Abstract

This guide provides guidance on planning for the deployment of Red Hat CloudForms to suit your cloud environment. If you have a suggestion for improving this guide or have found an error, please submit a Bugzilla report at <http://bugzilla.redhat.com> against Red Hat CloudForms Management Engine for the Documentation component. Please provide specific details, such as the section number, guide name, and CloudForms version so we can easily locate the content.

CHAPTER 1. INTRODUCTION TO RED HAT CLOUDFORMS

Red Hat CloudForms delivers the insight, control, and automation that enterprises need to address the challenges of managing virtual environments. This technology enables enterprises with existing virtual infrastructures to improve visibility and control, and those starting virtualization deployments to build and operate a well-managed virtual infrastructure.

Red Hat CloudForms provides the following feature sets:

- **Insight:** Discovery, Monitoring, Utilization, Performance, Reporting, Analytic, Chargeback, and Trending.
- **Control:** Security, Compliance, Alerting, and Policy-Based Resource, and Configuration Enforcement.
- **Automate:** IT Process, Task and Event, Provisioning, and Workload Management and Orchestration.
- **Integrate:** Systems Management, Tools and Processes, Event Consoles, Configuration Management Database (CMDB), Role-based Administration (RBA), and Web Services.

1.1. ARCHITECTURE

The diagram below describes the capabilities of Red Hat CloudForms. Its features are designed to work together to provide robust management and maintenance of your virtual infrastructure.

The architecture comprises the following components:

- The Red Hat CloudForms appliance (appliance) which is supplied as a secure, high-performance, preconfigured virtual machine. It provides support for HTTPS communications.
- The Red Hat CloudForms Server (Server) resides on the appliance. It is the software layer that communicates between the SmartProxy and the Virtual Management Database. It includes support for HTTPS communications.

- The Virtual Management Database (VMDB) resides either on the appliance or another computer accessible to the appliance. It is the definitive source of intelligence collected about your Virtual Infrastructure. It also holds status information regarding appliance tasks.
- The Red Hat CloudForms Console (Console) is the Web interface used to view and control the Server and appliance. It is consumed through Web 2.0 mash-ups and web services (WS Management) interfaces.
- The SmartProxy can reside on the appliance or on an ESX Server. If not embedded in the Server, the SmartProxy can be deployed from the appliance. A SmartProxy agent must be configured in each storage location, and must be visible to the appliance. The SmartProxy acts on behalf of the appliance communicating with it over HTTPS on standard port 443.

1.2. REQUIREMENTS

To use Red Hat CloudForms, certain virtual hardware, database, and browser requirements must be met in your environment.

1.2.1. Virtual Hardware Requirements

The Red Hat CloudForms appliance requires the following virtual hardware at minimum:

- 4 VCPUs
- 8 GB RAM
- 44 GB HDD + optional database disk

1.2.2. Database Requirements

Red Hat recommends allocating the virtual machine disk fully at the time of creation. Four main factors affect the size of your database over time:

- **Virtual Machine Count:** the most important factor in the calculation of virtual machine database (VMDB) size over time.
- **Host Count:** the number of hosts associated with the provider.
- **Storage Count:** the number of individual storage elements as seen from the perspective of the provider or host. It is not the total number of virtual disks for all virtual machines.
- **Metrics Count:** CloudForms will create a number of records per minute, rolled up hourly and daily, for each provider instance once capacity and utilization is enabled. See the second table for information on VMDB sizing to include metrics gathering.

Use the following table as a guideline to calculate minimum requirements for your database without capacity and utilization enabled:

Virtual Machine Count	Host Count	Storage Count	Estimated VMDB Size in GB	
			1 year	2 year
100	5	50	3.5	5
500	10	100	17	25
5000	50	500	173	251

**NOTE**

When enabling capacity and utilization for metrics gathering over a period of time, it is recommended that the VMDB size scale accordingly. Evaluate the number of instances in your provider inventory and storage duration requirements to plan for increased VMDB sizing requirements.

Use the following information to plan for your increased VMDB needs when working with metrics gathering:

- Realtime metrics data are stored for 4 hours.
- Rollup metrics data are stored for 6 months.

Example:

	Minute	Hour	Day
OpenStack Provider Instance	3 Realtime Metrics	181 (3 records * 60 minutes = 180 Realtime Metrics + 1 hourly Rollup Metric)	4,345 (3 records * 60 minutes * 24 hours = 4320 Realtime Metrics + 1 daily Rollup Metric)

- Metrics data storage times can be configured by editing the Advanced Settings.

1.2.3. Browser Requirements

To use Red Hat CloudForms, the following browser requirements must be met:

- One of the following web browsers:
 - Mozilla Firefox for versions supported under Mozilla's Extended Support Release (ESR)
 - Internet Explorer 10 or higher
 - Google Chrome for Business
- A monitor with minimum resolution of 1280x1024.

**IMPORTANT**

Due to browser limitations, Red Hat supports logging in to only one tab for each multi-tabbed browser. Console settings are saved for the active tab only. For the same reason, Red Hat CloudForms does not guarantee that the browser's **Back** button will produce the desired results. Red Hat recommends using the breadcrumbs provided in the Console.

1.2.4. Additional Requirements

Additionally, the following must be configured to use Red Hat CloudForms:

- The Red Hat CloudForms appliance must already be installed and activated in your enterprise environment.

- The SmartProxy must have visibility into the virtual machines and cloud instances that you want to control.
- For more information, see [SmartProxies](#) in the CloudForms *General Configuration* guide.

1.3. TERMINOLOGY

The following terms are used throughout this document. Review them before proceeding.

Account Role

The level of access a user has to different parts and functions of the Red Hat CloudForms console. There are a variety of Account Roles, which can be assigned to users to restrict or allow access to parts of the console and virtual infrastructure.

Action

An execution that is performed after a condition is evaluated.

Alert

Red Hat CloudForms alerts notify administrators and monitoring systems of critical configuration changes and threshold limits in the virtual environment. The notification can take the form of either an email or an SNMP trap.

Analysis Profile

A customized scan of hosts, virtual machines, or instances. You can collect information from categories, files, event logs, and registry entries.

Cloud

A pool of on-demand and highly available computing resources. The usage of these resources are scaled depending on the user requirements and metered for cost.

Red Hat CloudForms Appliance

A virtual machine where the virtual management database (VMDB) and Red Hat CloudForms reside.

Red Hat CloudForms Console

A web-based interface into the Red Hat CloudForms appliance.

Red Hat CloudForms Role

A designation assigned to a Red Hat CloudForms server that defines what a Red Hat CloudForms server can do.

Red Hat CloudForms Server

The application that runs on the Red Hat CloudForms appliance and communicates with the SmartProxy and the VMDB.

Cluster

Hosts that are grouped together to provide high availability and load balancing.

Condition

A control policy test triggered by an event, which determines a subsequent action.

Discovery

Process run by the Red Hat CloudForms server which finds virtual machine and cloud providers.

Drift

The comparison of a virtual machine, instance, host, cluster to itself at different points in time.

Event

A trigger to check a condition.

Event Monitor

Software on the Red Hat CloudForms appliance which monitors external providers for events and sends them to the Red Hat CloudForms server.

Host

A computer running a hypervisor, capable of hosting and monitoring virtual machines. Supported hypervisors include RHV-H, VMware ESX hosts, Windows Hyper-V hosts.

Instance/Cloud Instance

An on-demand virtual machine based upon a predefined image and uses a scalable set of hardware resources such as CPU, memory, networking interfaces.

Managed/Registered VM

A virtual machine that is connected to a host and exists in the VMDB. Also, a template that is connected to a provider and exists in the VMDB. Note that templates cannot be connected to a host.

Managed/Unregistered VM

A virtual machine or template that resides on a repository or is no longer connected to a provider or host and exists in the VMDB. A virtual machine that was previously considered registered may become unregistered if the virtual machine was removed from provider inventory.

Provider

An external management system that CloudForms integrates in order to collect data and perform operations.

Policy

A combination of an event, a condition, and an action used to manage a virtual machine.

Policy Profile

A set of policies.

Refresh

A process run by the Red Hat CloudForms server which checks for relationships of the provider or host to other resources, such as storage locations, repositories, virtual machines, or instances. It also checks the power states of those resources.

Regions

A region is the collection of zones that share the same database for reporting and charting. A master region may be added to synchronize multiple VMDBs into one VMDB for higher-level reporting, providing a "single pane of glass" view.

Resource

A host, provider, instance, virtual machine, repository, or datastore.

Resource Pool

A group of virtual machines across which CPU and memory resources are allocated.

Repository

A place on a datastore resource which contains virtual machines.

SmartProxy

The SmartProxy is a software agent that acts on behalf of the Red Hat CloudForms appliance to perform actions on hosts, providers, storage and virtual machines.

The SmartProxy can be configured to reside on the Red Hat CloudForms appliance or on an ESX server version. The SmartProxy can be deployed from the Red Hat CloudForms appliance, and provides visibility to the VMFS storage. Each storage location must have a SmartProxy with

visibility to it. The SmartProxy acts on behalf of the Red Hat CloudForms appliance. If the SmartProxy is not embedded in the Red Hat CloudForms server, it communicates with the Red Hat CloudForms appliance over HTTPS on standard port 443.

SmartState Analysis

Process run by the SmartProxy which collects the details of a virtual machine or instance. Such details include accounts, drivers, network information, hardware, and security patches. This process is also run by the Red Hat CloudForms server on hosts and clusters. The data is stored in the VMDB.

SmartTags

Descriptors that allow you to create a customized, searchable index for the resources in your clouds and infrastructure.

Storage Location

A device, such as a VMware datastore, where digital information resides that is connected to a resource.

Tags

Descriptive terms defined by a Red Hat CloudForms user or the system used to categorize a resource.

Template

A template is a copy of a preconfigured virtual machine, designed to capture installed software and software configurations, as well as the hardware configuration, of the original virtual machine.

Unmanaged Virtual Machine

Files discovered on a datastore that do not have a virtual machine associated with them in the VMDB. These files may be registered to a provider that the Red Hat CloudForms server does not have configuration information on. Possible causes may be that the provider has not been discovered or that the provider has been discovered, but no security credentials have been provided.

Virtual Machine

A software implementation of a system that functions similar to a physical machine. Virtual machines utilize the hardware infrastructure of a physical host, or a set of physical hosts, to provide a scalable and on-demand method of system provisioning.

Virtual Management Database (VMDB)

Database used by the Red Hat CloudForms appliance to store information about your resources, users, and anything else required to manage your virtual enterprise.

Virtual Thumbnail

An image in the web interface representing a resource, such as a provider or a virtual machine, showing the resource's properties at a glance. Each virtual thumbnail is divided into quadrants, which provide information about the resource, such as its software and power state.

Zones

Red Hat CloudForms Infrastructure can be organized into zones to configure failover and to isolate traffic. Zones can be created based on your environment. Zones can be based on geographic location, network location, or function. When first started, new servers are put into the default zone.

1.4. GETTING SUPPORT

If you experience difficulty with a procedure described in this documentation, visit the Red Hat Customer Portal at <http://access.redhat.com>. Through the Customer Portal, you can:

- search or browse through a knowledgebase of technical support articles about Red Hat products

- submit a support case to Red Hat Global Support Services (GSS)
- access other product documentation

Red Hat also hosts a large number of electronic mailing lists for discussion of Red Hat software and technology. You can find a list of publicly available mailing lists at <https://www.redhat.com/mailman/listinfo>. Click on the name of any mailing list to subscribe to that list or to access the list archives.

CHAPTER 2. PLANNING

This guide provides some general guidelines to planning a deployment on Red Hat CloudForms. This includes creating multiple regions containing Red Hat CloudForms appliances, CPU sizing recommendations, database sizing recommendations, and database configuration.

2.1. REGIONS

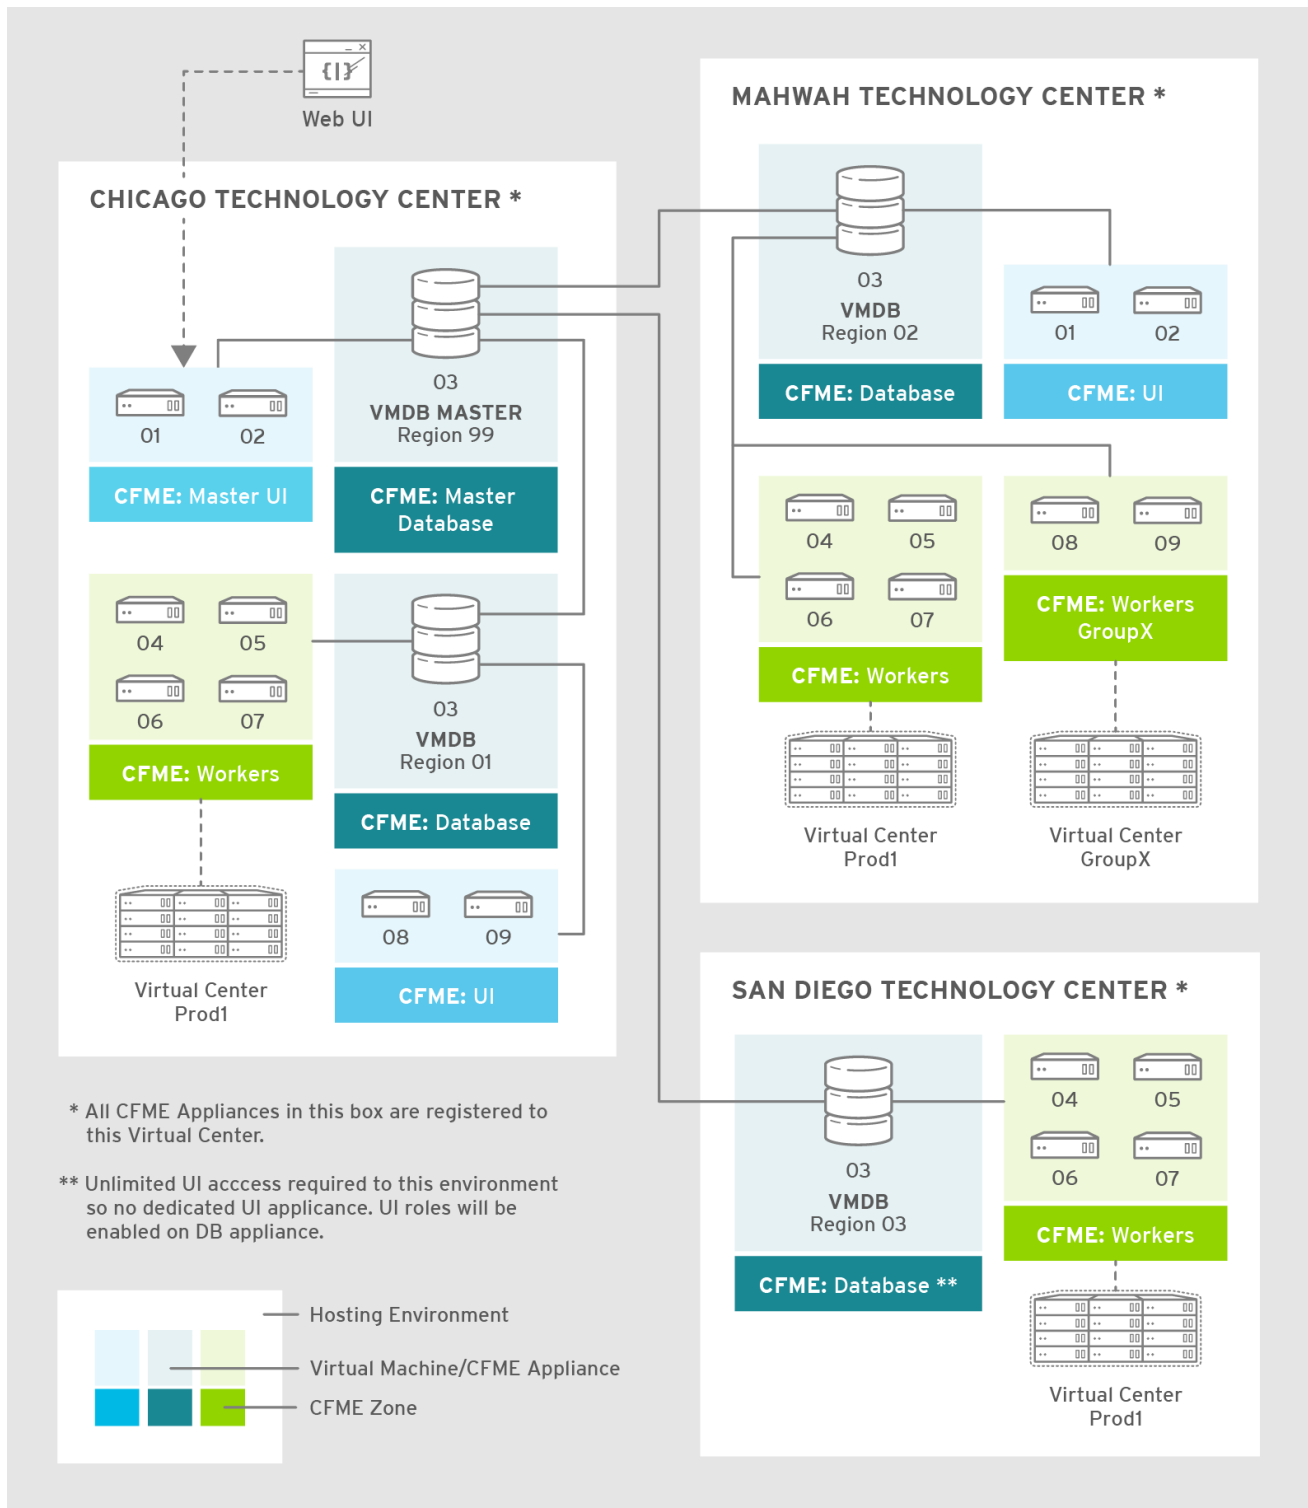

Regions are used for centralizing data which is collected from public and private virtualization environments. A region is ultimately represented as a single database for the VMDB. Regions are particularly useful when multiple geographical locations need to be managed, as they enable all the data collection to happen at each particular location and avoid data collection traffic across slow links between networks.

When multiple regions are being used, each with their own unique ID, a master region can be created to centralize the data of all the children regions into a single master database. To do this, configure each child region to replicate its data to the master region database (Red Hat recommends use of region 99, though any number up to three digits will work). This parent and child region is a one-to-many relationship.

Regions can contain multiple zones, which in turn contain appliances. Zones are used for further segregating network traffic along with enabling failover configurations. Each appliance has the capability to be configured for a number of specialized server roles. These roles are limited to the zone containing the appliance they run on.

Only one failover type of each server role can run in a zone. If multiple appliances have the same failover role, the extras are used as backups that activate only if the primary appliance fails. Non-failover server roles can run on multiple appliances simultaneously in a zone, so resources can be adjusted according to the workload those roles are responsible for.

The following diagram demonstrates an example of the multiple regions working together in a Red Hat CloudForms environment.

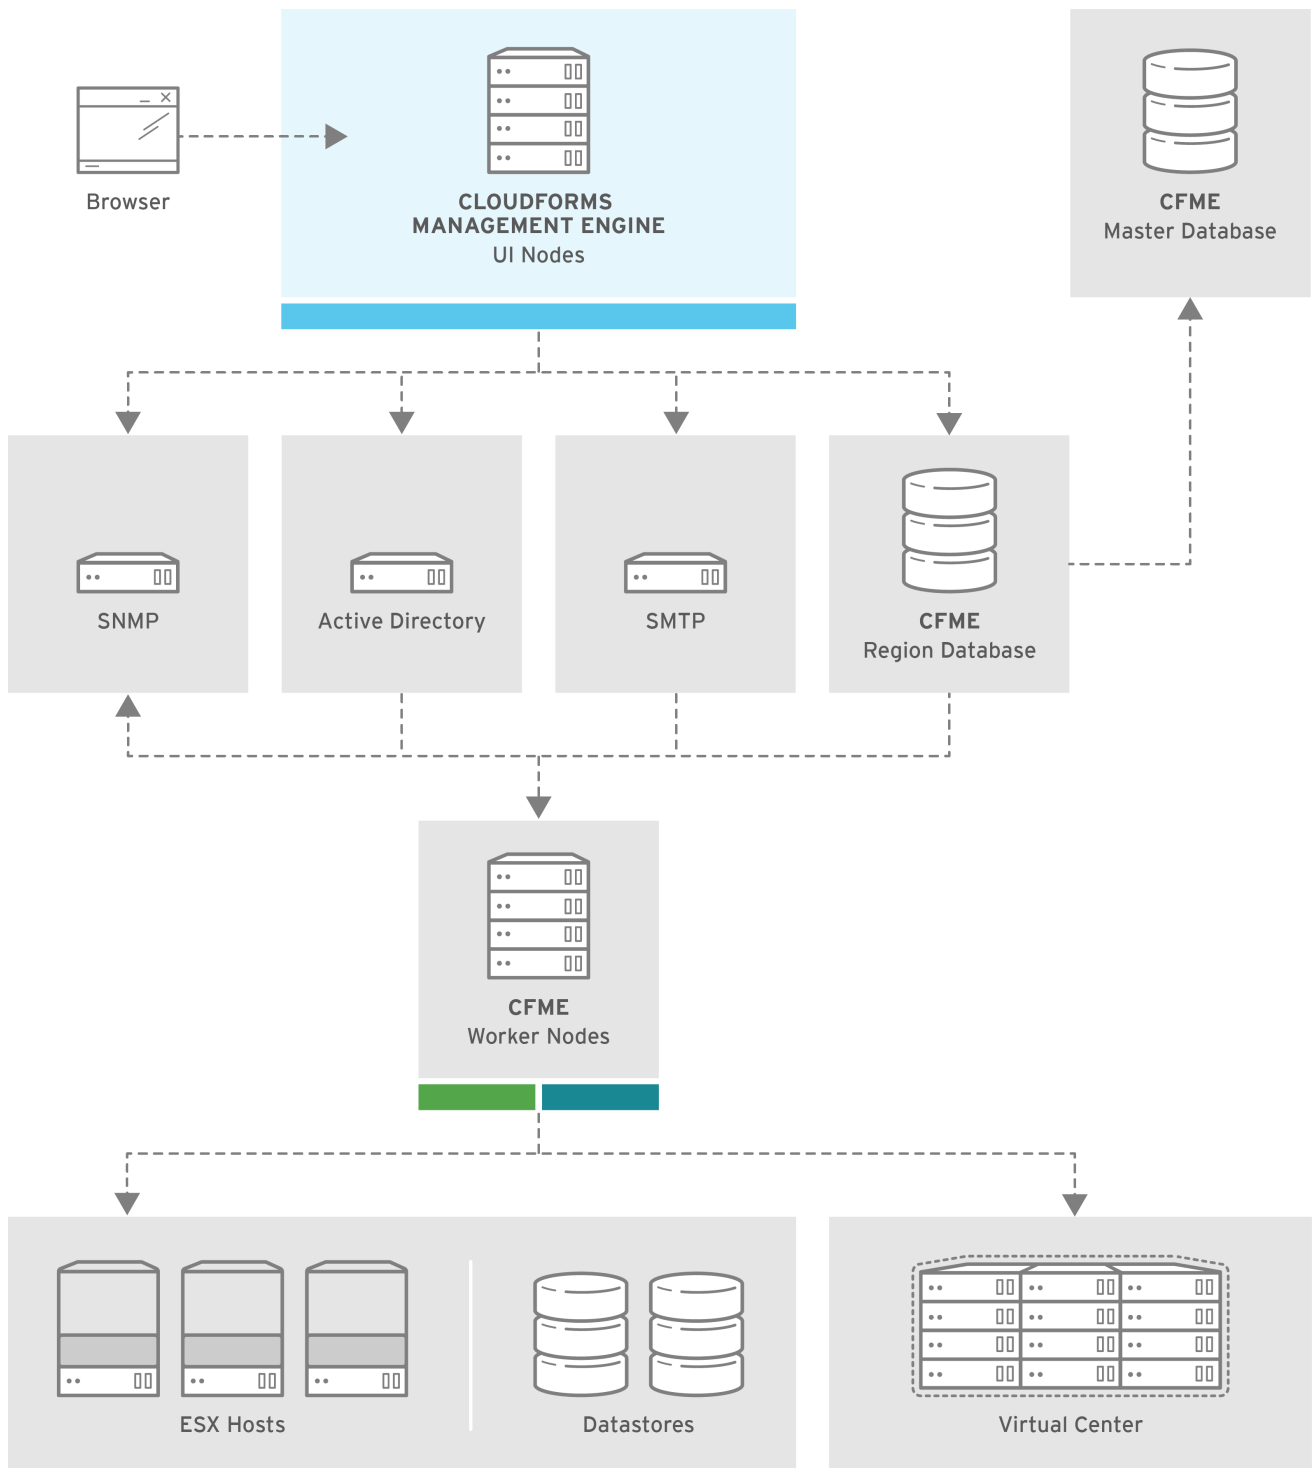

The master appliance is located in Chicago and contains a master region and a subregion that manages the worker appliances. The Mahwah technology center contains a single subregion that manages two zones. Likewise, the San Diego technology center contains a single subregion managing a single zone.

NOTE

- Replicating a parent region to a higher-level parent is not supported.
- Parent regions can be configured after the child regions are online.

The following diagram provides a closer look at a region:

CFME_337199_0215

In this region, we have several Red Hat CloudForms appliances acting as UI nodes and worker nodes. These worker nodes execute tasks on the providers in your environment. The region also uses a region database that reports to a master database on the main Red Hat CloudForms appliance. All appliances can connect to the authentication services (Active Directory, LDAP, Identity Management), outgoing mail (SMTP), and network services (SNMP).

NOTE

CloudForms can be configured in a highly available setup. In this case, all PostgreSQL instances must be running on a server that is deployed from the CloudForms appliance. High availability is achieved by database replication between two or more database servers. For more information, see [Configuring High Availability](#).

2.2. ROLES

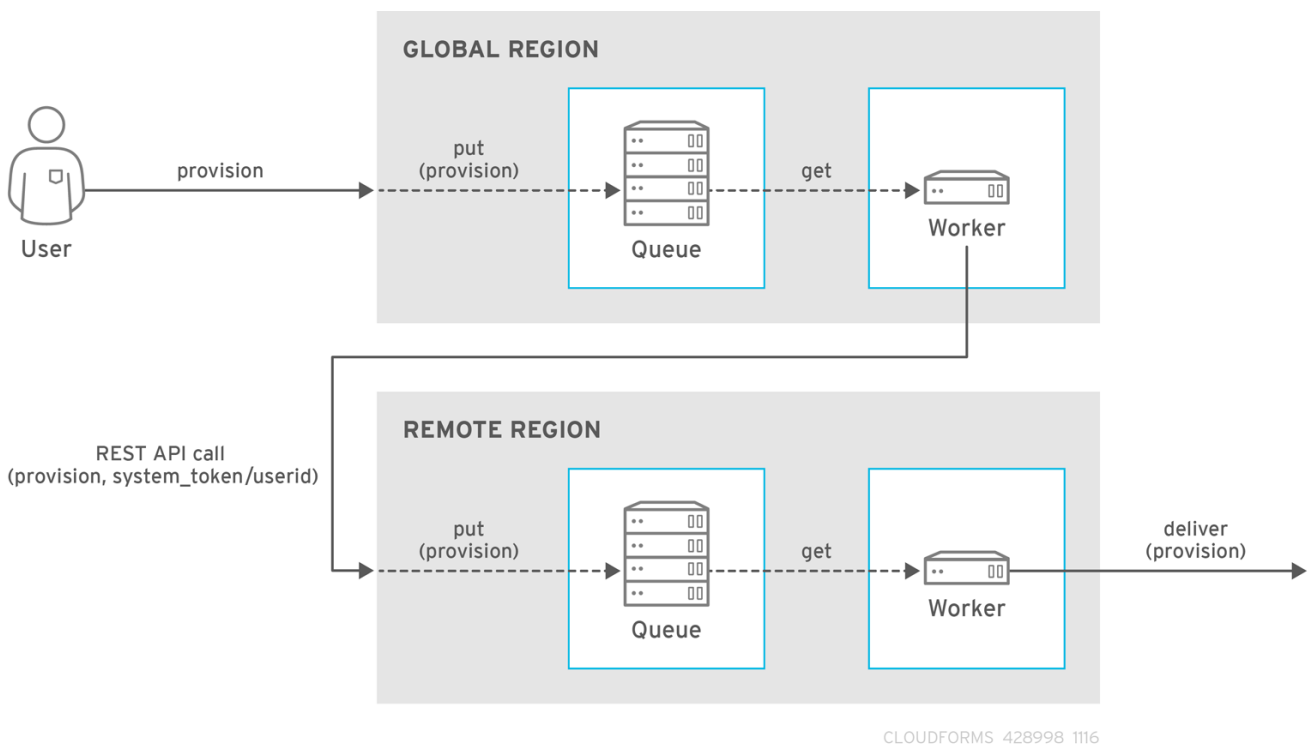

Server roles define what a server can do. Assigning different server roles to appliances can allow them to focus on specific functions. When planning a deployment, consider which roles to assign to each appliance. Some server roles are enabled by default in CloudForms.

Some roles are also dependent on other roles. For example, because the CloudForms user interface relies on the API for access, the Web Services role must be enabled with the User Interface role for users to log in to the appliance. See [Server Roles](#) in *General Configuration* for details on each server role and its function.

2.3. CENTRALIZED ADMINISTRATION

Red Hat CloudForms includes centralized administration capabilities, where operations can be initiated from the global region and processed and executed on the remote region. This includes the following life cycle management operations:

- Virtual machine provisioning
- Service provisioning
- Virtual machine power operations
- Virtual machine retirement
- Virtual machine reconfiguration

With centralized administration, the `remote_queue_put` leverages a new system-to-system REST API request to forward the original request to the remote region. This request is put in the local queue in the remote region, which is then delivered by a worker in the remote region as if it was queued there all along. As a result, a CloudForms operator in the global region can be seen as provisioning on behalf of a remote region.

**NOTE**

The operations initiated from the global region are subject to the role-based access control (RBAC) rules on the remote region. The user in the remote region which matches the logged-in user's **user ID** will be used to enforce RBAC in the target region. The operation will fail on the remote system if the user does not have the required permissions.

For information on how to configure centralized administration via database replication, see the section on *Configuring Database Replication and Centralized Administration* in the [General Configuration](#) guide.

2.4. TENANCY

Red Hat CloudForms supports multitenancy. Tenants can be totally separate or they can be in a parent-child or peer relationship. Tenants in a relationship can share or inherit a certain configuration. You can subdivide and create child tenants and they, in turn, can have child tenants, and so on. The ability to have multi-level (nested) tenants in a hierarchy enables those at the bottom to inherit permissions from those above. This configuration allows for granular user permissions to be set on specific tenants.

A tenant can also contain a self-contained child tenant known as a *project*. A project cannot have a child tenant, but is useful for allocating resources to a small group or team within a larger organization.

**NOTE**

If you do not add any additional tenants, all resources and user accounts are contained in a single base tenant which is your CloudForms appliance itself. In CloudForms, is sometimes referred as *tenant zero*.

Tenancy Account Roles

In CloudForms, the following two account roles are associated with tenancy:

- Tenant administrator
- Tenant quota administrator

See [Account Roles and Descriptions](#) in the *General Configuration* guide for more information about these roles.

**IMPORTANT**

Tenant administrator and tenant quota administrator roles are like administrator and super administrator. These roles are not limited to the tenant upon which they are acting and act across all tenants, and therefore should be considered privileged users. These are not roles inside a tenant.

Tenancy Models

The following two approaches exist for tenancy planning:

- **Tenantless** - You can create a single large tenant, sometimes referred as *tenant zero*, and perform all your operations in there without any subdivision of resources or user accounts.

- **Enterprise model** - A common scenario is to create a single tenant, and then subdivide it based on the structures or departments within your organization. Those departments are then able to further subdivide their resources into distinct projects. With this model, you have a single URL for user access, while still having the ability to divide resources into nested hierarchical tenants.

Tenancy Configuration

You can create and configure tenancy using the CloudForms user interface in the same place you set up users, groups and roles by selecting **Configuration** from the settings menu, and then clicking on the **Access Control** accordion. See the section on [Access Control](#) in the *General Configuration* guide for procedures on how to create tenants and projects, users, and groups.

Tenancy in Automation

One of the features of tenancy is that each tenant can have its own automate domain. Tenant-based domains can help in several use cases, such as if you have:

- groups that need their own naming routines
- varying types of approval needs
- departments that use different end ticketing systems
- a customer who is a holding company or centralized IT organization for managing different business units

Just like standard domains are nested, you can also add automate domains that are nested at the tenant level. For the procedure on how to create a new automate domain, see [Scripting Actions in CloudForms](#).

Tenancy Quota and Reporting

You can allocate and enforce quotas for the following attributes:

- Virtual CPUs
- Memory in GB
- Storage in GB
- Number of virtual machines
- Number of templates

See the section on [Managing Tenant and Project Quotas](#) in the *General Configuration* guide for procedures on how to create and manage quotas.

You can generate or schedule a report for **Tenant Quotas** similar to other reports. See [Reports](#) in the *Monitoring, Alerts, and Reporting* guide for procedures on how to view or schedule a report.

NOTE

Currently, in tenant quota reports you will see all of the tenants but there is no nesting information available by parent and child tenants.

Example:

In the following example of a tenant quota report, *DevOps Teams* is a parent tenant and *Team Alpha* and *Team Bravo* are child tenants.

Tenant Name	Quota Name	Total Quota	In Use	Allocated	Available
DevOps Teams	Allocated Virtual CPUs	125 Count	0 Count	75 Count	50 Count
DevOps Teams	Allocated Memory in GB	255.0 GB	0.0 GB	125.0 GB	130.0 GB
DevOps Teams	Allocated Storage in GB	1505.0 GB	0.0 GB	1100.0 GB	405.0 GB
DevOps Teams	Allocated Number of Templates	15 Count	0 Count	4 Count	11 Count
DevOps Teams	Allocated Number of Virtual Machines	160 Count	0 Count	70 Count	90 Count
DevOps Teams					
Team Alpha	Allocated Virtual CPUs	50 Count	0 Count	0 Count	50 Count
Team Alpha	Allocated Memory in GB	75.0 GB	0.0 GB	0.0 GB	75.0 GB
Team Alpha	Allocated Storage in GB	1000.0 GB	0.0 GB	0.0 GB	1000.0 GB
Team Alpha	Allocated Number of Virtual Machines	50 Count	0 Count	0 Count	50 Count
Team Alpha	Allocated Number of Templates	3 Count	0 Count	0 Count	3 Count
Team Alpha					
Team Bravo	Allocated Virtual CPUs	25 Count	0 Count	0 Count	25 Count
Team Bravo	Allocated Memory in GB	50.0 GB	0.0 GB	0.0 GB	50.0 GB
Team Bravo	Allocated Storage in GB	100.0 GB	0.0 GB	0.0 GB	100.0 GB
Team Bravo	Allocated Number of Virtual Machines	20 Count	0 Count	0 Count	20 Count
Team Bravo	Allocated Number of Templates	1 Count	0 Count	0 Count	1 Count
Team Bravo					

- **Total Quota:** Total quota enforced per attribute for a tenant
- **In Use:** Amount of quota currently in use by tenants
- **Allocated:** Amount of quota given to all child tenants
- **Available:** *Total Quota* minus (-) *In Use* minus (-) *Allocated*

Tenancy Chargeback

You have the ability to do tenancy in chargeback where you are able to assign rates and have a different rate for each tenant. You can make use of the default rate or create your own set of rates depending on the tenant. As well, there is an ability to create chargeback reports by tenant.

See [Chargeback](#) in the *Monitoring Alerts, and Reporting* guide for information on how to create and assign default or custom chargeback rates, and how CloudForms calculates chargeback costs.

Tenancy Service Catalogs

Similar to automate domains, you can have service catalogs at each level of tenancy. Once you add a service catalog at a particular level of tenancy, it is visible to that tenant and its children (unless you use tagging to exclude).

Tenancy Providers

Providers can be added at any level of tenancy. Once added, a provider is visible to any child or lower tenants, making it possible to easily separate resources that are owned or accessed by one group, and should not be available to other tenants.

2.5. USING A LOAD BALANCER

Deploying several CloudForms appliances with a load balancer can be useful for performance.

However, running several appliances behind a load balancer can cause login issues from the Self Service user interface because **memcached**, the service storing the session in memory, is not shared between the appliances. To prevent this, configure your environment using the steps below to run the **memcached** service on one appliance and have it shared with the other appliances.

IMPORTANT

When using this configuration, always start the appliance that owns **memcached** first, and ensure that **memcached** is running before starting the additional appliances. Starting another appliance before the **memcached** appliance may result in starting or login issues.

The following example shows configuration on two appliances, **appliance1** and **appliance2**:

1. On **appliance1**, open the 11211 port in the firewall:

```
# firewall-cmd --add-port=11211/tcp --permanent
# firewall-cmd --reload
```

2. On **appliance1**, configure the server's advanced settings by navigating to the settings menu, selecting **Configuration**, then the **Advanced** tab:

```
:session:
:memcache_server: 127.0.0.1:11211
:memcache_server_opts: "-l 0.0.0.0 -I 1M"
```

This configures **memcached** to run on **appliance1**, but listen to all servers (-l 0.0.0.0). The **memcache_server** line, which specifies where it connects to, remains set as itself (127.0.0.1).

3. Click **Save**.

4. Restart **appliance1**:

```
# systemctl restart evmserverd
```

5. Configure **appliance2** to point to **appliance1** by specifying the IP address for **appliance1** in the **memcache_server** line. Configure this in the server's advanced settings by navigating to the settings menu, selecting **Configuration**, then the **Advanced** tab:

```
:session:
:memcache_server: <appliance1>:11211
:memcache_server_opts: "-l 127.0.0.1 -I 1M"
```

6. Click **Save**.

7. Restart **appliance2**:

```
# systemctl restart evmserverd
```

You can then get an API token from **appliance1**, and use it to access the API from **appliance2**. See [Using Authentication Tokens](#) in the *REST API* guide for instructions.

The shared **memcached** service now runs only on **appliance1**, and any other appliance accesses **memcached** from that appliance. Configure additional appliances with the steps for **appliance2**.

CloudForms

CHAPTER 3. CAPACITY PLANNING

3.1. CAPACITY AND UTILIZATION COLLECTION

Red Hat CloudForms server can collect and analyze capacity and utilization data from your virtual infrastructure. Use this data to understand the limitations of your current environment and plan for growth.

For some capacity and utilization data, Red Hat CloudForms calculates and shows trend lines in the charts. Trend lines are created using linear regression, which is calculated using the capacity and utilization data collected by Red Hat CloudForms during the interval you specify for the chart. The more data you have the better the predictive value of the trend line.

There are three server roles associated with the collection and metric creation of capacity and utilization.

- The Capacity & Utilization Coordinator role checks to see if it is time to collect data, somewhat like a scheduler. If it is time, a job is queued for the Capacity & Utilization Data Collector. The Coordinator role is required to complete capacity and utilization data collection. If more than one server in a specific zone has this role, only one will be active at a time.
- The Capacity & Utilization Data Collector performs the actual collection of capacity and utilization data. This role has a dedicated worker, and there can be more than one server with this role in a zone.
- The Capacity & Utilization Data Processor processes all of the data collected, allowing Red Hat CloudForms to create charts. This role has a dedicated worker, and there can be more than one server with this role in a zone.

3.2. ASSIGNING THE CAPACITY AND UTILIZATION SERVER ROLES

1. From the settings menu, select **Configuration**, then select the server to configure from **Settings** → **Zone** in the accordion menu on the left.
2. Navigate to the **Server Roles** list in the **Server** → **Server Control** section. From there, set the required capacity and utilization roles to **ON**, namely:
 - a. **Capacity & Utilization Coordinator**
 - b. **Capacity & Utilization Data Collector**
 - c. **Capacity & Utilization Data Processor**
3. Click **Save**.

Data collection is enabled immediately. However, the first collection begins 5 minutes after the server is started, and every 10 minutes after that. Therefore, the longest the collection takes after enabling the Capacity & Utilization Collector role is 10 minutes. The first collection from a particular provider may take a few minutes since Red Hat CloudForms is gathering data points going one month back in time.

**NOTE**

In addition to setting the server role, you must also select which clusters and datastores to collect data for. For more information, see *General Configuration*. You must have super administrator rights to edit these settings.

3.3. ADDING DATABASE CREDENTIALS FOR DATA COLLECTION

After creating the new user, add the user's credentials to the settings for the provider.

1. From **Compute** → **Infrastructure** → **Providers**, select an infrastructure provider to update its settings.
2. Click  **Configuration**, and then  **Edit Selected Infrastructure Provider**.
3. In the **Credentials** area, click **C & U Database**.
4. Type in the credentials for the new database user you created.
5. Click **Save**.
6. Restart the Capacity and Utilization Data Collector.

3.4. DATA COLLECTION FOR RED HAT VIRTUALIZATION

To collect capacity and utilization data for Red Hat Virtualization (RHV), you must add a user to the RHV-M history database for Red Hat CloudForms to use.

Perform this procedure on the PostgreSQL server where the history database (ovirt_engine_history) is located. Usually, this is the RHV-M server.

1. Using SSH, access the RHV-M database server as the root user:

```
$ ssh root@example.postgres.server
```

2. Switch to the postgres user:

```
# su - postgres
```

3. Create the user for CloudForms to be granted read-only access to the history database:

```
$ psql -U postgres -c "CREATE ROLE cfme WITH LOGIN ENCRYPTED
PASSWORD '[password]';" -d ovirt_engine_history
```

4. Grant the newly created user permission to connect to the history database:

```
$ psql -U postgres -c "GRANT CONNECT ON DATABASE
ovirt_engine_history TO cfme;"
```

5. Grant the newly created user usage of the public schema:

```
$ psql -U postgres -c "GRANT USAGE ON SCHEMA public TO cfme;"
ovirt_engine_history
```

6. Generate the rest of the permissions that will be granted to the newly created user and save them to a file:

```
$ psql -U postgres -c "SELECT 'GRANT SELECT ON ' || relname || ' TO
cfme;' FROM pg_class JOIN pg_namespace ON pg_namespace.oid =
pg_class.relnamespace WHERE nspname = 'public' AND relkind IN ('r',
'v', 'S');" --pset=tuples_only=on ovirt_engine_history > grant.sql
```

7. Use the file you created in the previous step to grant permissions to the newly created user:

```
$ psql -U postgres -f grant.sql ovirt_engine_history
```

8. Remove the file you used to grant permissions to the newly created user:

```
$ rm grant.sql
```

9. Exit to the RHV-M database server prompt:

```
$ exit
```

10. Update the server's firewall to accept TCP communication on port 5432:

```
# firewall-cmd --add-port=5432/tcp --permanent
```

11. Enable external md5 authentication. Change the authentication method from `ident` to `md5` in the following line in `/var/lib/pgsql/data/pg_hba.conf`:

```
host      all      all      0.0.0.0/0      md5
```

12. Enable PostgreSQL to listen for remote connections. Update the `listen_addresses` line in `/var/lib/pgsql/data/postgresql.conf`:

```
listen_addresses = '*'
```

13. Reload the PostgreSQL configuration:

```
# systemctl reload postgresql
```

3.5. DATA COLLECTION FOR RED HAT ENTERPRISE LINUX OPENSTACK PLATFORM

Before you can collect data from a Red Hat Enterprise Linux OpenStack Platform (RHEL-OSP) provider, you must install Ceilometer and configure it to accept queries from external systems.

These instructions require a Red Hat Enterprise Linux 6.4 @base installation of RHEL-OSP and registration to a satellite that has access to both the **RHEL-OSP** and **RHEL Server Optional** channels. Perform all steps on your RHEL-OSP system.

1. Add the required channels and update your system:

```
# rhn-channel --add -c rhel-x86_64-server-6-ost-3 -c rhel-x86_64-
server-optional-6
```

```
# yum update -y
# reboot
```

2. Install Ceilometer:

```
# yum install *ceilometer*
```

3. Install and start the MongoDB store:

```
# yum install mongodb-server
# sed -i '/--smallfiles/!s/OPTIONS=\\"/OPTIONS=\\"--smallfiles /'
/etc/sysconfig/mongod
# service mongod start
```

4. Create the following users and roles:

```
# SERVICE_TENANT=$(keystone tenant-list | grep services | awk
'{print $2}')
# ADMIN_ROLE=$(keystone role-list | grep ' admin ' | awk '{print
$2}')
# SERVICE_PASSWORD=servicepass
# CEILOMETER_USER=$(keystone user-create --name=ceilometer \
--pass="$SERVICE_PASSWORD" \
--tenant_id $SERVICE_TENANT \
--email=ceilometer@example.com | awk '/ id / {print $4}')
# RESELLER_ROLE=$(keystone role-create --name=ResellerAdmin | awk '/
id / {print $4}')
# ADMIN_ROLE=$(keystone role-list | awk '/ admin / {print $2}')
# for role in $RESELLER_ROLE $ADMIN_ROLE ; do
keystone user-role-add --tenant_id $SERVICE_TENANT \
--user_id $CEILOMETER_USER --role_id $role
done
```

5. Configure the authtoken in `ceilometer.conf`:

```
# openstack-config --set /etc/ceilometer/ceilometer.conf
keystone_authtoken auth_host 127.0.0.1
# openstack-config --set /etc/ceilometer/ceilometer.conf
keystone_authtoken auth_port 35357
# openstack-config --set /etc/ceilometer/ceilometer.conf
keystone_authtoken auth_protocol http
# openstack-config --set /etc/ceilometer/ceilometer.conf
keystone_authtoken admin_tenant_name services
# openstack-config --set /etc/ceilometer/ceilometer.conf
keystone_authtoken admin_user ceilometer
# openstack-config --set /etc/ceilometer/ceilometer.conf
keystone_authtoken admin_password $SERVICE_PASSWORD
```

6. Configure the user credentials in `ceilometer.conf`:

```
# openstack-config --set /etc/ceilometer/ceilometer.conf DEFAULT
os_auth_url http://127.0.0.1:35357/v2.0
# openstack-config --set /etc/ceilometer/ceilometer.conf DEFAULT
os_tenant_name services
```

```
# openstack-config --set /etc/ceilometer/ceilometer.conf DEFAULT
os_password $SERVICE_PASSWORD
# openstack-config --set /etc/ceilometer/ceilometer.conf DEFAULT
os_username ceilometer
```

7. Start the Ceilometer services:

```
# for svc in compute central collector api ; do
  service openstack-ceilometer-$svc start
done
```

8. Register an endpoint with the service catalog. Replace **\$EXTERNALIFACE** with the IP address of your external interface:

```
# keystone service-create --name=ceilometer \
--type=metering --description="Ceilometer Service"
# CEILOMETER_SERVICE=$(keystone service-list | awk '/ceilometer/{print $2}')
# keystone endpoint-create \
--region RegionOne \
--service_id $CEILOMETER_SERVICE \
--publicurl "http://$EXTERNALIFACE:8777/" \
--adminurl "http://$EXTERNALIFACE:8777/" \
--internalurl "http://localhost:8777/"
```

9. Enable access to Ceilometer from external systems:

```
# iptables -I INPUT -p tcp -m multiport --dports 8777 -m comment --
comment "001 ceilometer incoming" -j ACCEPT
# iptables save
```

10. Confirm the status of OpenStack and the Ceilometer services:

```
# openstack-status
# for svc in compute central collector api ; do
  service openstack-ceilometer-$svc status
done
```

11. Verify Ceilometer is working correctly by authenticating as a user with instances running, for example **admin**. Pipe the sample for the CPU meter to count lines, and confirm that the value changes according to the interval specified in **/etc/ceilometer/pipeline.yaml**. The default interval is 600 seconds.

```
# . ~/keystonerc_admin
# ceilometer sample-list -m cpu |wc -l
```

12. Add the configured OpenStack provider to Red Hat CloudForms. See [Adding OpenStack Providers](#) in *Managing Providers*. After adding the provider, capacity and utilization data for your instances populate in a few minutes.

3.6. DATA COLLECTION FOR GOOGLE COMPUTE ENGINE

Red Hat CloudForms can collect capacity and utilization metrics from Google Compute Engine once Google Cloud Monitoring API is enabled. Visit [Google API Console](#) to enable the Cloud Monitoring API. Once enabled, it may take a few minutes to propagate to CloudForms.

3.7. CAPACITY AND UTILIZATION DATA COLLECTED

Red Hat CloudForms generates charts from the collected data which can be used to plan your hardware and virtual machine needs. Depending on the type of data, these charts may include lines for averages, maximums, minimums, and trends.

NOTE

For reporting of daily capacity and utilization data, incomplete days (days with less than 24 hourly data points from midnight to midnight) that are at the beginning or end of the requested interval are excluded. Days with less than 24 hourly data points would be inaccurate and including them would skew trend lines. Therefore, at least one full day of hourly data from midnight to midnight is necessary for displaying the capacity and utilization charts under the **Compute** → **Infrastructure** tab.

3.7.1. Capacity and Utilization Charts for Hosts, Clusters, and Virtual Machines

Table 3.1. Capacity and Utilization Charts for Hosts, Clusters, and Virtual Machines

Resource Type	CPU Usage	CPU States	Disk I/O	Memory Usage	Network I/O	Running VMS	Running Hosts
Host	Y	Y	Y	Y	Y	Y	NA
Cluster	Y	Y	Y	Y	Y	Y	Y
Virtual Machine	Y	Y	Y	Y	Y	NA	NA

For procedures to view capacity and utilization charts for hosts, clusters, and virtual machines, see the following sections in *Managing Infrastructure and Inventory*.

- [Viewing Capacity and Utilization Charts for a Host](#)
- [Viewing Capacity and Utilization Charts for a Cluster](#)
- [Viewing Capacity and Utilization Charts for a Virtual Machine](#)

3.7.2. Capacity and Utilization Charts for Datastores

Charts created include:

Table 3.2. Capacity and Utilization Charts for Datastores

Space by VM Type	Virtual Machines and Hosts
Used Space	Number of VMs by Type

Space by VM Type	Virtual Machines and Hosts
Disk files Space	Hosts
Snapshot Files Space	Virtual Machines
Memory Files Space	
Non-VM Files	
Used Disk Space	

See [Viewing Capacity and Utilization Charts for a Datastore](#) in *Managing Infrastructure and Inventory* for more information.

3.8. CAPACITY AND UTILIZATION CHART FEATURES

Capacity and utilization charts for hosts, clusters, virtual machines, and datastores provides its own set of special features including zooming in on a chart and shortcut menus.

3.8.1. Zooming into a Chart

1. Navigate to the chart you want to zoom. If you hover anywhere on the chart, two dashed lines will appear to target a coordinate of the chart.
2. Click  (Click to zoom in) in the lower left corner of the chart to zoom into it.
3. To go back to the regular view click  (Click to zoom out) on the enlarged chart.

3.8.2. Drilling into Chart Data

1. Navigate to the chart you want to get more detail from.
2. Hover over a data point to see the coordinates.
3. Click on a data point to open a shortcut menu for the chart. In this example, we can use the shortcut menu to go to the hourly chart or display the virtual machines that were running at the time the data was captured.
 - If you are viewing the **CPU**, **Disk**, **Memory**, or **Network** charts, selecting from the **Chart** option will change all of the charts on the page to the new interval selected.
 - If you are viewing the **CPU**, **Disk**, **Memory**, or **Network** charts, selecting from the **Display** option will allow you to drill into the virtual machines or **Hosts** that were running at the time.
 - If you are viewing the **VM** or **Hosts** chart, the **Display** menu will allow you to view running or stopped virtual machines. The time of the data point will be displayed in addition to the virtual machines that apply. From here, click on a virtual machine to view its details.

3.9. PLANNING WHERE TO PUT A NEW VIRTUAL MACHINE

You can use the data collected in the VMDB to plan where you can put additional virtual machines. Red Hat CloudForms allows you to use a reference virtual machine as an example to plan on which hosts and clusters you can place a new virtual machine.

NOTE

For information about utilization trends and identifying bottlenecks in your environment, see [Data Optimization](#) in *Managing Infrastructure and Inventory*.

1. Navigate to **Optimize** → **Planning**.
2. From **Reference VM Selection**, use the dropdowns to select the virtual machine that is most like the one that you want to add.

3. Select the required **VM Options** for what you want to base the calculations on.

Source	Allocation
vCPU Count	<input checked="" type="checkbox"/>
Memory Size	<input checked="" type="checkbox"/> MB
Disk Space	<input checked="" type="checkbox"/> GB

From the **Source** list, select the type of data to use as the source for your projections. For example, select **Allocation** to calculate based on the current allocation values of each resource (CPU, memory, or disk space) for the reference virtual machine. Use **Reservation** to project based on the current guaranteed value of the specific resource (CPU Speed, CPU count, memory, or disk space) although that amount may not be allocated to the virtual machine at a specific moment in time. Select **Usage** if you want to calculate based on usage history of the reference virtual machine. Use **Manual Input** to enter your own set of parameters for each resource.

4. From **Target Options / Limits**, select if you want to use clusters or hosts as your targets.

Target Options / Limits

Show	Clusters ↕
vCPUs per Core	10 ↕
Memory Size	90% ↕
Datastore Space	90% ↕

Also, select the limit of how high the projection can go for CPU, memory, and datastore space. If you are targeting hosts, you will be able to select a filter for which hosts can be targets.

- From **Trend Options**, select how far back you want to use the trend data for, a **Time Profile** and **Time Zone** if applicable. Note that **Time Profile** will only show if the logged on user has a **Time Profile** available.
- Click **Submit**.

The **Summary** tab shows the best clusters or hosts on which to place the virtual machines. The **Report** tab shows the best fit and statistics on the reference virtual machine in a tabular format. From the **Report** tab, you can also create a PDF of the report or download the data in `txt` or `csv` format.

APPENDIX A. APPENDIX

A.1. EXAMPLE POSTGRESQL CONFIGURATION FILE

```
# -----
# PostgreSQL configuration file - MIQ Dedicated Appliance Configuration
# -----
#
# This file consists of lines of the form:
#
#   name = value
#
# (The "=" is optional.)  Whitespace may be used.  Comments are introduced
# with
# "#" anywhere on a line.  The complete list of parameter names and
# allowed
# values can be found in the PostgreSQL documentation.
#
# The commented-out settings shown in this file represent the default
# values.
# Re-commenting a setting is NOT sufficient to revert it to the default
# value;
# you need to reload the server.
#
# This file is read on server startup and when the server receives a
# SIGHUP
# signal.  If you edit the file on a running system, you have to SIGHUP
# the
# server for the changes to take effect, or use "pg_ctl reload".  Some
# parameters, which are marked below, require a server shutdown and
# restart to
# take effect.
#
# Any parameter can also be given as a command-line option to the server,
# e.g.,
# "postgres -c log_connections=on".  Some parameters can be changed at run
# time
# with the "SET" SQL command.
#
# Memory units:  kB = kilobytes           Time units:  ms = milliseconds
#                MB = megabytes           s   = seconds
#                GB = gigabytes           min = minutes
#                                           h   = hours
#                                           d   = days

#-----
# FILE LOCATIONS
#-----

# The default values of these variables are driven from the -D command-
# line
# option or PGDATA environment variable, represented here as ConfigDir.
```

```

#data_directory = 'ConfigDir' # use data in another directory
# (change requires restart)
#hba_file = 'ConfigDir/pg_hba.conf' # host-based authentication file
# (change requires restart)
