Abstract

This guide describes how to install and configure the client, run hands-on examples, and use your client with other AMQ components.

CHAPTER 1. OVERVIEW

AMQ Python is a Python library for writing messaging applications. It allows you to write client and server applications that send and receive AMQP messages.

AMQ Python is part of AMQ Clients, a suite of messaging libraries supporting multiple languages and platforms. See Introducing Red Hat JBoss AMQ 7 for an overview of the clients and other AMQ components. See AMQ Clients 1.2 Release Notes for information about this release.

AMQ Python is based on the Proton API from Apache Qpid.

1.1. KEY FEATURES

AMQ Python is a flexible and capable messaging API. It enables any application to speak AMQP 1.0.

- An event-driven API that simplifies integration with existing applications
- Access to all the features and capabilities of AMQP 1.0
- SSL/TLS and SASL for secure communication
- Seamless conversion between AMQP and language-native data types
- Heartbeating and automatic reconnect for reliable network connections

1.2. SUPPORTED STANDARDS AND PROTOCOLS

AMQ Python supports the following industry-recognized standards and network protocols.

- Version 1.0 of the Advanced Message Queueing Protocol (AMQP)
- Versions 1.0, 1.1, and 1.2 of the Transport Layer Security (TLS) protocol, the successor to SSL
- Modern TCP with IPv6

1.3. SUPPORTED CONFIGURATIONS

AMQ Python supports the following OS and language versions. See Red Hat JBoss AMQ 7 Supported Configurations for more information.

AMQ Python is supported on Red Hat Enterprise Linux 6 and 7 with Python 2.6 and 2.7.

1.4. TERMS AND CONCEPTS

This section introduces the core API entities and describes how they operate together.

**Table 1.1. API Terms**

<table>
<thead>
<tr>
<th>Entity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Container</td>
<td>A top-level container of connections</td>
</tr>
<tr>
<td>Connection</td>
<td>A channel for communication between two peers on a network</td>
</tr>
</tbody>
</table>
### Entity | Description
--- | ---
Session | A serialized context for producing and consuming messages
Sender | A channel for sending messages to a target
Receiver | A channel for receiving messages from a source
Source | A named point of origin for messages
Target | A named destination for messages
Message | A mutable holder of application content
Delivery | A message transfer

AMQ Python sends and receives *messages*. Messages are transferred between connected peers over *senders* and *receivers*. Senders and receivers are established over *sessions*. Sessions are established over *connections*. Connections are established between two uniquely identified *containers*. Though a connection can have multiple sessions, often this is not needed. The API allows you to ignore sessions unless you require them.

A sending peer creates a sender to send messages. The sender has a *target* that identifies a queue or topic at the remote peer. A receiving peer creates a receiver to receive messages. The receiver has a *source* that identifies a queue or topic at the remote peer.

The sending of a message is called a *delivery*. The message is the content sent, including all metadata such as headers and annotations. The delivery is the protocol exchange associated with the transfer of that content.

To indicate that a delivery is complete, either the sender or the receiver settles it. When the other side learns that it has been settled, it will no longer communicate about that delivery. The receiver can also indicate whether it accepts or rejects the message.

### 1.5. DOCUMENT CONVENTIONS

In this document, *sudo* is used for any command that requires root privileges. You should always exercise caution when using *sudo*, as any changes can affect the entire system.

For more information about using *sudo*, see [The sudo Command](#).
CHAPTER 2. INSTALLATION

This chapter guides you through the steps required to install AMQ Python in your environment.

2.1. PREREQUISITES

To begin installation, use your subscription to access AMQ distribution archives and package repositories.

2.2. INSTALLING ON RED HAT ENTERPRISE LINUX

AMQ Python is distributed as a set of RPM packages for Red Hat Enterprise Linux. Follow these steps to install them.

1. Use the subscription-manager command to subscribe to the required package repositories.

   Red Hat Enterprise Linux 6
   $ sudo subscription-manager repos --enable=a-mq-clients-1-for-rhel-6-server-rpms

   Red Hat Enterprise Linux 7
   $ sudo subscription-manager repos --enable=a-mq-clients-1-for-rhel-7-server-rpms

2. Use the yum command to install the python-qpid-proton and python-qpid-proton-docs packages.

   $ sudo yum install python-qpid-proton python-qpid-proton-docs
CHAPTER 3. GETTING STARTED

This chapter guides you through a simple exercise to help you get started using AMQ Python. Before starting, make sure you have completed the steps in the Chapter 2, Installation chapter for your environment.

3.1. PREPARING THE BROKER

The example programs require a running broker with a queue named examples. Follow these steps to define the queue and start the broker.

1. Install the broker.

2. Create a broker instance. Enable anonymous access.

3. Start the broker instance and check the console for any critical errors logged during startup.

4. Use the artemis queue command to create a queue called examples.

3.2. RUNNING HELLO WORLD

The Hello World example sends a message to the examples queue on the broker and then fetches it back. On success it prints Hello World! to the console.

Using a new terminal window, change directory to the Python examples directory and run the helloworld.py example.

$ cd /usr/share/proton-0.18.0/examples/python/
$ python helloworld.py
Hello World!
CHAPTER 4. EXAMPLES

This chapter demonstrates the use of AMQ Python through example programs. To run them, make sure you have completed the steps in the Chapter 2, Installation chapter for your environment and you have a running and configured broker.

See the Qpid Proton Python examples for more sample programs.

4.1. SENDING MESSAGES

This client program connects to a server using CONNECTION_URL, creates a sender for target ADDRESS, sends a message containing MESSAGE_BODY, closes the connection, and exits.

Example: Sending Messages

```python
from __future__ import print_function
import sys
from proton import Message
from proton.handlers import MessagingHandler
from proton.reactor import Container

class SendHandler(MessagingHandler):
    def __init__(self, conn_url, address, message_body):
        super(SendHandler, self).__init__()

        self.conn_url = conn_url
        self.address = address
        self.message_body = message_body

    def on_start(self, event):
        conn = event.container.connect(self.conn_url)
        event.container.create_sender(conn, self.address)

    def on_link_opened(self, event):
        print("SEND: Opened sender for target address '{0}'".format(event.sender.target.address))

    def on_sendable(self, event):
        message = Message(self.message_body)
        event.sender.send(message)

        print("SEND: Sent message '{0}'".format(message.body))

        event.sender.close()
        event.connection.close()

def main():
    try:
        conn_url, address, message_body = sys.argv[1:4]
    except ValueError:
        sys.exit("Usage: send.py CONNECTION-URL ADDRESS MESSAGE-BODY")

    handler = SendHandler(conn_url, address, message_body)
```
Running the Example
To run the example program, copy it to a local file and invoke it using the `python` command.

```
$ python send.py amqp://localhost queue1 hello
```

4.2. RECEIVING MESSAGES

This client program connects to a server using `CONNECTION_URL`, creates a receiver for source `ADDRESS`, and receives messages until it is terminated or it reaches `COUNT` messages.

Example: Receiving Messages

```python
from __future__ import print_function
import sys
from proton.handlers import MessagingHandler
from proton.reactor import Container

class ReceiveHandler(MessagingHandler):
    def __init__(self, conn_url, address, desired):
        super(ReceiveHandler, self).__init__()

        self.conn_url = conn_url
        self.address = address
        self.desired = desired
        self.received = 0

    def on_start(self, event):
        conn = event.container.connect(self.conn_url)
        event.container.create_receiver(conn, self.address)

    def on_link_opened(self, event):
        print("RECEIVE: Created receiver for source address '{0}'".format(self.address))

    def on_message(self, event):
        message = event.message

        print("RECEIVE: Received message '{0}'".format(message.body))
        self.received += 1

        if self.received == self.desired:
            event.receiver.close()
```
Running the Example
To run the example program, copy it to a local file and invoke it using the python command.

$ python receive.py amqp://localhost queue1
CHAPTER 5. USING THE API

This chapter explains how to use the AMQ Python API to perform common messaging tasks.

5.1. BASIC OPERATION

5.1.1. Handling Messaging Events

AMQ Python is an asynchronous event-driven API. To define how the application handles events, the user implements callback methods on the `MessagingHandler` class. These methods are then called as network activity or timers trigger new events.

Example: Handling Messaging Events

```python
class ExampleHandler(MessagingHandler):
    def on_start(self, event):
        print("The container event loop has started")

    def on_sendable(self, event):
        print("A message can be sent")

    def on_message(self, event):
        print("A message is received")
```

These are only a few common-case events. The full set is documented in the API reference.

5.1.2. Creating a Container

The container is the top-level API object. It is the entry point for creating connections, and it is responsible for running the main event loop. It is often constructed with a global event handler.

Example: Creating a Container

```python
handler = ExampleHandler()
container = Container(handler)
container.run()
```

Setting the Container Identity

Each container instance has a unique identity called the container ID. When AMQ Python makes a connection, it sends the container ID to the remote peer. To set the container ID, pass it to the `Container` constructor.

Example: Setting the Container Identity

```python
container = Container(handler, "job-processor-3")
```

If the user does not set the ID, the library will generate a UUID when the container is constructed.

5.2. NETWORK CONNECTIONS

5.2.1. Connection URLs
Connection URLs encode the information used to establish new connections.

**Connection URL Syntax**

```
scheme://host[::port]
```

- **Scheme** - The connection transport, either `amqp` for unencrypted TCP or `amqps` for TCP with SSL/TLS encryption.
- **Host** - The remote network host. The value can be a hostname or a numeric IP address. IPv6 addresses must be enclosed in square brackets.
- **Port** - The remote network port. This value is optional. The default value is 5672 for the `amqp` scheme and 5671 for the `amqps` scheme.

**Connection URL Examples**

- `amqps://example.com`
- `amqps://example.net:56720`
- `amqp://127.0.0.1`
- `amqp://[::1]:2000`

### 5.2.2. Creating Outgoing Connections

To connect to a remote server, call the `Container.connect()` method with a connection URL. This is typically done inside the `MessagingHandler.on_start()` method.

**Example: Creating Outgoing Connections**

```python
class ExampleHandler(MessagingHandler):
    def on_start(self, event):
        event.container.connect("amqp://example.com")

    def on_connection_opened(self, event):
        print("Connection {0} is open".format(event.connection))
```

See the **Section 5.3, “Security”** section for information about creating secure connections.

### 5.2.3. Configuring Reconnect

Reconnect allows a client to recover from lost connections. It is used to ensure that the components in a distributed system reestablish communication after temporary network or component failures.

AMQ Python enables reconnect by default. If a connection is lost or a connection attempt fails, the client will try again after a brief delay. The delay increases exponentially for each new attempt, up to a default maximum of 10 seconds.

To disable reconnect, set the `reconnect` connection option to `False`.

**Example: Disabling Reconnect**

```python
container.connect("amqp://example.com", reconnect=False)
```
To control the delays between connection attempts, define a class implementing the `reset` and `next` methods and set the `reconnect` connection option to an instance of that class.

**Example: Configuring Reconnect**

```python
class ExampleReconnect(object):
    def init(self):
        self.delay = 0

    def reset(self):
        self.delay = 0

    def next(self):
        if self.delay == 0:
            self.delay = 0.1
        else:
            self.delay = min(10, 2 * self.delay)

        return self.delay

container.connect("amqp://example.com", reconnect=ExampleReconnect())
```

The `next` method returns the next delay in seconds. The `reset` method is called once before the reconnect process begins.

### 5.2.4. Configuring Failover

AMQ Python allows you to configure multiple connection endpoints. If connecting to one fails, the client attempts to connect to the next in the list. If the list is exhausted, the process starts over.

To specify multiple connection endpoints, set the `urls` connection option to a list of connection URLs.

**Example: Configuring Failover**

```python
urls = ["amqp://alpha.example.com", "amqp://beta.example.com"]
container.connect(urls=urls)
```

It is an error to use the `url` and `urls` options at the same time.

### 5.3. SECURITY

#### 5.3.1. Securing Connections with SSL/TLS

AMQ Python uses SSL/TLS to encrypt communication between clients and servers.

To connect to a remote server with SSL/TLS, use a connection URL with the `amqps` scheme.

**Example: Enabling SSL/TLS**

```python
container.connect("amqps://example.com")
```

#### 5.3.2. Connecting with a User and Password
AMQ Python can authenticate connections with a user and password.

To specify the credentials used for authentication, set the `user` and `password` options on the `connect` method.

**Example: Connecting with a User and Password**

```python
container.connect("amqps://example.com", user="alice", password="secret")
```

### 5.3.3. Configuring SASL Authentication

AMQ Python uses the SASL protocol to perform authentication. SASL can use a number of different authentication mechanisms. When two network peers connect, they exchange their allowed mechanisms, and the strongest mechanism allowed by both is selected.

**NOTE**

The client uses Cyrus SASL to perform authentication. Cyrus SASL uses plug-ins to support specific SASL mechanisms. Before you can use a particular SASL mechanism, the relevant plug-in must be installed. For example, you need the `cyrus-sasl-plain` plug-in in order to use SASL PLAIN authentication.

To see a list of Cyrus SASL plug-ins in Red Hat Enterprise Linux, use the `yum search cyrus-sasl` command. To install a Cyrus SASL plug-in, use the `yum install PLUG-IN` command.

By default, AMQ Python allows all of the mechanisms supported by the local SASL library configuration. To restrict the allowed mechanisms and thereby control what mechanisms can be negotiated, use the `allowed_mechs` connection option. It takes a string containing a space-separated list of mechanism names.

**Example: Configuring SASL Authentication**

```python
container.connect("amqps://example.com", allowed_mechs="ANONYMOUS")
```

This example forces the connection to authenticate using the `ANONYMOUS` mechanism even if the server we connect to offers other options. Valid mechanisms include `ANONYMOUS`, `PLAIN`, `SCRAM-SHA-256`, `SCRAM-SHA-1`, `GSSAPI`, and `EXTERNAL`.

AMQ Python enables SASL by default. To disable it, set the `sasl_enabled` connection option to false.

**Example: Disabling SASL**

```python
event.container.connect("amqps://example.com", sasl_enabled=False)
```

### 5.3.4. Authenticating Using Kerberos

Kerberos is a network protocol for centrally managed authentication based on the exchange of encrypted tickets. See *Using Kerberos* for more information.

1. Configure Kerberos in your operating system. See *Configuring Kerberos* to set up Kerberos on Red Hat Enterprise Linux.
2. Enable the **GSSAPI** SASL mechanism in your client application.

   ```python
   container.connect("amqps://example.com", allowed_mechs="GSSAPI")
   ```

3. Use the **kinit** command to authenticate your user credentials and store the resulting Kerberos ticket.

   ```bash
   $ kinit USER@REALM
   ```

4. Run the client program.

**5.4. MORE INFORMATION**

For more information, see the API reference.
CHAPTER 6. INTEROPERABILITY

This chapter discusses how to use AMQ Python in combination with other AMQ components. For an overview of the compatibility of AMQ components, see the product introduction.

6.1. INTEROPERATING WITH OTHER AMQP CLIENTS

AMQP messages are composed using the AMQP type system. This common format is one of the reasons AMQP clients in different languages are able to interoperate with each other.

When sending messages, AMQ Python automatically converts language-native types to AMQP-encoded data. When receiving messages, the reverse conversion takes place.

NOTE

More information about AMQP types is available at the interactive type reference maintained by the Apache Qpid project.

6.3. CONNECTING TO AMQ BROKER

AMQ Broker is designed to interoperate with AMQP 1.0 clients. Check the following to ensure the broker is configured for AMQP messaging.

- Port 5672 in the network firewall is open.
- The AMQ Broker AMQP acceptor is enabled. See Configuring Network Access.
- The necessary addresses are configured on the broker. See Addresses, Queues, and Topics.
- The broker is configured to permit access from your client, and the client is configured to send the required credentials. See Broker Security.

6.4. CONNECTING TO AMQ INTERCONNECT

AMQ Interconnect works with any AMQP 1.0 client. Check the following to ensure the components are configured correctly.

- Port 5672 in the network firewall is open.
- The router is configured to permit access from your client, and the client is configured to send the required credentials. See Interconnect Security.
APPENDIX A. USING YOUR SUBSCRIPTION

AMQ is provided through a software subscription. To manage your subscriptions, access your account at the Red Hat Customer Portal.

Accessing Your Account

1. Go to access.redhat.com.
2. If you do not already have an account, create one.
3. Log in to your account.

Activating a Subscription

1. Go to access.redhat.com.
2. Navigate to My Subscriptions.
3. Navigate to Activate a subscription and enter your 16-digit activation number.

Downloading Zip and Tar Files
To access zip or tar files, use the customer portal to find the relevant files for download. If you are using RPM packages, this step is not required.

1. Go to access.redhat.com.
2. Navigate to DOWNLOADS.
3. Locate the Red Hat JBoss AMQ entry in the JBOSS INTEGRATION AND AUTOMATION category.
4. Select the desired component type from the drop-down menu on the right side of the entry.
5. Select the Download link for your component.

Registering Your System for Packages
To install RPM packages on Red Hat Enterprise Linux, your system must be registered. If you are using zip or tar files, this step is not required.

1. Go to access.redhat.com.
2. Navigate to Registration Assistant.
3. Select your OS version and continue to the next page.
4. Use the listed command in your system terminal to complete the registration.

To learn more see How to Register and Subscribe a System to the Red Hat Customer Portal.
