Red Hat Ceph Storage 3

Operations Guide

Operational tasks for Red Hat Ceph Storage
Operational tasks for Red Hat Ceph Storage
Abstract

This document describes how to do operational tasks for Red Hat Ceph Storage.
# Table of Contents

## CHAPTER 1. MANAGING THE STORAGE CLUSTER SIZE

1.1. PREREQUISITES ................................................. 3

1.2. CEPH MONITORS

   1.2.1. Preparing a new Ceph Monitor node 3

   1.2.2. Adding a Ceph Monitor using Ansible 4

   1.2.3. Adding a Ceph monitor using the command-line interface 5

   1.2.4. Removing a Ceph Monitor using Ansible 9

   1.2.5. Removing a Ceph Monitor using the command-line interface 10

   1.2.6. Removing a Ceph Monitor from an unhealthy storage cluster 12

1.3. CEPH OSDS

   1.3.1. Ceph OSD node configuration 13

   1.3.2. Adding a Ceph OSD using Ansible with the same disk topology 13

   1.3.3. Adding a Ceph OSD using Ansible with different disk topologies 15

   1.3.4. Adding a Ceph OSD using the command-line interface 17

   1.3.5. Removing a Ceph OSD using Ansible 20

   1.3.6. Removing a Ceph OSD using the command-line interface 21

   1.3.7. Observing the data migration 23

1.4. RECALCULATING THE PLACEMENT GROUPS 24

1.5. ADDITIONAL RESOURCES 24

## CHAPTER 2. HANDLING A DISK FAILURE

2.1. PREREQUISITES ................................................. 26

2.2. DISK FAILURES

   2.2.1. Replacing a failed OSD disk 26

   2.2.2. Replacing an OSD drive while retaining the OSD ID 29

2.3. SIMULATING A DISK FAILURE 30

## CHAPTER 3. HANDLING A NODE FAILURE

3.1. PREREQUISITES ................................................. 32

3.2. CONSIDERATIONS BEFORE ADDING OR REMOVING A NODE 33

3.3. PERFORMANCE CONSIDERATIONS 33

3.4. RECOMMENDATIONS FOR ADDING OR REMOVING NODES 34

3.5. ADDING A CEPH OSD NODE 35

3.6. REMOVING A CEPH OSD NODE 36

3.7. SIMULATING A NODE FAILURE 38

## CHAPTER 4. HANDLING A DATA CENTER FAILURE

................................................................. 40
CHAPTER 1. MANAGING THE STORAGE CLUSTER SIZE

As a storage administrator, you can manage the storage cluster size by adding or removing Ceph Monitors or OSDs as storage capacity expands or shrinks.

NOTE

If you are bootstrapping a storage cluster for the first time, see the Red Hat Ceph Storage 3 Installation Guide for Red Hat Enterprise Linux or Ubuntu.

1.1. PREREQUISITES

- A running Red Hat Ceph Storage cluster.

1.2. CEPH MONITORS

Ceph monitors are light-weight processes that maintain a master copy of the cluster map. All Ceph clients contact a Ceph monitor and retrieve the current copy of the cluster map, enabling clients to bind to a pool and read and write data.

Ceph monitors use a variation of the Paxos protocol to establish consensus about maps and other critical information across the cluster. Due to the nature of Paxos, Ceph requires a majority of monitors running to establish a quorum thus establishing consensus.

IMPORTANT

Red Hat requires at least three monitors on separate hosts to receive support for a production cluster.

Red Hat recommends deploying an odd number of monitors. An odd number of monitors has a higher resiliency to failures than an even number of monitors. For example, to maintain a quorum on a two monitor deployment, Ceph cannot tolerate any failures; with three monitors, one failure; with four monitors, one failure; with five monitors, two failures. This is why an odd number is advisable. Summarizing, Ceph needs a majority of monitors to be running and to be able to communicate with each other, two out of three, three out of four, and so on.

For an initial deployment of a multi-node Ceph storage cluster, Red Hat requires three monitors, increasing the number two at a time if a valid need for more than three monitors exists.

Since monitors are light-weight, it is possible to run them on the same host as OpenStack nodes. However, Red Hat recommends running monitors on separate hosts.

IMPORTANT

Collocating monitors and OSDs on the same node can impair performance and is not supported.

When you remove monitors from a storage cluster, consider that Ceph monitors use the Paxos protocol to establish a consensus about the master storage cluster map. You must have a sufficient number of monitors to establish a quorum.

1.2.1. Preparing a new Ceph Monitor node
When adding a new Ceph Monitor to a storage cluster, deploy them on a separate node. The node hardware must be uniform for all monitor nodes in the storage cluster.

**Prerequisites**

- Network connectivity.
- Having root access to the new node.
- Review the Requirements for Installing Red Hat Ceph Storage chapter in the Installation Guide for Red Hat Enterprise Linux or Ubuntu.

**Procedure**

1. Add the new node to the server rack.

2. Connect the new node to the network.

3. Install either Red Hat Enterprise Linux 7 or Ubuntu 16.04 on the new node.

4. Install NTP and configure a reliable time source:

   ```bash
   [root@monitor ~]# yum install ntp
   ```

5. If using a firewall, open TCP port 6789:

   **Red Hat Enterprise Linux**

   ```bash
   [root@monitor ~]# firewall-cmd --zone=public --add-port=6789/tcp
   [root@monitor ~]# firewall-cmd --zone=public --add-port=6789/tcp --permanent
   ```

   **Ubuntu**

   ```bash
   iptables -I INPUT 1 -i $NIC_NAME -p tcp -s $IP_ADDR/$NETMASK_PREFIX --dport 6789 -j ACCEPT
   ```

   **Ubuntu example**

   ```bash
   [user@monitor ~]$ sudo iptables -I INPUT 1 -i enp6s0 -p tcp -s 192.168.0.11/24 --dport 6789 -j ACCEPT
   ```

**1.2.2. Adding a Ceph Monitor using Ansible**

Red Hat recommends adding two monitors at a time to maintain an odd number of monitors. For example, if you have a three monitors in the storage cluster, Red Hat recommends expanding it to a five monitors.

**Prerequisites**

- A running Red Hat Ceph Storage cluster.
- Having root access to the new nodes.
Procedure

1. Add the new Ceph Monitor nodes to the `/etc/ansible/hosts` Ansible inventory file, under a `[mons]` section:

   **Example**

   ```
   [mons]
   monitor01
   monitor02
   monitor03
   $NEW_MONITOR_NODE_NAME
   $NEW_MONITOR_NODE_NAME
   ```

2. Verify that Ansible can contact the Ceph nodes:

   ```
   # ansible all -m ping
   ```

3. Change directory to the Ansible configuration directory:

   ```
   # cd /usr/share/ceph-ansible
   ```

4. Run the Ansible playbook:

   ```
   $ ansible-playbook site.yml
   ```

   If adding new monitors to a containerized deployment of Ceph, run the `site-docker.yml` playbook:

   ```
   $ ansible-playbook site-docker.yml
   ```

5. After the Ansible playbook is finish, the new monitor nodes will be in the storage cluster.

1.2.3. Adding a Ceph monitor using the command-line interface

Red Hat recommends adding two monitors at a time to maintain an odd number of monitors. For example, if you have a three monitors in the storage cluster, Red Hat recommends expanding it to a five monitors.

**IMPORTANT**

Red Hat recommends only running one Ceph monitor daemon per node.

**Prerequisites**

- A running Red Hat Ceph Storage cluster.
- Having `root` access to the new nodes.

**Procedure**

1. Add the Red Hat Ceph Storage 3 monitor repository.
Red Hat Enterprise Linux

```
[root@monitor ~]# subscription-manager repos --enable=rhel-7-server-rhceph-3-mon-rpms
```

Ubuntu

```
[user@monitor ~]$ sudo bash -c 'umask 0077; echo deb https://$CUSTOMER_NAME:$CUSTOMER_PASSWORD@rhcs.download.redhat.com/3-updates/Tools $(lsb_release -sc) main | tee /etc/apt/sources.list.d/Tools.list'
[user@monitor ~]$ sudo bash -c 'wget -O - https://www.redhat.com/security/fd431d51.txt | apt-key add -'
```

2. Install the `ceph-mon` package on the new Ceph Monitor nodes:

Red Hat Enterprise Linux

```
[root@monitor ~]# yum install ceph-mon
```

Ubuntu

```
[user@monitor ~]$ sudo apt-get install ceph-mon
```

3. To ensure the storage cluster identifies the monitor on start or restart, add the monitor’s IP address to the Ceph configuration file.

To add the new monitors to the `[mon]` or `[global]` section of the Ceph configuration file on an existing monitor node in the storage cluster. The `mon_host` setting, which is a list of DNS-resolvable host names or IP addresses, separated by “,” or “;” or “.”. Optionally, you can also create a specific section in the Ceph configuration file for the new monitor nodes:

**Syntax**

```
[mon]
mon host = $MONITOR_IP:$PORT $MONITOR_IP:$PORT ...
$NEW_MONITOR_IP:$PORT
```

or

```
[mon.$MONITOR_ID]
host = $MONITOR_ID
mon addr = $MONITOR_IP
```

To make the monitors part of the initial quorum group, you must also add the host name to the `mon_initial_members` parameter in the `[global]` section of the Ceph configuration file.

**Example**

```
[global]
mon initial members = node1 node2 node3 node4 node5 ...
[mon]
```
mon host = 192.168.0.1:6789 192.168.0.2:6789 192.168.0.3:6789 192.168.0.4:6789 192.168.0.5:6789
...
[mon.node4]
host = node4
mon addr = 192.168.0.4

[mon.node5]
host = node5
mon addr = 192.168.0.5

**IMPORTANT**

Production storage clusters REQUIRE at least three monitors set in `mon_initial_members` and `mon_host` to ensure high availability. If a storage cluster with only one initial monitor adds two more monitors, but does not add them to `mon_initial_members` and `mon_host`, the failure of the initial monitor will cause the storage cluster to lock up. If the monitors you are adding are replacing monitors that are part of `mon_initial_members` and `mon_host`, the new monitors must be added to `mon_initial_members` and `mon_host` too.

4. Copy updated Ceph configuration file to the Ceph nodes and Ceph clients:

**Syntax**

```
scp /etc/ceph/$CLUSTER_NAME.conf $TARGET_NODE_NAME:/etc/ceph
```

**Example**

```
[root@monitor ~]# scp /etc/ceph/ceph.conf node4:/etc/ceph
```

5. Create the default monitor directory on the new nodes:

**Syntax**

```
mkdir /var/lib/ceph/mon/$CLUSTER_NAME-$MONITOR_ID
```

**Example**

```
[root@monitor ~]# mkdir /var/lib/ceph/mon/ceph-node4
```

6. Create a temporary directory to keep the files needed during this process. This directory should be different from the monitor’s default directory created in the previous step, and can be removed after all the steps are completed:

**Syntax**

```
mkdir $TEMP_DIRECTORY
```

**Example**

```
[root@monitor ~]# mkdir /tmp/ceph
```
7. Copy the admin key from a running monitor node to the new monitor node so that you can run `ceph` commands:

**Syntax**

```bash
scp /etc/ceph/$CLUSTER_NAME.client.admin.keyring
$TARGET_NODE_NAME:/etc/ceph
```

**Example**

```bash
[root@monitor ~]# scp /etc/ceph/ceph.client.admin.keyring
node4:/etc/ceph
```

8. Retrieve the monitor keyring:

**Syntax**

```bash
ceph auth get mon. -o /$TEMP_DIRECTORY/$KEY_FILE_NAME
```

**Example**

```bash
[root@monitor ~]# ceph auth get mon. -o /tmp/ceph/ceph_keyring.out
```

9. Retrieve the monitor map:

**Syntax**

```bash
ceph mon getmap -o /$TEMP_DIRECTORY/$MONITOR_MAP_FILE
```

**Example**

```bash
[root@monitor ~]# ceph mon getmap -o /tmp/ceph/ceph_mon_map.out
```

10. Prepare the monitor's data directory created in the fourth step. You must specify the path to the monitor map so that you can retrieve the information about a quorum of monitors and their `fsid`. You must also specify a path to the monitor keyring:

**Syntax**

```bash
ceph-mon -i $MONITOR_ID --mkfs --monmap
/$TEMP_DIRECTORY/$MONITOR_MAP_FILE --keyring
/$TEMP_DIRECTORY/$KEY_FILE_NAME
```

**Example**

```bash
[root@monitor ~]# ceph-mon -i node4 --mkfs --monmap
/tmp/ceph/ceph_mon_map.out --keyring /tmp/ceph/ceph_keyring.out
```

11. For storage clusters with custom names, add the following line to the `/etc/sysconfig/ceph` file:
Red Hat Enterprise Linux

[root@monitor ~]# echo "CLUSTER=<custom_cluster_name>" >> /etc/sysconfig/ceph

Ubuntu

[user@monitor ~]$ sudo echo "CLUSTER=<custom_cluster_name>" >> /etc/default/ceph

12. Update the owner and group permissions:

**Syntax**

```
chown -R $OWNER:$GROUP $DIRECTORY_PATH
```

**Example**

[root@monitor ~]# chown -R ceph:ceph /var/lib/ceph/mon
[root@monitor ~]# chown -R ceph:ceph /var/log/ceph
[root@monitor ~]# chown -R ceph:ceph /var/run/ceph
[root@monitor ~]# chown -R ceph:ceph /etc/ceph

13. Enable and start the **ceph-mon** process on the new monitor nodes:

**Syntax**

```
systemctl enable ceph-mon.target
systemctl enable ceph-mon@$MONITOR_ID
systemctl start ceph-mon@$MONITOR_ID
```

**Example**

[root@monitor ~]# systemctl enable ceph-mon.target
[root@monitor ~]# systemctl enable ceph-mon@node4
[root@monitor ~]# systemctl start ceph-mon@node4

**Additional Resources**

- See the *Enabling the Red Hat Ceph Storage Repositories* section in the Installation Guide for Red Hat Enterprise Linux or Ubuntu.

### 1.2.4. Removing a Ceph Monitor using Ansible

To remove a Ceph Monitor with Ansible, use the `shrink-mon.yml` playbook.

**Prerequisites**

- An Ansible administration node.
- A running Red Hat Ceph Storage cluster deployed by Ansible.
Procedure

1. Change to the `/usr/share/ceph-ansible/` directory.

   ```bash
   [user@admin ~]$ cd /usr/share/ceph-ansible
   ```

2. Copy the `shrink-mon.yml` playbook from the `infrastructure-playbooks` directory to the current directory.

   ```bash
   [root@admin ceph-ansible]# cp infrastructure-playbooks/shrink-mon.yml .
   ```

3. Use the playbook.

   ```bash
   [user@admin ceph-ansible]$ ansible-playbook shrink-mon.yml -e mon_to_kill=<hostname> -u <ansible-user>
   ```

   Replace:
   
   - `<hostname>` with the short host name of the Monitor node. To remove more Monitors, separate their host names with comma.
   
   - `<ansible-user>` with the name of the Ansible user

   For example, to remove a Monitor that is located on a node with `monitor1` host name:

   ```bash
   [user@admin ceph-ansible]$ ansible-playbook shrink-mon.yml -e mon_to_kill=monitor1 -u user
   ```

4. Remove the Monitor entry from all Ceph configuration files in the cluster.

5. Ensure that the Monitor has been successfully removed.

   ```bash
   [root@monitor ~]# ceph -s
   ```

Additional Resources

- For more information on installing Red Hat Ceph Storage, see the *Installation Guide for Red Hat Enterprise Linux* or *Ubuntu*.

1.2.5. Removing a Ceph Monitor using the command-line interface

Removing a Ceph Monitor involves removing a `ceph-mon` daemon from the storage cluster and updating the storage cluster map.

Prerequisites

- A running Red Hat Ceph Storage cluster.
- Having `root` access to the monitor node.

Procedure
1. Stop the monitor service:

   Syntax
   
   systemctl stop ceph-mon@$MONITOR_ID

   Example
   
   [root@monitor ~]# systemctl stop ceph-mon@node3

2. Remove the monitor from the storage cluster:

   Syntax
   
   ceph mon remove $MONITOR_ID

   Example
   
   [root@monitor ~]# ceph mon remove node3

3. Remove the monitor entry from the Ceph configuration file, by default /etc/ceph/ceph.conf.

4. Redistribute the Ceph configuration file to all remaining Ceph nodes in the storage cluster:

   Syntax
   
   scp /etc/ceph/$CLUSTER_NAME.conf $USER_NAME@$TARGET_NODE_NAME:/etc/ceph/

   Example
   
   [root@monitor ~]# scp /etc/ceph/ceph.conf root@$node1:/etc/ceph/

5. Optionally, you can archive the monitor data:

   Syntax
   
   mv /var/lib/ceph/mon/$CLUSTER_NAME-$MONITOR_ID /var/lib/ceph/mon/removed-$CLUSTER_NAME-$MONITOR_ID

   Example
   
   [root@monitor ~]# mv /var/lib/ceph/mon/ceph-node3 /var/lib/ceph/mon/removed-ceph-node3

6. Optionally, you can delete the monitor data:

   Syntax
   
   rm -r /var/lib/ceph/mon/$CLUSTER_NAME-$MONITOR_ID
Example

[root@monitor ~]# rm -r /var/lib/ceph/mon/ceph-node3

1.2.6. Removing a Ceph Monitor from an unhealthy storage cluster

This procedure removes a ceph-mon daemon from an unhealthy storage cluster. An unhealthy storage cluster that has placement groups persistently not active + clean.

Prerequisites

- A running Red Hat Ceph Storage cluster.
- Having root access to the monitor node.
- At least one running Ceph Monitor node.

Procedure

1. Identify a surviving monitor and log in to that node:

   [root@monitor ~]# ceph mon dump
   [root@monitor ~]# ssh $MONITOR_HOST_NAME

2. Stop the ceph-mon daemon and extract a copy of the monmap file:

   Syntax

   systemctl stop ceph-mon@$MONITOR_ID
   ceph-mon -i $MONITOR_ID --extract-monmap $TEMPORARY_PATH

   Example

   [root@monitor ~]# systemctl stop ceph-mon@node1
   [root@monitor ~]# ceph-mon -i node1 --extract-monmap /tmp/monmap

3. Remove the non-surviving monitor(s):

   Syntax

   monmaptool $TEMPORARY_PATH --rm $MONITOR_ID

   Example

   [root@monitor ~]# monmaptool /tmp/monmap --rm node2

4. Inject the surviving monitor map with the removed monitor(s) into the surviving monitor:

   Syntax

   ceph-mon -i $MONITOR_ID --inject-monmap $TEMPORARY_PATH
1.3. CEPH OSDS

When a Red Hat Ceph Storage cluster is up and running, you can add OSDs to the storage cluster at runtime.

A Ceph OSD generally consists of one `ceph-osd` daemon for one storage drive and its associated journal within a node. If a node has multiple storage drives, then map one `ceph-osd` daemon for each drive.

Red Hat recommends checking the capacity of a cluster regularly to see if it is reaching the upper end of its storage capacity. As a storage cluster reaches its near full ratio, add one or more OSDs to expand the storage cluster’s capacity.

When you want to reduce the size of a Red Hat Ceph Storage cluster or replace the hardware, you can also remove an OSD at runtime. If the node has multiple storage drives, you might also need to remove one of the `ceph-osd` daemon for that drive. Generally, it’s a good idea to check the capacity of the storage cluster to see if you are reaching the upper end of its capacity. Ensure that when you remove an OSD that the storage cluster is not at its near full ratio.

IMPORTANT

Do not let a storage cluster reach the full ratio before adding an OSD. OSD failures that occur after the storage cluster reaches the near full ratio can cause the storage cluster to exceed the full ratio. Ceph blocks write access to protect the data until you resolve the storage capacity issues. Do not remove OSDs without considering the impact on the full ratio first.

1.3.1. Ceph OSD node configuration

Ceph OSDs and their supporting hardware should be similarly configured as a storage strategy for the pool(s) that will use the OSDs. Ceph prefers uniform hardware across pools for a consistent performance profile. For best performance, consider a CRUSH hierarchy with drives of the same type or size. See the Storage Strategies guide for more details.

If you add drives of dissimilar size, then you will need to adjust their weights accordingly. When you add the OSD to the CRUSH map, consider the weight for the new OSD. Hard drive capacity grows approximately 40% per year, so newer OSD nodes might have larger hard drives than older nodes in the storage cluster, that is, they might have a greater weight.

Before doing a new installation, review the Requirements for Installing Red Hat Ceph Storage chapter in the Installation Guide for Red Hat Enterprise Linux or Ubuntu.

1.3.2. Adding a Ceph OSD using Ansible with the same disk topology

For Ceph OSDs with the same disk topology, Ansible will add the same number of OSDs as other OSD nodes using the same device paths specified in the `devices:` section of the `/usr/share/ceph-ansible/group_vars/osds` file.
The new Ceph OSD node(s) will have the same configuration as the rest of the OSDs.

Prerequisites

- A running Red Hat Ceph Storage cluster.
- Review the Requirements for Installing Red Hat Ceph Storage chapter in the Installation Guide for Red Hat Enterprise Linux or Ubuntu.
- Having root access to the new nodes.
- The same number of OSD data drives as other OSD nodes in the storage cluster.

Procedure

1. Add the Ceph OSD node(s) to the /etc/ansible/hosts file, under the [osds] section:

   **Example**

   ```yaml
   [osds]
   ...
   osd06
   $NEW_OSD_NODE_NAME
   ```

2. Verify that Ansible can reach the Ceph nodes:

   ```bash
   [user@admin ~]$ ansible all -m ping
   ```

3. Navigate to the Ansible configuration directory:

   ```bash
   [user@admin ~]$ cd /usr/share/ceph-ansible
   ```

4. Copy the add-osd.yml file to the /usr/share/ceph-ansible/ directory:

   ```bash
   [user@admin ceph-ansible]$ sudo cp infrastructure-playbooks/add-osd.yml .
   ```

5. Run the Ansible playbook for either normal or containerized deployments of Ceph:

   ```bash
   [user@admin ceph-ansible]$ ansible-playbook add-osd.yml
   ```

**NOTE**

When adding an OSD, if the playbook fails with PGs were not reported as active+clean, configure the following variables in the all.yml file to adjust the retries and delay:

```yaml
# OSD handler checks
handler_health_osd_check_retries: 50
handler_health_osd_check_delay: 30
```
For Ceph OSDs with different disk topologies, there are two approaches for adding the new OSD node(s) to an existing storage cluster.

**Prerequisites**

- A running Red Hat Ceph Storage cluster.
- Review the *Requirements for Installing Red Hat Ceph Storage* chapter in the *Installation Guide for Red Hat Enterprise Linux* or *Ubuntu*.
- Having **root** access to the new nodes.

**Procedure**

1. **First Approach**
   a. Add the new Ceph OSD node(s) to the *etc/ansible/hosts* file, under the **[osds]** section:

   ```
   [osds]
   ...
   osd06
   $NEW_OSD_NODE_NAME
   ```

   b. Create a new file for each new Ceph OSD node added to the storage cluster, under the *etc/ansible/host_vars/* directory:

   **Syntax**

   ```
   touch /etc/ansible/host_vars/$NEW_OSD_NODE_NAME
   ```

   **Example**

   ```
   [root@admin ~]# touch /etc/ansible/host_vars/osd07
   ```

   c. Edit the new file, and add the **devices**: and **dedicated_devices**: sections to the file. Under each of these sections add a `-`, space, then the full path to the block device names for this OSD node:

   **Example**

   ```
   devices:
   - /dev/sdc
   - /dev/sdd
   - /dev/sde
   - /dev/sdf
   
   dedicated_devices:
   - /dev/sda
   ```
- /dev/sda
- /dev/sdb
- /dev/sdb

d. Verify that Ansible can reach all the Ceph nodes:

```
[user@admin ~]$ ansible all -m ping
```

e. Change directory to the Ansible configuration directory:

```
[user@admin ~]$ cd /usr/share/ceph-ansible
```

f. Copy the `add-osd.yml` file to the `/usr/share/ceph-ansible/` directory:

```
[user@admin ceph-ansible]$ sudo cp infrastructure-playbooks/add-osd.yml .
```

g. Run the Ansible playbook:

```
[user@admin ceph-ansible]$ ansible-playbook add-osd.yml
```

2. Second Approach

a. Add the new OSD node name to the `/etc/ansible/hosts` file, and use the `devices` and `dedicated_devices` options, specifying the different disk topology:

Example

```
[osds]
...
osd07 devices="["/dev/sdc", "/dev/sdd", "/dev/sde", "/dev/sdf"]"
dedicated_devices="["/dev/sda", "/dev/sda", "/dev/sdb", "/dev/sdb"]"
```

b. Verify that Ansible can reach the all Ceph nodes:

```
[user@admin ~]$ ansible all -m ping
```

c. Change directory to the Ansible configuration directory:

```
[user@admin ~]$ cd /usr/share/ceph-ansible
```

d. Copy the `add-osd.yml` file to the `/usr/share/ceph-ansible/` directory:

```
[user@admin ceph-ansible]$ sudo cp infrastructure-playbooks/add-osd.yml .
```

e. Run the Ansible playbook:

```
[user@admin ceph-ansible]$ ansible-playbook add-osd.yml
```
1.3.4. Adding a Ceph OSD using the command-line interface

Here is the high-level workflow for manually adding an OSD to a Red Hat Ceph Storage:

1. Install the `ceph-osd` package and create a new OSD instance
2. Prepare and mount the OSD data and journal drives
3. Add the new OSD node to the CRUSH map
4. Update the owner and group permissions
5. Enable and start the `ceph-osd` daemon

**IMPORTANT**

The `ceph-disk` command is deprecated. The `ceph-volume` command is now the preferred method for deploying OSDs from the command-line interface. Currently, the `ceph-volume` command only supports the `lvm` plugin. Red Hat will provide examples throughout this guide using both commands as a reference, allowing time for storage administrators to convert any custom scripts that rely on `ceph-disk` to `ceph-volume` instead.

See the Red Hat Ceph Storage Administration Guide, for more information on using the `ceph-volume` command.

**NOTE**

For custom storage cluster names, use the `--cluster $CLUSTER_NAME` option with the `ceph` and `ceph-osd` commands.

**Prerequisites**

- A running Red Hat Ceph Storage cluster.
- Review the Requirements for Installing Red Hat Ceph Storage chapter in the Installation Guide for Red Hat Enterprise Linux or Ubuntu.
- Having `root` access to the new nodes.

**Procedure**

1. Enable the Red Hat Ceph Storage 3 OSD software repository.

**Red Hat Enterprise Linux**

```
[root@osd ~]# subscription-manager repos --enable=rhel-7-server-rhceph-3-osd-rpms
```

**Ubuntu**

```
[user@osd ~]$ sudo bash -c 'umask 0077; echo deb https://customername:customerpasswd@rhcs.download.redhat.com/3-updates/Tools $\{lsb_release -sc\} main | tee
```
1. Download the Red Hat Ceph Storage 3 Operations Guide.

2. Create the /etc/ceph/ directory:

   ```
   # mkdir /etc/ceph
   ```

3. On the new OSD node, copy the Ceph administration keyring and configuration files from one of the Ceph Monitor nodes:

   ```
   scp $USER_NAME@$MONITOR_HOST_NAME:/etc/ceph/$CLUSTER_NAME.client.admin.keyring /etc/ceph
   scp $USER_NAME@$MONITOR_HOST_NAME:/etc/ceph/$CLUSTER_NAME.conf /etc/ceph
   ```

4. Install the ceph-osd package on the new Ceph OSD node:

   ```
   [root@osd ~]# yum install ceph-osd
   [user@osd ~]$ sudo apt-get install ceph-osd
   ```

5. Decide if you want to collocate a journal or use a dedicated journal for the new OSDs.

   **NOTE**

   The --filestore option is required.

   a. For OSDs with a collocated journal:

      ```
      Syntax
      [root@osd ~]# ceph-disk --setuser ceph --setgroup ceph prepare --filestore /dev/$DEVICE_NAME
      ```

      **Examples**

      ```
      [root@osd ~]# ceph-disk --setuser ceph --setgroup ceph prepare --filestore /dev/sda
      ```

   b. For OSDs with a dedicated journal:

      ```
      Syntax
      ```
[root@osd ~]# ceph-disk --setuser ceph --setgroup ceph prepare - -filestore /dev/$DEVICE_NAME /dev/$JOURNAL_DEVICE_NAME

or

[root@osd ~]# ceph-volume lvm prepare --filestore --data /dev/$DEVICE_NAME --journal /dev/$JOURNAL_DEVICE_NAME

Examples

[root@osd ~]# ceph-disk --setuser ceph --setgroup ceph prepare - -filestore /dev/sda /dev/sdb

[root@osd ~]# ceph-volume lvm prepare --filestore --data /dev/vg00/lvol1 --journal /dev/sdb

6. Activate the new OSD:

Syntax

[root@osd ~]# ceph-disk activate /dev/$DEVICE_NAME

or

[root@osd ~]# ceph-volume lvm activate --filestore $OSD_ID $OSD_FSID

Example

[root@osd ~]# ceph-disk activate /dev/sda

[root@osd ~]# ceph-volume lvm activate --filestore 0 6cc43680-4f6e-4feb-92ff-9c7ba204120e

7. Add the OSD to the CRUSH map:

Syntax

ceph osd crush add $OSD_ID $WEIGHT [$BUCKET_TYPE=$BUCKET_NAME ...]

[root@osd ~]# ceph osd crush add 4 1 host=node4

NOTE

If you specify more than one bucket, the command places the OSD into the most specific bucket out of those you specified, and it moves the bucket underneath any other buckets you specified.
NOTE

You can also edit the CRUSH map manually. See the Editing a CRUSH map section in the Storage Strategies guide for Red Hat Ceph Storage 3.

IMPORTANT

If you specify only the root bucket, then the OSD attaches directly to the root, but the CRUSH rules expect OSDs to be inside of the host bucket.

8. Update the owner and group permissions for the newly created directories:

Syntax

```bash
chown -R $OWNER:$GROUP $PATH_TO_DIRECTORY
```

Example

```
[root@osd ~]# chown -R ceph:ceph /var/lib/ceph/osd
[root@osd ~]# chown -R ceph:ceph /var/log/ceph
[root@osd ~]# chown -R ceph:ceph /var/run/ceph
[root@osd ~]# chown -R ceph:ceph /etc/ceph
```

9. If you use clusters with custom names, then add the following line to the appropriate file:

```
[root@osd ~]# echo "CLUSTER=$CLUSTER_NAME" >> /etc/sysconfig/ceph
```

Replace `$CLUSTER_NAME` with the custom cluster name.

10. To ensure that the new OSD is up and ready to receive data, enable and start the OSD service:

Syntax

```
systemctl enable ceph-osd@$OSD_ID
systemctl start ceph-osd@$OSD_ID
```

```
[root@osd ~]# systemctl enable ceph-osd@4
[root@osd ~]# systemctl start ceph-osd@4
```

1.3.5. Removing a Ceph OSD using Ansible

At times, you might need to scale down the capacity of a Red Hat Ceph Storage cluster. To remove an OSD from a Red Hat Ceph Storage cluster using Ansible, run the `shrink-osd.yml` playbook.

IMPORTANT

Removing an OSD from the storage cluster will destroy all the data contained on that OSD.
Prerequisites

- A running Red Hat Ceph Storage deployed by Ansible.
- A running Ansible administration node.

Procedure

1. Change to the `/usr/share/ceph-ansible/` directory.
   
   ```
   [user@admin ~]$ cd /usr/share/ceph-ansible
   ```

2. Copy the `shrink-osd.yml` playbook from the `infrastructure-playbooks` directory to the current directory.
   
   ```
   [root@admin ceph-ansible]$ cp infrastructure-playbooks/shrink-osd.yml .
   ```

3. Run the Ansible playbook:
   
   ```
   ansible-playbook shrink-osd.yml -e osd_to_kill=$ID -u $ANSIBLE_USER
   ```
   
   Replace:
   
   - `$ID` with the ID of the OSD node. To remove more OSDs, separate the OSD IDs with a comma.
   - `$ANSIBLE_USER` with the name of the Ansible user

4. Verify that the OSD has been successfully removed:
   
   ```
   [root@monitor ~]$ ceph osd tree
   ```

Additional Resources

- See the *Installation Guide for Red Hat Enterprise Linux* or *Ubuntu* for details.

### 1.3.6. Removing a Ceph OSD using the command-line interface

Removing an OSD from a storage cluster involves updating the cluster map, removing its authentication key, removing the OSD from the OSD map, and removing the OSD from the `ceph.conf` file. If the node has multiple drives, you might need to remove an OSD for each drive by repeating this procedure.

Prerequisites

- A running Red Hat Ceph Storage cluster.
- Enough available OSDs so that the storage cluster is not at its near full ratio.
Having root access to the OSD node.

Procedure

1. Disable and stop the OSD service:

   Syntax
   
   ```
   systemctl disable ceph-osd@$OSD_ID
   systemctl stop ceph-osd@$OSD_ID
   ```

   Example
   
   ```
   [root@osd ~]# systemctl disable ceph-osd@4
   [root@osd ~]# systemctl stop ceph-osd@4
   ```

   Once the OSD is stopped, it is down.

2. Remove the OSD from the storage cluster:

   Syntax
   
   ```
   ceph osd out $OSD_ID
   ```

   Example
   
   ```
   [root@osd ~]# ceph osd out 4
   ```

   **IMPORTANT**

   Once the OSD is out, Ceph will start rebalancing and copying data to other OSDs in the storage cluster. Red Hat recommends waiting until the storage cluster becomes active+clean before proceeding to the next step. To observe the data migration, run the following command:

   ```
   [root@monitor ~]# ceph -w
   ```

3. Remove the OSD from the CRUSH map so that it no longer receives data.

   Syntax
   
   ```
   ceph osd crush remove $OSD_NAME
   ```

   Example
   
   ```
   [root@osd ~]# ceph osd crush remove osd.4
   ```
NOTE

You can also decompile the CRUSH map, remove the OSD from the device list, remove the device as an item in the host bucket or remove the host bucket. If it is in the CRUSH map and you intend to remove the host, recompile the map and set it. See the Storage Strategies Guide for details.

4. Remove the OSD authentication key:

**Syntax**

```plaintext
ceph auth del osd.$OSD_ID
```

**Example**

```
[root@osd ~]# ceph auth del osd.4
```

5. Remove the OSD:

**Syntax**

```plaintext
ceph osd rm $OSD_ID
```

**Example**

```
[root@osd ~]# ceph osd rm 4
```

6. Edit the storage cluster’s configuration file, by default `/etc/ceph.conf`, and remove the OSD entry, if it exists:

**Example**

```
[osd.4]
host = $HOST_NAME
```

7. Remove the reference to the OSD in the `/etc/fstab` file, if the OSD was added manually.

8. Copy the updated configuration file to the `/etc/ceph/` directory of all other nodes in the storage cluster.

**Syntax**

```plaintext
scp /etc/ceph/$CLUSTER_NAME.conf $USER_NAME@$HOST_NAME:/etc/ceph/

[root@osd ~]# scp /etc/ceph/ceph.conf root@node4:/etc/ceph/
```

### 1.3.7. Observing the data migration

When you add or remove an OSD to the CRUSH map, Ceph begins rebalancing the data by migrating placement groups to the new or existing OSD(s).
Prerequisites

- A running Red Hat Ceph Storage cluster.
- Recently added or removed an OSD.

Procedure

1. To observe the data migration:
   ```bash
   [root@monitor ~]# ceph -w
   ```

2. Watch as the placement group states change from active+clean to active, some degraded objects, and finally active+clean when migration completes.

3. To exit the utility, press `Ctrl + C`.

1.4. RECALCULATING THE PLACEMENT GROUPS

Placement groups (PGs) define the spread of any pool data across the available OSDs. A placement group is build upon the given redundancy algorithm to be used. For a 3-way replication, the redundancy is defined to use three different OSDs. For erasure-coded pools, the number of OSDs to use is defined by the number of chunks.

When defining a pool the number of placement groups defines the grade of granularity the data is spread with across all available OSDs. The higher the number the better the equalization of capacity load can be. However, since handling the placement groups is also important in case of reconstruction of data, the number is significant to be carefully chosen upfront. To support calculation a tool is available to produce agile environments.

During lifetime of a storage cluster a pool may grow above the initially anticipated limits. With the growing number of drives a recalculation is recommended. The number of placement groups per OSD should be around 100. When adding more OSDs to the storage cluster the number of PGs per OSD will lower over time. Starting with 120 drives initially in the storage cluster and setting the `pg_num` of the pool to 4000 will end up in 100 PGs per OSD, given with the replication factor of three. Over time, when growing to ten times the number of OSDs, the number of PGs per OSD will go down to ten only. Because small number of PGs per OSD will tend to an unevenly distributed capacity, consider adjusting the PGs per pool.

Adjusting the number of placement groups can be done online. Recalculating is not only a recalculation of the PG numbers, but will involve data relocation, which will be a lengthy process. However, the data availability will be maintained at any time.

Very high numbers of PGs per OSD should be avoided, because reconstruction of all PGs on a failed OSD will start at once. A high number of IOPS is required to perform reconstruction in a timely manner, which might not be available. This would lead to deep I/O queues and high latency rendering the storage cluster unusable or will result in long healing times.

Additional Resources

- See the PG calculator for calculating the values by a given use case.

1.5. ADDITIONAL RESOURCES
See the Placement Groups (PGs) chapter in the Red Hat Ceph Storage Strategies Guide for more information.
CHAPTER 2. HANDLING A DISK FAILURE

As a storage administrator, you will have to deal with a disk failure at some point over the life time of the storage cluster. Testing and simulating a disk failure before a real failure happens will ensure you are ready for when the real thing does happen.

Here is the high-level workflow for replacing a failed disk:

1. Find the failed OSD.
2. Take OSD out.
3. Stop the OSD daemon on the node.
4. Check Ceph’s status.
5. Remove the OSD from the CRUSH map.
6. Delete the OSD authorization.
7. Remove the OSD from the storage cluster.
8. Unmount the filesystem on node.
9. Replace the failed drive.
10. Add the OSD back to the storage cluster.
11. Check Ceph’s status.

2.1. PREREQUISITES

- A running Red Hat Ceph Storage cluster.
- A failed disk.

2.2. DISK FAILURES

Ceph is designed for fault tolerance, which means Ceph can operate in a degraded state without losing data. Ceph can still operate even if a data storage drive fails. The degraded state means the extra copies of the data stored on other OSDs will backfill automatically to other OSDs in the storage cluster. When an OSD gets marked down this can mean the drive has failed.

When a drive fails, initially the OSD status will be down, but still in the storage cluster. Networking issues can also mark an OSD as down even if it is really up. First check for any network issues in the environment. If the networking checks out okay, then it is likely the OSD drive has failed.

Modern servers typically deploy with hot-swappable drives allowing you to pull a failed drive and replace it with a new one without bringing down the node. However, with Ceph you will also have to remove the software-defined part of the OSD.

2.2.1. Replacing a failed OSD disk

The general procedure for replacing an OSD involves removing the OSD from the storage cluster, replacing the drive and then recreating the OSD.
Prerequisites

- A running Red Hat Ceph Storage cluster.
- A failed disk.

Procedure

1. Check storage cluster health:
   
   ```
   # ceph health
   ```

2. Identify the OSD location in the CRUSH hierarchy:
   
   ```
   # ceph osd tree | grep -i down
   ```

3. Log into the OSD node and try to restart the OSD:
   
   ```
   # ssh $OSD_NODE
   # systemctl start ceph-osd@$OSD_NUMBER
   ```

   If the command indicates that the OSD is already running, there might be a heartbeat or networking issue. If you cannot restart the OSD, then the drive might have failed.

   **NOTE**

   If the OSD is down, then the OSD will eventually get marked out. This is normal behavior for Ceph Storage. When the OSD gets marked out, other OSDs with copies of the failed OSD’s data will begin backfilling to ensure that the required number of copies exist within the storage cluster. While the storage cluster is backfilling, the cluster will be in a degraded state.

4. Check the failed OSD’s mount point:
   
   ```
   # df -h
   ```

   If you cannot restart the OSD, you can check the mount point. If the mount point no longer appears, then you can try remounting the OSD drive and restarting the OSD. If you cannot restore the mount point, then you might have a failed OSD drive.

   Using the **smartctl** utility can help determine if the drive is healthy. For example:

   ```
   # yum install smartmontools
   # smartctl -H /dev/$DRIVE
   ```

   If the drive has failed, you will need to replace it.

5. Stop the OSD process:
   
   ```
   # systemctl stop ceph-osd@$OSD_NUMBER
   ```

6. Remove the OSD out of storage cluster:
# ceph osd out $OSD_NUMBER

7. Ensure the failed OSD is backfilling:
   
   # ceph -w

8. Remove the OSD from the CRUSH Map:
   
   # ceph osd crush remove osd.$OSD_NUMBER

   **NOTE**
   This step is only needed, if you are permanently removing the OSD and not redeploying it.

9. Remove the OSD’s authentication keys:
   
   # ceph auth del osd.$OSD_NUMBER

10. Verify that the keys for the OSD are not listed:
   
   # ceph auth list

11. Remove the OSD from the storage cluster:
   
   # ceph osd rm osd.$OSD_NUMBER

12. Unmount the failed drive path:
   
   # umount /var/lib/ceph/osd/$CLUSTER_NAME-$OSD_NUMBER

13. Replace the physical drive. Refer to the hardware vendor’s documentation for the node. If the drive is hot swappable, simply replace the failed drive with a new drive. If the drive is NOT hot swappable and the node contains multiple OSDs, you MIGHT need to bring the node down to replace the physical drive. If you need to bring the node down temporarily, you might set the cluster to noout to prevent backfilling:
   
   # ceph osd set noout

   Once you replace the drive and you bring the node and its OSDs back online, remove the noout setting:

   # ceph osd unset noout

   Allow the new drive to appear under the /dev/ directory and make a note of the drive path before proceeding further.

14. Find the OSD drive and format the disk.

15. Recreate the OSD:
   
   a. Using **Ansible**.
b. Using the command-line interface.

16. Check the CRUSH hierarchy to ensure it is accurate:

   # ceph osd tree

   If you are not satisfied with the location of the OSD in the CRUSH hierarchy, you might move it with the `move` command:

   # ceph osd crush move $BUCKET_TO_MOVE $BUCKET_TYPE=$PARENT_BUCKET

17. Verify the OSD is online.

2.2.2. Replacing an OSD drive while retaining the OSD ID

When replacing a failed OSD drive, you can keep the original OSD ID and CRUSH map entry.

**NOTE**

The `ceph-volume lvm` commands defaults to BlueStore for OSDs. To use FileStore OSDs, then use the `--filestore`, `--data` and `--journal` options.

See the Preparing the OSD Data and Journal Drives section for more details.

**Prerequisites**

- A running Red Hat Ceph Storage cluster.
- A failed disk.

**Procedure**

1. Destroy the OSD:

   ceph osd destroy $OSD_ID --yes-i-really-mean-it

   **Example**

   $ ceph osd destroy 1 --yes-i-really-mean-it

2. Optionally, if the replacement disk was used previously, then you need to zap the disk:

   ceph-volume lvm zap $DEVICE

   **Example**

   $ ceph-volume lvm zap /dev/sdb

3. Create the new OSD with the existing OSD ID:

   ceph-volume lvm create --osd-id $OSD_ID --data $DEVICE
2.3. SIMULATING A DISK FAILURE

There are two disk failure scenarios: hard and soft. A hard failure means replacing the disk. Soft failure might be an issue with the device driver or some other software component.

In the case of a soft failure, replacing the disk might not be needed. If replacing a disk, then steps need to be followed to remove the failed disk and add the replacement disk to Ceph. In order to simulate a soft disk failure the best thing to do is delete the device. Choose a device and delete the device from the system.

```
echo 1 > /sys/block/$DEVICE/device/delete
```

Example

```
[root@ceph1 ~]# echo 1 > /sys/block/sdb/device/delete
```

In the Ceph OSD log, on the OSD node, Ceph detected the failure and started the recovery process automatically.

Example

```
[root@ceph1 ~]# tail -50 /var/log/ceph/ceph-osd.1.log
2017-02-02 12:15:27.490889 7f3e1fa3d800 -1 ^[0;31m ** ERROR: unable to open OSD superblock on /var/lib/ceph/osd/ceph-1: (5) Input/output error^[0m

  0 0.09659 osd.0 up 1.00000 1.00000
```
CHAPTER 3. HANDLING A NODE FAILURE

As a storage administrator, you might experience a whole node failing within the storage cluster, and handling a node failure is similar to handling a disk failure. With a node failure, instead of Ceph recovering PGs (placement groups) for only one disk, all PGs on the disks within that node must be recovered. Ceph will detect that the OSDs are all down and automatically start the recovery process, known as self-healing.

There are three node failure scenarios. Here is the high-level workflow for each scenario when replacing a node:

- Replacing the node, but using the root and Ceph OSD disks from the failed node.
  1. Disable backfilling.
  2. Replace the node, taking the disks from old node, and adding them to the new node.
  3. Enable backfilling.

- Replacing the node, reinstalling the operating system, and using the Ceph OSD disks from the failed node.
  1. Disable backfilling.
  2. Create a backup of the Ceph configuration.
  3. Replace the node and add the Ceph OSD disks from failed node.
     a. Configuring disks as JBOD.
  4. Install the operating system.
  5. Restore the Ceph configuration.
  6. Run `ceph-ansible`.
  7. Enable backfilling.

- Replacing the node, reinstalling the operating system, and using all new Ceph OSDs disks.
  1. Disable backfilling.
  2. Remove all OSDs on the failed node from the storage cluster.
  3. Create a backup of the Ceph configuration.
  4. Replace the node and add the Ceph OSD disks from failed node.
     a. Configuring disks as JBOD.
  5. Install the operating system.
  6. Run `ceph-ansible`.
  7. Enable backfilling.

3.1. PREREQUISITES
3.2. CONSIDERATIONS BEFORE ADDING OR REMOVING A NODE

One of the outstanding features of Ceph is the ability to add or remove Ceph OSD nodes at run time. This means you can resize the storage cluster capacity or replace hardware without taking down the storage cluster. The ability to serve Ceph clients while the cluster is in a **degraded** state also has operational benefits, for example, you can add or remove or replace hardware during regular business hours, rather than working overtime or weekends. However, adding and removing Ceph OSD nodes can have a significant impact on performance, and you must consider the performance impact of adding, removing or replacing hardware on the storage cluster before you act.

From a capacity perspective, removing a node removes the OSDs contained within the node and effectively reduces the capacity of the storage cluster. Adding a node adds the OSDs contained within the node, and effectively expands the capacity of the storage cluster. Whether you are expanding or reducing the storage cluster capacity, adding or removing Ceph OSD nodes will induce backfilling as the cluster rebalances. During that rebalancing time period, Ceph uses additional resources which can impact storage cluster performance.

Imagine a storage cluster that contains Ceph nodes where each node has four OSDs. In a storage cluster of four nodes, with 16 OSDs, removing a node removes 4 OSDs and cuts capacity by 25%. In a storage cluster of three nodes, with 12 OSDs, adding a node adds 4 OSDs and increases capacity by 33%.

In a production Ceph storage cluster, a Ceph OSD node has a particular hardware configuration that facilitates a particular type of storage strategy. For more details, see [Storage Strategies](#) guide for Red Hat Ceph Storage 3.

Since a Ceph OSD node is part of a CRUSH hierarchy, the performance impact of adding or removing a node typically affects the performance of pools that use that CRUSH hierarchy, that is, the CRUSH ruleset.

### 3.3. PERFORMANCE CONSIDERATIONS

The following factors typically have an impact on storage cluster’s performance when adding or removing Ceph OSD nodes:

**Current Client Load on Affected Pools:**

Ceph clients place load on the I/O interface to Ceph; namely, load on a pool. A pool maps to a CRUSH ruleset. The underlying CRUSH hierarchy allows Ceph to place data across failure domains. If the underlying Ceph OSD node involves a pool under high client loads, the client load may have a significant impact on recovery time and impact performance. More specifically, since write operations require data replication for durability, write-intensive client loads will increase the time for the storage cluster to recover.

**Capacity Added or Removed:**

Generally, the capacity you are adding or removing as a percentage of the overall cluster will have an impact on the storage cluster’s time to recover. Additionally, the storage density of the node you add or remove may have an impact on the time to recover for example, a node with 36 OSDs will typically take longer to recover compared to a node with 12 OSDs. When removing nodes, you MUST ensure that you have sufficient spare capacity so that you will not reach the **full ratio** or near **full ratio**. If the storage cluster reaches the **full ratio**, Ceph will suspend write operations to prevent data loss.
**Pools and CRUSH Ruleset:**
A Ceph OSD node maps to at least one Ceph CRUSH hierarchy, and the hierarchy maps to at least one pool. Each pool that uses the CRUSH hierarchy (ruleset) where you add or remove a Ceph OSD node will experience a performance impact.

**Pool Type and Durability:**
Replication pools tend to use more network bandwidth to replicate deep copies of the data, whereas erasure coded pools tend to use more CPU to calculate $k+m$ coding chunks. The more copies of the data, for example, the size or the more $k+m$ chunks, the longer it will take for the storage cluster to recover.

**Total Throughput Characteristics:**
Drives, controllers and network interface cards all have throughput characteristics that may impact the recovery time. Generally, nodes with higher throughput characteristics, for example, 10 Gbps and SSDs will recover faster than nodes with lower throughput characteristics, for example, 1 Gbps and SATA drives.

### 3.4. RECOMMENDATIONS FOR ADDING OR REMOVING NODES

The failure of a node may preclude removing one OSD at a time before changing the node. Circumstances can allow you to reduce a negative performance impact when adding or removing Ceph OSD nodes, Red Hat recommends adding or removing one OSD at a time within a node and allowing the cluster to recover before proceeding to the next OSD. For details on removing an OSD:

- Using Ansible.
- Using the command-line interface.

When adding a Ceph node, Red hat also recommends adding one OSD at a time. For details on adding an OSD:

- Using Ansible.
- Using the command-line interface.

When adding or removing Ceph OSD nodes, consider that other ongoing processes will have an impact on performance too. To reduce the impact on client I/O, Red Hat recommends the following:

**Calculate capacity:**
Before removing a Ceph OSD node, ensure that the storage cluster can backfill the contents of all its OSDs **WITHOUT** reaching the **full ratio**. Reaching the **full ratio** will cause the cluster to refuse write operations.

**Temporarily Disable Scrubbing:**
Scrubbing is essential to ensuring the durability of the storage cluster’s data; however, it is resource intensive. Before adding or removing a Ceph OSD node, disable scrubbing and deep scrubbing and let the current scrubbing operations complete before proceeding, for example:

```bash
ceph osd set noscrub
ceph osd set nodeep-scrub
```

Once you have added or removed a Ceph OSD node and the storage cluster has returned to an **active+clean** state, unset the **noscrub** and **nodeep-scrub** settings.
Limit Backfill and Recovery:

If you have reasonable data durability, for example, `osd pool default size = 3` and `osd pool default min size = 2`, there is nothing wrong with operating in a degraded state. You can tune the storage cluster for the fastest possible recovery time, but this will impact Ceph client I/O performance significantly. To maintain the highest Ceph client I/O performance, limit the backfill and recovery operations and allow them to take longer, for example:

```
osd_max_backfills = 1
osd_recovery_max_active = 1
osd_recovery_op_priority = 1
```

You can also set sleep and delay parameters such as `osd_recovery_sleep`.

Finally, if you are expanding the size of the storage cluster, you may need to increase the number of placement groups. If you determine that you need to expand the number of placement groups, Red Hat recommends making incremental increases in the number of placement groups. Increasing the number of placement groups by a significant number will cause performance to degrade considerably.

### 3.5. ADDING A CEPH OSD NODE

To expand the capacity of the Red Hat Ceph Storage cluster, add an OSD node.

**Prerequisites**

- A running Red Hat Ceph Storage cluster.
- A provisioned node with a network connection.
- Installation of Red Hat Enterprise Linux 7 or Ubuntu 16.04.
- Review the Requirements for Installing Red Hat Ceph Storage chapter in the Installation Guide for Red Hat Enterprise Linux or Ubuntu.

**Procedure**

1. Verify that other nodes in the storage cluster can reach the new node by its short host name.
2. Temporarily disable scrubbing:
   ```bash
   [root@monitor ~]# ceph osd set noscrub
   [root@monitor ~]# ceph osd set nodeep-scrub
   ```
3. Limit the back-fill and recovery features:

   **Syntax**
   ```bash
   ceph tell $DAEMON_TYPE.* injectargs --$OPTION_NAME $VALUE [--$OPTION_NAME $VALUE]
   ```

   **Example**
   ```bash
   [root@monitor ~]# ceph tell osd.* injectargs --osd-max-backfills 1 --osd-recovery-max-active 1 --osd-recovery-op-priority 1
   ```
4. Add the new node to the CRUSH Map:

**Syntax**

```
ceph osd crush add-bucket $BUCKET_NAME $BUCKET_TYPE
```

**Example**

```
[root@monitor ~]# ceph osd crush add-bucket node2 host
```

5. Add an OSD for each disk on the node to the storage cluster.

- Using Ansible.
- Using the command-line interface.

**IMPORTANT**

When adding an OSD node to a Red Hat Ceph Storage cluster Red Hat recommends adding one OSD at a time within the node and allowing the cluster to recover to an `active+clean` state before proceeding to the next OSD.

**Additional Resources**

- See the Setting a Specific Configuration Setting at Runtime section in the Red Hat Ceph Storage Configuration Guide for more details.
- See the Add a Bucket and Move a Bucket sections in the Red Hat Ceph Storage Storage Strategies Guide for details on placing the node at an appropriate location in the CRUSH hierarchy.

### 3.6. REMOVING A CEPH OSD NODE

To reduce the capacity of a storage cluster remove an OSD node.

**WARNING**

Before removing a Ceph OSD node, ensure that the storage cluster can backfill the contents of all OSDs WITHOUT reaching the full ratio. Reaching the full ratio will cause the cluster to refuse write operations.

**Prerequisites**

- A running Red Hat Ceph Storage cluster.

**Procedure**

1. Check storage cluster’s capacity:
[root@monitor ~]# ceph df
[root@monitor ~]# rados df
[root@monitor ~]# ceph osd df

2. Temporarily disable scrubbing:

   [root@monitor ~]# ceph osd set noscrub
   [root@monitor ~]# ceph osd set nodeep-scrub

3. Limit the back-fill and recovery features:

   Syntax

   ceph tell $DAEMON_TYPE.* injectargs --$OPTION_NAME $VALUE [--$OPTION_NAME $VALUE]

   Example

   [root@monitor ~]# ceph tell osd.* injectargs --osd-max-backfills 1 -
   --osd-recovery-max-active 1 --osd-recovery-op-priority 1

4. Remove each OSD on the node from the storage cluster:

   - Using Ansible.
   - Using the command-line interface.

   **IMPORTANT**

   When removing an OSD node from the storage cluster, Red Hat recommends removing one OSD at a time within the node and allowing the cluster to recover to an active+clean state before proceeding to the next OSD.

   a. After removing an OSD check to verify the storage cluster is not getting to the near-full ratio:

      [root@monitor ~]# ceph -s
      [root@monitor ~]# ceph df

   b. Repeat this step until all OSDs on the node are removed from the storage cluster.

5. Once all OSDs are removed, remove the host bucket from the CRUSH map:

   Syntax

   ceph osd crush rm $BUCKET_NAME

   Example

   [root@monitor ~]# ceph osd crush rm node2

**Additional Resources**
To simulate hard node failure power-off the node and reinstall the operating system.

**Prerequisites**

- A healthy running Red Hat Ceph Storage cluster.

**Procedure**

1. Check storage capacity to understand what removing node means to storage cluster:
   ```bash
   # ceph df
   # rados df
   # ceph osd df
   ```

2. Optionally, disable recovery and backfilling:
   ```bash
   # ceph osd set noout
   # ceph osd set noscrub
   # ceph osd set nodeep-scrub
   ```

3. Shutdown the node.

4. If the host name will change, then remove the node from CRUSH map:
   ```bash
   [root@ceph1 ~]# ceph osd crush rm ceph3
   ```

5. Check status of cluster:
   ```bash
   [root@ceph1 ~]# ceph -s
   ```

6. Reinstall the operating system on the node.

7. Add an Ansible user and SSH keys:
   ```bash
   [root@ceph3 ~]# useradd ansible
   [root@ceph3 ~]# passwd ansible
   [root@ceph3 ~]# cat << EOF > /etc/sudoers.d/ansible
   ansible ALL = (root) NOPASSWD:ALL
   Defaults:ansible !requiretty
   EOF
   [root@ceph3 ~]# su - ansible
   [ansible@ceph3 ~]# ssh-keygen
   ```

8. From the administration node, copy the SSH keys for **ansible** user:
   ```bash
   [ansible@admin ~]$ ssh-copy-id ceph3
   ```
9. From the administration node, re-run the Ansible playbook:

```
[ansible@admin ~]$ cd /usr/share/ceph-ansible
[ansible@admin ~]$ ansible-playbook site.yml
```

**Example Output**

```
PLAY RECAP
********************************************************************************
ceph1                      : ok=368  changed=2    unreachable=0
failed=0
ceph2                      : ok=284  changed=0    unreachable=0
failed=0
ceph3                      : ok=284  changed=15   unreachable=0
failed=0
```

10. Optionally, enable recovery and backfilling:

```
[root@ceph3 ~]# ceph osd unset noout
[root@ceph3 ~]# ceph osd unset noscrub
[root@ceph3 ~]# ceph osd unset nodeep-scrub
```

11. Check Ceph’s health:

```
[root@ceph3 ~]# ceph -s
    cluster 1e0c9c34-901d-4b46-8001-0d1f93ca5f4d
    health HEALTH_OK
    monmap e1: 3 mons at
    {ceph1=192.168.122.81:6789/0,ceph2=192.168.122.82:6789/0,ceph3=192.168.122.83:6789/0}
    election epoch 36, quorum 0,1,2 ceph1,ceph2,ceph3
    osdmap e95: 3 osds: 3 up, 3 in
    flags sortbitwise
    pgmap v1190: 152 pgs, 12 pools, 1024 MB data, 441 objects
    3197 MB used, 293 GB / 296 GB avail
    152 active+clean
```

CHAPTER 4. HANDLING A DATA CENTER FAILURE

Red Hat Ceph Storage can withstand catastrophic failures to the infrastructure, such as losing one of three data centers in a stretch cluster. For the standard object store use case, configuring all three data centers can be done independently with replication set up between them. In this scenario, the cluster configuration in each of the data centers might be different, reflecting the local capabilities and dependencies.

A logical structure of the placement hierarchy should be considered. A proper CRUSH map can be used, reflecting the hierarchical structure of the failure domains within the infrastructure. Using logical hierarchical definitions improves the reliability of the storage cluster, versus using the standard hierarchical definitions. Failure domains are defined in the CRUSH map. The default CRUSH map contains all nodes in a flat hierarchy.

In three data center environment example, with a stretch cluster, the placement of nodes should be managed in a way that one data center can go down, but the storage cluster stays up and running. Consider which failure domain a node resides in when using 3-way replication for the data, in the case of an outage of one data center, it is possible that some data can be left with one copy. When this scenario happens, there are two options:

- Leave the data in read-only status with the standard settings.
- Live with only one copy for the duration of the outage.

With the standard settings, and because of the randomness of data placement across the nodes, not all the data will be affected, but some data can have only one copy and the storage cluster would revert to read-only mode.

In the example below the resulting map is derived from the initial setup of the cluster with 6 OSD nodes. In this example all nodes have only one disk and hence one OSD. All of the nodes are arranged under the default root, that is the standard root of the hierarchy tree. Because there is a weight assigned to two of the OSDs, these OSDs receive fewer chunks of data than the other OSDs. These nodes were introduced later with bigger disks than the initial OSD disks. This does not affect the data placement to withstand a failure of a group of nodes.

Standard CRUSH map

```
$ sudo ceph osd tree
ID  WEIGHT  TYPE  NAME           UP/DOWN  REWEIGHT  PRIMARY-AFFINITY
-1  0.33554  root  default       up     1.00000  1.00000
 0  0.04779  host  ceph-node3
-2  0.04779  osd.0  osd.0         up     1.00000  1.00000
-3  0.04779  host  ceph-node2
 1  0.04779  osd.1  osd.1         up     1.00000  1.00000
-4  0.04779  host  ceph-node1
 2  0.04779  osd.2  osd.2         up     1.00000  1.00000
-5  0.04779  host  ceph-node4
 3  0.04779  osd.3  osd.3         up     1.00000  1.00000
-6  0.07219  host  ceph-node6
 4  0.07219  osd.4  osd.4         up     0.79999  1.00000
-7  0.07219  host  ceph-node5
 5  0.07219  osd.5  osd.5         up     0.79999  1.00000
```

Using logical hierarchical definitions to group the nodes into same data center, can achieve data placement maturity. Possible definition types of root, datacenter, rack, row and host allow the reflection of the failure domains for the three data center stretch cluster:
Nodes ceph-node1 and ceph-node2 reside in data center 1 (DC1)
Nodes ceph-node3 and ceph-node5 reside in data center 2 (DC2)
Nodes ceph-node4 and ceph-node6 reside in data center 3 (DC3)
All data centers belong to the same structure (allDC)

Since all OSDs in a host belong to the host definition there is no change needed. All the other assignments can be adjusted during runtime of the storage cluster by:

- Defining the *bucket* structure with the following commands:

  ```
  ceph osd crush add-bucket allDC root
  ceph osd crush add-bucket DC1 datacenter
  ceph osd crush add-bucket DC2 datacenter
  ceph osd crush add-bucket DC3 datacenter
  ```

- Moving the nodes into the appropriate place within this structure by modifying the CRUSH map:

  ```
  ceph osd crush move DC1 root=allDC
  ceph osd crush move DC2 root=allDC
  ceph osd crush move DC3 root=allDC
  ceph osd crush move ceph-node1 datacenter=DC1
  ceph osd crush move ceph-node2 datacenter=DC1
  ceph osd crush move ceph-node3 datacenter=DC2
  ceph osd crush move ceph-node5 datacenter=DC2
  ceph osd crush move ceph-node4 datacenter=DC3
  ceph osd crush move ceph-node6 datacenter=DC3
  ``

Within this structure any new hosts can be added too, as well as new disks. By placing the OSDs at the right place in the hierarchy the CRUSH algorithm is changed to place redundant pieces into different failure domains within the structure.

The above example results in the following:

```
$ sudo ceph osd tree
ID  WEIGHT  TYPE NAME               UP/DOWN REWEIGHT PRIMARY-AFFINITY
-8       6.00000 root allDC
-9  2.00000     datacenter DC1
-4  1.00000         host ceph-node1
  2 1.00000             osd.2            up  1.00000          1.00000
-3  1.00000         host ceph-node2
  1 1.00000             osd.1            up  1.00000          1.00000
-10  2.00000     datacenter DC2
-2  1.00000         host ceph-node3
  0 1.00000             osd.0            up  1.00000          1.00000
-7  1.00000         host ceph-node5
  5 1.00000             osd.5            up  0.79999          1.00000
-11  2.00000     datacenter DC3
-6  1.00000         host ceph-node6
  4 1.00000             osd.4            up  0.79999          1.00000
-5  1.00000         host ceph-node4
  3 1.00000             osd.3            up  1.00000          1.00000
-1       0 root default
```
The listing from above shows the resulting CRUSH map by displaying the osd tree. Easy to see is now how the hosts belong to a data center and all data centers belong to the same top level structure but clearly distinguishing between locations.

**NOTE**

Placing the data in the proper locations according to the map works only properly within the healthy cluster. Misplacement might happen under circumstances, when some OSDs not available. Those misplacements will be corrected automatically once it’s possible to do so.
