Red Hat Decision Manager 7.7

Packaging and deploying a Red Hat Decision Manager project
Abstract

This document describes how to package and deploy a project in Red Hat Decision Manager 7.7.

APPENDIX A. VERSIONING INFORMATION .............................................................................. 36
PREFACE

As a business rules developer, you must build and deploy a developed Red Hat Decision Manager project to a KIE Server in order to begin using the services you have created in Red Hat Decision Manager. You can develop and deploy a project from Business Central, from an independent Maven project, from a Java application, or using a combination of various platforms. For example, you can develop a project in Business Central and deploy it using the KIE Server REST API, or develop a project in Maven configured with Business Central and deploy it using Business Central.

Prerequisites

- The project to be deployed has been developed and tested. For projects in Business Central, consider using test scenarios to test the assets in your project. For example, see Testing a decision service using test scenarios.
CHAPTER 1. RED HAT DECISION MANAGER PROJECT PACKAGING

Red Hat Decision Manager projects contain the business assets that you develop in Red Hat Decision Manager. Each project in Red Hat Decision Manager is packaged as a Knowledge JAR (KJAR) file with configuration files such as a Maven project object model file (pom.xml), which contains build, environment, and other information about the project, and a KIE module descriptor file (kmodule.xml), which contains the KIE base and KIE session configurations for the assets in the project. You deploy the packaged KJAR file to a KIE Server that runs the decision services and other deployable assets (collectively referred to as services) from that KJAR file. These services are consumed at run time through an instantiated KIE container, or deployment unit. Project KJAR files are stored in a Maven repository and identified by three values: GroupId, ArtifactId, and Version (GAV). The Version value must be unique for every new version that might need to be deployed. To identify an artifact (including a KJAR file), you need all three GAV values.

Projects in Business Central are packaged automatically when you build and deploy the projects. For projects outside of Business Central, such as independent Maven projects or projects within a Java application, you must configure the KIE module descriptor settings in an appended kmodule.xml file or directly in your Java application in order to build and deploy the projects.
CHAPTER 2. PROJECT DEPLOYMENT IN BUSINESS CENTRAL

You can use Business Central to develop your business assets and services and to manage KIE Servers configured for project deployment. When your project is developed, you can build the project in Business Central and deploy it automatically to the KIE Server. To enable automatic deployment, Business Central includes a built-in Maven repository. From Business Central, you can start, stop, or remove the deployment units (KIE containers) that contain the services and their project versions that you have built and deployed.

You can also connect several KIE Servers to the same Business Central instance and group them into different server configurations (in Menu → Deploy → Execution Servers). Servers belonging to the same server configuration run the same services, but you can deploy different projects or different versions of projects on different configurations.

For example, you could have test servers in the Test configuration and production servers in a Production configuration. As you develop business assets and services in a project, you deploy the project on the Test server configuration and then, when a version of the project is sufficiently tested, you can deploy it on the Production server configuration. In this case, to keep developing the project, change the version in the project settings. Then the new version and the old version are seen as different artifacts in the built-in Maven repository. You can deploy the new version on the Test server configuration and keep running the old version on the Production server configuration. This deployment process is simple but has significant limitations. Notably, there is not enough access control: a developer can deploy a project directly into a production environment.

IMPORTANT

You cannot move a KIE Server into a different server configuration using Business Central. You must change the configuration file of the server to change the server configuration name for it.

2.1. CONFIGURING A KIE SERVER TO CONNECT TO BUSINESS CENTRAL

If a KIE Server is not already configured in your Red Hat Decision Manager environment, or if you require additional KIE Servers in your Red Hat Decision Manager environment, you must configure a KIE Server to connect to Business Central.

NOTE

If you are deploying KIE Server on Red Hat OpenShift Container Platform, see Deploying a Red Hat Decision Manager authoring or managed server environment on Red Hat OpenShift Container Platform for instructions about configuring it to connect to Business Central.

Prerequisites

- KIE Server is installed. For installation options, see Planning a Red Hat Decision Manager installation.

Procedure

1. In your Red Hat Decision Manager installation directory, navigate to the standalone-full.xml file. For example, if you use a Red Hat JBoss EAP installation for Red Hat Decision Manager, go to $SEAP_HOME/standalone/configuration/standalone-full.xml.
2. Open standalone-full.xml and under the <system-properties> tag, set the following properties:

- **org.kie.server.controller.user**: The user name of a user who can log in to the Business Central.
- **org.kie.server.controller.pwd**: The password of the user who can log in to the Business Central.
- **org.kie.server.controller**: The URL for connecting to the API of Business Central. Normally, the URL is http://<centralhost>:<centralport>/decision-central/rest/controller, where <centralhost> and <centralport> are the host name and port for Business Central. If Business Central is deployed on OpenShift, remove decision-central/ from the URL.
- **org.kie.server.location**: The URL for connecting to the API of KIE Server. Normally, the URL is http://<serverhost>:<serverport>/kie-server/services/rest/server, where <serverhost> and <serverport> are the host name and port for KIE Server.
- **org.kie.server.id**: The name of a server configuration. If this server configuration does not exist in Business Central, it is created automatically when KIE Server connects to Business Central.

Example:

```
<property name="org.kie.server.controller.user" value="central_user"/>
<property name="org.kie.server.controller.pwd" value="central_password"/>
<property name="org.kie.server.controller" value="http://central.example.com:8080/decision-central/rest/controller"/>
<property name="org.kie.server.location" value="http://kieserver.example.com:8080/kie-server/services/rest/server"/>
<property name="org.kie.server.id" value="production-servers"/>
```

3. Start or restart the KIE Server.

2.2. CONFIGURING THE ENVIRONMENT MODE IN KIE SERVER AND BUSINESS CENTRAL

You can set KIE Server to run in **production** mode or in **development** mode. Development mode provides a flexible deployment policy that enables you to update existing deployment units (KIE containers) while maintaining active process instances for small changes. It also enables you to reset the deployment unit state before updating active process instances for larger changes. Production mode is optimal for production environments, where each deployment creates a new deployment unit.

In a development environment, you can click **Deploy** in Business Central to deploy the built KJAR file to a KIE Server without stopping any running instances (if applicable), or click **Redeploy** to deploy the built KJAR file and replace all instances. The next time you deploy or redeploy the built KJAR, the previous deployment unit (KIE container) is automatically updated in the same target KIE Server.

In a production environment, the **Redeploy** option in Business Central is disabled and you can click only **Deploy** to deploy the built KJAR file to a new deployment unit (KIE container) on a KIE Server.

**Procedure**

1. To configure the KIE Server environment mode, set the **org.kie.server.mode** system property to **org.kie.server.mode=development** or **org.kie.server.mode=production**.
2. To configure the deployment behavior for a project in Business Central, go to project Settings → General Settings → Version and toggle the Development Mode option.

NOTE

By default, KIE Server and all new projects in Business Central are in development mode.

You cannot deploy a project with Development Mode turned on or with a manually added SNAPSHOT version suffix to a KIE Server that is in production mode.

2.3. CONFIGURING AN EXTERNAL MAVEN REPOSITORY FOR BUSINESS CENTRAL AND KIE SERVER

You can configure Business Central and KIE Server to use an external Maven repository, such as Nexus or Artifactory, instead of the built-in repository. This enables Business Central and KIE Server to access and download artifacts that are maintained in the external Maven repository.

NOTE

For information about configuring an external Maven repository for an authoring environment on Red Hat OpenShift Container Platform, see the following documents:

- Deploying a Red Hat Decision Manager authoring or managed server environment on Red Hat OpenShift Container Platform
- Deploying a Red Hat Decision Manager environment on Red Hat OpenShift Container Platform using Operators

Prerequisites

- Business Central and KIE Server are installed. For installation options, see Planning a Red Hat Decision Manager installation.

Procedure

1. Create a Maven settings.xml file with connection and access details for your external repository. For details about the settings.xml file, see the Maven Settings Reference.

2. Save the file in a known location, for example,/opt/custom-config/settings.xml.

3. In your Red Hat Decision Manager installation directory, navigate to the standalone-full.xml file. For example, if you use a Red Hat JBoss EAP installation for Red Hat Decision Manager, go to $EAP_HOME/standalone/configuration/standalone-full.xml.

4. Open standalone-full.xml and under the <system-properties> tag, set the kie.maven.settings.custom property to the full path name of the settings.xml file. For example:

   `<property name="kie.maven.settings.custom" value="/opt/custom-config/settings.xml"/>

5. Start or restart Business Central and KIE Server.
Next steps

For each Business Central project that you want to export or push as a KJAR artifact to the external Maven repository, you must add the repository information in the project pom.xml file. For instructions, see Section 2.4, “Exporting a Business Central project to an external Maven repository”.

2.4. EXPORTING A BUSINESS CENTRAL PROJECT TO AN EXTERNAL MAVEN REPOSITORY

If you configured an external Maven repository for Business Central and KIE Server, you must add the repository information in the pom.xml file for each Business Central project that you want to export or push as a KJAR artifact to that external repository. You can then progress the project KJAR files through the repository as necessary to implement your integration process, and deploy the KJAR files using Business Central or the KIE Server REST API.

Prerequisites

- You configured Business Central and KIE Server to use an external Maven repository. If you deployed Business Central on-premise, for more information about configuring an external Maven repository, see Section 2.3, “Configuring an external Maven repository for Business Central and KIE Server”. If you deployed your authoring environment on Red Hat OpenShift Container Platform, for more information, see the following documents:
  - Deploying a Red Hat Decision Manager authoring or managed server environment on Red Hat OpenShift Container Platform
  - Deploying a Red Hat Decision Manager environment on Red Hat OpenShift Container Platform using Operators

Procedure

1. In Business Central, go to Menu → Design → Projects, click the project name, and select any asset in the project.

2. In the Project Explorer menu on the left side of the screen, click the Customize View gear icon and select Repository View → pom.xml.

3. Add the following settings at the end of the project pom.xml file (before the </project> closing tag). The values must correspond to the settings that you defined in your settings.xml file.

   ```xml
   <distributionManagement>
   <repository>
   <id>${maven-repo-id}</id>
   <url>${maven-repo-url}</url>
   <layout>default</layout>
   </repository>
   </distributionManagement>
   
   `<distributionManagement>
   <repository>
   <id>${maven-repo-id}</id>
   <url>${maven-repo-url}</url>
   <layout>default</layout>
   </repository>
   
   `<distributionManagement>
   <repository>
   <id>${maven-repo-id}</id>
   <url>${maven-repo-url}</url>
   <layout>default</layout>
   </repository>
   ```

4. Click Save to save the pom.xml file changes.

Repeat this procedure for each Business Central project that you want to export or push as a KJAR artifact to the external Maven repository.

2.5. BUILDING AND DEPLOYING A PROJECT IN BUSINESS CENTRAL
After your project is developed, you can build the project in Business Central and deploy it to the configured KIE Server. Projects in Business Central are packaged automatically as KJARs with all necessary components when you build and deploy the projects.

**Procedure**

1. In Business Central, go to **Menu → Design → Projects** and click the project name.

2. In the upper-right corner, click **Deploy** to build the project and deploy it to a KIE Server. To compile the project without deploying it to KIE Server, click **Build**.

**NOTE**

You can also select the **Build & Install** option to build the project and publish the KJAR file to the configured Maven repository without deploying to a KIE Server. In a development environment, you can click **Deploy** to deploy the built KJAR file to a KIE Server without stopping any running instances (if applicable), or click **Redeploy** to deploy the built KJAR file and replace all instances. The next time you deploy or redeploy the built KJAR, the previous deployment unit (KIE container) is automatically updated in the same target KIE Server. In a production environment, the **Redeploy** option is disabled and you can click **Deploy** only to deploy the built KJAR file to a new deployment unit (KIE container) on a KIE Server.

To configure the KIE Server environment mode, set the `org.kie.server.mode` system property to `org.kie.server.mode=development` or `org.kie.server.mode=production`. To configure the deployment behavior for a corresponding project in Business Central, go to project **Settings → General Settings → Version** and toggle the **Development Mode** option. By default, KIE Server and all new projects in Business Central are in development mode. You cannot deploy a project with **Development Mode** turned on or with a manually added **SNAPSHOT** version suffix to a KIE Server that is in production mode.

If only one KIE Server is connected to Business Central, or if all connected KIE Servers are in the same server configuration, the services in the project are started automatically in a deployment unit (KIE container).

If multiple server configurations are available, a deployment dialog is displayed in Business Central, prompting you to specify server and deployment details.

3. If the deployment dialog appears, verify or set the following values:

   - **Deployment Unit Id / Deployment Unit Alias**: Verify the name and alias of the deployment unit (KIE container) running the service within the KIE Server. You normally do not need to change these settings. For more information about KIE container aliases, see **Section 2.6.3, “KIE container aliases”**.

   - **Server Configuration**: Select the server configuration for deploying this project. You can later deploy it to other configured servers without rebuilding the project.

   - **Start Deployment Unit?**: Verify that this box is selected to start the deployment unit (KIE container). If you clear this box, the service is deployed onto the server but not started.

To review project deployment details, click **View deployment details** in the deployment banner at the top of the screen or in the **Deploy** drop-down menu. This option directs you to the **Menu → Deploy → Execution Servers** page.
2.6. DEPLOYMENT UNITS IN BUSINESS CENTRAL

The services in a project are consumed at runtime through an instantiated KIE container, or deployment unit, on a configured KIE Server. When you build and deploy a project in Business Central, the deployment unit is created automatically in the configured server. You can start, stop, or remove deployment units in Business Central as needed. You can also create additional deployment units from previously built projects and start them on existing or new KIE Servers configured in Business Central.

2.6.1. Creating a deployment unit in Business Central

One or more deployment units should already exist as part of your Red Hat Decision Manager configuration, but if not, you can create a deployment unit from a project that was previously built in Business Central.

Prerequisites

- The project for which you are creating the new deployment unit has been built in Business Central.

Procedure

1. In Business Central, go to Menu → Deploy → Execution servers.
2. Under Server Configurations, select an existing configuration or click New Server Configuration to create a configuration.
3. Under Deployment Units, click Add Deployment Unit.
4. Add an alias in the Alias field if required.
5. In the table within the window, select a GAV and click Select next to the GAV to populate the deployment unit data fields.
6. Select the Start Deployment Unit? box to start the service immediately, or clear the box to start it later.
7. Click Finish.

The new deployment unit for the service is created and placed on the KIE Servers that are configured for this server configuration. If you have selected Start Deployment Unit?, the service is started.

2.6.2. Starting, stopping, and removing deployment units in Business Central

When a deployment unit is started, the services in the deployment unit are available for use. If only one KIE Server is connected to Business Central, or if all connected KIE Servers are in the same server configuration, services are started in a deployment unit automatically when a project is deployed. If multiple server configurations are available, you are prompted upon deployment to specify server and deployment details and to start the deployment unit. However, at any time you can manually start, stop, or remove deployment units in Business Central to manage your deployed services as needed.

Procedure

1. In Business Central, go to Menu → Deploy → Execution servers.
2. Under Server Configurations, select a configuration.
3. Under Deployment Units, select a deployment unit.

4. Click Start, Stop, or Remove in the upper-right corner. To remove a running deployment unit, stop it and then remove it.

2.6.3. KIE container aliases

An alias for a KIE container (deployment unit) is a proxy in the KIE Server instance that helps in handling different versions of the same container deployment. You can link a single alias to different versions of a container. When a container is upgraded, the linked alias automatically points to the new version of the container. For information about creating a KIE container alias, see Section 2.6.1, “Creating a deployment unit in Business Central”.

For example, if a client application is changing every time a new version of a container is deployed, then the client application can point to the container alias. When a new container version is deployed, the associated alias is updated and all the requests are routed automatically to the new container without changing the client application.

Consider an example project that contains a single process and uses the following properties:

- **GroupId**: org.jbpm
- **ArtifactId**: my-project
- **Version**: 1.0
- **containerID**: my-project

When you update, build, and deploy the above project, the associated project is updated in the KIE Server with the latest version and contains the following properties:

- **GroupId**: org.jbpm
- **ArtifactId**: my-project
- **Version**: 2.0

If you want to deploy the latest version of the project, you need to update the **containerID** as my-project2 because the **my-project** container points to the old version.

**NOTE**

Every project version contains a different **containerID** name. The associated client applications need to be aware of all versions of the projects they interact with.

Container aliases also help you manage KIE containers. You can set the container aliases explicitly when creating a container, or implicitly based on the associated **ArtifactId** name. You can add a single alias to multiple containers if required. If you do not specify a container alias, then the **ArtifactId** of a project is set as the container alias by default.

When you set an alias for multiple containers that contain different **GroupId** and **ArtifactId** names, then you can use the same alias every time to interact with the KIE Server.

You typically use container aliases in the following use cases:

- **Starting a new process instance** on the client application with the latest version of the process
• Interacting with an existing process of a specific version
• Interacting with an existing task in a process
• Interacting with a process definition image and form

For example, after you deploy the 1.0 version of a project, you send a POST request to the following KIE Server REST API endpoint to start the process in the project:

/http://localhost:8230/kie-server/services/rest/server/containers/my-project/processes/evaluation/instances

The sent request starts a new process instance from org.jbpm:my-project:1.0 in which my-project is defined as the container alias. Later, when you deploy the 2.0 version of the project and send the same request, a new instance starts from org.jbpm:my-project:2.0. You can deploy the latest version of the process without adding the containerID name.

2.7. EDITING THE GAV VALUES FOR A PROJECT IN BUSINESS CENTRAL

The GroupId, ArtifactId, and Version (GAV) values identify a project in a Maven repository. When Business Central and KIE Server are on the same file system and use the same Maven repository, the project is automatically updated in the repository each time you build a new version of your project. However, if Business Central and KIE Server are on separate file systems and use separate local Maven repositories, you must update a project GAV value, usually the version, for any new versions of the project to ensure that the project is seen as a different artifact alongside the old version.

NOTE

For development purposes only, you can toggle the Development Mode option in project Settings → General Settings → Version to add the SNAPSHOT suffix in the project version. This suffix instructs Maven to get a new snapshot update according to the Maven policy. Do not use Development Mode or manually add the SNAPSHOT version suffix for a production environment.

You can set the GAV values in the project Settings screen.

Procedure

1. In Business Central, go to Menu → Design → Projects and click the project name.

2. Click the project Settings tab.

3. In General Settings, modify the Group ID, Artifact ID, or Version fields as necessary. If you have deployed the project and are developing a new version, usually you need to increase the version number.

NOTE

For development purposes only, you can toggle the Development Mode option in project Settings → General Settings → Version to add the SNAPSHOT suffix in the project version. This suffix instructs Maven to get a new snapshot update according to the Maven policy. Do not use Development Mode or manually add the SNAPSHOT version suffix for a production environment.
4. Click **Save** to finish.

## 2.8. DUPLICATE GAV DETECTION IN BUSINESS CENTRAL

In Business Central, all Maven repositories are checked for any duplicated **GroupId**, **ArtifactId**, and **Version** (GAV) values in a project. If a GAV duplicate exists, the performed operation is canceled.

**NOTE**

Duplicate GAV detection is disabled for projects in **Development Mode**. To enable duplicate GAV detection in Business Central, go to project **Settings → General Settings → Version** and toggle the **Development Mode** option to **OFF** (if applicable).

Duplicate GAV detection is executed every time you perform the following operations:

- Save a project definition for the project.
- Save the **pom.xml** file.
- Install, build, or deploy a project.

The following Maven repositories are checked for duplicate GAVs:

- Repositories specified in the `<repositories>` and `<distributionManagement>` elements of the **pom.xml** file.
- Repositories specified in the Maven **settings.xml** configuration file.

### 2.8.1. Managing duplicate GAV detection settings in Business Central

Business Central users with the **admin** role can modify the list of repositories that are checked for duplicate **GroupId**, **ArtifactId**, and **Version** (GAV) values for a project.

**NOTE**

Duplicate GAV detection is disabled for projects in **Development Mode**. To enable duplicate GAV detection in Business Central, go to project **Settings → General Settings → Version** and toggle the **Development Mode** option to **OFF** (if applicable).

**Procedure**

1. In Business Central, go to **Menu → Design → Projects** and click the project name.
2. Click the project **Settings** tab and then click **Validation** to open the list of repositories.
3. Select or clear any of the listed repository options to enable or disable duplicate GAV detection. In the future, duplicate GAVs will be reported for only the repositories you have enabled for validation.
NOTE

To disable this feature, set the `org.guvnor.project.gav.check.disabled` system property to `true` for Business Central at system startup:

```
$ ~/EAP_HOME/bin/standalone.sh -c standalone-full.xml
   -Dorg.guvnor.project.gav.check.disabled=true
```
CHAPTER 3. PROJECT DEPLOYMENT WITHOUT BUSINESS CENTRAL

As an alternative to developing and deploying projects in the Business Central interface, you can use independent Maven projects or your own Java applications to develop Red Hat Decision Manager projects and deploy them in KIE containers (deployment units) to a configured KIE Server. You can then use the KIE Server REST API to start, stop, or remove the KIE containers that contain the services and their project versions that you have built and deployed. This flexibility enables you to continue to use your existing application workflow to develop business assets using Red Hat Decision Manager features.

Projects in Business Central are packaged automatically when you build and deploy the projects. For projects outside of Business Central, such as independent Maven projects or projects within a Java application, you must configure the KIE module descriptor settings in an appended kmodule.xml file or directly in your Java application in order to build and deploy the projects.

3.1. CONFIGURING A KIE MODULE DESCRIPTOR FILE

A KIE module is a Maven project or module with an additional metadata file META-INF/kmodule.xml. All Red Hat Decision Manager projects require a kmodule.xml file in order to be properly packaged and deployed. This kmodule.xml file is a KIE module descriptor that defines the KIE base and KIE session configurations for the assets in a project. A KIE base is a repository that contains all rules and other business assets in Red Hat Decision Manager but does not contain any runtime data. A KIE session stores and executes runtime data and is created from a KIE base or directly from a KIE container if you have defined the KIE session in the kmodule.xml file.

If you create projects outside of Business Central, such as independent Maven projects or projects within a Java application, you must configure the KIE module descriptor settings in an appended kmodule.xml file or directly in your Java application in order to build and deploy the projects.

Procedure

1. In the ~/resources/META-INF directory of your project, create a kmodule.xml metadata file with at least the following content:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<kmodule xmlns="http://www.drools.org/xsd/kmodule">
</kmodule>
```

This empty kmodule.xml file is sufficient to produce a single default KIE base that includes all files found under your project resources path. The default KIE base also includes a single default KIE session that is triggered when you create a KIE container in your application at build time.

The following example is a more advanced kmodule.xml file:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<kmodule xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" 
xmns="http://www.drools.org/xsd/kmodule">
  <configuration>
    <property key="drools.evaluator.supersetOf" 
    value="org.mycompany.SupersetOfEvaluatorDefinition"/>
  </configuration>
  <kbase name="KBase1" default="true" eventProcessingMode="cloud" 
equalsBehavior="equality" declarativeAgenda="enabled" packages="org.domain.pkg1">
```

This example defines two KIE bases. Specific packages of rule assets are included with both KIE bases. When you specify packages in this way, you must organize your rule files in a folder structure that reflects the specified packages. Two KIE sessions are instantiated from the KBase1 KIE base, and one KIE session from KBase2. The KIE session from KBase2 is a stateless KIE session, which means that data from a previous invocation of the KIE session (the previous session state) is discarded between session invocations. That KIE session also specifies a file (or a console) logger, a WorkItemHandler, and listeners of the three supported types shown: ruleRuntimeEventListener, agendaEventListener, and processEventListener. The <configuration> element defines optional properties that you can use to further customize your kmodule.xml file.

As an alternative to manually appending a kmodule.xml file to your project, you can use a KieModuleModel instance within your Java application to programmatically create a kmodule.xml file that defines the KIE base and a KIE session, and then add all resources in your project to the KIE virtual file system KieFileSystem.

**Creating kmodule.xml programmatically and adding it to KieFileSystem**

```java
import org.kie.api.KieServices;
import org.kie.api.builder.model.KieModuleModel;
import org.kie.api.builder.model.KieBaseModel;
import org.kie.api.builder.model.KieSessionModel;
import org.kie.api.builder.KieFileSystem;

KieServices kieServices = KieServices.Factory.get();
KieModuleModel kieModuleModel = kieServices.newKieModuleModel();

KieBaseModel kieBaseModel1 = kieModuleModel.newKieBaseModel("KBase1")
    .setDefault(true)
    .setEqualsBehavior(EqualityBehaviorOption.EQUALITY)
    .setEventProcessingMode(EventProcessingOption.STREAM);

KieSessionModel ksessionModel1 = kieBaseModel1.newKieSessionModel("KSession1_1")
    .setDefault(true)
    .setType(KieSessionModel.KieSessionType.STATEFUL)
```
After you configure the `kmodule.xml` file either manually or programmatically in your project, retrieve the KIE bases and KIE sessions from the KIE container to verify the configurations:

To increase or decrease the maximum number of KIE modules or artifact versions that are cached in the decision engine, you can modify the values of the following system properties in your Red Hat Decision Manager distribution:

- `kie.repository.project.cache.size`: Maximum number of KIE modules that are cached in the decision engine. Default value: 100
- `kie.repository.project.versions.cache.size`: Maximum number of versions of the same artifact that are cached in the decision engine. Default value: 10

For the full list of KIE repository configurations, download the Red Hat Decision Manager 7.7.0 Source Distribution ZIP file from the Red Hat Customer Portal and navigate to `~/rhdm-7.7.0-sources/src/drools-$VERSION/drools-compiler/src/main/java/org/drools/compiler/kie/builder/impl/KieRepositoryImpl.java`.

For more information about the `kmodule.xml` file, download the Red Hat Decision Manager 7.7.0 Source Distribution ZIP file from the Red Hat Customer Portal (if not downloaded already) and see the `kmodule.xsd` XML schema located at `$FILE_HOME/rhdm-$VERSION-sources/kie-api-parent-$VERSION/kie-api/src/main/resources/org/kie/api/`.  

```java
.setClockType(ClockTypeOption.get("realtime"));

KieFileSystem kfs = kieServices.newKieFileSystem();
kfs.writeKModuleXML(kieModuleModel.toXML());

2. After you configure the `kmodule.xml` file either manually or programatically in your project, retrieve the KIE bases and KIE sessions from the KIE container to verify the configurations:

```
NOTE

KieBase or KiePackage serialization is not supported in Red Hat Decision Manager 7.7. For more information, see Is serialization of kbase/package supported in BRMS 6/BPM Suite 6/RHDM 7?

3.1.1. KIE module configuration properties

The optional <configuration> element in the KIE module descriptor file (kmodule.xml) of your project defines property key and value pairs that you can use to further customize your kmodule.xml file.

Example configuration property in a kmodule.xml file

```xml
<kmodule>

  ...

  <configuration>
    <property key="drools.dialect.default" value="java"/>
    ...
  </configuration>

  ...

</kmodule>
```

The following are the <configuration> property keys and values supported in the KIE module descriptor file (kmodule.xml) for your project:

- **drools.dialect.default**
  
  Sets the default Drools dialect.
  
  Supported values: java, mvel

  ```xml
  <property key="drools.dialect.default" value="java"/>
  ```

- **drools.accumulate.function.$FUNCTION**
  
  Links a class that implements an accumulate function to a specified function name, which allows you to add custom accumulate functions into the decision engine.

  ```xml
  <property key="drools.accumulate.function.hyperMax" value="org.drools.custom.HyperMaxAccumulate"/>
  ```

- **drools.evaluator.$EVALUATION**
  
  Links a class that implements an evaluator definition to a specified evaluator name so that you can add custom evaluators into the decision engine. An evaluator is similar to a custom operator.

  ```xml
  <property key="drools.evaluator.soundslike" value="org.drools.core.base.evaluators.SoundslikeEvaluatorsDefinition"/>
  ```

- **drools.dump.dir**
  
  Sets a path to the Red Hat Decision Manager dump/log directory.

  ```xml
  <property key="drools.dump.dir" value="$DIR_PATH/dump/log"/>
  ```
drools.defaultPackageName
Sets a default package for the business assets in your project.

<property key="drools.defaultPackageName" value="org.domain.pkg1"/>

drools.parser.processStringEscapes
Sets the String escape function. If this property is set to false, the \n character will not be interpreted as the newline character.
Supported values: true (default), false

<property key="drools.parser.processStringEscapes" value="true"/>

drools.kbuilder.severity.$DUPLICATE
Sets a severity for instances of duplicate rules, processes, or functions reported when a KIE base is built. For example, if you set duplicateRule to ERROR, then an error is generated for any duplicated rules detected when the KIE base is built.
Supported key suffixes: duplicateRule, duplicateProcess, duplicateFunction

Supported values: INFO, WARNING, ERROR

<property key="drools.kbuilder.severity.duplicateRule" value="ERROR"/>

drools.propertySpecific
Sets the property reactivity of the decision engine.
Supported values: DISABLED, ALLOWED, ALWAYS

<property key="drools.propertySpecific" value="ALLOWED"/>

drools.lang.level
Sets the DRL language level.
Supported values: DRL5, DRL6, DRL6_STRICT (default)

<property key="drools.lang.level" value="DRL_STRICT"/>

3.1.2. KIE base attributes supported in KIE modules

A KIE base is a repository that you define in the KIE module descriptor file (kmodule.xml) for your project and contains all rules and other business assets in Red Hat Decision Manager. When you define KIE bases in the kmodule.xml file, you can specify certain attributes and values to further customize your KIE base configuration.

Example KIE base configuration in a kmodule.xml file

<kmodule>
The following are the `kbase` attributes and values supported in the KIE module descriptor file (`kmodule.xml`) for your project:

Table 3.1. KIE base attributes supported in KIE modules

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Supported values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong></td>
<td>Any name</td>
<td>Defines the name that retrieves <code>KieBase</code> from <code>KieContainer</code>. <em>This attribute is mandatory.</em></td>
</tr>
<tr>
<td><strong>includes</strong></td>
<td>Comma-separated list of other KIE base objects in the KIE module</td>
<td>Defines other KIE base objects and artifacts to be included in this KIE base. A KIE base can be contained in multiple KIE modules if you declare it as a dependency in the <code>pom.xml</code> file of the modules.</td>
</tr>
<tr>
<td><strong>packages</strong></td>
<td>Comma-separated list of packages to include in the KIE base</td>
<td>Defines packages of artifacts (such as rules and processes) to be included in this KIE base. By default, all artifacts in the <code>~/.resources</code> directory are included into a KIE base. This attribute enables you to limit the number of compiled artifacts. Only the packages belonging to the list specified in this attribute are compiled.</td>
</tr>
<tr>
<td><strong>default</strong></td>
<td><code>true, false</code></td>
<td>Determines whether a KIE base is the default KIE base for a module so that it can be created from the KIE container without passing any name. Each module can have only one default KIE base.</td>
</tr>
</tbody>
</table>
### 3.1.3. KIE session attributes supported in KIE modules

A KIE session stores and executes runtime data and is created from a KIE base or directly from a KIE container if you have defined the KIE session in the KIE module descriptor file (kmodule.xml) for your project. When you define KIE bases and KIE sessions in the kmodule.xml file, you can specify certain attributes and values to further customize your KIE session configuration.

#### Example KIE session configuration in a kmodule.xml file

```xml
<kmodule>
  ...
  <kbase>
    ...
    <ksession name="KSession2_1" type="stateless" default="true" clockType="realtime">  
```
The following are the `ksession` attributes and values supported in the KIE module descriptor file (`kmodule.xml`) for your project:

Table 3.2. KIE session attributes supported in KIE modules

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Supported values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Any name</td>
<td>Defines the name that retrieves <code>KieSession</code> from <code>KieContainer</code>. This attribute is mandatory.</td>
</tr>
<tr>
<td>type</td>
<td>stateful, stateless</td>
<td>Determines whether data is retained (stateful) or discarded (stateless) between invocations of the KIE session. A session set to stateful enables you to iteratively work with the working memory, while a session set to stateless is typically used for one-off execution of assets. A stateless session stores a knowledge state that is changed every time a new fact is added, updated, or deleted, and every time a rule is executed. An execution in a stateless session has no information about previous actions, such rule executions.</td>
</tr>
<tr>
<td>default</td>
<td>true, false</td>
<td>Determines whether a KIE session is the default session for a module so that it can be created from the KIE container without passing any name. Each module can have only one default KIE session.</td>
</tr>
<tr>
<td>clockType</td>
<td>realtime, pseudo</td>
<td>Determines whether event time stamps are assigned by the system clock or by a pseudo clock controlled by the application. This clock is especially useful for unit testing on temporal rules.</td>
</tr>
<tr>
<td>beliefSystem</td>
<td>simple, jtms, defeasible</td>
<td>Defines the type of belief system used by the KIE session. A belief system deduces the truth from knowledge (facts). For example, if a new fact is inserted based on another fact which is later removed from the decision engine, the system can determine that the newly inserted fact should be removed as well.</td>
</tr>
</tbody>
</table>
3.2. PACKAGING AND DEPLOYING A RED HAT DECISION MANAGER PROJECT IN MAVEN

If you want to deploy a Maven project outside of Business Central to a configured KIE Server, you can edit the project pom.xml file to package your project as a KJAR file and add a kmodule.xml file with the KIE base and KIE session configurations for the assets in your project.

Prerequisites

- You have a Maven project that contains Red Hat Decision Manager business assets.
- KIE Server is installed and kie-server user access is configured. For installation options, see Planning a Red Hat Decision Manager installation.

Procedure

1. In the pom.xml file of your Maven project, set the packaging type to kjar and add the kie-maven-plugin build component:

```xml
<packaging>kjar</packaging>
...
<build>
<plugins>
<plugin>
<groupId>org.kie</groupId>
<artifactId>kie-maven-plugin</artifactId>
<version>${rhdm.version}</version>
<extensions>true</extensions>
</plugin>
</plugins>
</build>
```

The kjar packaging type activates the kie-maven-plugin component to validate and pre-compile artifact resources. The <version> is the Maven artifact version for Red Hat Decision Manager currently used in your project (for example, 7.33.0.Final-redhat-00002). These settings are required to properly package the Maven project for deployment.
NOTE

Instead of specifying a Red Hat Decision Manager <version> for individual dependencies, consider adding the Red Hat Business Automation bill of materials (BOM) dependency to your project pom.xml file. The Red Hat Business Automation BOM applies to both Red Hat Decision Manager and Red Hat Process Automation Manager. When you add the BOM files, the correct versions of transitive dependencies from the provided Maven repositories are included in the project.

Example BOM dependency:

```
<dependency>
  <groupId>com.redhat.ba</groupId>
  <artifactId>ba-platform-bom</artifactId>
  <version>7.7.0.redhat-00002</version>
  <scope>import</scope>
  <type>pom</type>
</dependency>
```

For more information about the Red Hat Business Automation BOM, see What is the mapping between Red Hat Decision Manager and the Maven library version?.

2. (Optional) If your project contains Decision Model and Notation (DMN) assets, also add the following dependency in the pom.xml file to enable DMN executable models. DMN executable models enable DMN decision table logic in DMN projects to be evaluated more efficiently.

```
<dependency>
  <groupId>org.kie</groupId>
  <artifactId>kie-dmn-core</artifactId>
  <scope>provided</scope>
  <version>${rhdm.version}</version>
</dependency>
```

3. In the ~/resources directory of your Maven project, create a META-INF/kmodule.xml metadata file with at least the following content:

```
<?xml version="1.0" encoding="UTF-8"?>
<kmodule xmlns="http://www.drools.org/xsd/kmodule">
</kmodule>
```

This kmodule.xml file is a KIE module descriptor that is required for all Red Hat Decision Manager projects. You can use the KIE module to define one or more KIE bases and one or more KIE sessions from each KIE base.

For more information about kmodule.xml configuration, see Section 3.1, “Configuring a KIE module descriptor file”.

4. In the relevant resource in your Maven project, configure a java class to create a KIE container and a KIE session to load the KIE base:

```java
import org.kie.api.KieServices;
import org.kie.api.runtime.KieContainer;
import org.kie.api.runtime.KieSession;
```
In this example, the KIE container reads the files to be built from the class path for a testApp project. The KieServices API enables you to access all KIE building and runtime configurations.

You can also create the KIE container by passing the project ReleaseId to the KieServices API. The ReleaseId is generated from the GroupId, ArtifactId, and Version (GAV) values in the project pom.xml file.

```java
import org.kie.api.KieServices;
import org.kie.api.builder.ReleaseId;
import org.kie.api.runtime.KieContainer;
import org.kie.api.runtime.KieSession;
import org.drools.compiler.kproject.ReleaseIdImpl;

public void testApp() {
    // Load the KIE base:
    KieServices ks = KieServices.Factory.get();
    KieContainer kContainer = ks.getKieClasspathContainer();
    KieSession kSession = kContainer.newKieSession();
}
```

In this example, the KIE container reads the files to be built from the class path for a testApp project. The KieServices API enables you to access all KIE building and runtime configurations.

You can also create the KIE container by passing the project ReleaseId to the KieServices API. The ReleaseId is generated from the GroupId, ArtifactId, and Version (GAV) values in the project pom.xml file.

```java
import org.kie.api.KieServices;
import org.kie.api.builder.ReleaseId;
import org.kie.api.runtime.KieContainer;
import org.kie.api.runtime.KieSession;
import org.drools.compiler.kproject.ReleaseIdImpl;

public void testApp() {
    // Identify the project in the local repository:
    ReleaseId rid = new ReleaseIdImpl("com.sample", "my-app", "1.0.0");

    // Load the KIE base:
    KieServices ks = KieServices.Factory.get();
    KieContainer kContainer = ks.newKieContainer(rid);
    KieSession kSession = kContainer.newKieSession();
}
```

5. In a command terminal, navigate to your Maven project directory and run the following command to build the project:

```
mvn clean install
```

For DMN executable models, run the following command:

```
mvn clean install -DgenerateDMNModel=YES
```

If the build fails, address any problems described in the command line error messages and try again to validate the files until the build is successful.
NOTE

If the rule assets in your Maven project are not built from an executable rule model by default, verify that the following dependency is in the `pom.xml` file of your project and rebuild the project:

```xml
<dependency>
    <groupId>org.drools</groupId>
    <artifactId>drools-model-compiler</artifactId>
    <version>${rhdm.version}</version>
</dependency>
```

This dependency is required for rule assets in Red Hat Decision Manager to be built from executable rule models by default. This dependency is included as part of the Red Hat Decision Manager core packaging, but depending on your Red Hat Decision Manager upgrade history, you may need to manually add this dependency to enable the executable rule model behavior.

For more information about executable rule models, see Section 3.4, “Executable rule models”.

6. After you successfully build and test the project locally, deploy the project to the remote Maven repository:

```
mvn deploy
```

3.3. PACKAGING AND DEPLOYING A RED HAT DECISION MANAGER PROJECT IN A JAVA APPLICATION

If you want to deploy a project from within your own Java application to a configured KIE Server, you can use a `KieModuleModel` instance to programmatically create a `kmodule.xml` file that defines the KIE base and a KIE session, and then add all resources in your project to the KIE virtual file system `KieFileSystem`.

Prerequisites

- You have a Java application that contains Red Hat Decision Manager business assets.
- KIE Server is installed and `kie-server` user access is configured. For installation options, see Planning a Red Hat Decision Manager installation.

Procedure

1. (Optional) If your project contains Decision Model and Notation (DMN) assets, add the following dependency to the relevant class path of your Java project to enable DMN executable models. DMN executable models enable DMN decision table logic in DMN projects to be evaluated more efficiently.

```xml
<dependency>
    <groupId>org.kie</groupId>
    <artifactId>kie-dmn-core</artifactId>
    <scope>provided</scope>
    <version>${rhdm.version}</version>
</dependency>
```
The `<version>` is the Maven artifact version for Red Hat Decision Manager currently used in your project (for example, 7.33.0.Final-redhat-00002).

**NOTE**

Instead of specifying a Red Hat Decision Manager `<version>` for individual dependencies, consider adding the Red Hat Business Automation bill of materials (BOM) dependency to your project `pom.xml` file. The Red Hat Business Automation BOM applies to both Red Hat Decision Manager and Red Hat Process Automation Manager. When you add the BOM files, the correct versions of transitive dependencies from the provided Maven repositories are included in the project.

Example BOM dependency:

```
<dependency>
  <groupId>com.redhat.ba</groupId>
  <artifactId>ba-platform-bom</artifactId>
  <version>7.7.0.redhat-00002</version>
  <scope>import</scope>
  <type>pom</type>
</dependency>
```

For more information about the Red Hat Business Automation BOM, see What is the mapping between Red Hat Decision Manager and the Maven library version?.

2. Use the `KieServices` API to create a `KieModuleModel` instance with the desired KIE base and KIE session. The `KieServices` API enables you to access all KIE building and runtime configurations. The `KieModuleModel` instance generates the `kmodule.xml` file for your project. For more information about `kmodule.xml` configuration, see Section 3.1, "Configuring a KIE module descriptor file".

3. Convert your `KieModuleModel` instance into XML and add the XML to `KieFileSystem`.

**Creating kmodule.xml programmatically and adding it to KieFileSystem**

```
import org.kie.api.KieServices;
import org.kie.api.builder.model.KieModuleModel;
import org.kie.api.builder.model.KieBaseModel;
import org.kie.api.builder.model.KieSessionModel;
import org.kie.api.builder.KieFileSystem;

KieServices kieServices = KieServices.Factory.get();
KieModuleModel kieModuleModel = kieServices.newKieModuleModel();

KieBaseModel kieBaseModel1 = kieModuleModel.newKieBaseModel("KBase1")
  .setDefault(true)
  .setEqualsBehavior(EqualityBehaviorOption.EQUALITY)
  .setEventProcessingMode(EventProcessingOption STREAM);

KieSessionModel ksessionModel1 = kieBaseModel1.newKieSessionModel("KSession1")
  .setDefault(true)
  .setType(KieSessionModel.KieSessionType.STATEFUL)
  .setClockType(ClockTypeOption.get("realtime"));
```
4. Add any remaining Red Hat Decision Manager assets that you use in your project to your `KieFileSystem` instance. The artifacts must be in a Maven project file structure.

```java
import org.kie.api.builder.KieFileSystem;

KieFileSystem kfs = ...;
kfs.write("src/main/resources/KBase1/ruleSet1.drl", stringContainingAValidDRL)
    .write("src/main/resources/dtable.xls",
           kieServices.getResources().newInputStreamResource(dtableFileStream));
```

In this example, the project assets are added both as a `String` variable and as a `Resource` instance. You can create the `Resource` instance using the `KieResources` factory, also provided by the `KieServices` instance. The `KieResources` class provides factory methods to convert `InputStream`, `URL`, and `File` objects, or a `String` representing a path of your file system to a `Resource` instance that the `KieFileSystem` can manage.

You can also explicitly assign a `ResourceType` property to a `Resource` object when you add project artifacts to `KieFileSystem`:

```java
import org.kie.api.builder.KieFileSystem;

KieFileSystem kfs = ...;
kfs.write("src/main/resources/myDrl.txt",
         kieServices.getResources().newInputStreamResource(drlStream)
           .setResourceType(ResourceType.DRL));
```

5. Use `KieBuilder` with the `buildAll()` method to build the content of `KieFileSystem`, and create a KIE container to deploy it:

```java
import org.kie.api.KieServices;
import org.kie.api.KieServices.Factory;
import org.kie.api.builder.KieFileSystem;
import org.kie.api.builder.KieBuilder;
import org.kie.api.runtime.KieContainer;

KieServices kieServices = KieServices.Factory.get();
KieFileSystem kfs = ...

KieBuilder kieBuilder = ks.newKieBuilder(kfs);
kieBuilder.buildAll()
    assertEquals(0, kieBuilder.getResults().getMessages(Message.Level.ERROR).size());

KieContainer kieContainer = kieServices
    .newKieContainer(kieServices.getRepository().getDefaultReleaseId());
```

A build `ERROR` indicates that the project compilation failed, no `KieModule` was produced, and nothing was added to the `KieRepository` singleton. A `WARNING` or an `INFO` result indicates that the compilation of the project was successful, with information about the build process.
NOTE

To build the rule assets in your Java application project from an executable rule model, verify that the following dependency is in the `pom.xml` file of your project:

```xml
<dependency>
  <groupId>org.drools</groupId>
  <artifactId>drools-model-compiler</artifactId>
  <version>${rhdm.version}</version>
</dependency>
```

This dependency is required for rule assets in Red Hat Decision Manager to be built from executable rule models. This dependency is included as part of the Red Hat Decision Manager core packaging, but depending on your Red Hat Decision Manager upgrade history, you may need to manually add this dependency to enable the executable rule model behavior.

After you verify the dependency, use the following modified `buildAll()` option to enable the executable model:

```java
kieBuilder.buildAll(ExecutableModelProject.class)
```

For more information about executable rule models, see Section 3.4, “Executable rule models”.

### 3.4. EXECUTABLE RULE MODELS

Rule assets in Red Hat Decision Manager are built from executable rule models by default with the standard `kie-maven-plugin` plugin. Executable rule models are embedded models that provide a Java-based representation of a rule set for execution at build time. The executable model is a more efficient alternative to the standard asset packaging in previous versions of Red Hat Decision Manager and enables KIE containers and KIE bases to be created more quickly, especially when you have large lists of DRL (Drools Rule Language) files and other Red Hat Decision Manager assets.

If you do not use the `kie-maven-plugin` plugin or if the required `drools-model-compiler` dependency is missing from your project, then rule assets are built without executable models.

Executable rule models provide the following specific advantages for your projects:

- **Compile time**: Traditionally, a packaged Red Hat Decision Manager project (KJAR) contains a list of DRL files and other Red Hat Decision Manager artifacts that define the rule base together with some pre-generated classes implementing the constraints and the consequences. Those DRL files must be parsed and compiled when the KJAR is downloaded from the Maven repository and installed in a KIE container. This process can be slow, especially for large rule sets. With an executable model, you can package within the project KJAR the Java classes that implement the executable model of the project rule base and re-create the KIE container and its KIE bases out of it in a much faster way. In Maven projects, you use the `kie-maven-plugin` plugin to automatically generate the executable model sources from the DRL files during the compilation process.

- **Run time**: In an executable model, all constraints are defined as Java lambda expressions. The same lambda expressions are also used for constraints evaluation, so you no longer need to use `mvel` expressions for interpreted evaluation nor the just-in-time (JIT) process to transform the `mvel`-based constraints into bytecode. This creates a quicker and more efficient run time.
• **Development time:** An executable model enables you to develop and experiment with new features of the decision engine without needing to encode elements directly in the DRL format or modify the DRL parser to support them.

**NOTE**

For query definitions in executable rule models, you can use up to 10 arguments only.

For variables within rule consequences in executable rule models, you can use up to 24 bound variables only (including the built-in *drools* variable). For example, the following rule consequence uses more than 24 bound variables and creates a compilation error:

```java
... then
    $input.setNo25Count(functions.sumOf(new Object[]{$no1Count_1, $no2Count_1, $no3Count_1, ..., $no25Count_1}).intValue());
    $input.getFirings().add("fired");
    update($input);
```

### 3.4.1. Modifying or disabling executable rule models in a Red Hat Decision Manager project

Rule assets in Red Hat Decision Manager are built from executable rule models by default with the standard *kie-maven-plugin* plugin. The executable model is a more efficient alternative to the standard asset packaging in previous versions of Red Hat Decision Manager. However, if needed, you can modify or disable executable rule models to build a Red Hat Decision Manager project as a DRL-based KJAR instead of the default model-based KJAR.

**Procedure**

Build your Red Hat Decision Manager project in the usual way, but provide an alternate build option, depending on the type of project:

- For a Maven project, navigate to your Maven project directory in a command terminal and run the following command:

  ```bash
  mvn clean install -DgenerateModel=<VALUE>
  ```

  Replace `<VALUE>` with one of three values:

  - **YES_WITHDRL:** (Default) Generates the executable model corresponding to the DRL files in the original project and also adds the DRL files to the generated KJAR for documentation purposes (the KIE base is built from the executable model regardless).

  - **YES:** Generates the executable model corresponding to the DRL files in the original project and excludes the DRL files from the generated KJAR.

  - **NO:** Does not generate the executable model.

  Example build command to disable the default executable model behavior:

  ```bash
  mvn clean install -DgenerateModel=NO
  ```
• For a Java application configured programmatically, the executable model is disabled by default. Add rule assets to the KIE virtual file system KieFileSystem and use KieBuilder with one of the following buildAll() methods:

  - buildAll() (Default) or buildAll(DrlProject.class): Does not generate the executable model.
  - buildAll(ExecutableModelProject.class): Generates the executable model corresponding to the DRL files in the original project.

Example code to enable executable model behavior:

```java
import org.kie.api.KieServices;
import org.kie.api.builder.KieFileSystem;
import org.kie.api.builder.KieBuilder;

KieServices ks = KieServices.Factory.get();
KieFileSystem kfs = ks.newKieFileSystem()
  .write("src/main/resources/KBase1/ruleSet1.drl", stringContainingAValidDRL)

KieBuilder kieBuilder = ks.newKieBuilder( kfs );
kieBuilder.buildAll(ExecutableModelProject.class); // Enable executable model
assertEquals(0, kieBuilder.getResults().getMessages(Message.Level.ERROR).size());
```

3.5. USING A KIE SCANNER TO MONITOR AND UPDATE KIE CONTAINERS

The KIE scanner in Red Hat Decision Manager monitors your Maven repository for new SNAPSHOT versions of your Red Hat Decision Manager project and then deploys the latest version of the project to a specified KIE container. You can use a KIE scanner in a development environment to maintain your Red Hat Decision Manager project deployments more efficiently as new versions become available.

**IMPORTANT**

For production environments, do not use a KIE scanner with SNAPSHOT project versions to avoid accidental or unexpected project updates. The KIE scanner is intended for development environments that use SNAPSHOT project versions.

**Prerequisites**

• The kie-ci.jar file is available on the class path of your Red Hat Decision Manager project.

**Procedure**

1. In the relevant .java class in your project, register and start the KIE scanner as shown in the following example code:

   ```java
   import org.kie.api.KieServices;
   import org.kie.api.builder.ReleaseId;
   ```

   ```java
   ```
In this example, the KIE scanner is configured to run with a fixed time interval. The minimum KIE scanner polling interval is 1 millisecond (ms) and the maximum polling interval is the maximum value of the data type `long`. A polling interval of 0 or less results in a `java.lang.IllegalArgumentException: pollingInterval must be positive` error. You can also configure the KIE scanner to run on demand by invoking the `scanNow()` method.

The project group ID, artifact ID, and version (GAV) settings in the example are defined as `com.sample:my-app:1.0-SNAPSHOT`. The project version must contain the `-SNAPSHOT` suffix to enable the KIE scanner to retrieve the latest build of the specified artifact version. If you change the snapshot project version number, such as increasing to `1.0.1-SNAPSHOT`, then you must also update the version in the GAV definition in your KIE scanner configuration. The KIE scanner does not retrieve updates for projects with static versions, such as `com.sample:my-app:1.0`.

2. In the `settings.xml` file of your Maven repository, set the `updatePolicy` configuration to `always` to enable the KIE scanner to function properly:

```xml
<profile>
  <id>guvnor-m2-repo</id>
  <repositories>
    <repository>
      <id>guvnor-m2-repo</id>
      <name>BA Repository</name>
      <url>http://localhost:8080/decision-central/maven2/</url>
      <layout>default</layout>
      <releases>
        <enabled>true</enabled>
        <updatePolicy>always</updatePolicy>
      </releases>
      <snapshots>
        <enabled>true</enabled>
        <updatePolicy>always</updatePolicy>
      </snapshots>
    </repository>
  </repositories>
</profile>
```

After the KIE scanner starts polling, if the KIE scanner detects an updated version of the `SNAPSHOT` project in the specified KIE container, the KIE scanner automatically downloads the new project version and triggers an incremental build of the new project. From that moment, all of the new `KieBase` and `KieSession` objects that were created from the KIE container use the new project version.
3.6. STARTING A SERVICE IN KIE SERVER

If you have deployed Red Hat Decision Manager assets from a Maven or Java project outside of Business Central, you use a KIE Server REST API call to start the KIE container (deployment unit) and the services in it. You can use the KIE Server REST API to start services regardless of your deployment type, including deployment from Business Central, but projects deployed from Business Central either are started automatically or can be started within the Business Central interface.

Prerequisites

- KIE Server is installed and kie-server user access is configured. For installation options, see Planning a Red Hat Decision Manager installation.

Procedure

In your command terminal, run the following API request to load a service into a KIE container in the KIE Server and to start it:

```
```

Replace the following values:

- `<username>`, `<password>`: The user name and password of a user with the kie-server role.
- `<containerID>`: The identifier for the KIE container (deployment unit). You can use any random identifier but it must be the same in both places in the command (the URL and the data).
- `<groupID>`, `<artifactID>`, `<version>`: The project GAV values.
- `<serverhost>`: The host name for the KIE Server, or localhost if you are running the command on the same host as the KIE Server.
- `<serverport>`: The port number for the KIE Server.

Example:

```
```

3.7. STOPPING AND REMOVING A SERVICE IN KIE SERVER

If you have started Red Hat Decision Manager services from a Maven or Java project outside of Business Central, you use a KIE Server REST API call to stop and remove the KIE container (deployment unit) containing the services. You can use the KIE Server REST API to stop services regardless of your deployment type, including deployment from Business Central, but services from Business Central can also be stopped within the Business Central interface.
Prerequisites

- KIE Server is installed and kie-server user access is configured. For installation options, see [Planning a Red Hat Decision Manager installation](#).

Procedure

In your command terminal, run the following API request to stop and remove a KIE container with services on KIE Server:

```bash
$ curl --user "<username>:<password>" -X DELETE http://<serverhost>:<serverport>/kie-server/services/rest/server/containers/<containerID>
```

Replace the following values:

- `<username>`, `<password>`: The user name and password of a user with the kie-server role.
- `<containerID>`: The identifier for the KIE container (deployment unit). You can use any random identifier but it must be the same in both places in the command (the URL and the data).
- `<serverhost>`: The host name for the KIE Server, or localhost if you are running the command on the same host as the KIE Server.
- `<serverport>`: The port number for the KIE Server.

Example:

```bash
curl --user "rhdmAdmin:password@1" -X DELETE http://localhost:39043/kie-server/services/rest/server/containers/kie1
```
