](#)

3.1. APICAST DEPLOYMENT OPTIONS

You can use hosted or self-managed APICast. In both cases, APICast must be connected to the rest of the 3scale API Management platform:

- **Embedded APICast:** Two APICast gateways (staging and production) come by default with the 3scale API Management installation. They come pre-configured and ready to use out-of-the-box.
- **Self-managed APICast:** You can deploy APICast wherever you want. Here are a few recommended options to deploy APICast:
 - [Deploying APICast on the Docker containerized environment](#): Download a ready to use Docker-formatted container image, which includes all of the dependencies to run APICast in a Docker-formatted container.
 - [Running APICast on Red Hat OpenShift](#): Run APICast on a [supported version](#) of OpenShift. You can connect self-managed APICasts to a 3scale On-premises installation or to a 3scale Hosted (SaaS) account. For this, [deploy an APICast gateway self-managed solution using the operator](#).

3.2. APICAST ENVIRONMENTS

By default, when you create a 3scale account, you get embedded APICast in two different environments:

- **Staging:** Intended to be used only while configuring and testing your API integration. When you have confirmed that your setup is working as expected, then you can choose to deploy it to the production environment.

- **Production:** This environment is intended for production use. The following parameters are set for the Production APIcast in the OpenShift template: **APICAST_CONFIGURATION_LOADER: boot**, **APICAST_CONFIGURATION_CACHE: 300**. This means that the configuration will be fully loaded when APIcast is started, and will be cached for 300 seconds (5 minutes). After 5 minutes the configuration will be reloaded. This means that when you promote the configuration to production, it may take up to 5 minutes to be applied, unless you trigger a new deployment of APIcast.

3.3. CONFIGURING THE INTEGRATION SETTINGS

As a 3scale administrator, configure the integration settings for the environment you require 3scale to run in.

Prerequisites

A 3scale account with administrator privileges.

Procedure

1. Navigate to **[Your_product_name] > Integration > Settings**
2. Under **Deployment**, the default options are as follows:
 - Deployment Option: APIcast 3scale managed
 - Authentication mode: API key.
3. Change to your preferred option.
4. To save your changes, click **Update Product**.

3.4. CONFIGURING YOUR PRODUCT

You must declare your API back-end in the *Private Base URL* field, which is the endpoint host of your API back-end. APIcast will redirect all traffic to your API back-end after all authentication, authorization, rate limits and statistics have been processed.

This section will guide you through configuring your product:

- [Declaring the API backend](#)
- [Configuring the authentication settings](#)
- [Configuring the API test call](#)

3.4.1. Declaring the API backend

Typically, the Private Base URL of your API will be something like <https://api-backend.yourdomain.com:443>, on the domain that you manage (**yourdomain.com**). For instance, if you were integrating with the Twitter API the Private Base URL would be <https://api.twitter.com/>.

In this example, you will use the **Echo API** hosted by 3scale, a simple API that accepts any path and returns information about the request (path, request parameters, headers, etc.). Its Private Base URL is <https://echo-api.3scale.net:443>.

Procedure

- Test your private (unmanaged) API is working. For example, for the Echo API you can make the following call with **curl** command:

```
$ curl "https://echo-api.3scale.net:443"
```

You will get the following response:

```
{
  "method": "GET",
  "path": "/",
  "args": "",
  "body": "",
  "headers": {
    "HTTP_VERSION": "HTTP/1.1",
    "HTTP_HOST": "echo-api.3scale.net",
    "HTTP_ACCEPT": "*/*",
    "HTTP_USER_AGENT": "curl/7.51.0",
    "HTTP_X_FORWARDED_FOR": "2.139.235.79, 10.0.103.58",
    "HTTP_X_FORWARDED_HOST": "echo-api.3scale.net",
    "HTTP_X_FORWARDED_PORT": "443",
    "HTTP_X_FORWARDED_PROTO": "https",
    "HTTP_FORWARDED": "for=10.0.103.58;host=echo-api.3scale.net;proto=https"
  },
  "uuid": "ee626b70-e928-4cb1-a1a4-348b8e361733"
}
```

3.4.2. Configuring the authentication settings

You can configure authentication settings for your API in the **AUTHENTICATION** section under **[Your_product_name] > Integration > Settings**

Table 3.1. Optional authentication fields

Field	Description
Auth user key	Set the user key associated with the credentials location.
Credentials location	Define whether credentials are passed as HTTP headers, query parameters or as HTTP basic authentication.
Host Header	Define a custom Host request header. This is required if your API backend only accepts traffic from a specific host.
Secret Token	Used to block direct developer requests to your API backend. Set the value of the header here, and ensure your backend only allows calls with this secret header.

Furthermore, you can configure the **GATEWAY RESPONSE** error codes under **[Your_product_name] > Integration > Settings**. Define the *Response Code*, *Content-type*, and *Response Body* for the errors: Authentication failed, Authentication missing, and No match.

Table 3.2. Response codes and default response body

Response code	Response body
403	Authentication failed
403	Authentication parameters missing
404	No Mapping Rule matched
429	Usage limit exceeded

3.4.3. Configuring the API test call

Configuring the API involves testing the backends with a product and promoting the APIcast configuration to staging and production environments to make tests based on request calls.

For each product, requests get redirected to their corresponding backend according to the path. This path is configured when you add the backend to the product. For example, if you have two backends added to a product, each backend has its own path.

Prerequisites

- One or more [backends added to a product](#) .
- A [mapping rule](#) for each backend added to a product.
- An [application plan](#) to define the access policies.
- An [application](#) that subscribes to the application plan.

Procedure

1. Promote an APIcast configuration to Staging, by navigating to **[Your_product_name] > Integration > Configuration**.
2. Under *APIcast Configuration*, you will see the mapping rules for each backend added to the product. Click **Promote v.[n] to Staging APIcast**
 - **v.[n]** indicates the version number to be promoted.
3. Once promoted to staging, you can promote to Production. Under *Staging APIcast*, click **Promote v.[n] to Production APIcast**
 - **v.[n]** indicates the version number to be promoted.
4. To test requests to your API in the command line, use the command provided in *Example curl for testing*.
 - The curl command example is based on the first mapping rule in the product.

When testing requests to your API, you can modify the mapping rules by [adding methods and metrics](#).

Every time you modify the configuration and before making calls to your API, make sure you promote to the Staging and Production environments. When there are pending changes to be promoted to the Staging environment, you will see an exclamation mark in the Admin Portal, next to the **Integration** menu item.

3scale Hosted APIcast gateway does the validation of the credentials and applies the rate limits that you defined for the application plan of your API. If you make a call without credentials, or with invalid credentials, you will see the error message, **Authentication failed**.

3.5. DEPLOYING APICAST ON THE DOCKER CONTAINERIZED ENVIRONMENT

This is a step-by-step guide to deploy APIcast inside a Docker container engine that is ready to be used as a Red Hat 3scale API Management API gateway.

NOTE

When deploying APIcast on the Docker containerized environment, the supported versions of Red Hat Enterprise Linux (RHEL) and Docker are as follows:

- RHEL 7.7
- Docker 1.13.1

Prerequisites

- You must configure APIcast in your 3scale Admin Portal as per [Chapter 3, Installing APIcast](#).
- Access to the [Red Hat Ecosystem Catalog](#).
 - To create a registry service account, see [Creating and modifying registry service accounts](#).

To deploy APIcast on the docker containerized environment, perform the steps outlined in the following sections:

- [Section 3.5.1, "Installing the Docker containerized environment"](#)
- [Section 3.5.2, "Running the Docker containerized environment gateway"](#)

3.5.1. Installing the Docker containerized environment

This guide covers the steps to set up the Docker containerized environment on RHEL 7.x.

The Docker container engine provided by Red Hat is released as part of the Extras channel in RHEL. To enable additional repositories, you can use either the [Subscription Manager](#) or the *yum-config-manager* option. For details, see the [RHEL product documentation](#).

To deploy RHEL 7.x on an Amazon Web Services (AWS), Amazon Elastic Compute Cloud (Amazon EC2) instance, take the following steps:

Procedure

1. List all repositories: **sudo yum repolist all**.

2. Find the ***-extras** repository.
3. Enable the **extras** repository: **sudo yum-config-manager --enable rhui-REGION-rhel-server-extras**.
4. Install the Docker containerized environment package: **sudo yum install docker**.

Additional resources

For other operating systems, refer to the following Docker documentation:

- [Installing the Docker containerized environment on Linux distributions](#)
- [Installing the Docker containerized environment on Mac](#)
- [Installing the Docker containerized environment on Windows](#)

3.5.2. Running the Docker containerized environment gateway

IMPORTANT

In 3scale 2.11, support for an APIcast deployment running as a container in RHEL 7 and Docker is deprecated. In future releases, 3scale will support only RHEL 8 and Podman. If you are running APIcast self-managed as a container, upgrade your installation to the supported configuration.

To run the docker containerized environment gateway, do the following:

Procedure

1. Start the Docker daemon:

```
$ sudo systemctl start docker.service
```

2. Check if the Docker daemon is running:

```
$ sudo systemctl status docker.service
```

3. Download a ready to use Docker container engine image from the Red Hat registry:

```
$ sudo docker pull registry.redhat.io/3scale-amp2/apicast-gateway-rhel8:3scale2.13
```

4. Run APIcast in a Docker container engine:

```
$ sudo docker run --name apicast --rm -p 8080:8080 -e
THREESCALE_PORTAL_ENDPOINT=https://<access_token>@<domain>-admin.3scale.net
registry.redhat.io/3scale-amp2/apicast-gateway-rhel8:3scale2.13
```

Here, **<access_token>** is the Access Token for the 3scale Account Management API. You can use the Provider Key instead of the access token. **<domain>-admin.3scale.net** is the URL of your 3scale Admin Portal.

This command runs a Docker container engine called "apicast" on port **8080** and fetches the JSON configuration file from your 3scale Admin Portal. For other configuration options, see [Installing APIcast](#).

3.5.2.1. The docker command options

You can use the following options with the **docker run** command:

- **--rm**: Automatically removes the container when it exits.
- **-d** or **--detach**: Runs the container in the background and prints the container ID. When it is not specified, the container runs in the foreground mode and you can stop it using **CTRL + c**. When started in the detached mode, you can reattach to the container with the **docker attach** command, for example, **docker attach apicast**.
- **-p** or **--publish**: Publishes a container's port to the host. The value should have the format **<host port=""><container port=">**, so **-p 80:8080** will bind port **8080** of the container to port **80** of the host machine. For example, the Management API uses port **8090**, so you may want to publish this port by adding **-p 8090:8090** to the **docker run** command.
- **-e** or **--env**: Sets environment variables.
- **-v** or **--volume**: Mounts a volume. The value is typically represented as **<host path=""><container path=">[:<options>]**. **<options>** is an optional attribute; you can set it to **:ro** to specify that the volume will be read only (by default, it is mounted in read-write mode). Example: **-v /host/path:/container/path:ro**.

3.5.2.2. Testing APICast

The preceding steps ensure that your Docker container engine is running with your own configuration file and the Docker container image from the 3scale registry. You can test calls through APICast on port **8080** and provide the correct authentication credentials, which you can get from your 3scale account.

Test calls will not only verify that APICast is running correctly but also that authentication and reporting is being handled successfully.

NOTE

Ensure that the host you use for the calls is the same as the one configured in the *Public Base URL* field on the **Integration** page.

Additional resources

- For more information on available options, see [Docker run reference](#).

3.5.3. Additional resources

- For more information about tested and supported configuration, see [Red Hat 3scale API Management Supported Configurations](#)

3.5.4. Deploying APICast on Podman

This is a step-by-step guide for deploying APICast on a Pod Manager (Podman) container environment to be used as a Red Hat 3scale API Management API gateway.

NOTE

When deploying APIcast on a Podman container environment, the supported versions of Red Hat Enterprise Linux (RHEL) and Podman are as follows:

- RHEL 8.x/9.x
- Podman 4.2.0/4.11

Prerequisites

- You must configure APIcast in your 3scale Admin Portal as per [Chapter 3, Installing APIcast](#).
- Access to the [Red Hat Ecosystem Catalog](#).
 - To create a registry service account, see [Creating and modifying registry service accounts](#).

To deploy APIcast on the Podman container environment, perform the steps outlined in the following sections:

- [Section 3.5.4.1, “Installing the Podman container environment”](#)
- [Section 3.5.4.2, “Running the Podman environment”](#)

3.5.4.1. Installing the Podman container environment

This guide covers the steps to set up the Podman container environment on RHEL 8.x. Docker is not included in RHEL 8.x, therefore, use Podman for working with containers.

For more details about Podman with RHEL 8.x, see the [Container command-line reference](#).

Procedure

- Install the Podman container environment package:

```
$ sudo dnf install podman
```

Additional resources

For other operating systems, refer to the following Podman documentation:

- [Podman Installation Instructions](#)

3.5.4.2. Running the Podman environment

To run the Podman container environment, follow the procedure below.

Procedure

1. Download a ready to use Podman container image from the Red Hat registry:

```
$ podman pull registry.redhat.io/3scale-amp2/apicast-gateway-rhel8:3scale2.13
```

2. Run APIcast in a Podman:

```
$ podman run --name apicast --rm -p 8080:8080 -e
THREESCALE_PORTAL_ENDPOINT=https://<access_token>@<domain>-admin.3scale.net
registry.redhat.io/3scale-amp2/apicast-gateway-rhel8:3scale2.13
```

Here, **<access_token>** is the Access Token for the 3scale Account Management API. You can use the Provider Key instead of the access token. **<domain>-admin.3scale.net** is the URL of your 3scale Admin Portal.

This command runs a Podman container engine called "apicast" on port **8080** and fetches the JSON configuration file from your 3scale Admin Portal. For other configuration options, see [Installing APICast](#).

3.5.4.2.1. Testing APICast with Podman

The preceding steps ensure that your Podman container engine is running with your own configuration file and the Podman container image from the 3scale registry. You can test calls through APICast on port **8080** and provide the correct authentication credentials, which you can get from your 3scale account.

Test calls will not only verify that APICast is running correctly but also that authentication and reporting is being handled successfully.

NOTE

Ensure that the host you use for the calls is the same as the one configured in the *Public Base URL* field on the **Integration** page.

3.5.4.3. The podman command options

You can use the following option examples with the **podman** command:

- **-d**: Runs the container in *detached mode* and prints the container ID. When it is not specified, the container runs in the foreground mode and you can stop it using **CTRL + c**. When started in the detached mode, you can reattach to the container with the **podman attach** command, for example, **podman attach apicast**.
- **ps** and **-a**: Podman **ps** is used to list creating and running containers. Adding **-a** to the **ps** command will show all containers, both running and stopped, for example, **podman ps -a**.
- **inspect** and **-l**: Inspect a running container. For example, use **inspect** to see the ID that was assigned to the container. Use **-l** to get the details for the latest container, for example, **podman inspect -l | grep Id**:

3.5.4.4. Additional resources

- [Red Hat 3scale API Management Supported Configurations](#)
- [Basic Setup and Use of Podman](#)

3.6. DEPLOYING AN APICAST GATEWAY SELF-MANAGED SOLUTION USING THE OPERATOR

This guide provides steps for deploying an APICast gateway self-managed solution using the APICast operator via the Openshift Container Platform console.

The default settings are for production environment when you deploy APIcast. You can always adjust these settings for deploying a staging environment. For example, use the following **oc** command:

```
$ oc patch apicast/{apicast_name} --type=merge -p '{"spec":  
{"deploymentEnvironment":"staging","configurationLoadMode":"lazy"}}'
```

For more information, see the: [APIcast Custom Resource reference](#)

Prerequisites

- OpenShift Container Platform (OCP) 4.x or later with administrator privileges.
- You followed the steps in [Installing the APIcast operator on OpenShift](#).

Procedure

1. Log in to the OCP console using an account with administrator privileges.
2. Click **Operators > Installed Operators**
3. Click the *APIcast Operator* from the list of *Installed Operators*.
4. Click **APIcast > Create APIcast**

3.6.1. APIcast deployment and configuration options

You can deploy and configure an APIcast gateway self-managed solution using two approaches:

- [Providing a 3scale system endpoint](#)
- [Providing a configuration secret](#)

See also:

- [Injecting custom environments with the APIcast operator](#)
- [Injecting custom policies with the APIcast operator](#)
- [Configuring OpenTracing with the APIcast operator](#)

3.6.1.1. Providing a 3scale system endpoint

Procedure

1. Create an OpenShift secret that contains 3scale System Admin Portal endpoint information:

```
$ oc create secret generic ${SOME_SECRET_NAME} --from-  
literal=AdminPortalURL=${MY_3SCALE_URL}
```

- **`\${SOME_SECRET_NAME}`** is the name of the secret and can be any name you want as long as it does not conflict with an existing secret.
- **`\${MY_3SCALE_URL}`** is the URI that includes your 3scale access token and 3scale System portal endpoint. For more details, see [THREESCALE_PORTAL_ENDPOINT](#)

Example

```
$ oc create secret generic 3scaleportal --from-literal=AdminPortalURL=https://access-token@account-admin.3scale.net
```

For more information about the contents of the secret see the [Admin portal configuration secret](#) reference.

2. Create the OpenShift object for APICast

```
apiVersion: apps.3scale.net/v1alpha1
kind: APICast
metadata:
  name: example-apicast
spec:
  adminPortalCredentialsRef:
    name: SOME_SECRET_NAME
```

The **spec.adminPortalCredentialsRef.name** must be the name of the existing OpenShift secret that contains the 3scale system Admin Portal endpoint information.

3. Verify the APICast pod is running and ready, by confirming that the **readyReplicas** field of the OpenShift Deployment associated with the APICast object is *1*. Alternatively, wait until the field is set with:

```
$ echo $(oc get deployment apicast-example-apicast -o jsonpath='{.status.readyReplicas}')
1
```

3.6.1.1.1. Verifying the APICast gateway is running and available

Procedure

1. Ensure the OpenShift Service APICast is exposed to your local machine, and perform a test request. Do this by port-forwarding the APICast OpenShift Service to **localhost:8080**:

```
$ oc port-forward svc/apicast-example-apicast 8080
```

2. Make a request to a configured 3scale service to verify a successful HTTP response. Use the domain name configured in **Staging Public Base URL** or **Production Public Base URL** settings of your service. For example:

```
$ curl 127.0.0.1:8080/test -H "Host: localhost"
{
  "method": "GET",
  "path": "/test",
  "args": "",
  "body": "",
  "headers": {
    "HTTP_VERSION": "HTTP/1.1",
    "HTTP_HOST": "echo-api.3scale.net",
    "HTTP_ACCEPT": "*/*",
    "HTTP_USER_AGENT": "curl/7.65.3",
    "HTTP_X_REAL_IP": "127.0.0.1",
    "HTTP_X_FORWARDED_FOR": ...
```

```

"HTTP_X_FORWARDED_HOST": "echo-api.3scale.net",
"HTTP_X_FORWARDED_PORT": "80",
"HTTP_X_FORWARDED_PROTO": "http",
"HTTP_FORWARDED": "for=10.0.101.216;host=echo-api.3scale.net;proto=http"
},
"uuid": "603ba118-8f2e-4991-98c0-a9edd061f0f0"

```

3.6.1.1.2. Exposing APIcast externally via a Kubernetes Ingress

To expose APIcast externally via a Kubernetes Ingress, set and configure the **exposedHost** section. When the **host** field in the **exposedHost** section is set, this creates a Kubernetes Ingress object. The Kubernetes Ingress object can then be used by a previously installed and existing Kubernetes Ingress Controller to make APIcast accessible externally.

To learn what Ingress Controllers are available to make APIcast externally accessible and how they are configured see the [Kubernetes Ingress Controllers documentation](#).

The following example to expose APIcast with the hostname **myhostname.com**:

```

apiVersion: apps.3scale.net/v1alpha1
kind: APIcast
metadata:
  name: example-apicast
spec:
  ...
  exposedHost:
    host: "myhostname.com"
  ...

```

The example creates a Kubernetes Ingress object on the port 80 using HTTP. When the APIcast deployment is in an OpenShift environment, the OpenShift default Ingress Controller will create a Route object using the Ingress object APIcast creates which allows external access to the APIcast installation.

You may also configure TLS for the **exposedHost** section. Details about the available fields in the following table:

Table 3.3. APIcastExposedHost reference table

json/yaml field	Type	Required	Default value	Description
host	string	Yes	N/A	Domain name being routed to the gateway
tls	[]networkv1.Ingress TLS	No	N/A	Array of ingress TLS objects. See more on TLS .

3.6.1.1.2. Providing a configuration secret

Procedure

1. Create a secret with the configuration file:

```
$ curl
https://raw.githubusercontent.com/3scale/APIcast/master/examples/configuration/echo.json -
o $PWD/config.json

$ oc create secret generic apicast-echo-api-conf-secret --from-file=$PWD/config.json
```

The configuration file must be called **config.json**. This is an [APIcast CRD reference](#) requirement.

For more information about the contents of the secret see the [Admin portal configuration secret](#) reference.

2. Create an [APIcast custom resource](#):

```
$ cat my-echo-apicast.yaml
apiVersion: apps.3scale.net/v1alpha1
kind: APIcast
metadata:
  name: my-echo-apicast
spec:
  exposedHost:
    host: YOUR DOMAIN
  embeddedConfigurationSecretRef:
    name: apicast-echo-api-conf-secret

$ oc apply -f my-echo-apicast.yaml
```

- a. The following is an example of an embedded configuration secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: SOME_SECRET_NAME
type: Opaque
stringData:
  config.json: |
    {
      "services": [
        {
          "proxy": {
            "policy_chain": [
              { "name": "apicast.policy.upstream",
                "configuration": {
                  "rules": [{
                    "regex": "/",
                    "url": "http://echo-api.3scale.net"
                  }]
                }
            ]
          }
        }
      ]
    }
  }
```

- Set the following content when creating the APIcast object:

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIcast
metadata:
  name: example-apicast
spec:
  embeddedConfigurationSecretRef:
    name: SOME_SECRET_NAME
```

The **spec.embeddedConfigurationSecretRef.name** must be the name of the existing OpenShift secret that contains the configuration of the gateway.

- Verify the APIcast pod is running and ready, by confirming that the **readyReplicas** field of the OpenShift Deployment associated with the APIcast object is *1*. Alternatively, wait until the field is set with:

```
$ echo $(oc get deployment apicast-example-apicast -o jsonpath='{.status.readyReplicas}')
1
```

3.6.1.2.1. Verifying APIcast gateway is running and available

Procedure

- Ensure the OpenShift Service APIcast is exposed to your local machine, and perform a test request. Do this by port-forwarding the APIcast OpenShift Service to **localhost:8080**:

```
$ oc port-forward svc/apicast-example-apicast 8080
```

- Next: [Make a request to a configured 3scale service and verify a successful HTTP response](#) .

3.6.1.3. Injecting custom environments with the APIcast operator

In a 3scale installation that uses self-managed APIcast, you can use the **APIcast** operator to inject custom environments. A custom environment defines behavior that APIcast applies to all upstream APIs that the gateway serves. To create a custom environment, define a global configuration in Lua code.

You can inject a custom environment as part of or after APIcast installation. After injecting a custom environment, you can remove it and the **APIcast** operator reconciles the changes.

Prerequisites

- The APIcast operator is installed.

Procedure

- Write Lua code that defines the custom environment that you want to inject. For example, the following **env1.lua** file shows a custom logging policy that the **APIcast** operator loads for all services.

```
local cJSON = require('cjson')
local PolicyChain = require('apicast.policy_chain')
local policy_chain = context.policy_chain
```

```

local logging_policy_config = cjson.decode([[
{
  "enable_access_logs": false,
  "custom_logging": "\"{{request}}\" to service {{service.id}} and {{service.name}}"
}
]])

policy_chain:insert( PolicyChain.load_policy('logging', 'builtin', logging_policy_config), 1)

return {
  policy_chain = policy_chain,
  port = { metrics = 9421 },
}

```

2. Create a secret from the Lua file that defines the custom environment. For example:

```
$ oc create secret generic custom-env-1 --from-file=./env1.lua
```

A secret can contain multiple custom environments. Specify the **–from-file** option for each file that defines a custom environment. The operator loads each custom environment.

3. Define an **APICast** custom resource that references the secret you just created. The following example shows only content relative to referencing the secret that defines the custom environment.

```

apiVersion: apps.3scale.net/v1alpha1
kind: APICast
metadata:
  name: apicast1
spec:
  customEnvironments:
    - secretRef:
      name: custom-env-1

```

An **APICast** custom resource can reference multiple secrets that define custom environments. The operator loads each custom environment.

4. Create the **APICast** custom resource that adds the custom environment. For example, if you saved the **APICast** custom resource in the **apicast.yaml** file, run the following command:

```
$ oc apply -f apicast.yaml
```

Next steps

If you update your custom environment be sure to re-create its secret so the secret contains the update. The **APICast** operator watches for updates and automatically redeploys when it finds an update.

3.6.1.4. Injecting custom policies with the APICast operator

In a 3scale installation that uses self-managed APICast, you can use the **APICast** operator to inject custom policies. Injecting a custom policy adds the policy code to APICast. You can then use either of the following to add the custom policy to an API product’s policy chain:

- 3scale API

- **Product** custom resource

To use the 3scale Admin Portal to add the custom policy to a product's policy chain, you must also register the custom policy's schema with a **CustomPolicyDefinition** custom resource. Custom policy registration is a requirement only when you want to use the Admin Portal to configure a product's policy chain.

You can inject a custom policy as part of or after APIcast installation. After injecting a custom policy, you can remove it and the **APIcast** operator reconciles the changes.

Prerequisites

- The APIcast operator is installed or you are in the process of installing it.
- You have defined a custom policy as described in [Write your own policy](#). That is, you have already created, for example, the **my-first-custom-policy.lua**, **apicast-policy.json**, and **init.lua** files that define a custom policy,

Procedure

1. Create a secret from the files that define one custom policy. For example:

```
$ oc create secret generic my-first-custom-policy-secret \
  --from-file=./apicast-policy.json \
  --from-file=./init.lua \
  --from-file=./my-first-custom-policy.lua
```

If you have more than one custom policy, create a secret for each custom policy. A secret can contain only one custom policy.

2. Define an **APIcast** custom resource that references the secret you just created. The following example shows only content relative to referencing the secret that defines the custom policy.

```
apiVersion: apps.3scale.net/v1alpha1
kind: APIcast
metadata:
  name: apicast1
spec:
  customPolicies:
    - name: my-first-custom-policy
      version: "0.1"
      secretRef:
        name: my-first-custom-policy-secret
```

An **APIcast** custom resource can reference multiple secrets that define custom policies. The operator loads each custom policy.

3. Create the **APIcast** custom resource that adds the custom policy. For example, if you saved the **APIcast** custom resource in the **apicast.yaml** file, run the following command:

```
$ oc apply -f apicast.yaml
```

Next steps

If you update your custom policy be sure to re-create its secret so the secret contains the update. The **APICast** operator watches for updates and automatically redeploys when it finds an update.

Additional resources

- [APICast custom resource definition](#)

3.6.1.5. Configuring OpenTracing with the APICast operator

In a 3scale installation that uses self-managed APICast, you can use the **APICast** operator to configure OpenTracing. By enabling OpenTracing, you get more insight and better observability on the APICast instance.

Prerequisites

- The **APICast** operator is installed or you are in the process of installing it.
- Prerequisites listed in [Configuring APICast to use OpenTracing](#).
- [Jaeger is installed](#).

Procedure

1. Define a secret that contains your OpenTracing configuration details in **stringData.config**. This is the only valid value for the attribute that contains your OpenTracing configuration details. Any other specification prevents APICast from receiving your OpenTracing configuration details. The following example shows a valid secret definition:

```
apiVersion: v1
kind: Secret
metadata:
  name: myjaeger
stringData:
  config: |-
    {
      "service_name": "apicast",
      "disabled": false,
      "sampler": {
        "type": "const",
        "param": 1
      },
      "reporter": {
        "queueSize": 100,
        "bufferFlushInterval": 10,
        "logSpans": false,
        "localAgentHostPort": "jaeger-all-in-one-inmemory-agent:6831"
      },
      "headers": {
        "jaegerDebugHeader": "debug-id",
        "jaegerBaggageHeader": "baggage",
        "TraceContextHeaderName": "uber-trace-id",
        "traceBaggageHeaderPrefix": "testctx-"
      },
      "baggage_restrictions": {
        "denyBaggageOnInitializationFailure": false,
```

```

        "hostPort": "127.0.0.1:5778",
        "refreshInterval": 60
    }
}
type: Opaque

```

2. Create the secret. For example, if you saved the previous secret definition in the **myjaeger.yaml** file, you would run the following command:

```
$ oc create -f myjaeger.yaml
```

3. Define an **APIcast** custom resource that specifies the **OpenTracing** attributes. In the CR definition, set the **spec.tracingConfigSecretRef.name** attribute to the name of the secret that contains your OpenTracing configuration details. The following example shows only content relative to configuring OpenTracing.

```

apiVersion: apps.3scale.net/v1alpha1
kind: APIcast
metadata:
  name: apicast1
spec:
  ...
  openTracing:
    enabled: true
    tracingConfigSecretRef:
      name: myjaeger
    tracingLibrary: jaeger
  ...

```

4. Create the **APIcast** custom resource that configures OpenTracing. For example, if you saved the **APIcast** custom resource in the **apicast1.yaml** file, you would run the following command:

```
$ oc apply -f apicast1.yaml
```

Next steps

Depending on how OpenTracing is installed, you should see the traces in the Jaeger service user interface.

Additional resource

- [APIcast custom resource definition](#)

3.7. ADDITIONAL RESOURCES

To get information about the latest released and supported version of APIcast, see the articles:

- [Red Hat 3scale API Management Supported Configurations](#)
- [Red Hat 3scale API Management - Component Details](#) .

CHAPTER 4. EXTERNAL REDIS DATABASE CONFIGURATION FOR HIGH AVAILABILITY SUPPORT IN 3SCALE

IMPORTANT

Red Hat supports 3scale configurations that use an external Redis database. However, does not officially support setting up Redis for zero downtime, configuring back-end components for 3scale, or Redis database replication and sharding. The content is for reference only. Additionally, Redis **cluster mode** is not supported in 3scale.

High availability (HA) is provided for most components by the OpenShift Container Platform (OCP). For more information see [OpenShift Container Platform 3.11 Chapter 30. High Availability](#) .

NOTE

When you externalize databases from a Red Hat 3scale API Management deployment, this means to provide isolation from the application and resilience against service disruptions at the database level. The resilience to service disruptions depends on the service level agreements (SLAs) provided by the infrastructure or platform provider where you host the databases. This is not offered by 3scale. For more details on externalizing of databases offered by your chosen deployment, see the associated documentation.

The external database components for HA in Red Hat 3scale API Management include:

- **backend-redis**: used for statistics storage and temporary job storage.
- **system-redis**: provides temporary storage for background jobs for 3scale and is also used as a message bus for *Ruby* processes of **system-app** pods.

Both **backend-redis** and **system-redis** work with supported Redis high availability variants for Redis Sentinel and Redis Enterprise.

If the Redis pod comes to a stop, or if the OpenShift Container Platform stops it, a new pod is automatically created. Persistent storage will restore the data so the pod continues to work. In these scenarios, there will be a small amount of downtime while the new pod starts. This is due to a limitation in Redis that does not support a multi-master setup. You can reduce downtime by preinstalling the Redis images onto all nodes that have Redis deployed to them. This will speed up the pod restart time.

Set up Redis for zero downtime and configure back-end components for 3scale:

- [Setting up Redis for zero downtime](#)
- [Configuring back-end components for 3scale](#)
- [Redis database sharding and replication](#)

Prerequisites

- A 3scale account with an administrator role.

4.1. SETTING UP REDIS FOR ZERO DOWNTIME

As a 3scale administrator, configure Redis outside of OCP if you require zero downtime. There are several ways to set it up using the configuration options of 3scale pods:

- Set up your own self-managed Redis
- Use Redis Sentinel: [Reference Redis Sentinel Documentation](#)
- Redis provided as a service:
For example by:
 - Amazon ElastiCache
 - Redis Labs

NOTE

Red Hat does not provide support for the above mentioned services. The mention of any such services does not imply endorsement by Red Hat of the products or services. You agree that Red Hat is not responsible or liable for any loss or expenses that may result due to your use of (or reliance on) any external content.

4.2. CONFIGURING BACK-END COMPONENTS FOR 3SCALE

As a 3scale administrator, configure Redis HA (failover) for the **back-end** component environment variables in the following deployment configurations: **backend-cron**, **backend-listener**, and **backend-worker**. These configurations are necessary for Redis HA in 3scale.

NOTE

If you want to use Redis with sentinels, you must provide sentinel configuration in either **backend-redis**, **system-redis**, or both secrets.

4.2.1. Creating backend-redis and system-redis secrets

Follow these steps to create **backend-redis** and **system-redis** secrets accordingly:

- [Deploying a fresh installation of 3scale for HA](#)
- [Migrating a non-HA deployment of 3scale to HA](#)

4.2.2. Deploying a fresh installation of 3scale for HA

Procedure

1. Create the **backend-redis** and **system-redis** secrets with the fields below:

backend-redis

```

REDIS_QUEUES_SENTINEL_HOSTS
REDIS_QUEUES_SENTINEL_ROLE
REDIS_QUEUES_URL
REDIS_STORAGE_SENTINEL_HOSTS
REDIS_STORAGE_SENTINEL_ROLE
REDIS_STORAGE_URL

```

-

system-redis

```

NAMESPACE
SENTINEL_HOSTS
SENTINEL_ROLE
URL

```

- When configuring for Redis with sentinels, the corresponding **URL** fields in **backend-redis** and **system-redis** refer to the Redis group in the format **redis://[:redis-password@]redis-group[/db]**, where [x] denotes optional element x and **redis-password**, **redis-group**, and **db** are variables to be replaced accordingly:

Example

```
redis://:redispwd@mymaster/5
```

- The **SENTINEL_HOSTS** fields are comma-separated lists of sentinel connection strings in the following format:

```
redis://:sentinel-password@sentinel-hostname-or-ip:port
```

- For each element of the list, [x] denotes optional element x and **sentinel-password**, **sentinel-hostname-or-ip**, and **port** are variables to be replaced accordingly:

Example

```
:sentinelpwd@123.45.67.009:2711,:sentinelpwd@other-sentinel:2722
```

- The **SENTINEL_ROLE** fields are either **master** or **slave**.
2. Deploy 3scale as indicated in [Deploying 3scale using the operator](#).
 - a. Ignore the errors due to **backend-redis** and **system-redis** already present.

4.2.3. Migrating a non-HA deployment of 3scale to HA

1. Edit the **backend-redis** and **system-redis** secrets with all fields as shown in [Deploying a fresh installation of 3scale for HA](#).
2. Make sure the following **backend-redis** environment variables are defined for the back-end pods.

```

name: BACKEND_REDIS_SENTINEL_HOSTS
valueFrom:
  secretKeyRef:
    key: REDIS_STORAGE_SENTINEL_HOSTS
    name: backend-redis
name: BACKEND_REDIS_SENTINEL_ROLE
valueFrom:
  secretKeyRef:
    key: REDIS_STORAGE_SENTINEL_ROLE
    name: backend-redis

```

3. Make sure the following **system-redis** environment variables are defined for the **system-(app|sidekiq|sphinx)** pods.

```

name: REDIS_SENTINEL_HOSTS
valueFrom:
  secretKeyRef:
    key: SENTINEL_HOSTS
    name: system-redis
name: REDIS_SENTINEL_ROLE
valueFrom:
  secretKeyRef:
    key: SENTINEL_ROLE
    name: system-redis

```

4. Proceed with instructions to continue [Upgrading 3scale using templates](#).

4.2.3.1. Using Redis Enterprise

1. Use Redis Enterprise deployed in OpenShift, with three different **redis-enterprise** instances:
 - a. Edit **system-redis** secret:
 - i. Set the system redis database in **system-redis** to **URL**.
 - b. Set the back-end database in **backend-redis** to **REDIS_QUEUES_URL**.
 - c. Set the third database to **REDIS_STORAGE_URL** for **backend-redis**.

4.2.3.2. Using Redis Sentinel

NOTE

You can optionally apply Redis Sentinels to any of the databases. However, Red Hat recommends that you apply Redis Sentinels to all of them for HA.

1. Backend redis for statistics: update **backend-redis** secret and provide values for:
 - **REDIS_STORAGE_URL**
 - **REDIS_STORAGE_SENTINEL_ROLE**
 - **REDIS_STORAGE_SENTINEL_HOSTS**
Set **REDIS_STORAGE_SENTINEL_ROLE** to a comma-separated list of sentinels hosts and ports, for example: **:sentinelpwd@123.45.67.009:2711,:sentinelpwd@other-sentinel:2722**
2. Backend redis for queue: update **backend-redis** secret and provide values for:
 - **REDIS_QUEUES_URL**
 - **REDIS_QUEUES_SENTINEL_ROLE**
 - **REDIS_QUEUES_SENTINEL_HOSTS**

Set **REDIS_QUEUES_SENTINEL_ROLE** to a comma-separated list of sentinels hosts and ports, for example: **:sentinelpwd@123.45.67.009:2711, :sentinelpwd@other-sentinel:2722**

3. Use Redis Sentinel, with these Redis databases:
4. System redis for data: update **system-redis** secret and provide values for:

NOTE

Edit **system-redis** secret: **URL**

- **SENTINEL_ROLE**
- **NAMESPACE**
- **URL**
- **SENTINEL_HOSTS**

Set **SENTINEL_HOSTS** to a comma-separated list of sentinels hosts and ports, for example: **:sentinelpwd@123.45.67.009:2711, :sentinelpwd@other-sentinel:2722**

Notes

- The *system-app* and *system-sidekiq* components connect directly to **back-end** Redis for retrieving statistics.
 - As of 3scale 2.7, these system components can also connect to **back-end** Redis (storage) when using sentinels.
- The *system-app* and *system-sidekiq* components uses **only backend-redis** storage, not **backend-redis** queues.
 - Changes made to the system components support **backend-redis** storage with sentinels.

4.3. REDIS DATABASE SHARDING AND REPLICATION

Sharding, sometimes referred to as partitioning, separates large databases in to smaller databases called shards. With replication, your database is set up with copies of the same dataset hosted on separate machines.

Sharding

Sharding facilitates adding more leader instances, which is also useful when you have so much data that it does not fit in a single database, or when the CPU load is close to 100%.

With Redis HA for 3scale, the following two reasons are why sharding is important:

- Splitting and scaling large volumes of data and adjusting the number of shards for a particular index to help avoid bottlenecks.
- Distributing operations across different node, therefore increasing performance, for example, when multiple machines are working on the same query.

The three main solutions for Redis database sharding with cluster mode disabled are:

- Amazon ElastiCache
- Standard Redis via Redis sentinels
- Redis Enterprise

Replication

Redis database replication ensures redundancy by having your dataset replicated across different machines. Using replication allows you to keep Redis working when the leader goes down. Data is then pulled from a single instance, the leader, ensuring high availability.

With Redis HA for 3scale, database replication ensures high availability replicas of a primary shard. The principles of operation involve:

- When the primary shard fails, the replica shard will automatically be promoted to the new primary shard.
- Upon recovery of the original primary shard, it automatically becomes the replica shard of the new primary shard.

The three main solutions for Redis database replication are:

- Redis Enterprise
- Amazon ElastiCache
- Standard Redis via Redis sentinels

Sharding with twemproxy

For Amazon ElastiCache and Standard Redis, sharding involves splitting data up based on keys. You need a proxy component that given a particular key knows which shard to find, for example **twemproxy**. Also known as nutcracker, **twemproxy** is a lightweight proxy solution for Redis protocols that finds shards based on specific keys or server maps assigned to them. Adding sharding capabilities to your Amazon ElastiCache or Standard Redis instance with **twemproxy**, has the following advantages:

- The capability of sharding data automatically across multiple servers.
- Support of multiple hashing modes and consistent hashing and distribution.
- The capability to run in multiple instances, which allows clients to connect to the first available proxy server.
- Reduce the number of connections to the caching servers on the backend.

NOTE

Redis Enterprise uses its own proxy, so it does not need **twemproxy**.

Additional resources

- [Redis Sentinel Documentation](#).
- [twemproxy](#).

4.4. ADDITIONAL INFORMATION

- For more information about 3scale and Redis database support, see [Red Hat 3scale API Management Supported Configurations](#).
- For more information about Amazon ElastiCache for Redis, see the official [Amazon ElastiCache Documentation](#).
- For more information about Redis Enterprise, see the latest [Documentation](#).

CHAPTER 5. CONFIGURING AN EXTERNAL MYSQL DATABASE

IMPORTANT

When you externalize databases from a Red Hat 3scale API Management deployment, this means to provide isolation from the application and resilience against service disruptions at the database level. The resilience to service disruptions depends on the service level agreements (SLAs) provided by the infrastructure or platform provider where you host the databases. This is not offered by 3scale. For more details on externalizing of databases offered by your chosen deployment, see the associated documentation.

Red Hat supports 3scale configurations that use an external MySQL database. However, the database itself is not within the scope of support.

This guide provides information for externalizing the MySQL database. This is useful where there are several infrastructure issues, such as network or filesystem, using the default **system-mysql** pod.

Prerequisites

- Access to an OpenShift Container Platform 4.x cluster using an account with administrator privileges.
- A 3scale instance installation on the OpenShift cluster. See [Installing 3scale on OpenShift](#).

To configure an external MySQL database, perform the steps outlined in the following sections:

- [Section 5.1, "External MySQL database limitations"](#)
- [Section 5.2, "Externalizing the MySQL database"](#)
- [Section 5.3, "Rolling back"](#)

5.1. EXTERNAL MYSQL DATABASE LIMITATIONS

There are limitations with the process of externalizing your MySQL database:

3scale On-premises versions

It has only been tested and verified on the 2.5 On-premises and 2.6 On-premises versions from 3scale.

MySQL database user

The URL must be in the following format:

<database_scheme>://<admin_user>:<admin_password>@<database_host>/<database_name>

An **<admin_user>** must be an existing user in the external database with full permissions on the **<database_name>** logical database. The **<database_name>** must be an already existing logical database in the external database.

MySQL host

Use the *IP* address from the external MySQL database instead of the *hostname* or it will not resolve. For example, use *1.1.1.1* instead of *mysql.mydomain.com*.

5.2. EXTERNALIZING THE MYSQL DATABASE

Use the following steps to fully externalize the MySQL database.

WARNING

This will cause downtime in the environment while the process is ongoing.

Procedure

1. Login to the OpenShift node where your 3scale On-premises instance is hosted and change to its project:

```
$ oc login -u <user> <url>
$ oc project <3scale-project>
```

Replace **<user>**, **<url>**, and **<3scale-project>** with your own credentials and the project name.

2. Follow the steps below in the order shown to scale down all the pods. This will avoid loss of data.

Stop 3scale On-premises

From the OpenShift web console or from the command line interface (CLI), scale down all the deployment configurations to zero replicas in the following order:

- **apicast-wildcard-router** and **zync** for versions before 3scale 2.6 or **zync-que** and **zync** for 3scale 2.6 and above.
- **apicast-staging** and **apicast-production**.
- **system-sidekiq**, **backend-cron**, and **system-sphinx**.
 - 3scale 2.3 includes **system-resque**.
- **system-app**.
- **backend-listener** and **backend-worker**.
- **backend-redis**, **system-memcache**, **system-mysql**, **system-redis**, and **zync-database**.
The following example shows how to perform this in the CLI for **apicast-wildcard-router** and **zync**:

```
$ oc scale dc/apicast-wildcard-router --replicas=0
$ oc scale dc/zync --replicas=0
```

**NOTE**

The deployment configuration for each step can be scaled down at the same time. For example, you could scale down **apicast-wildcard-router** and **zync** together. However, it is better to wait for the pods from each step to terminate before scaling down the ones that follow. The 3scale instance will be completely inaccessible until it is fully started again.

- To confirm that no pods are running on the 3scale project use the following command:

```
oc get pods -n <3scale_namespace>
```

The command should return *No resources found*.

- Scale up the database level pods again using the following command:

```
$ oc scale dc/{backend-redis,system-memcache,system-mysql,system-redis,zync-database}
--replicas=1
```

- Ensure that you are able to login to the external MySQL database through the **system-mysql** pod before proceeding with the next steps:

```
$ oc rsh system-mysql-<system_mysql_pod_id>
mysql -u root -p -h <host>
```

- `<system_mysql_pod_id>`: The identifier of the `system-mysql` pod.
- The user should always be `root`. For more information see [External MySQL database limitations](#).
 - The CLI will now display **mysql>**. Type `exit`, then press `return`. Type `exit` again at the next prompt to go back to the OpenShift node console.

- Perform a full MySQL dump using the following command:

```
$ oc rsh system-mysql-<system_mysql_pod_id> /bin/bash -c "mysqldump -u root --single-transaction --routines --triggers --all-databases" > system-mysql-dump.sql
```

- Replace `<system_mysql_pod_id>` with your unique **system-mysql** pod *ID* .
- Validate that the file **system-mysql-dump.sql** contains a valid MySQL level dump as in the following example:

```
$ head -n 10 system-mysql-dump.sql
-- MySQL dump 10.13 Distrib 8.0, for Linux (x86_64)
--
-- Host: localhost Database:
-----
-- Server version 8.0

/*!40101 SET @OLD_CHARACTER_SET_CLIENT=@@CHARACTER_SET_CLIENT */;
/*!40101 SET
@OLD_CHARACTER_SET_RESULTS=@@CHARACTER_SET_RESULTS */;
```

```
/*!40101 SET @OLD_COLLATION_CONNECTION=@@COLLATION_CONNECTION
*/;
/*!40101 SET NAMES utf8 */;
```

- Scale down the **system-mysql** pod and leave it with 0 (zero) replicas:

```
$ oc scale dc/system-mysql --replicas=0
```

- Find the *base64* equivalent of the URL **mysql2://root:<password>@<host>/system**, replacing *<password>* and *<host>* accordingly:

```
$ echo "mysql2://root:<password>@<host>/system" | base64
```

- Create a default *'user'@'%'* on the remote MySQL database. It only needs to have SELECT privileges. Also find its *base64* equivalents:

```
$ echo "user" | base64
$ echo "<password>" | base64
```

- Replace *<password>* with the password for *'user'@'%'*.

- Perform a backup and edit the OpenShift secret **system-database**:

```
$ oc get secret system-database -o yaml > system-database-orig.bkp.yml
$ oc edit secret system-database
```

- URL**: Replace it with the value from [\[step-8\]](#).
- DB_USER** and **DB_PASSWORD**: Use the values from the previous step for both.

- Send **system-mysql-dump.sql** to the remote database server and import the dump into it. Use the command to import it:
- Use the command below to send **system-mysql-dump.sql** to the remote database server and import the dump into the server:

```
mysql -u root -p < system-mysql-dump.sql
```

- Ensure that a new database called *system* was created:

```
mysql -u root -p -se "SHOW DATABASES"
```

- Use the following instructions to *Start 3scale On-premises*, which scales up all the pods in the correct order.

Start 3scale On-premises

- backend-redis**, **system-memcache**, **system-mysql**, **system-redis**, and **zync-database**.
- backend-listener** and **backend-worker**.
- system-app**.
- system-sidekiq**, **backend-cron**, and **system-sphinx**

- 3scale 2.3 includes **system-resque**.
- **apicast-staging** and **apicast-production**.
- **apicast-wildcard-router** and **zync** for versions before 3scale 2.6 or **zync-que** and **zync** for 3scale 2.6 and above.

The following example shows how to perform this in the CLI for **backend-redis**, **system-memcache**, **system-mysql**, **system-redis**, and **zync-database**:

```
$ oc scale dc/backend-redis --replicas=1
$ oc scale dc/system-memcache --replicas=1
$ oc scale dc/system-mysql --replicas=1
$ oc scale dc/system-redis --replicas=1
$ oc scale dc/zync-database --replicas=1
```

The **system-app** pod should now be up and running without any issues.

15. After validation, scale back up the other pods in the [order shown](#).
16. Backup the **system-mysql** *DeploymentConfig* object. You may delete after a few days once you are sure everything is running properly. Deleting **system-mysql** *DeploymentConfig* avoids any future confusion if this procedure is done again in the future.

5.3. ROLLING BACK

Perform a rollback procedure if the **system-app** pod is not fully back online and the root cause for it could not be determined or addressed after following [step 14](#).

1. Edit the secret **system-database** using the original values from **system-database-orig.bkp.yml**. See [\[step-10\]](#):

```
$ oc edit secret system-database
```

Replace *URL*, *DB_USER*, and *DB_PASSWORD* with their original values.

2. Scale down all the pods and then scale them back up again, including **system-mysql**. The **system-app** pod and the other pods to be started after it should be up and running again. Run the following command to confirm all pods are back up and running:

```
$ oc get pods -n <3scale-project>
```

5.4. ADDITIONAL INFORMATION

- For more information about 3scale and MySQL database support, see [Red Hat 3scale API Management Supported Configurations](#).
