Abstract

Read more to learn how to use add-ons for your cluster.
CHAPTER 1. ADD-ONS OVERVIEW

1.1. SUBMARINER MULTICLUSTER NETWORKING AND SERVICE DISCOVERY

1.1.1. Prerequisites

1.1.2. subctl command utility

1.1.2.1. Installing the subctl command utility

1.1.2.2. Using the subctl commands

1.1.3. Globalnet

1.1.4. Deploying Submariner

1.1.4.1. Deploying Submariner with the console

1.1.4.2. Deploying Submariner manually

1.1.4.2.1. Preparing selected hosts to deploy Submariner

1.1.4.2.1.1. Preparing Microsoft Azure for Submariner

1.1.4.2.1.2. Preparing IBM Cloud for Submariner

1.1.4.2.1.3. Preparing VMware vSphere for Submariner

1.1.4.2.1.4. Preparing bare metal for Submariner

1.1.4.2.1.5. Preparing Red Hat OpenStack Platform for Submariner

1.1.4.2.2. Deploy Submariner with the ManagedClusterAddOn API

1.1.4.2.3. Customizing Submariner deployments

1.1.4.2.3.1. NATT port

1.1.4.2.3.2. Number of gateway nodes

1.1.4.2.3.3. Instance types of gateway nodes

1.1.4.3. Managing service discovery for Submariner

1.1.4.3.1. Enabling service discovery for Submariner

1.1.4.3.2. Disabling service discovery for Submariner

1.1.4.4. Uninstalling Submariner

1.1.4.4.1. Console method

1.1.4.4.2. Command-line method

1.1.4.4.3. Manual removal steps for early versions of Submariner

1.1.4.4.4. Verifying Submariner resource removal

1.2. VOLSYNC PERSISTENT VOLUME REPLICATION SERVICE (TECHNOLOGY PREVIEW)

1.2.1. Replicating persistent volumes with VolSync

1.2.1.1. Prerequisites

1.2.1.2. Installing VolSync on the managed clusters

1.2.1.2.1. Installing VolSync using labels

1.2.1.2.2. Installing VolSync using a ManagedClusterAddOn

1.2.1.3. Configuring Rsync replication across managed clusters

1.2.2. Converting a replicated image to a usable persistent volume claim

1.2.3. Scheduling your synchronization

1.3. ENABLING KLUSTERLET ADD-ONS ON CLUSTERS FROM THE MULTICLUSTER ENGINE FOR KUBERNETES OPERATOR
CHAPTER 1. ADD-ONS OVERVIEW

Red Hat Advanced Cluster Management for Kubernetes add-ons can improve some areas of performance and add function to enhance your applications. The following sections provide a summary of the add-ons that are available for Red Hat Advanced Cluster Management:

- Submariner multicluster networking and service discovery
- VolSync persistent volume replicating service
- Enabling klusterlet add-ons on clusters from the multicluster engine for Kubernetes operator

1.1. SUBMARINER MULTICLUSTER NETWORKING AND SERVICE DISCOVERY

The Submariner service is an open source tool that can be used with Red Hat Advanced Cluster Management for Kubernetes to provide direct networking between pods across two or more Kubernetes clusters in your environment, either on-premises or in the cloud. For more information about Submariner, see the Submariner site.

You can enable Submariner on OpenShift Container Platform clusters that are hosted in the following environments:

- Amazon Web Services (AWS)
- Google Cloud Platform (GCP)
- IBM Cloud
- Microsoft Azure
- Red Hat OpenShift Dedicated
- VMware vSphere
- Bare metal
- Red Hat OpenStack Platform

Red Hat Advanced Cluster Management for Kubernetes provides a Submariner component that you can deploy in your environment by using your hub cluster.

- Prerequisites
- Preparing selected hosts for Submariner
  - Preparing Microsoft Azure for Submariner
  - Preparing IBM Cloud for Submariner
  - Preparing VMware vSphere for Submariner
  - Preparing bare metal for Submariner
  - Preparing Red Hat OpenStack Platform for Submariner
1.1.1. Prerequisites

Ensure that you have the following prerequisites before using Submariner:

- A credential to access the hub cluster with `cluster-admin` permissions.
- IP connectivity must be configured between the Gateway nodes. When connecting two clusters, at least one of the clusters must be accessible to the Gateway node using its public or private IP address designated to the Gateway node. See Submariner NAT Traversal for more information.
- Firewall configuration across all nodes in each of the managed clusters must allow 4800/UDP in both directions.
- Firewall configuration on the Gateway nodes must allow ingress 8080/TCP so the other nodes in the cluster can access it.
- Firewall configuration open for 4500/UDP and any other ports that are used for IPsec traffic on the gateway nodes. **Note:** This is configured automatically when your clusters are deployed in an AWS or GCP environment, but must be configured manually for clusters on other environments and for the firewalls that protect private clouds.
- The `managedcluster` name must follow the DNS label standard as defined in RFC 1123. This means the name must meet the following criteria:
  - Contain at most 63 characters
  - Contain only lowercase alphanumeric characters or '-'
  - Start with an alphanumeric character
  - End with an alphanumeric character

Table 1.1. Submariner required ports

<table>
<thead>
<tr>
<th>Name</th>
<th>Default value</th>
<th>Customizable</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPsec NATT</td>
<td>4500/UDP</td>
<td>Yes</td>
</tr>
<tr>
<td>VXLAN</td>
<td>4800/UDP</td>
<td>No</td>
</tr>
<tr>
<td>Submariner metrics port</td>
<td>8080/TCP</td>
<td>No</td>
</tr>
</tbody>
</table>

See the Submariner upstream prerequisites documentation for more detailed information about the prerequisites.

1.1.2. subctl command utility

Submariner contains the `subctl` utility that provides additional commands that simplify running tasks on your Submariner environment.

1.1.2.1. Installing the subctl command utility
The **subctl** utility is shipped in a container image. Complete the following steps to install the **subctl** utility locally:

1. Download the **subctl** container and extract a compressed version of the **subctl** binary to `/tmp` by entering the following command:

   ```bash
   oc image extract registry.redhat.io/rhacm2/subctl-rhel8:v0.12 --path=/dist/subctl-v0.12.1-linux-amd64.tar.xz:/tmp/ --confirm
   ```

   **Note:** You might have to change `subctl-v0.12.1-linux-amd64.tar.xz` to the version of Submariner that you are using.

2. Decompress the **subctl** utility by entering the following command:

   ```bash
   tar -C /tmp/ -xf /tmp/subctl-v0.12-linux-amd64.tar.xz
   ```

3. Install the **subctl** utility by entering the following command:

   ```bash
   install -m744 /tmp/subctl-v0.12/subctl-v0.12-linux-amd64 /$HOME/.local/bin/subctl
   ```

### 1.1.2.2. Using the subctl commands

After adding the utility to your path, view the following table for a brief description of the available commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>export service</strong></td>
<td>Creates a <strong>ServiceExport</strong> resource for the specified service, which enables other clusters in the Submariner deployment to discover the corresponding service.</td>
</tr>
<tr>
<td><strong>unexport service</strong></td>
<td>Removes the <strong>ServiceExport</strong> resource for the specified service, which prevents other clusters in the Submariner deployment from discovering the corresponding service.</td>
</tr>
<tr>
<td><strong>show</strong></td>
<td>Provides information about Submariner resources.</td>
</tr>
<tr>
<td><strong>verify</strong></td>
<td>Verifies connectivity, service discovery, and other Submariner features when Submariner is configured across a pair of clusters.</td>
</tr>
<tr>
<td><strong>benchmark</strong></td>
<td>Benchmarks throughput and latency across a pair of clusters that are enabled with Submariner or within a single cluster.</td>
</tr>
<tr>
<td><strong>diagnose</strong></td>
<td>Runs checks to identify issues that prevent the Submariner deployment from working correctly.</td>
</tr>
<tr>
<td><strong>gather</strong></td>
<td>Collects information from the clusters to help troubleshoot a Submariner deployment.</td>
</tr>
</tbody>
</table>
1.1.3. Globalnet

Globalnet is a feature included with the Submariner add-on which supports connectivity between clusters with overlapping CIDRs. Globalnet is a cluster set wide configuration, and can be selected when the first managed cluster is added to the cluster set. When Globalnet is enabled, each managed cluster is allocated a global CIDR from the virtual Global Private Network. The global CIDR is used for supporting inter-cluster communication.

If there is a chance that your clusters running Submariner might have overlapping CIDRs, consider enabling Globalnet. When using the Red Hat Advanced Cluster Management console, the ClusterAdmin can enable Globalnet for a cluster set by selecting the option Enable Globalnet when enabling the Submariner add-on for clusters in the cluster set. After you enable Globalnet, you cannot disable it without removing Submariner.

When using the Red Hat Advanced Cluster Management APIs, the ClusterAdmin can enable Globalnet by creating a submariner-broker object in the <ManagedClusterSet>-broker namespace.

The ClusterAdmin role has the required permissions to create this object in the broker namespace. The ManagedClusterSetAdmin role, which is sometimes created to act as a proxy administrator for the cluster set, does not have the required permissions. To provide the required permissions, the ClusterAdmin must associate the role permissions for the access-to-brokers-submariner-crd to the ManagedClusterSetAdmin user.

Complete the following steps to create the submariner-broker object:

1. Create submariner-broker object that specifies the Globalnet configuration by creating a YAML file named submariner-broker.yaml that contains content that resembles the following example:

```
apiVersion: submariner.io/v1alpha1
class: Broker
metadata:
  name: submariner-broker
  namespace: <broker-namespace>
spec:
  globalnetEnabled: <true-or-false>
```

   Replace broker-namespace with the name of your broker namespace.

   Replace true-or-false with true to enable Globalnet.

2. Apply the file to your YAML file by entering the following command:

```
oc apply -f submariner-broker.yaml
```

For more information about Globalnet, see Globalnet controller in the Submariner documentation.

1.1.4. Deploying Submariner
You can deploy Submariner to network clusters on the following providers:

**Automatic deployment process:**

- Amazon Web Services
- Google Cloud Platform
- Red Hat OpenStack Platform

**Manual deployment process:**

- Microsoft Azure
- IBM Cloud
- VMware vSphere
- Bare metal

### 1.1.4.1. Deploying Submariner with the console

You can deploy Submariner on Red Hat OpenShift Container Platform managed clusters that are deployed on Amazon Web Services, Google Cloud Platform, and VMware vSphere by using the Red Hat Advanced Cluster Management for Kubernetes console. To deploy Submariner on other providers, follow the instructions in [Deploying Submariner manually](#). Complete the following steps to deploy Submariner with the Red Hat Advanced Cluster Management for Kubernetes console:

**Required access:** Cluster administrator

1. From the console navigation menu, select **Infrastructure > Clusters**.

2. On the **Clusters** page, select the **Cluster sets** tab. The clusters that you want enable with Submariner must be in the same cluster set.

3. If the clusters on which you want to deploy Submariner are already in the same cluster set, skip to step 5 to deploy Submariner.

4. If the clusters on which you want to deploy Submariner are not in the same cluster set, create a cluster set for them by completing the following steps:
   
   a. Select **Create cluster set**
   
   b. Name the cluster set, and select **Create**.
   
   c. Select **Manage resource assignments** to assign clusters to the cluster set.
   
   d. Select the managed clusters that you want to connect with Submariner to add them to the cluster set.
   
   e. Select **Review** to view and confirm the clusters that you selected.
   
   f. Select **Save** to save the cluster set, and view the resulting cluster set page.

5. On the cluster set page, select the **Submariner add-ons** tab.

6. Select **Install Submariner add-ons**.
7. Select the clusters on which you want to deploy Submariner.

8. Enter the following information in the Install Submariner add-ons editor:

- **AWS Access Key ID** - This field is only visible when you import an AWS cluster.
- **AWS Secret Access Key** - This field is only visible when you import an AWS cluster.
- **Google Cloud Platform service account JSON key** - This field is only visible when you import a Google Cloud Platform cluster.
- **Instance type** - The Amazon Web Services EC2 instance type of the gateway node that is created on the managed cluster. The default value is `c5d.large`. This field is only visible when your managed cluster environment is AWS.
- **IPsec NAT-T port** - The default value for the IPsec NAT traversal port is port 4500. If your managed cluster environment is VMware vSphere, ensure that this port is opened on your firewalls.
- **Gateway count** - The number of worker nodes that are used to deploy the Submariner gateway component on your managed cluster. The default value is 1. If the value is greater than 1, the Submariner gateway High Availability (HA) is automatically enabled.
- **Cable driver** - The Submariner gateway cable engine component that maintains the cross-cluster tunnels. The default value is **Libreswan IPsec**.

9. Select Next at the end of the editor to move to the editor for the next cluster, and complete the editor for each of the remaining clusters that you selected.

10. Verify your configuration for each managed cluster.

11. Click Install to deploy Submariner on the selected managed clusters.

   It might take several minutes for the installation and configuration to complete. You can check the Submariner status in the list on the Submariner add-ons tab:

   - **Connection status** indicates how many Submariner connections are established on the managed cluster.
   - **Agent status** indicates whether Submariner is successfully deployed on the managed cluster. The console might report a status of **Degraded** until it is installed and configured.
   - **Gateway nodes labeled** indicates how many worker nodes are labeled with the Submariner gateway label: `submariner.io/gateway=true` on the managed cluster.

Submariner is now deployed on the clusters.

### 1.1.4.2. Deploying Submariner manually

Before you deploy Submariner with Red Hat Advanced Cluster Management for Kubernetes, you must prepare the clusters on the hosting environment for the connection. Currently, you can use the SubmarinerConfig API to automatically prepare the clusters on Amazon Web Services, Google Cloud Platform and VMware vSphere. For other platforms, you need to prepare them manually, see Preparing selected hosts to deploy Submariner for the steps.

### 1.1.4.2.1. Preparing selected hosts to deploy Submariner

Before you deploy Submariner with Red Hat Advanced Cluster Management for Kubernetes, you must prepare the clusters on the hosting environment for the connection. Currently, you can use the SubmarinerConfig API to automatically prepare the clusters on Amazon Web Services, Google Cloud Platform and VMware vSphere. For other platforms, you need to prepare them manually, see Preparing selected hosts to deploy Submariner for the steps.
Before you deploy Submariner with Red Hat Advanced Cluster Management for Kubernetes, you must manually prepare the clusters on the hosting environment for the connection. The requirements are different for different hosting environments, so follow the instructions for your hosting environment.

1.1.4.2.1.1 Preparing Microsoft Azure for Submariner

To prepare the clusters on your Microsoft Azure for deploying the Submariner component, complete the following steps:

1. Tag a node as a gateway node by running the following command:

   ```
kubectl label nodes <worker-node-name> "submariner.io/gateway=true" --overwrite
   ```

2. Create a public IP and assign it to the VM of the node that was tagged as gateway node by running the following commands:

   ```
az network public-ip create --name <public-ip-name> --resource-group <res-group>
az network nic ip-config update --name <name> --nic-name <gw-vm-nic> --resource-group <res-group> --public-ip-address <public-ip-name>
   ```

   Replace `res-group` with the resource group of the cluster.

   Replace `gw-vm-nic` with the interface address.

3. Create a network security group for the Submariner gateway by running the following command:

   ```
az network nsg create --name <gw-nsg-name> --resource-group <res-group>
   ```

4. Create network security groups rules in your Azure environment to open the tunnel port (4500/UDP by default), NAT discovery port (4490/UDP by default) and metrics port (8080/TCP and 8081/TCP by default) for Submariner. This needs to be created in both inbound and outbound directions for each of the ports.

   ```
az network nsg rule create --resource-group <res-group> 
   --nsg-name <gw-nsg-name> --priority <priority> 
   --name <name> --direction Inbound --access Allow 
   --protocol <Protocol> --destination-port-ranges <port>

az network nsg rule create --resource-group <res-group> 
   --nsg-name <gw-nsg-name> --priority <priority> 
   --name <name> --direction Outbound --access Allow 
   --protocol <Protocol> --destination-port-ranges <port>
   ```

5. Attach the security group to the gateway VM interface by entering the following command:

   ```
az network nic update -g <res-group> -n <gw-vm-nic> --network-security-group <gw-nsg-name>
   ```

6. Create network security group rules in your Azure environment to open the VXLAN port (4800/UDP by default) on the existing security groups (`<resource-group-name>-nsg` by default) that are associated with the worker and the main nodes.

   ```
az network nsg rule create --resource-group <res-group> 
   ```
1.1.4.2.1.2. Preparing IBM Cloud for Submariner

There are two kinds of Red Hat OpenShift Kubernetes Service (ROKS) on IBM Cloud: the classic cluster and the second generation of compute infrastructure in a virtual private cloud (VPC). Submariner cannot run on the classic ROKS cluster since it cannot configure the IPsec ports for the classic cluster.

To configure the ROKS clusters on a VPC to use Submariner, complete the steps in the following links:

1. Before you create a cluster, specify subnets for pods and services, which avoids overlapping CIDRs with other clusters. Make sure there are no overlapping pods and services CIDRs between clusters if you are using an existing cluster. See VPC Subnets for the procedure.

2. Attach a public gateway to subnets used in the cluster. See Public Gateway for the procedure.

3. Create inbound rules for the default security group of the cluster by completing the steps in Security Group. Ensure that the firewall allows inbound and outbound traffic on 4500/UDP and 500/UDP ports for Gateway nodes, and allows inbound and outbound UDP/4800 for all the other nodes.

4. Label a node that has the public gateway as submariner.io/gateway=true in the cluster.

5. Refer to Calico to configure Calico CNI by creating IPPools in the cluster.

1.1.4.2.1.3. Preparing VMware vSphere for Submariner

Submariner uses IPsec to establish the secure tunnels between the clusters on the gateway nodes. You can use the default port or specify a custom port. When you run this procedure without specifying an IPsec NATT port, the default port is automatically used for the communication. The default port is 4500/UDP.

Submariner uses virtual extensible LAN (VXLAN) to encapsulate traffic when it moves from the worker and master nodes to the gateway nodes. The VXLAN port cannot be customized, and is always port 4800/UDP.

Submariner uses 8080/TCP to send its metrics information among nodes in the cluster, this port cannot be customized.

The following ports must be opened by your VMWare vSphere administrator before you can enable Submariner:

Table 1.2. VMware vSphere and Submariner ports

<table>
<thead>
<tr>
<th>Name</th>
<th>Default value</th>
<th>Customizable</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPsec NATT</td>
<td>4500/UDP</td>
<td>Yes</td>
</tr>
<tr>
<td>Name</td>
<td>Default value</td>
<td>Customizable</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------</td>
<td>--------------</td>
</tr>
<tr>
<td>VXLAN</td>
<td>4800/UDP</td>
<td>No</td>
</tr>
<tr>
<td>Submariner metrics</td>
<td>8080/TCP</td>
<td>No</td>
</tr>
</tbody>
</table>

To prepare VMware vSphere clusters for deploying Submariner, complete the following steps:

1. Ensure that the IPsec NATT, VXLAN, and metrics ports are open.

2. Customize and apply YAML content that is similar to the following example:

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>
spec: {}
```

Replace `managed-cluster-namespace` with the namespace of your managed cluster.

**Note:** The name of the `SubmarinerConfig` must be `submariner`, as shown in the example.

This configuration uses the default network address translation - traversal (NATT) port (4500/UDP) for your Submariner and one worker node is labeled as the Submariner gateway on your vSphere cluster.

Submariner uses IP security (IPsec) to establish the secure tunnels between the clusters on the gateway nodes. You can either use the default IPsec NATT port, or you can specify a different port that you configured. When you run this procedure without specifying an IPsec NATT port of 4500/UDP is automatically used for the communication.

### 1.4.2.1.4. Preparing bare metal for Submariner

To prepare bare metal clusters for deploying Submariner, complete the following steps:

1. Ensure that the IPsec NATT, VXLAN, and metrics ports are open.

2. Customize and apply YAML content that is similar to the following example:

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>
spec: {}
```

Replace `managed-cluster-namespace` with the namespace of your managed cluster.

**Note:** The name of the `SubmarinerConfig` must be `submariner`, as shown in the example.

This configuration uses the default network address translation - traversal (NATT) port (4500/UDP) for your Submariner and one worker node is labeled as the Submariner gateway on your bare metal cluster.
Submariner uses IP security (IPsec) to establish the secure tunnels between the clusters on the gateway nodes. You can either use the default IPsec NATT port, or you can specify a different port that you configured. When you run this procedure without specifying an IPsec NATT port of 4500/UDP is automatically used for the communication.

See Customizing Submariner deployments for information about the customization options.

1.1.4.2.1.5. Preparing Red Hat OpenStack Platform for Submariner

You can use the SubmarinerConfig API to configure the Red Hat OpenStack Platform cluster to integrate with a Submariner deployment. To prepare Red Hat OpenStack Platform clusters for deploying Submariner, complete the following steps:

1. Create a base 64-encoded file titled clouds.yaml with the authentication information for your Red Hat OpenStack Platform environment. The file should resemble the following example:

   ```yaml
   clouds:
   openstack:
   auth:
     auth_url: https://rhos-d.infra.prod.upshift.rdu2.redhat.com:13000
     application_credential_id:
     application_credential_secret:
     region_name: "regionOne"
     interface: "public"
     identity_api_version: 3
     auth_type: "v3applicationcredential"
   
   Replace managed-cluster-name with the name of your managed cluster. The value of managed-cluster-name-rhos-creds is your Red Hat OpenStack Platform credential secret name, which you can find in the cluster namespace of your hub cluster.

   Replace managed-cluster-namespace with the namespace of your managed cluster.

   Replace clouds.yaml with the path to your encoded Red Hat OpenStack Platform clouds.yaml: $(base64 -w0) file.

   Replace rhos-cloud-name with your encoded Red Hat OpenStack Platform cloud name <cloud-name>: $base64 -w0

   b. Run the following command to apply the file:
3. If you created the managed cluster with Red Hat Advanced Cluster Management, or created the secret in the previous step, prepare the cluster.

a. Create a file named `submar_addon.yaml` with content that is similar to the following example:

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>
spec:
  credentialsSecret:
    name: <managed-cluster-name>-rhos-creds
```

Replace `managed-cluster-namespace` with the namespace of your managed cluster.

Replace `managed-cluster-name` with the name of your managed cluster. The value of `managed-cluster-name-rhos-creds` is your Red Hat OpenStack Platform credential secret name, which you can find in the cluster namespace of your hub cluster.

**Note:** The name of the `SubmarinerConfig` custom resource must be `submariner`, as shown in the example.

b. Run the following command to apply the file:

```shell
oc apply -f submar_addon.yaml
```

This configuration automatically opens the Submariner required ports: network address translation - traversal (NATT) port (4500/UDP), virtual extensible LAN (VXLAN) port (4800/UCP), and Submariner metrics port (8080/TCP) on your RHOS instance. It also labels one worker node as the Submariner gateway and enables the public IP address of this node in your Red Hat OpenStack Platform cluster.

If you want to customize the Network Address Translation-Traversal (NATT) port, number of gateway nodes, or instance type of your gateway nodes for your deployment, see [Customizing Submariner deployments](#) for the required steps.

### 1.1.4.2.2. Deploy Submariner with the ManagedClusterAddOn API

To deploy Submariner by using the ManagedClusterAddOn API, complete the following steps:

1. Create a ManagedClusterSet resource on the hub cluster by using the instructions provided in the [Creating and managing ManagedClusterSets](#) topic of the [Managing your clusters](#) documentation. Your entry for the ManagedClusterSet should resemble the following content:

```yaml
apiVersion: cluster.open-cluster-management.io/v1beta1
kind: ManagedClusterSet
metadata:
  name: <managed-cluster-set-name>
```

Replace `managed-cluster-set-name` with a name for the ManagedClusterSet that you are creating.
Note: The maximum length of the name of the Kubernetes namespace is 63 characters, so the maximum length of the `<managed-cluster-set-name>` is 56 characters. If the length of `<managed-cluster-set-name>` exceeds 56, the `<managed-cluster-set-name>` is truncated from the head.

After the ManagedClusterSet is created, the submariner-addon creates a namespace called `<managed-cluster-set-name>-broker` and deploys the Submariner broker to it.

2. Create the Broker configuration on the hub cluster in the `<managed-cluster-set-name>-broker` namespace by customizing and applying YAML content that is similar to the following example:

```yaml
apiVersion: submariner.io/v1alpha1
kind: Broker
metadata:
  name: submariner-broker
  namespace: `<managed-cluster-set-name>-broker`
spec:
  globalnetEnabled: false
```

Replace `<managed-cluster-set-name>` with the name of the managed cluster.

Set the the value of `globalnetEnabled` to `true` if you want to enable Submariner Globalnet in the ManagedClusterSet.

3. Add one managed cluster to the ManagedClusterSet by entering the following command:

```bash
oc label managedclusters `<managed-cluster-name>` "cluster.open-cluster-management.io/clusterset=<managed-cluster-set-name>" --overwrite
```

Replace `<managed-cluster-name>` with the name of the managed cluster that you want to add to the ManagedClusterSet.

Replace `<managed-cluster-set-name>` with the name of the ManagedClusterSet to which you want to add the managed cluster.

4. Deploy Submariner on the managed cluster by customizing and applying YAML content that is similar to the following example:

```yaml
apiVersion: addon.open-cluster-management.io/v1alpha1
kind: ManagedClusterAddOn
metadata:
  name: submariner
  namespace: `<managed-cluster-name>`
spec:
  installNamespace: submariner-operator
```

Replace `<managed-cluster-name>` with the name of the managed cluster that you want to use with Submariner.

The `installNamespace` field in the spec of the ManagedClusterAddOn is the namespace on the managed cluster where it installs Submariner. Currently, Submariner must be installed in the `submariner-operator` namespace.
After the ManagedClusterAddOn is created, the submariner-addon deploys Submariner to the submariner-operator namespace on the managed cluster. You can view the deployment status of Submariner from the status of this ManagedClusterAddOn.

Note: The name of ManagedClusterAddOn must be submariner.

5. Repeat steps three and four for all of the managed clusters that you want to enable Submariner on.

6. After Submariner is deployed on the managed cluster, you can verify the Submariner deployment status by checking the status of submariner ManagedClusterAddOn by entering the following command:

   oc -n <managed-cluster-name> get managedclusteringaddons submariner -oyaml

Replace managed-cluster-name with the name of the managed cluster.

In the status of the Submariner ManagedClusterAddOn, three conditions indicate the deployment status of Submariner:

- **SubmarinerGatewayNodesLabeled** condition indicates whether there are labeled Submariner gateway nodes on the managed cluster.
- **SubmarinerAgentDegraded** condition indicates whether the Submariner is successfully deployed on the managed cluster.
- **SubmarinerConnectionDegraded** condition indicates how many connections are established on the managed cluster with Submariner.

1.1.4.2.3. Customizing Submariner deployments

You can customize some of the settings of your Submariner deployments, including your Network Address Translation-Traversal (NATT) port, number of gateway nodes, and instance type of your gateway nodes. These customizations are consistent across all of the providers.

1.1.4.2.3.1. NATT port

If you want to customize your NATT port, customize and apply the following YAML content for your provider environment:

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>
spec:
  credentialsSecret:
    name: <managed-cluster-name>-<provider>-creds
  IPSecNATTPort: <NATTPort>

- Replace managed-cluster-namespace with the namespace of your managed cluster.
- Replace managed-cluster-name with the name of your managed cluster
```

AWS: Replace provider with aws. The value of <managed-cluster-name>-aws-creds is

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>
spec:
  credentialsSecret:
    name: <managed-cluster-name>-aws-creds
  IPSecNATTPort: <NATTPort>

- Replace managed-cluster-namespace with the namespace of your managed cluster.
- Replace managed-cluster-name with the name of your managed cluster
```
- AWS: Replace `provider` with `aws`. The value of `<managed-cluster-name>-aws-creds` is your AWS credential secret name, which you can find in the cluster namespace of your hub cluster.

- GCP: Replace `provider` with `gcp`. The value of `<managed-cluster-name>-gcp-creds` is your Google Cloud Platform credential secret name, which you can find in the cluster namespace of your hub cluster.

  - Replace `managed-cluster-namespace` with the namespace of your managed cluster.
  
  - Replace `managed-cluster-name` with the name of your managed cluster. The value of `managed-cluster-name-gcp-creds` is your Google Cloud Platform credential secret name, which you can find in the cluster namespace of your hub cluster.

  - Replace `NATTPort` with the NATT port that you want to use.

Note: The name of the `SubmarinerConfig` must be `submariner`, as shown in the example.

To customize your NATT port in the VMware vSphere environment, customize and apply the following YAML content:

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>

spec:
  IPSecNATTPort: <NATTPort>
```

  - Replace `managed-cluster-namespace` with the namespace of your managed cluster.

  - Replace `NATTPort` with the NATT port that you want to use.

Note: The name of the `SubmarinerConfig` must be `submariner`, as shown in the example.

1.1.4.2.3.2. Number of gateway nodes

If you want to customize the number of your gateway nodes, customize and apply YAML content that is similar to the following example:

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>

spec:
  credentialsSecret:
    name: <managed-cluster-name>-<provider>-creds
  gatewayConfig:
    gateways: <gateways>
```

  - Replace `managed-cluster-namespace` with the namespace of your managed cluster.

  - Replace `managed-cluster-name` with the name of your managed cluster.
● AWS: Replace provider with aws. The value of managed-cluster-name-aws-creds is your AWS credential secret name, which you can find in the cluster namespace of your hub cluster.

● GCP: Replace provider with gcp. The value of <managed-cluster-name>-gcp-creds is your Google Cloud Platform credential secret name, which you can find in the cluster namespace of your hub cluster.

● Replace gateways with the number of gateways that you want to use. If the value is greater than 1, the Submariner gateway automatically enables high availability.

**Note:** The name of the SubmarinerConfig must be submariner, as shown in the example.

If you want to customize the number of your gateway nodes in the VMware vSphere environment, customize and apply YAML content that is similar to the following example:

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>
spec:
gatewayConfig:
gateways: 3

spec:
  credentialsSecret:
    name: <managed-cluster-name>-<provider>-creds

spec:
gatewayConfig:
instanceType: <instance-type>
```

● Replace managed-cluster-namespace with the namespace of your managed cluster.

● Replace gateways with the number of gateways that you want to use. If the value is greater than 1, the Submariner gateway automatically enables high availability.

### 1.1.4.2.3.3. Instance types of gateway nodes

If you want to customize the instance type of your gateway node, customize and apply YAML content that is similar to the following example:

```yaml
apiVersion: submarineraddon.open-cluster-management.io/v1alpha1
kind: SubmarinerConfig
metadata:
  name: submariner
  namespace: <managed-cluster-namespace>
spec:
credentialsSecret:
  name: <managed-cluster-name>-<provider>-creds
spec:
gatewayConfig:
  instanceType: <instance-type>
```

● Replace managed-cluster-namespace with the namespace of your managed cluster.

● Replace managed-cluster-name with the name of your managed cluster.

  ● AWS: Replace provider with aws. The value of managed-cluster-name-aws-creds is your AWS credential secret name, which you can find in the cluster namespace of your hub cluster.
GCP: Replace **provider** with `gcp`. The value of `<managed-cluster-name>-gcp-creds` is your Google Cloud Platform credential secret name, which you can find in the cluster namespace of your hub cluster.

- Replace **instance-type** with the AWS instance type that you want to use.

**Note:** The name of the SubmarinerConfig must be `submariner`, as shown in the example.

1.1.4.3. Managing service discovery for Submariner

After Submariner is deployed into the same environment as your managed clusters, the routes are configured for secure IP routing between the pod and services across the clusters in the managed cluster set.

1.1.4.3.1. Enabling service discovery for Submariner

To make a service from a cluster visible and discoverable to other clusters in the managed cluster set, you must create a **ServiceExport** object. After a service is exported with a **ServiceExport** object, you can access the service by the following format: `<service>.<namespace>.svc.clusterset.local`. If multiple clusters export a service with the same name, and from the same namespace, they are recognized by other clusters as a single logical service.

This example uses the nginx service in the default namespace, but you can discover any Kubernetes ClusterIP service or headless service:

1. Apply an instance of the nginx service on a managed cluster that is in the ManagedClusterSet by entering the following commands:

   ```
   oc -n default create deployment nginx --image=nginxinc/nginx-unprivileged:stable-alpine
   oc -n default expose deployment nginx --port=8080
   ```

2. Export the service by creating a **ServiceExport** entry by entering a command with the subctl tool that is similar to the following command:

   ```
   subctl export service --namespace <service-namespace> <service-name>
   ```

Replace **service-namespace** with the name of the namespace where the service is located. In this example, it is default.

Replace **service-name** with the name of the service that you are exporting. In this example, it is nginx.

See export in the Submariner documentation for more information about other available flags.

3. Run the following command from a different managed cluster to confirm that it can access the nginx service:

   ```
   oc -n default run --generator=run-pod/v1 tmp-shell --rm -i --tty --image quay.io/submariner/nettest -- /bin/bash curl nginx.default.svc.clusterset.local:8080
   ```

The nginx service discovery is now configured for Submariner.

1.1.4.3.2. Disabling service discovery for Submariner
To disable a service from being exported to other clusters, enter a command similar to the following example for `nginx`:

```
subctl unexport service --namespace <service-namespace> <service-name>
```

Replace `service-namespace` with the name of the namespace where the service is located.

Replace `service-name` with the name of the service that you are exporting.

See `unexport` in the Submariner documentation for more information about other available flags.

The service is no longer available for discovery by clusters.

### 1.1.4.4. Uninstalling Submariner

You can uninstall the Submariner components from your clusters using the Red Hat Advanced Cluster Management for Kubernetes console or the command-line. For Submariner versions earlier than 0.12, additional steps are needed to completely remove all data plane components.

#### 1.1.4.4.1. Console method

To uninstall Submariner from a cluster by using the Red Hat Advanced Cluster Management console, complete the following steps:

1. From the Red Hat Advanced Cluster Management console navigation, select **Infrastructure > Clusters**, and select the **Cluster sets** tab.

2. Select the cluster set that contains the clusters from which you want to remove the Submariner components.

3. Select the **Submariner Add-ons** tab to view the clusters in the cluster set that have Submariner deployed.

4. In the **Actions** menu for the cluster that you want to uninstall Submariner, select **Uninstall Add-on**.

5. Repeat those steps for other clusters from which you are removing Submariner.

   **Tip:** You can remove the Submariner add-on from multiple clusters in the same cluster set by selecting multiple clusters and clicking **Actions**. Select **Uninstall Submariner add-ons**.

If the version of Submariner that you are removing is earlier than version 0.12, continue with [Manual removal steps for early versions of Submariner](#). If the Submariner version is 0.12, or later, Submariner is removed.

**Important:** Verify that all of the cloud resources are removed from the cloud provider to avoid additional charges by your cloud provider. See [Verifying Submariner resource removal](#) for more information.

#### 1.1.4.4.2. Command-line method

To uninstall Submariner by using the command line, complete the following steps:

1. Locate the clusters that contain the Submariner add-on by entering the following command:

   ```
   oc get resource submariner-addon -n open-cluster-management
   ```

2. Run a command similar to the following example to uninstall Submariner from the cluster:
oc delete resource submariner-addon -n <CLUSTER_NAME>

Replace **CLUSTER_NAME** with the name of the cluster.

3. Confirm that you want to remove all of the Submariner components from the cluster.

4. Repeat the steps for each cluster to remove Submariner.

If the version of Submariner that you are removing is earlier than version 0.12, continue with Manual removal steps for early versions of Submariner. If the Submariner version is 0.12, or later, Submariner is removed.

**Important:** Verify that all of the cloud resources are removed from the cloud provider to avoid additional charges by your cloud provider. See Verifying Submariner resource removal for more information.

1.1.4.4.3. Manual removal steps for early versions of Submariner

When uninstalling versions of Submariner that are earlier than version 0.12, complete steps 5–8 in the Manual Uninstall section in the Submariner documentation.

After completing those steps, your Submariner components are removed from the cluster.

**Important:** Verify that all of the cloud resources are removed from the cloud provider to avoid additional charges by your cloud provider. See Verifying Submariner resource removal for more information.

1.1.4.4.4. Verifying Submariner resource removal

After uninstalling Submariner, verify that all of the Submariner resources are removed from your clusters. If they remain on your clusters, some resources continue to accrue charges from infrastructure providers. Ensure that you have no additional Submariner resources on your cluster by completing the following steps:

1. Run the following command to list any Submariner resources that remain on the cluster:

   oc get cluster <CLUSTER_NAME> grep submariner

   Replace **CLUSTER_NAME** with the name of your cluster.

2. Remove any resources on the list by entering the following command:

   oc delete resource <RESOURCE_NAME> cluster <CLUSTER_NAME>

   Replace **RESOURCE_NAME** with the name of the Submariner resource that you want to remove.

3. Repeat steps 1-2 for each of the clusters until your search does not identify any resources.

The Submariner resources are removed from your cluster.

1.2. VOLSYNC PERSISTENT VOLUME REPLICATION SERVICE (TECHNOLOGY PREVIEW)

VolSync is a Kubernetes operator that enables asynchronous replication of persistent volumes within a cluster, or across clusters with storage types that are not otherwise compatible for replication. It uses
the Container Storage Interface (CSI) to overcome the compatibility limitation. After deploying the VolSync operator in your environment, you can leverage it to create and maintain copies of your persistent data. VolSync can only replicate persistent volume claims on Red Hat OpenShift Container Platform clusters that are at version 4.8, or later.

- Replicating persistent volumes with VolSync
- Converting a replicated image to a usable persistent volume claim
- Scheduling your synchronization

1.2.1. Replicating persistent volumes with VolSync

You can use three methods to replicate persistent volumes with VolSync, which depend on the number of synchronization locations that you have. The Rsync method is used for this example. For information about the other methods and more information about Rsync, see Usage in the VolSync documentation.

Rsync replication is a commonly used, one-to-one replication of persistent volumes. This is used for replicating data to a remote site.

VolSync does not create its own namespace, so it is in the same namespace as other OpenShift Container Platform all-namespace operators. Any changes that you make to the operator settings for VolSync also affects the other operators in the same namespace, such as if you change to manual approval for channel updates.

1.2.1.1. Prerequisites

Before installing VolSync on your clusters, you must have the following requirements:

- A configured Red Hat OpenShift Container Platform environment running a Red Hat Advanced Cluster Management version 2.4, or later, hub cluster
- At least two configured clusters that are managed by the same Red Hat Advanced Cluster Management hub cluster
- Network connectivity between the clusters that you are configuring with VolSync; If the clusters are not on the same network, you can configure the Submariner multicluster networking and service discovery and use the ClusterIP value for ServiceType to network the clusters, or use a load balancer with the LoadBalancer value for ServiceType.
- The storage driver that you use for your source persistent volume must be CSI-compatible and able to support snapshots.

1.2.1.2. Installing VolSync on the managed clusters

To enable VolSync to replicate the persistent volume claim on one cluster to the persistent volume claim of another cluster, you must install VolSync on both the source and the target managed clusters.

You can use either of two methods to install VolSync on two clusters in your environment. You can either add a label to each of the managed clusters in the hub cluster, or you can manually create and apply a ManagedClusterAddOn, as they are described in the following sections:

1.2.1.2.1. Installing VolSync using labels

To install VolSync on the managed cluster by adding a label.
Complete the following steps from the Red Hat Advanced Cluster Management console:

1. Select one of the managed clusters from the **Clusters** page in the hub cluster console to view its details.

2. In the **Labels** field, add the following label:

   ```
   addons.open-cluster-management.io/volsync=true
   ```

   The VolSync service pod is installed on the managed cluster.

3. Add the same label to the other managed cluster.

4. Run the following command on each managed cluster to confirm that the VolSync operator is installed:

   ```
   oc get csv -n openshift-operators
   ```

   There is an operator listed for VolSync when it is installed.

Complete the following steps from the command-line interface:

1. Start a command-line session on the hub cluster.

2. Enter the following command to add the label to the first cluster:

   ```
   oc label managedcluster <managed-cluster-1> "addons.open-cluster-management.io/volsync"="true"
   ```

   Replace **managed-cluster-1** with the name of one of your managed clusters.

3. Enter the following command to add the label to the second cluster:

   ```
   oc label managedcluster <managed-cluster-2> "addons.open-cluster-management.io/volsync"="true"
   ```

   Replace **managed-cluster-2** with the name of your other managed cluster.

   A **ManagedClusterAddOn** resource should be created automatically on your hub cluster in the namespace of each corresponding managed cluster.

### 1.2.1.2.2 Installing VolSync using a ManagedClusterAddOn

To install VolSync on the managed cluster by adding a **ManagedClusterSetAddOn** manually, complete the following steps:

1. On the hub cluster, create a YAML file called **volsync-mcao.yaml** that contains content that is similar to the following example:

   ```yaml
   apiVersion: addon.open-cluster-management.io/v1alpha1
   kind: ManagedClusterAddOn
   metadata:
     name: volsync
     namespace: <managed-cluster-1-namespace>
   spec: {}
   ```
Replace `managed-cluster-1-namespace` with the namespace of one of your managed clusters. This namespace is the same as the name of the managed cluster.

**Note:** The name must be `volsync`.

2. Apply the file to your configuration by entering a command similar to the following example:

   ```bash
   oc apply -f volsync-mcao.yaml
   ```

3. Repeat the procedure for the other managed cluster. A `ManagedClusterAddOn` resource should be created automatically on your hub cluster in the namespace of each corresponding managed cluster.

### 1.2.1.3. Configuring Rsync replication across managed clusters

For Rsync-based replication, configure custom resources on the source and destination clusters. The custom resources use the `address` value to connect the source to the destination, and the `sshKeys` to ensure that the transferred data is secure.

**Note:** You must copy the values for `address` and `sshKeys` from the destination to the source, so configure the destination before you configure the source.

This example provides the steps to configure an Rsync replication from a persistent volume claim on the source cluster in the `source-ns` namespace to a persistent volume claim on a destination cluster in the `destination-ns` namespace. You can replace those values with other values, if necessary.

1. Configure your destination cluster.
   a. Run the following command on the destination cluster to create the namespace:

      ```bash
      $ kubectl create ns <destination-ns>
      ```

      Replace `destination-ns` with a name for the namespace that will contain your destination persistent volume claim.

   b. Copy the following YAML content to create a new file called `replication_destination.yaml`:

      ```yaml
      ---
      apiVersion: volsync.backube/v1alpha1
      kind: ReplicationDestination
      metadata:
        name: <destination>
        namespace: <destination-ns>
      spec:
        rsync:
          serviceType: LoadBalancer
          copyMethod: Snapshot
          capacity: 2Gi
          accessModes: [ReadWriteOnce]
          storageClassName: gp2-csi
          volumeSnapshotClassName: csi-aws-vsc
      ```

      **Note:** The `capacity` value should match the capacity of the persistent volume claim that is being replicated.
Replace **destination** with the name of your replication destination CR.

Replace **destination-ns** with the name of the namespace where your destination is located.

For this example, the **ServiceType** value of **LoadBalancer** is used. The load balancer service is created by the source cluster to enable your source managed cluster to transfer information to a different destination managed cluster. You can use **ClusterIP** as the service type if your source and destinations are on the same cluster, or if you have Submariner network service configured. Note the address and the name of the secret to refer to when you configure the source cluster.

The **storageClassName** and **volumeSnapshotClassName** are optional parameters. Specify the values for your environment, particularly if you are using a storage class and volume snapshot class name that are different than the default values for your environment.

c. Run the following command on the destination cluster to create the **replicationdestination** resource:

   ```bash
   $ kubectl create -n <destination-ns> -f replication_destination.yaml
   ```

   Replace **destination-ns** with the name of the namespace where your destination is located.

   After the **replicationdestination** resource is created, following parameters and values are added to the resource:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>.status.rsync.address</td>
<td>IP address of the destination cluster that is used to enable the source and destination clusters to communicate.</td>
</tr>
<tr>
<td>.status.rsync.sshKeys</td>
<td>Name of the SSH key file that enables secure data transfer from the source cluster to the destination cluster.</td>
</tr>
</tbody>
</table>

   d. Run the following command to copy the value of **.status.rsync.address** to use on the source cluster:

   ```bash
   $ ADDRESS=`kubectl get replicationdestination <destination> -n <destination-ns> --template={{.status.rsync.address}}`
   $ echo $ADDRESS
   ```

   Replace **destination** with the name of your replication destination CR.

   Replace **destination-ns** with the name of the namespace where your destination is located.

   The output should appear similar to the following output, which is for an Amazon Web Services environment:

   ```bash
   a831264645yhrjiyer6f9e4a02eb2-5592c0b3d94dd376.elb.us-east-1.amazonaws.com
   ```

e. Run the following command to copy the name of the secret and the contents of the secret that are provided as the value of **.status.rsync.sshKeys**.
$ SSHKEYS=`kubectl get replicationdestination <destination> -n <destination-ns> --template={{.status.rsync.sshKeys}}`
$ echo $SSHKEYS

Replace `destination` with the name of your replication destination CR.

Replace `destination-ns` with the name of the namespace where your destination is located.

You will have to enter it on the source cluster when you configure the source. The output should be the name of your SSH keys secret file, which might resemble the following name:

```
volsync-rsync-dst-src-destination-name
```

2. Identify the source persistent volume claim that you want to replicate.
   **Note:** The source persistent volume claim must be on a CSI storage class.

3. Create the **ReplicationSource** items.

   a. Copy the following YAML content to create a new file called `replication_source.yaml` on the source cluster:

   ```yaml
   ---
   apiVersion: volsync.backube/v1alpha1
   kind: ReplicationSource
   metadata:
     name: <source>
     namespace: <source-ns>
   spec:
     sourcePVC: <persistent_volume_claim>
     trigger:
       schedule: "*/3 * * * *"
     rsync:
       sshKeys: <mysshkeys>
       address: <my.host.com>
       copyMethod: Snapshot
       storageClassName: gp2-csi
       volumeSnapshotClassName: gp2-csi
   ```

   Replace `source` with the name for your replication source CR. See step 3-vi of this procedure for instructions on how to replace this automatically.

   Replace `source-ns` with the namespace of the persistent volume claim where your source is located. See step 3-vi of this procedure for instructions on how to replace this automatically.

   Replace `persistent_volume_claim` with the name of your source persistent volume claim.

   Replace `mysshkeys` with the keys that you copied from the `.status.rsync.sshKeys` field of the `ReplicationDestination` when you configured it.

   Replace `my.host.com` with the host address that you copied from the `.status.rsync.address` field of the `ReplicationDestination` when you configured it.

   If your storage driver supports cloning, using **Clone** as the value for `copyMethod` might be a more streamlined process for the replication.
**StorageClassName** and **volumeSnapshotClassName** are optional parameters. If you are using a storage class and volume snapshot class name that are different than the defaults for your environment, specify those values.

You can now set up the synchronization method of the persistent volume.

b. Copy the SSH secret from the destination cluster by entering the following command against the destination cluster:

```
$ kubectl get secret -n <destination-ns> $SSHKEYS -o yaml > /tmp/secret.yaml
```

Replace `destination-ns` with the namespace of the persistent volume claim where your destination is located.

c. Open the secret file in the **vi** editor by entering the following command:

```
$ vi /tmp/secret.yaml
```

d. In the open secret file on the destination cluster, make the following changes:

- Change the namespace to the namespace of your source cluster. For this example, it is `source-ns`.

- Remove the owner references (`.metadata.ownerReferences`).

e. On the source cluster, create the secret file by entering the following command on the source cluster:

```
$ kubectl create -f /tmp/secret.yaml
```

f. On the source cluster, modify the **replication_source.yaml** file by replacing the value of the **address** and **sshKeys** in the **ReplicationSource** object with the values that you noted from the destination cluster by entering the following commands:

```
$ sed -i "s/<my.host.com>/$ADDRESS/g" replication_source.yaml
$ sed -i "s/<mysshkeys>/$SSHKEYS/g" replication_source.yaml
$ kubectl create -n <source> -f replication_source.yaml
```

Replace `my.host.com` with the host address that you copied from the `.status.rsync.address` field of the **ReplicationDestination** when you configured it.

Replace `mysshkeys` with the keys that you copied from the `.status.rsync.sshKeys` field of the **ReplicationDestination** when you configured it.

Replace `source` with the name of the persistent volume claim where your source is located.

**Note:** You must create the file in the same namespace as the persistent volume claim that you want to replicate.

g. Verify that the replication completed by running the following command on the **ReplicationSource** object:

```
$ kubectl describe ReplicationSource -n <source-ns> <source>
```
Replace **source-ns** with the namespace of the persistent volume claim where your source is located.

Replace **source** with the name of your replication source CR.

If the replication was successful, the output should be similar to the following example:

```
Status: 
Conditions: 
  Last Transition Time: 2021-10-14T20:48:00Z 
  Message: Synchronization in-progress 
  Reason: SyncInProgress 
  Status: True 
  Type: Synchronizing 
  Last Transition Time: 2021-10-14T20:41:41Z 
  Message: Reconcile complete 
  Reason: ReconcileComplete 
  Status: True 
  Type: Reconciled 
  Last Sync Duration: 5m20.764642395s 
  Last Sync Time: 2021-10-14T20:47:01Z 
  Next Sync Time: 2021-10-14T20:48:00Z 
```

If the **Last Sync Time** has no time listed, then the replication is not complete.

You have a replica of your original persistent volume claim.

### 1.2.2. Converting a replicated image to a usable persistent volume claim

You might need to use the replicated image to recover data, or create a new instance of a persistent volume claim. The copy of the image must be converted to a persistent volume claim before it can be used. To convert a replicated image to a persistent volume claim, complete the following steps:

1. When the replication is complete, identify the latest snapshot from the **ReplicationDestination** object by entering the following command:

   ```
   $ kubectl get replicationdestination <destination> -n <destination-ns> --template={{.status.latestImage.name}}
   ```

   Note the value of the latest snapshot for when you create your persistent volume claim.

   Replace **destination** with the name of your replication destination.

   Replace **destination-ns** with the namespace of your destination.

2. Create a **pvc.yaml** file that resembles the following example:

   ```yaml
   apiVersion: v1
   kind: PersistentVolumeClaim
   metadata:
     name: <pvc-name>
     namespace: <destination-ns>
   spec:
     accessModes:
       - ReadWriteOnce
     dataSource:
   ```
kind: VolumeSnapshot
apiGroup: snapshot.storage.k8s.io
name: <snapshot_to_replace>
resources:
requests:
storage: 2Gi

Replace **pvc-name** with a name for your new persistent volume claim.

Replace **destination-ns** with the namespace where the persistent volume claim is located.

Replace **snapshot_to_replace** with the **VolumeSnapshot** name that you found in the previous step.

**Best practice:** You can update **resources.requests.storage** with a different value when the value is at least the same size as the initial source persistent volume claim.

3. Validate that your persistent volume claim is running in the environment by entering the following command:

```
$ kubectl get pvc -n <destination-ns>
```

Your original backup image is running as the main persistent volume claim.

### 1.2.3. Scheduling your synchronization

Select from three options when determining how you start your replications: always running, on a schedule, or manually. Scheduling your replications is an option that is often selected.

The **Schedule** option runs replications at scheduled times. A schedule is defined by a **crontab** spec, so the schedule can be configured as intervals of time or as specific times. The order of the schedule values are:

"minute (0-59) hour (0-23) day-of-month (1-31) month (1-12) day-of-week (0-6)"

The replication starts when the scheduled time occurs. Your setting for this replication option might resemble the following content:

```
spec:
  trigger:
    schedule: "*/6 * * * *"
```

After enabling one of these methods, your synchronization schedule runs according to the method that you configured.

See the **VolSync** documentation for additional information and options.

### 1.3. ENABLING KLUSTERLET ADD-ONS ON CLUSTERS FROM THE MULTICLUSTER ENGINE FOR KUBERNETES OPERATOR

After you install Red Hat Advanced Cluster Management for Kubernetes and then create or import clusters with the multicluster engine for Kubernetes operator, you can enable the klusterlet add-ons for those managed clusters.
The klusterlet add-ons are not enabled by default if you created or imported clusters with the multicluster engine for Kubernetes operator. Additionally, klusterlet add-ons are not enabled by default after Red Hat Advanced Cluster Management is installed.

See the following available klusterlet add-ons:

- application-manager
- cert-policy-controller
- config-policy-controller
- iam-policy-controller
- governance-policy-framework
- search-collector

Complete the following steps to enable the klusterlet add-ons for the managed clusters after the Red Hat Advanced Cluster Management is installed:

1. Create a YAML file that is similar to the following `KlusterletAddonConfig`, with the `spec` value that represents the add-ons:
   
   ```yaml
   apiVersion: agent.open-cluster-management.io/v1
   kind: KlusterletAddonConfig
   metadata:
     name: <cluster_name>
     namespace: <cluster_name>
   spec:
     applicationManager:
       enabled: true
     certPolicyController:
       enabled: true
     iamPolicyController:
       enabled: true
     policyController:
       enabled: true
     searchCollector:
       enabled: true
   
   Note: The `policy-controller` add-on is divided into two add-ons: The `governance-policy-framework` and the `config-policy-controller`. As a result, the `policyController` controls the `governance-policy-framework` and the `config-policy-controller managedClusterAddons`.
   ```

2. Save the file as `klusterlet-addon-config.yaml`.

3. Apply the YAML by running the following command on the hub cluster:
   ```bash
   oc apply -f klusterlet-addon-config.yaml
   ```

4. To verify whether the enabled `managedClusterAddons` are created after the `KlusterletAddonConfig` is created, run the following command:
   ```bash
   oc get managedclusteraddons -n <cluster namespace>
   ```
