Red Hat Enterprise Linux 8

Administration and configuration tasks using System Roles in RHEL

Applying RHEL System Roles using Red Hat Ansible Automation Platform playbooks to perform system administration tasks
Red Hat Enterprise Linux 8 Administration and configuration tasks using System Roles in RHEL

Applying RHEL System Roles using Red Hat Ansible Automation Platform playbooks to perform system administration tasks
Abstract

This document describes configuring system roles using Ansible on Red Hat Enterprise Linux 8. The title focuses on: the RHEL System Roles are a collection of Ansible roles, modules, and playbooks that provide a stable and consistent configuration interface to manage and configure Red Hat Enterprise Linux. They are designed to be forward compatible with multiple major release versions of Red Hat Enterprise Linux 8.

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Please let us know how we could make it better.

- For simple comments on specific passages:
  1. Make sure you are viewing the documentation in the *Multi-page HTML* format. In addition, ensure you see the **Feedback** button in the upper right corner of the document.
  2. Use your mouse cursor to highlight the part of text that you want to comment on.
  3. Click the **Add Feedback** pop-up that appears below the highlighted text.
  4. Follow the displayed instructions.

- For submitting feedback via Bugzilla, create a new ticket:
  1. Go to the [Bugzilla](http://example.com) website.
  2. As the Component, use **Documentation**.
  3. Fill in the **Description** field with your suggestion for improvement. Include a link to the relevant part(s) of documentation.
  4. Click **Submit Bug**.
CHAPTER 1. GETTING STARTED WITH RHEL SYSTEM ROLES

This section explains what RHEL System Roles are. Additionally, it describes how to apply a particular role through an Ansible playbook to perform various system administration tasks.

1.1. INTRODUCTION TO RHEL SYSTEM ROLES

RHEL System Roles is a collection of Ansible roles and modules. RHEL System Roles provide a configuration interface to remotely manage multiple RHEL systems. The interface enables managing system configurations across multiple versions of RHEL, as well as adopting new major releases.

On Red Hat Enterprise Linux 8, the interface currently consists of the following roles:

- kdump
- network
- selinux
- storage
- certificate
- kernel_settings
- logging
- metrics
- nbde_client and nbde_server
- timesync
- tlog

All these roles are provided by the rhel-system-roles package available in the AppStream repository.

Additional resources

- Red Hat Enterprise Linux (RHEL) System Roles
- /usr/share/doc/rhel-system-roles documentation [1]
- Introduction to the SELinux system role
- Introduction to the storage role
- Administration and configuration tasks using System Roles in RHEL

1.2. RHEL SYSTEM ROLES TERMINOLOGY

You can find the following terms across this documentation:

System Roles terminology
Ansible playbook

Playbooks are Ansible’s configuration, deployment, and orchestration language. They can describe a policy you want your remote systems to enforce, or a set of steps in a general IT process.

Control node

Any machine with Ansible installed. You can run commands and playbooks, invoking /usr/bin/ansible or /usr/bin/ansible-playbook, from any control node. You can use any computer that has Python installed on it as a control node – laptops, shared desktops, and servers can all run Ansible. However, you cannot use a Windows machine as a control node. You can have multiple control nodes.

Inventory

A list of managed nodes. An inventory file is also sometimes called a “hostfile”. Your inventory can specify information like IP address for each managed node. An inventory can also organize managed nodes, creating and nesting groups for easier scaling. To learn more about inventory, see the Working with Inventory section.

Managed nodes

The network devices, servers, or both that you manage with Ansible. Managed nodes are also sometimes called “hosts”. Ansible is not installed on managed nodes.

1.3. APPLYING A ROLE

The following procedure describes how to apply a particular role.

Prerequisites

- Ensure that the rhel-system-roles package is installed on the system that you want to use as a control node:

  # yum install rhel-system-roles

- You need the ansible package to run playbooks that use RHEL System Roles. Ensure that the Ansible Engine repository is enabled, and the ansible package is installed on the system that you want to use as a control node.

  - If you do not have a Red Hat Ansible Engine Subscription, you can use a limited supported version of Red Hat Ansible Engine provided with your Red Hat Enterprise Linux subscription. In this case, follow these steps:

    1. Enable the RHEL Ansible Engine repository:

       # subscription-manager refresh
       # subscription-manager repos --enable ansible-2-for-rhel-8-x86_64-rpms

    2. Install Ansible Engine:

       # yum install ansible

      - If you have a Red Hat Ansible Engine Subscription, follow the procedure described in How do I Download and Install Red Hat Ansible Engine?.

- Ensure that you are able to create an Ansible inventory. Inventories represent the hosts, host groups, and some of the configuration parameters used by the Ansible playbooks.
Playbooks are typically human-readable, and are defined in ini, yaml, json, and other file formats.

- Ensure that you are able to create an Ansible playbook. Playbooks represent Ansible’s configuration, deployment, and orchestration language. By using playbooks, you can declare and manage configurations of remote machines, deploy multiple remote machines or orchestrate steps of any manual ordered process.

A playbook is a list of one or more plays. Every play can include Ansible variables, tasks, or roles.

Playbooks are human-readable, and are defined in the yaml format.

Procedure

1. Create the required Ansible inventory containing the hosts and groups that you want to manage. Here is an example using a file called inventory.ini of a group of hosts called webservers:

   ```ini
   [webservers]
   host1
   host2
   host3
   ```

2. Create an Ansible playbook including the required role. The following example shows how to use roles through the roles: option for a playbook:

   The following example shows how to use roles through the roles: option for a given play:

   ```yaml
   ---
   - hosts: webservers
     roles:
       - rhel-system-roles.network
       - rhel-system-roles.timesync
   ```

   **NOTE**

   Every role includes a README file, which documents how to use the role and supported parameter values. You can also find an example playbook for a particular role under the documentation directory of the role. Such documentation directory is provided by default with the rhel-system-roles package, and can be found in the following location:

   ```bash
   /usr/share/doc/rhel-system-roles/SUBSYSTEM/
   ```

   Replace SUBSYSTEM with the name of the required role, such as selinux, kdump, network, timesync, or storage.

3. To execute the playbook on specific hosts, you must perform one of the following:

   - Edit the playbook to use hosts: host1[,host2,…], or hosts: all, and execute the command:

     ```bash
     # ansible-playbook name.of.the.playbook
     ```

   - Edit the inventory to ensure that the hosts you want to use are defined in a group, and execute the command:
# ansible-playbook -i name.of.the.inventory name.of.the.playbook

- Specify all hosts when executing the **ansible-playbook** command:

  # ansible-playbook -i host1,host2,... name.of.the.playbook

**IMPORTANT**

Be aware that the `-i` flag specifies the inventory of all hosts that are available. If you have multiple targeted hosts, but want to select a host against which you want to run the playbook, you can add a variable in the playbook to be able to select a host. For example:

Ansible Playbook | example-playbook.yml:

```yaml
- hosts: "{{ target_host }}"
  roles:
    - rhel-system-roles.network
    - rhel-system-roles.timesync
```

Playbook execution command:

# ansible-playbook -i host1,...hostn -e target_host=host5 example-playbook.yml

**Additional resources**

- Ansible playbooks
- Using roles in Ansible playbook
- Examples of Ansible playbooks
- How to create and work with inventory?
- ansible-playbook

**1.4. ADDITIONAL RESOURCES**

- Red Hat Enterprise Linux (RHEL) System Roles
- Managing local storage using RHEL System Roles
- Deploying the same SELinux configuration on multiple systems using RHEL System Roles

[1] This documentation is installed automatically with the **rhel-system-roles** package.
CHAPTER 2. INSTALLING RHEL SYSTEM ROLES IN YOUR SYSTEM

To use the RHEL System Roles, install the required packages in your system.

Prerequisites

- You have a Red Hat Ansible Engine Subscription. See the procedure How do I Download and Install Red Hat Ansible Engine?
- You have Ansible packages installed in the system you want to use as a control node:

Procedure

1. Install the rhel-system-roles package on the system that you want to use as a control node:

   # yum install rhel-system-roles

If you do not have a Red Hat Ansible Engine Subscription, you can use a limited supported version of Red Hat Ansible Engine provided with your Red Hat Enterprise Linux subscription. In this case, follow these steps:

   a. Enable the RHEL Ansible Engine repository:

      # subscription-manager refresh

      # subscription-manager repos --enable ansible-2-for-rhel-8-x86_64-rpms

   b. Install Ansible Engine:

      # yum install ansible

As a result, you are able to create an Ansible playbook.

Additional resources

- The Red Hat Enterprise Linux (RHEL) System Roles
- The ansible-playbook man page.
CHAPTER 3. INSTALLING AND USING COLLECTIONS

3.1. INTRODUCTION TO ANSIBLE COLLECTIONS

Ansible Collections are the new way of distributing, maintaining, and consuming automation. By combining multiple types of Ansible content such as playbooks, roles, modules, and plugins, you can benefit from improvements in flexibility and scalability.

The Ansible Collections are an option to the traditional RHEL System Roles format. Using the RHEL System Roles in the Ansible Collection format is almost the same as using it in the traditional RHEL System Roles format. The difference is that Ansible Collections use the concept of a **fully qualified collection name** (FQCN), which consists of a namespace and the collection name. The namespace we use is `redhat` and the collection name is `rhel_system_roles`. So, while the traditional RHEL System Roles format for the Kernel role is presented as `rhel-system-roles.kernel_settings`, using the Collection fully qualified collection name for the Kernel role would be presented as `redhat.rhel_system_roles.kernel_settings`.

The combination of a namespace and a collection name guarantees that the objects are unique. It also ensures that objects are shared across the Ansible Collections and namespaces without any conflicts.

**Additional resources**

- To use the Red Hat Certified Collections by accessing the Automation Hub, you must have an Ansible Automation Platform (AAP subscription).

3.2. COLLECTIONS STRUCTURE

Collections are a package format for Ansible content. The data structure is as below:

- docs/: local documentation for the collection, with examples, if the role provides the documentation
- galaxy.yml: source data for the MANIFEST.json that will be part of the Ansible Collection package
- playbooks/: playbooks are available here
  - tasks/: this holds 'task list files' for include_tasks/import_tasks usage
- plugins/: all Ansible plugins and modules are available here, each in its subdirectory
  - modules/: Ansible modules
  - modules_utils/: common code for developing modules
  - lookup/: search for a plugin
  - filter/: Jinja2 filter plugin
  - connection/: connection plugins required if not using the default
- roles/: directory for Ansible roles
- tests/: tests for the collection’s content
3.3. INSTALLING COLLECTIONS BY USING THE CLI

Collections are a distribution format for Ansible content that can include playbooks, roles, modules, and plugins.

You can install Collections through Ansible Galaxy, through the browser, or by using the command line.

Prerequisites

- Red Hat Ansible Engine version 2.9 and later is installed.
- An inventory file that lists the managed nodes exists.

Procedure

- Install the collection via RPM package:

  ```
  # yum install rhel-system-roles
  ```

  After the installation is finished, the roles are available as `redhat.rhel_system_roles.<role_name>`.
  Additionally, you can find the documentation for each role at
  `/usr/share/ansible/collections/ansible_collections/redhat/rhel_system_roles/roles/<role_name>/README.md`.

Verification steps

To verify that the Collections were successfully installed, you can apply the kernel_settings on your localhost:

1. Copy one of the `tests_default.yml` to your working directory.

   ```
   $ cp /usr/share/ansible/collections/ansible_collections/redhat/rhel_system_roles/tests/kernel_settings/tests_default.yml .
   ```

2. Edit the file, replacing "hosts: all" with "hosts: localhost" to make the playbook run only on the local system.

3. Run the ansible-playbook in the check mode. This does not change any settings on your system.

   ```
   $ ansible-playbook --check tests_default.yml
   ```

   The command returns the value `failed=0`.

Additional resources

- The `ansible-playbook` man page.

3.4. INSTALLING COLLECTIONS FROM AUTOMATION HUB

If you are using the Automation Hub, you can install the System Roles Collection hosted on the Automation Hub.

Prerequisites
Red Hat Ansible Engine version 2.9 or later is installed.

- Red Hat Ansible Automation Platform subscription.
- The `python3-jmespath` package is installed.
- An inventory file that lists the managed nodes exists.

**Procedure**

1. Define Red Hat Automation Hub as the default source for content in the `ansible.cfg` configuration file. See [Configuring Red Hat Automation Hub as the primary source for content](#).

2. Install the `redhat.rhel_system_roles` collection from the Automation Hub:

   ```bash
   # ansible-galaxy collection install redhat.rhel_system_roles
   ```

   After the installation is finished, the roles are available as `redhat.rhel_system_roles.<role_name>`. Additionally, you can find the documentation for each role at `/usr/share/ansible/collections/ansible_collections/redhat/rhel_system_roles/roles/<role_name>/README.md`.

**Verification steps**

To verify that the Collections were successfully installed, you can apply the `kernel_settings` on your localhost:

1. Copy one of the `tests_default.yml` to your working directory.

   ```bash
   $ cp /usr/share/ansible/collections/ansible_collections/redhat/rhel_system_roles/tests/kernel_settings/tests_default.yml .
   ```

2. Edit the file, replacing "hosts: all" with "hosts: localhost" to make the playbook run only on the local system.

3. Run the ansible-playbook on the check mode. This does not change any settings on your system.

   ```bash
   $ ansible-playbook --check tests_default.yml
   ```

   You can see the command returns with the value `failed=0`.

**Additional resources**

- The `ansible-playbook` man page.

### 3.5. APPLYING A LOCAL LOGGING SYSTEM ROLE USING COLLECTIONS

Following is an example using Collections to prepare and apply a Red Hat Ansible Engine playbook to configure a logging solution on a set of separate machines.

**Prerequisites**
A Galaxy collection is installed.

**Procedure**

1. Create a playbook that defines the required role:
   a. Create a new YAML file and open it in a text editor, for example:

   ```
   # vi logging-playbook.yml
   ```

   b. Insert the following content into the YAML file:

   ```
   ---
   - name: Deploying basics input and implicit files output
     hosts: all
     roles:
     - redhat.rhel_system_roles.logging
     vars:
       logging_inputs:
       - name: system_input
         type: basics
       logging_outputs:
       - name: files_output
         type: files
       logging_flows:
       - name: flow1
         inputs: [system_input]
         outputs: [files_output]
   ```

2. Execute the playbook on a specific inventory:

   ```
   # ansible-playbook -i inventory-file logging-playbook.yml
   ```

   Where:

   - `inventory-file` is the name of your inventory file.
   - `logging-playbook.yml` is the playbook you use.

**Verification steps**

1. Test the syntax of the `/etc/rsyslog.conf` file:

   ```
   # rsyslogd -N 1
   rsyslogd: version 8.1911.0-6.el8, config validation run (level 1), master config
   /etc/rsyslog.conf
   ```

2. Verify that the system sends messages to the log:
   a. Send a test message:

   ```
   # logger test
   ```
b. View the /var/log/messages log, for example:

```
# cat /var/log/messages
Aug 5 13:48:31 hostname root[6778]: test
```

The **hostname** is the hostname of the client system. The log displays the user name of the user that entered the logger command, in this case, **root**.
CHAPTER 4. ANSIBLE IPMI MODULES IN RHEL

4.1. THE RHEL_MGMT COLLECTION

The Intelligent Platform Management Interface (IPMI) is a specification for a set of standard protocols to communicate with baseboard management controller (BMC) devices. The IPMI modules allow you to enable and support hardware management automation. The IPMI modules are available in:

- The rhel_mgmt Collection. The package name is ansible-collection-redhat-rhel_mgmt.
- The RHEL 8 AppStream, as part of the new ansible-collection-redhat-rhel_mgmt package.

The following IPMI modules are available in the rhel_mgmt collection:

- ipmi_boot: Management of boot device order
- ipmi_power: Power management for machine

The mandatory parameters used for the IPMI Modules are:

- **ipmi_boot** parameters:

<table>
<thead>
<tr>
<th>Module name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Hostname or ip address of the BMC</td>
</tr>
<tr>
<td>password</td>
<td>Password to connect to the BMC</td>
</tr>
<tr>
<td>bootdev</td>
<td>Device to be used on next boot</td>
</tr>
<tr>
<td>User</td>
<td>Username to connect to the BMC</td>
</tr>
</tbody>
</table>

- **ipmi_power** parameters:

<table>
<thead>
<tr>
<th>Module name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>BMC Hostname or IP address</td>
</tr>
<tr>
<td>Module name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>password</td>
<td>Password to connect to the BMC</td>
</tr>
<tr>
<td>user</td>
<td>Username to connect to the BMC</td>
</tr>
<tr>
<td>State</td>
<td>Check if the machine is on the desired status</td>
</tr>
<tr>
<td></td>
<td>* on</td>
</tr>
<tr>
<td></td>
<td>* off</td>
</tr>
<tr>
<td></td>
<td>* shutdown</td>
</tr>
<tr>
<td></td>
<td>* reset</td>
</tr>
<tr>
<td></td>
<td>* boot</td>
</tr>
</tbody>
</table>

### 4.2. INSTALLING THE RHEL MGMT COLLECTION USING THE CLI

You can install the `rhel_mgmt` Collection using the command line.

**Prerequisites**
- Red Hat Ansible Engine version 2.9 is installed.

**Procedure**
- Install the collection via RPM package:

```bash
# yum install ansible-collection-redhat-rhel_mgmt
```

After the installation is finished, the IPMI modules are available in the `redhat.rhel_mgmt` Ansible collection.

**Additional resources**
- The `ansible-playbook` man page.

### 4.3. EXAMPLE USING THE IPMI_BOOT MODULE

The following example shows how to use the `ipmi_boot` module in a playbook to set a boot device for the next boot. For simplicity, the examples use the same host as the Ansible control host and managed host, thus executing the modules on the same host where the playbook is executed.

**Prerequisites**
- The `rhel_mgmt` collection is installed.
- The `pyghmi` library in the `python3-pyghmi` package is installed in one of the following locations:
  - The host where you execute the playbook.
The managed host. If you use localhost as the managed host, install the `python3-pyghmi` package on the host where you execute the playbook instead.

- The IPMI BMC that you want to control is accessible via network from the host where you execute the playbook, or the managed host (if not using localhost as the managed host). Note that the host whose BMC is being configured by the module is generally different from the host where the module is executing (the Ansible managed host), as the module contacts the BMC over the network using the IPMI protocol.

- You have credentials to access BMC with an appropriate level of access.

### Procedure

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   ---
   - name: Sets which boot device will be used on next boot
     hosts: localhost
     tasks:
       - redhat.rhel_mgmt.ipmi_boot:
           name: bmc.host.example.com
           user: admin_user
           password: basics
           bootdev: hd
   ```

2. Execute the playbook against localhost:

   ```bash
   # ansible-playbook playbook.yml
   ```

   As a result, the output returns the value “success”.

### 4.4. EXAMPLE USING THE IPMI_POWER MODULE

This example shows how to use the `ipmi_boot` module in a playbook to check if the system is turned on. For simplicity, the examples use the same host as the Ansible control host and managed host, thus executing the modules on the same host where the playbook is executed.

### Prerequisites

- The `rhel_mgmt` collection is installed.

- The `pyghmi` library in the `python3-pyghmi` package is installed in one of the following locations:
  - The host where you execute the playbook.
  - The managed host. If you use localhost as the managed host, install the `python3-pyghmi` package on the host where you execute the playbook instead.

- The IPMI BMC that you want to control is accessible via network from the host where you execute the playbook, or the managed host (if not using localhost as the managed host). Note that the host whose BMC is being configured by the module is generally different from the host where the module is executing (the Ansible managed host), as the module contacts the BMC over the network using the IPMI protocol.

- You have credentials to access BMC with an appropriate level of access.
Procedure

1. Create a new playbook.yml file with the following content:

```yaml
---
- name: Turn the host on
  hosts: localhost
  tasks:
  - redhat.rhel_mgmt.ipmi_power:
      name: bmc.host.example.com
      user: admin_user
      password: basics
      state: on
```

2. Execute the playbook:

```
# ansible-playbook playbook.yml
```

The output returns the value “true”.

CHAPTER 5. USING ANSIBLE ROLES TO PERMANENTLY CONFIGURE KERNEL PARAMETERS

As an experienced user with good knowledge of Red Hat Ansible, you can use the `kernel_settings` role to configure kernel parameters on multiple clients at once. This solution:

- Provides a friendly interface with efficient input setting.
- Keeps all intended kernel parameters in one place.

After you run the `kernel_settings` role from the control machine, the kernel parameters are applied to the managed systems immediately and persist across reboots.

IMPORTANT

Note that RHEL System Roles delivered over RHEL channels are available to RHEL customers as an RPM package in the default AppStream repository. RHEL System Roles are also available as a collection to customers with Ansible subscriptions over Ansible Automation Hub.

5.1. INTRODUCTION TO THE KERNEL SETTINGS ROLE

RHEL System Roles is a set of roles that provide a consistent configuration interface to remotely manage multiple systems.

RHEL System Roles were introduced for automated configurations of the kernel using the `kernel_settings` system role. The `rhel-system-roles` package contains this system role, and also the reference documentation.

To apply the kernel parameters on one or more systems in an automated fashion, use the `kernel_settings` role with one or more of its role variables of your choice in a playbook. A playbook is a list of one or more plays that are human-readable, and are written in the YAML format.

You can use an inventory file to define a set of systems that you want Ansible to configure according to the playbook.

With the `kernel_settings` role you can configure:

- The kernel parameters using the `kernel_settings_sysctl` role variable
- Various kernel subsystems, hardware devices, and device drivers using the `kernel_settings_sysfs` role variable
- The CPU affinity for the `systemd` service manager and processes it forks using the `kernel_settings_systemd_cpu_affinity` role variable
- The kernel memory subsystem transparent hugepages using the `kernel_settings_transparent_hugepages` and `kernel_settings_transparent_hugepages_defrag` role variables

Additional resources

- README.md and README.html files in the /usr/share/doc/rhel-system-roles/kernel_settings/ directory
5.2. APPLYING SELECTED KERNEL PARAMETERS USING THE KERNEL SETTINGS ROLE

Follow these steps to prepare and apply an Ansible playbook to remotely configure kernel parameters with persisting effect on multiple managed operating systems.

Prerequisites

- You have root permissions.
- Entitled by your RHEL subscription, you installed the ansible-core and rhel-system-roles packages on the control machine.
- An inventory of managed hosts is present on the control machine and Ansible is able to connect to them.

IMPORTANT

RHEL 8.0 - 8.5 provided access to a separate Ansible repository that contains Ansible Engine 2.9 for automation based on Ansible. Ansible Engine contains command-line utilities such as ansible, ansible-playbook; connectors such as docker and podman; and the entire world of plugins and modules. For information on how to obtain and install Ansible Engine, refer to How do I Download and Install Red Hat Ansible Engine?.

RHEL 8.6 and 9.0 has introduced Ansible Core (provided as ansible-core RPM), which contains the Ansible command-line utilities, commands, and a small set of built-in Ansible plugins. The AppStream repository provides ansible-core, which has a limited scope of support. You can learn more by reviewing Scope of support for the ansible-core package included in the RHEL 9 AppStream.

Procedure

1. Optionally, review the inventory file for illustration purposes:

   # cat /home/jdoe/<ansible_project_name>/inventory
   [testingservers]
   pdoe@192.168.122.98
   fdoe@192.168.122.226

   [db-servers]
   db1.example.com
   db2.example.com

   [webservers]
   web1.example.com
   web2.example.com
   192.0.2.42

The file defines the [testing_servers] group and other groups. It allows you to run Ansible more effectively against a specific set of systems.
2. Create a configuration file to set defaults and privilege escalation for Ansible operations.

   a. Create a new YAML file and open it in a text editor, for example:

   ```
   # vi /home/jdoe/<ansible_project_name>/ansible.cfg
   ```

   b. Insert the following content into the file:

   ```
   [defaults]
   inventory = ./inventory

   [privilege_escalation]
   become = true
   become_method = sudo
   become_user = root
   become_ask_pass = true
   ```

   The `[defaults]` section specifies a path to the inventory file of managed hosts. The `[privilege_escalation]` section defines that user privileges be shifted to `root` on the specified managed hosts. This is necessary for successful configuration of kernel parameters. When Ansible playbook is run, you will be prompted for user password. The user automatically switches to `root` by means of `sudo` after connecting to a managed host.

3. Create an Ansible playbook that uses the `kernel_settings` role.

   a. Create a new YAML file and open it in a text editor, for example:

   ```
   # vi /home/jdoe/<ansible_project_name>/kernel-roles.yml
   ```

   This file represents a playbook and usually contains an ordered list of tasks, also called `plays`, that are run against specific managed hosts selected from your `inventory` file.

   b. Insert the following content into the file:

   ```
   ---
   -
      hosts: testingservers
      name: "Configure kernel settings"
      roles:
        - rhel-system-roles.kernel_settings
      vars:
        kernel_settings_sysctl:
          - name: fs.file-max
            value: 400000
          - name: kernel.threads-max
            value: 65536
        kernel_settings_sysfs:
          - name: /sys/class/net/lo/mtu
            value: 65000
        kernel_settings_transparent_hugepages: madvise
   ```

   The `name` key is optional. It associates an arbitrary string with the play as a label and identifies what the play is for. The `hosts` key in the play specifies the hosts against which the play is run. The value or values for this key can be provided as individual names of managed hosts or as groups of hosts as defined in the `inventory` file.
The **vars** section represents a list of variables containing selected kernel parameter names and values to which they have to be set.

The **roles** key specifies what system role is going to configure the parameters and values mentioned in the **vars** section.

**NOTE**

You can modify the kernel parameters and their values in the playbook to fit your needs.

4. Optionally, verify that the syntax in your play is correct.

    ```bash
    # ansible-playbook --syntax-check kernel-roles.yml
    playbook: kernel-roles.yml
    ```

    This example shows the successful verification of a playbook.

5. Execute your playbook.

    ```bash
    # ansible-playbook kernel-roles.yml
    ...
    BECOME password:
    PLAY [Configure kernel settings]
    ******************************************************************************
    PLAY RECAP
    ******************************************************************************
    fdoe@192.168.122.226       : ok=10   changed=4    unreachable=0    failed=0    skipped=6    rescued=0    ignored=0
    pdoe@192.168.122.98        : ok=10   changed=4    unreachable=0    failed=0    skipped=6    rescued=0    ignored=0
    ```

    Before Ansible runs your playbook, you are going to be prompted for your password and so that a user on managed hosts can be switched to **root**, which is necessary for configuring kernel parameters.

    The recap section shows that the play finished successfully (**failed=0**) for all managed hosts, and that 4 kernel parameters have been applied (**changed=4**).

6. Restart your managed hosts and check the affected kernel parameters to verify that the changes have been applied and persist across reboots.

CHAPTER 6. USING SYSTEM ROLES TO CONFIGURE NETWORK CONNECTIONS

The network system role on RHEL enables administrators to automate network-related configuration and management tasks using Ansible.

6.1. CONFIGURING A STATIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH THE INTERFACE NAME

This procedure describes how to use the network RHEL System Role to remotely add an Ethernet connection for the enp7s0 interface with the following settings by running an Ansible playbook:

- A static IPv4 address - `192.0.2.1` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `192.0.2.254`
- An IPv6 default gateway - `2001:db8:1::ffe`
- An IPv4 DNS server - `192.0.2.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`

Run this procedure on the Ansible control node.

Prerequisites

- The ansible and rhel-system-roles packages are installed on the control node.
- If you use a different remote user than root when you run the playbook, this user has appropriate sudo permissions on the managed node.
- The host uses NetworkManager to configure the network.

Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

```
node.example.com
```

2. Create the `~/ethernet-static-IP.yml` playbook with the following content:

```yaml
---
- name: Configure an Ethernet connection with static IP
  hosts: node.example.com
  become: true
  tasks:
    - include_role:
        name: rhel-system-roles.network
```
vars:
  network_connections:
    - name: enp7s0
      interface_name: enp7s0
      type: ethernet
      autoconnect: yes
      ip:
        address:
          - 192.0.2.1/24
          - 2001:db8:1::1/64
        gateway4: 192.0.2.254
        gateway6: 2001:db8:1::ffe
      dns:
        - 192.0.2.200
        - 2001:db8:1::ffbb
      dns_search:
        - example.com
      state: up

3. Run the playbook:

   - To connect as root user to the managed host, enter:
     ```bash
     # ansible-playbook -u root ~/ethernet-static-IP.yml
     ```

   - To connect as a user to the managed host, enter:
     ```bash
     # ansible-playbook -u user_name --ask-become-pass ~/ethernet-static-IP.yml
     ```

     The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

     If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md
- ansible-playbook(1) man page

6.2. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH THE INTERFACE NAME

This procedure describes how to use RHEL System Roles to remotely add a dynamic Ethernet connection for the enp7s0 interface by running an Ansible playbook. With this setting, the network connection requests the IP settings for this connection from a DHCP server. Run this procedure on the Ansible control node.

Prerequisites

- A DHCP server is available in the network.
- The ansible and rhel-system-roles packages are installed on the control node.
If you use a different remote user than root when you run the playbook, this user has appropriate sudo permissions on the managed node.

The host uses NetworkManager to configure the network.

Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the /etc/ansible/hosts Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the ~/ethernet-dynamic-IP.yml playbook with the following content:

   ```yaml
   ---
   - name: Configure an Ethernet connection with dynamic IP
     hosts: node.example.com
     become: true
     tasks:
     - include_role:
       name: rhel-system-roles.network
     vars:
       network_connections:
       - name: enp7s0
         interface_name: enp7s0
         type: ethernet
         autoconnect: yes
         ip:
           dhcp4: yes
           auto6: yes
         state: up
   ```

3. Run the playbook:

   - To connect as root user to the managed host, enter:
     ```
     # ansible-playbook -u root ~/ethernet-dynamic-IP.yml
     ```
   - To connect as a user to the managed host, enter:
     ```
     # ansible-playbook -u user_name --ask-become-pass ~/ethernet-dynamic-IP.yml
     ```

   The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

   If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file
- ansible-playbook(1) man page
6.3. CONFIGURING VLAN TAGGING USING SYSTEM ROLES

You can use the networking RHEL System Role to configure VLAN tagging. This procedure describes how to add an Ethernet connection and a VLAN with ID 10 on top of this Ethernet connection. As the child device, the VLAN connection contains the IP, default gateway, and DNS configurations.

Depending on your environment, adjust the play accordingly. For example:

- To use the VLAN as a port in other connections, such as a bond, omit the `ip` attribute, and set the IP configuration in the child configuration.

- To use team, bridge, or bond devices in the VLAN, adapt the `interface_name` and `type` attributes of the ports you use in the VLAN.

Prerequisites

- The `ansible` and `rhel-system-roles` packages are installed on the control node.

- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.

Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/vlan-ethernet.yml` playbook with the following content:

   ```
   ---
   - name: Configure a VLAN that uses an Ethernet connection
     hosts: node.example.com
     become: true
     tasks:
       - include_role:
         name: rhel-system-roles.network

     vars:
       network_connections:
         # Add an Ethernet profile for the underlying device of the VLAN
         - name: enp1s0
           type: ethernet
           interface_name: enp1s0
           autoconnect: yes
           state: up
           ip:
             dhcp4: no
             auto6: no

         # Define the VLAN profile
         - name: enp1s0.10
           type: vlan
           ip:
             address:
   ```
The `parent` attribute in the VLAN profile configures the VLAN to operate on top of the `enp1s0` device.

3. Run the playbook:

   - To connect as root user to the managed host, enter:
     ```bash
     # ansible-playbook -u root ~/vlan-ethernet.yml
     ```
   - To connect as a user to the managed host, enter:
     ```bash
     # ansible-playbook -u user_name --ask-become-pass ~/vlan-ethernet.yml
     ```

     The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

     If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
- `ansible-playbook(1)` man page

### 6.4. Configuring a Network Bridge Using RHEL System Roles

You can use the networking RHEL System Role to configure a Linux bridge. This procedure describes how to configure a network bridge that uses two Ethernet devices, and sets IPv4 and IPv6 addresses, default gateways, and DNS configuration.

**NOTE**

Set the IP configuration on the bridge and not on the ports of the Linux bridge.

**Prerequisites**

- The `ansible` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than root when you run the playbook, this user has appropriate `sudo` permissions on the managed node.
Two or more physical or virtual network devices are installed on the server.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

```
node.example.com
```

2. Create the `~bridge-ethernet.yml` playbook with the following content:

```yaml
---
- name: Configure a network bridge that uses two Ethernet ports
  hosts: node.example.com
  become: true
  tasks:
    - include_role:
      name: rhel-system-roles.network
  vars:
    network_connections:
      # Define the bridge profile
      - name: bridge0
        type: bridge
        interface_name: bridge0
        ip:
          - "192.0.2.1/24"
          - "2001:db8:1::1/64"
        gateway4: 192.0.2.254
        gateway6: 2001:db8:1::fffe
        dns:
          - 192.0.2.200
          - 2001:db8:1::ffbb
        dns_search:
          - example.com
        state: up
      # Add an Ethernet profile to the bridge
      - name: bridge0-port1
        interface_name: enp7s0
        type: ethernet
        controller: bridge0
        port_type: bridge
        state: up
      # Add a second Ethernet profile to the bridge
      - name: bridge0-port2
        interface_name: enp8s0
        type: ethernet
        controller: bridge0
        port_type: bridge
        state: up
```

3. Run the playbook:
To connect as root user to the managed host, enter:

```
# ansible-playbook -u root ~/bridge-ethernet.yml
```

To connect as a user to the managed host, enter:

```
# ansible-playbook -u user_name --ask-become-pass ~/bridge-ethernet.yml
```

The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
- `ansible-playbook(1)` man page

### 6.5. CONFIGURING A NETWORK BOND USING RHEL SYSTEM ROLES

You can use the `network` RHEL System Role to configure a network bond. This procedure describes how to configure a bond in active-backup mode that uses two Ethernet devices, and sets an IPv4 and IPv6 addresses, default gateways, and DNS configuration.

**NOTE**

Set the IP configuration on the bond and not on the ports of the Linux bond.

**Prerequisites**

- The `ansible` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.
- Two or more physical or virtual network devices are installed on the server.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/bond-ethernet.yml` playbook with the following content:

   ```yaml
   ---
   - name: Configure a network bond that uses two Ethernet ports
     hosts: node.example.com
     become: true
     tasks:
     - include_role:
   ```
name: rhel-system-roles.network

vars:

network_connections:
  # Define the bond profile
  - name: bond0
    type: bond
    interface_name: bond0
    ip:
      address:
        - "192.0.2.1/24"
        - "2001:db8:1::1/64"
    gateway4: 192.0.2.254
    gateway6: 2001:db8:1::fffe
    dns:
      - 192.0.2.200
      - 2001:db8:1::ffbb
    dns_search:
      - example.com
    bond:
      mode: active-backup
      state: up

  # Add an Ethernet profile to the bond
  - name: bond0-port1
    interface_name: enp7s0
    type: ethernet
    controller: bond0
    state: up

  # Add a second Ethernet profile to the bond
  - name: bond0-port2
    interface_name: enp8s0
    type: ethernet
    controller: bond0
    state: up

3. Run the playbook:

- To connect as root user to the managed host, enter:

  # ansible-playbook -u root ~/bond-ethernet.yml

- To connect as a user to the managed host, enter:

  # ansible-playbook -u user_name --ask-become-pass ~/bond-ethernet.yml

The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Additional resources
6.6. CONFIGURING A STATIC ETHERNET CONNECTION WITH 802.1X NETWORK AUTHENTICATION USING RHEL SYSTEM ROLES

Using the RHEL `networking` System Role, you can automate the creation of an Ethernet connection that uses the 802.1X standard to authenticate the client. This procedure describes how to remotely add an Ethernet connection for the `enp1s0` interface with the following settings by running an Ansible playbook:

- A static IPv4 address - `192.0.2.1` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `192.0.2.254`
- An IPv6 default gateway - `2001:db8:1::fffe`
- An IPv4 DNS server - `192.0.2.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`
- 802.1X network authentication using the TLS Extensible Authentication Protocol (EAP)

Run this procedure on the Ansible control node.

**Prerequisites**

- The `ansible` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, you must have appropriate `sudo` permissions on the managed node.
- The network supports 802.1X network authentication.
- The managed node uses NetworkManager.
- The following files required for TLS authentication exist on the control node:
  - The client key is stored in the `/srv/data/client.key` file.
  - The client certificate is stored in the `/srv/data/client.crt` file.
  - The Certificate Authority (CA) certificate is stored in the `/srv/data/ca.crt` file.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```
2. Create the ~/enable-802.1x.yml playbook with the following content:

```yaml
---
- name: Configure an Ethernet connection with 802.1X authentication
  hosts: node.example.com
  become: true
  tasks:
    - name: Copy client key for 802.1X authentication
      copy:
        src: "/srv/data/client.key"
        dest: "/etc/pki/tls/private/client.key"
        mode: 0600
    - name: Copy client certificate for 802.1X authentication
      copy:
        src: "/srv/data/client.crt"
        dest: "/etc/pki/tls/certs/client.crt"
    - name: Copy CA certificate for 802.1X authentication
      copy:
        src: "/srv/data/ca.crt"
        dest: "/etc/pki/ca-trust/source/anchors/ca.crt"
    - include_role:
      name: rhel-system-roles.network
      vars:
        network_connections:
          - name: enp1s0
            type: ethernet
            autoconnect: yes
            ip:
              - address: 192.0.2.1/24
              - 2001:db8:1::1/64
            gateway4: 192.0.2.254
            gateway6: 2001:db8:1::fffe
            dns:
              - 192.0.2.200
              - 2001:db8:1::ffbb
            dns_search:
              - example.com
            ieee802_1x:
              identity: user_name
              eap: tls
              private_key: "/etc/pki/tls/private/client.key"
              private_key_password: "password"
              client_cert: "/etc/pki/tls/certs/client.crt"
              ca_cert: "/etc/pki/ca-trust/source/anchors/ca.crt"
              domain_suffix_match: example.com
              state: up
```

3. Run the playbook:

   - To connect as root user to the managed host, enter:

     ```bash
     # ansible-playbook -u root ~/enable-802.1x.yml
     ```
To connect as a user to the managed host, enter:

```
# ansible-playbook -u user_name --ask-become-pass ~/ethernet-static-IP.yml
```

The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
- `ansible-playbook(1)` man page

### 6.7. SETTING THE DEFAULT GATEWAY ON AN EXISTING CONNECTION USING SYSTEM ROLES

You can use the `networking` RHEL System Role to set the default gateway.

**IMPORTANT**

When you run a play that uses the `networking` RHEL System Role, the System Role overrides an existing connection profile with the same name if the value of settings does not match the ones specified in the play. Therefore, always specify the whole configuration of the network connection profile in the play, even if, for example, the IP configuration already exists. Otherwise, the role resets these values to their defaults.

Depending on whether it already exists, the procedure creates or updates the `enp1s0` connection profile with the following settings:

- A static IPv4 address - `198.51.100.20` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `198.51.100.254`
- An IPv6 default gateway - `2001:db8:1::fffe`
- An IPv4 DNS server - `198.51.100.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`

**Prerequisites**

- The `ansible` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.
Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/ethernet-connection.yml` playbook with the following content:

   ```yaml
   ---
   - name: Configure an Ethernet connection with static IP and default gateway
     hosts: node.example.com
     become: true
     tasks:
       - include_role:
           name: rhel-system-roles.network
     vars:
       network_connections:
         - name: enp1s0
           type: ethernet
           autoconnect: yes
           ip:
             address:
               - 198.51.100.20/24
               - 2001:db8:1::1/64
           gateway4: 198.51.100.254
           gateway6: 2001:db8:1::fffe
           dns:
             - 198.51.100.200
             - 2001:db8:1::ffbb
           dns_search:
             - example.com
           state: up
   ```

3. Run the playbook:

   - To connect as `root` user to the managed host, enter:
     ```
     # ansible-playbook -u root ~/ethernet-connection.yml
     ```
   - To connect as a user to the managed host, enter:
     ```
     # ansible-playbook -u user_name --ask-become-pass ~/ethernet-connection.yml
     ```

     The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

     If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md`
6.8. CONFIGURING A STATIC ROUTE USING RHEL SYSTEM ROLES

You can use the `networking` RHEL System Role to configure static routes.

**IMPORTANT**

When you run a play that uses the `networking` RHEL System Role, the System Role overrides an existing connection profile with the same name if the value of settings does not match the ones specified in the play. Therefore, always specify the whole configuration of the network connection profile in the play, even if, for example, the IP configuration already exists. Otherwise, the role resets these values to their defaults.

Depending on whether it already exists, the procedure creates or updates the `enp7s0` connection profile with the following settings:

- A static IPv4 address - `198.51.100.20` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `198.51.100.254`
- An IPv6 default gateway - `2001:db8:1::ffff`
- An IPv4 DNS server - `198.51.100.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`
- Static routes:
  - `192.0.2.0/24` with gateway `198.51.100.1`
  - `203.0.113.0/24` with gateway `198.51.100.2`

**Prerequisites**

- The `ansible` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than root when you run the playbook, this user has appropriate `sudo` permissions on the managed node.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/.add-static-routes.yml` playbook with the following content:

   ```
   ---
   - name: Configure an Ethernet connection with static IP and additional routes
   ```
hosts: node.example.com
become: true
tasks:
  - include_role:
    name: rhel-system-roles.network

vars:
  network_connections:
    - name: enp7s0
      type: ethernet
      autoconnect: yes
      ip:
        - address:
            - 198.51.100.20/24
            - 2001:db8:1::1/64
        gateway4: 198.51.100.254
        gateway6: 2001:db8:1::ffee
        dns:
          - address:
              - 198.51.100.200
              - 2001:db8:1::ffbb
          dns_search:
            - example.com
        route:
          - network: 192.0.2.0
            prefix: 24
            gateway: 198.51.100.1
          - network: 203.0.113.0
            prefix: 24
            gateway: 198.51.100.2
  state: up

3. Run the playbook:
   - To connect as root user to the managed host, enter:

     ```
     # ansible-playbook -u root ~/add-static-routes.yml
     ```
   - To connect as a user to the managed host, enter:

     ```
     # ansible-playbook -u user_name --ask-become-pass ~/add-static-routes.yml
     ```

     The --ask-become-pass option makes sure that the ansible-playbook command prompts
     for the sudo password of the user defined in the -u user_name option.

     If you do not specify the -u user_name option, ansible-playbook connects to the managed
     host as the user that is currently logged in to the control node.

Verification steps

   - Display the routing table:

     ```
     # ip -4 route
default via 198.51.100.254 dev enp7s0 proto static metric 100
     192.0.2.0/24 via 198.51.100.1 dev enp7s0 proto static metric 100
     ```
203.0.113.0/24 via 198.51.100.2 dev enp7s0 proto static metric 100

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
- `ansible-playbook(1)` man page

## 6.9. USING SYSTEM ROLES TO SET ETHTOOL FEATURES

You can use the `networking` RHEL System Role to configure `ethtool` features of a NetworkManager connection.

**IMPORTANT**

When you run a play that uses the `networking` RHEL System Role, the System Role overrides an existing connection profile with the same name if the value of settings does not match the ones specified in the play. Therefore, always specify the whole configuration of the network connection profile in the play, even if, for example the IP configuration, already exists. Otherwise the role resets these values to their defaults.

Depending on whether it already exists, the procedure creates or updates the `enp1s0` connection profile with the following settings:

- A static **IPv4** address - 198.51.100.20 with a /24 subnet mask
- A static **IPv6** address - 2001:db8:1::1 with a /64 subnet mask
- An **IPv4** default gateway - 198.51.100.254
- An **IPv6** default gateway - 2001:db8:1::ffe
- An **IPv4** DNS server - 198.51.100.200
- An **IPv6** DNS server - 2001:db8:1::ffbb
- A DNS search domain - example.com
- `ethtool` features:
  - Generic receive offload (GRO): disabled
  - Generic segmentation offload (GSO): enabled
  - TX stream control transmission protocol (SCTP) segmentation: disabled

**Prerequisites**

- The `ansible` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than root when you run the playbook, this user has appropriate `sudo` permissions on the managed node.

**Procedure**
1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   node.example.com

2. Create the `~/configure-ethernet-device-with-ethtool-features.yml` playbook with the following content:

   ```yaml
   ---
   - name: Configure an Ethernet connection with ethtool features
     hosts: node.example.com
     become: true
     tasks:
     - include_role:
       name: rhel-system-roles.network

     vars:
     network_connections:
     - name: enp1s0
       type: ethernet
       autoconnect: yes
       ip:
         address:
          - 198.51.100.20/24
          - 2001:db8:1::1/64
       gateway4: 198.51.100.254
       gateway6: 2001:db8:1::fffe
       dns:
         - 198.51.100.200
         - 2001:db8:1::ffbb
       dns_search:
         - example.com
       ethtool:
       features:
         gro: "no"
         gso: "yes"
         tx_sctp_segmentation: "no"
       state: up
   ```

3. Run the playbook:

   - To connect as `root` user to the managed host, enter:
     ```bash
     # ansible-playbook -u root ~/configure-ethernet-device-with-ethtool-features.yml
     ```
   - To connect as a user to the managed host, enter:
     ```bash
     # ansible-playbook -u user_name --ask-become-pass ~/configure-ethernet-device-with-ethtool-features.yml
     ```

   The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

   If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.
6.10. USING SYSTEM ROLES TO CONFIGURE ETHTOOL COALESCE SETTINGS

You can use the networking RHEL System Role to configure ethtool coalesce settings of a NetworkManager connection.

**IMPORTANT**

When you run a play that uses the networking RHEL System Role, the System Role overrides an existing connection profile with the same name if the value of settings does not match the ones specified in the play. Therefore, always specify the whole configuration of the network connection profile in the play, even if, for example the IP configuration, already exists. Otherwise the role resets these values to their defaults.

Depending on whether it already exists, the procedure creates or updates the enp1s0 connection profile with the following settings:

- A static IPv4 address - 198.51.100.20 with a /24 subnet mask
- A static IPv6 address - 2001:db8:1::1 with a /64 subnet mask
- An IPv4 default gateway - 198.51.100.254
- An IPv6 default gateway - 2001:db8:1::fffe
- An IPv4 DNS server - 198.51.100.200
- An IPv6 DNS server - 2001:db8:1::ffbb
- A DNS search domain - example.com
- **ethtool** coalesce settings:
  - RX frames: 128
  - TX frames: 128

**Prerequisites**

- The **ansible** and **rhel-system-roles** packages are installed on the control node.
- If you use a different remote user than root when you run the playbook, this user has appropriate **sudo** permissions on the managed node.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the **/etc/ansible/hosts** Ansible inventory file:
node.example.com

2. Create the `~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml` playbook with the following content:

```yaml
---
- name: Configure an Ethernet connection with ethtool coalesce settings
  hosts: node.example.com
  become: true
  tasks:
    - include_role:
      name: rhel-system-roles.network

  vars:
    network_connections:
      - name: enp1s0
        type: ethernet
        autoconnect: yes
        ip:
          - 198.51.100.20/24
          - 2001:db8:1::1/64
        gateway4: 198.51.100.254
        gateway6: 2001:db8:1::fffe
        dns:
          - 198.51.100.200
          - 2001:db8:1::ffbb
        dns_search:
          - example.com
        ethtool:
          coalesce:
            rx_frames: 128
            tx_frames: 128
          state: up
```

3. Run the playbook:

   - To connect as **root** user to the managed host, enter:

     ```bash
     # ansible-playbook -u root ~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml
     ```

   - To connect as a user to the managed host, enter:

     ```bash
     # ansible-playbook -u user_name --ask-become-pass ~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml
     ```

     The **--ask-become-pass** option makes sure that the **ansible-playbook** command prompts for the **sudo** password of the user defined in the **-u user_name** option.

     If you do not specify the **-u user_name** option, **ansible-playbook** connects to the managed host as the user that is currently logged in to the control node.

Additional resources
• /usr/share/ansible/roles/rhel-system-roles.network/README.md

• ansible-playbook(1) man page
CHAPTER 7. POSTFIX ROLE VARIABLES IN SYSTEM ROLES

The postfix role variables allow the user to install, configure, and start the Postfix Mail Transfer Agent (MTA).

The following role variables are defined in this section:

- **postfix_conf**: It includes key/value pairs of all the supported Postfix configuration parameters. By default, the `postfix_conf` does not have a value.

  For example: `postfix_conf`:
  
  ```
  relayhost: "example.com"
  ```

- **postfix_check**: It determines if a check has been executed before starting the Postfix to verify the configuration changes. The default value is true.

  For example: `postfix_check: true`

- **postfix_backup**: It determines if a single backup copy of the configuration is created. By default the `postfix_backup` value is false.

  To overwrite any previous backup run the following command:
  
  ```
  cp /etc/postfix/main.cf /etc/postfix/main.cf.backup
  ```

  If the `postfix_backup` value is changed to `true`, you must also set the `postfix_backup_multiple` value to false.

  For example: `postfix_backup: true`
  
  ```
  postfix_backup_multiple: false
  ```

- **postfix_backup_multiple**: It determines if the role will make a timestamped backup copy of the configuration.

  To keep multiple backup copies, run the following command:
  
  ```
  cp /etc/postfix/main.cf /etc/postfix/main.cf.$(date -Isec)
  ```

  By default the value of `postfix_backup_multiple` is true. The `postfix_backup_multiple: true` setting overrides `postfix_backup`. If you want to use `postfix_backup` you must set the `postfix_backup_multiple: false`.

  **IMPORTANT**

  The configuration parameters cannot be removed. Before running the Postfix role, set the `postfix_conf` to all the required configuration parameters and use the file module to remove `/etc/postfix/main.cf`

7.1. ADDITIONAL RESOURCES

- `/usr/share/doc/rhel-system-roles/postfix/README.md`
CHAPTER 8. CONFIGURING SELINUX USING SYSTEM ROLES

8.1. INTRODUCTION TO THE SELINUX SYSTEM ROLE

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems. The SELinux System Role enables the following actions:

- Cleaning local policy modifications related to SELinux booleans, file contexts, ports, and logins.
- Setting SELinux policy booleans, file contexts, ports, and logins.
- Restoring file contexts on specified files or directories.
- Managing SELinux modules.

The following table provides an overview of input variables available in the SELinux system role.

<table>
<thead>
<tr>
<th>Role variable</th>
<th>Description</th>
<th>CLI alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>selinux_policy</td>
<td>Chooses a policy protecting targeted processes or Multi Level Security protection.</td>
<td>SELINUXTYPE in /etc/selinux/config</td>
</tr>
<tr>
<td>selinux_state</td>
<td>Switches SELinux modes. See ansible-doc selinux</td>
<td>setenforce and SELINUX in /etc/selinux/config.</td>
</tr>
<tr>
<td>selinux_booleans</td>
<td>Enables and disables SELinux booleans. See ansible-doc seboolean.</td>
<td>setsebool</td>
</tr>
<tr>
<td>selinux_fcontexts</td>
<td>Adds or removes a SELinux file context mapping. See ansible-doc sefcontext.</td>
<td>semanage fcontext</td>
</tr>
<tr>
<td>selinux_restore_dirs</td>
<td>Restores SELinux labels in the file-system tree.</td>
<td>restorecon -R</td>
</tr>
<tr>
<td>selinux_ports</td>
<td>Sets SELinux labels on ports. See ansible-doc seport.</td>
<td>semanage port</td>
</tr>
<tr>
<td>selinux_logins</td>
<td>Sets users to SELinux user mapping. See ansible-doc selogin.</td>
<td>semanage login</td>
</tr>
<tr>
<td>selinux_modules</td>
<td>Installs, enables, disables, or removes SELinux modules.</td>
<td>semodule</td>
</tr>
</tbody>
</table>

The /usr/share/doc/rhel-system-roles/selinux/example-selinux-playbook.yml example playbook
installed by the `rhel-system-roles` package demonstrates how to set the targeted policy in enforcing mode. The playbook also applies several local policy modifications and restores file contexts in the `/tmp/test_dir/` directory.

For a detailed reference on SELinux role variables, install the `rhel-system-roles` package, and see the `README.md` or `README.html` files in the `/usr/share/doc/rhel-system-roles/selinux/` directory.

Additional resources
- [Introduction to RHEL System Roles](#).

### 8.2. USING THE SELINUX SYSTEM ROLE TO APPLY SELINUX SETTINGS ON MULTIPLE SYSTEMS

Follow the steps to prepare and apply an Ansible playbook with your verified SELinux settings.

**Prerequisites**

- Access and permissions to one or more managed nodes, which are systems you want to configure with the SELinux System Role.

- Access and permissions to a control node, which is a system from which Red Hat Ansible Engine configures other systems.

On the control node:

- Red Hat Ansible Engine is installed.

- The `rhel-system-roles` package is installed.

- An inventory file which lists the managed nodes.

**Procedure**

1. Prepare your playbook. You can either start from the scratch or modify the example playbook installed as a part of the `rhel-system-roles` package:

   ```
   # cp /usr/share/doc/rhel-system-roles/selinux/example-selinux-playbook.yml my-selinux-playbook.yml
   # vi my-selinux-playbook.yml
   ```

2. Change the content of the playbook to fit your scenario. For example, the following part ensures that the system installs and enables the `selinux-local-1.pp` SELinux module:

   ```
   selinux_modules:
   - { path: "selinux-local-1.pp", priority: "400" }
   ```

3. Save the changes, and exit the text editor.

4. Run your playbook on the `host1`, `host2`, and `host3` systems:

   ```
   # ansible-playbook -i host1,host2,host3 my-selinux-playbook.yml
   ```

**Additional resources**
For more information, install the `rhel-system-roles` package, and see the `/usr/share/doc/rhel-system-roles/selinux/` and `/usr/share/ansible/roles/rhel-system-roles.selinux/` directories.

- How do I download and install Red Hat Ansible Engine
CHAPTER 9. USING THE LOGGING SYSTEM ROLE

As a system administrator, you can use the Logging System Role to configure a RHEL host as a logging server to collect logs from many client systems.

9.1. THE LOGGING SYSTEM ROLE

With the Logging System Role, you can deploy logging configurations on local and remote hosts.

To apply a Logging System Role on one or more systems, you define the logging configuration in a playbook. A playbook is a list of one or more plays. Playbooks are human-readable, and they are written in the YAML format. For more information about playbooks, see Working with playbooks in Ansible documentation.

The set of systems that you want to configure according to the playbook is defined in an inventory file. For more information on creating and using inventories, see How to build your inventory in Ansible documentation.

Logging solutions provide multiple ways of reading logs and multiple logging outputs.

For example, a logging system can receive the following inputs:

- local files,
- systemd/journal,
- another logging system over the network.

In addition, a logging system can have the following outputs:

- logs stored in the local files in the /var/log directory,
- logs sent to Elasticsearch,
- logs forwarded to another logging system.

With the Logging System Role, you can combine the inputs and outputs to fit your scenario. For example, you can configure a logging solution that stores inputs from journal in a local file, whereas inputs read from files are both forwarded to another logging system and stored in the local log files.

9.2. LOGGING SYSTEM ROLE PARAMETERS

In a Logging System Role playbook, you define the inputs in the logging_inputs parameter, outputs in the logging_outputs parameter, and the relationships between the inputs and outputs in the logging_flows parameter. The Logging System Role processes these variables with additional options to configure the logging system. You can also enable encryption.

**NOTE**

Currently, the only available logging system in the Logging System Role is Rsyslog.

- **logging_inputs**: List of inputs for the logging solution.
  - **name**: Unique name of the input. Used in the logging_flows inputs list and a part of the generated config file name.
- **type**: Type of the input element. The type specifies a task type which corresponds to a directory name in `roles/rsyslog/(tasks,vars)/inputs/`.
  - **basics**: Inputs configuring inputs from systemd journal or unix socket.
    - **kernel_message**: Load imklog if set to `true`. Default to `false`.
    - **use_imuxsock**: Use imuxsock instead of imjournal. Default to `false`.
    - **ratelimit_burst**: Maximum number of messages that can be emitted within `ratelimit_interval`. Default to `20000` if `use_imuxsock` is false. Default to `200` if `use_imuxsock` is true.
    - **ratelimit_interval**: Interval to evaluate `ratelimit_burst`. Default to 600 seconds if `use_imuxsock` is false. Default to 0 if `use_imuxsock` is true. 0 indicates rate limiting is turned off.
    - **persist_state_interval**: Journal state is persisted every `value` messages. Default to 10. Effective only when `use_imuxsock` is false.
  - **files**: Inputs configuring inputs from local files.
  - **remote**: Inputs configuring inputs from the other logging system over network.
    - **state**: State of the configuration file. `present` or `absent`. Default to `present`.
  - **logging_outputs**: List of outputs for the logging solution.
    - **files**: Outputs configuring outputs to local files.
    - **forwards**: Outputs configuring outputs to another logging system.
    - **remote_files**: Outputs configuring outputs from another logging system to local files.
  - **logging_flows**: List of flows that define relationships between `logging_inputs` and `logging_outputs`. The `logging_flows` variable has the following keys:
    - **name**: Unique name of the flow
    - **inputs**: List of `logging_inputs` name values
    - **outputs**: List of `logging_outputs` name values.

Additional resources

- Documentation installed with the `rhel-system-roles` package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`

### 9.3. APPLYING A LOCAL LOGGING SYSTEM ROLE

Follow these steps to prepare and apply a Red Hat Ansible Engine playbook to configure a logging solution on a set of separate machines. Each machine will record logs locally.

**Prerequisites**

- Access and permissions to one or more *managed nodes*, which are systems you want to configure with the Logging System Role.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Engine configures other systems.
  
  On the control node:
  
  - Red Hat Ansible Engine is installed.
  - The rhel-system-roles package is installed.
  - An inventory file which lists the managed nodes.

NOTE

You do not have to have the rsyslog package installed, because the system role installs rsyslog when deployed.

Procedure

1. Create a playbook that defines the required role:
   
   a. Create a new YAML file and open it in a text editor, for example:

      ```
      vi logging-playbook.yml
      ```

   b. Insert the following content:

      ```yaml
      ---
      - name: Deploying basics input and implicit files output
        hosts: all
        roles:
        - rhel-system-roles.logging
        vars:
          logging_inputs:
            - name: system_input
              type: basics
          logging_outputs:
            - name: files_output
              type: files
          logging_flows:
            - name: flow1
              inputs: [system_input]
              outputs: [files_output]
      ```

2. Run the playbook on a specific inventory:

   ```
   ansible-playbook -i inventory-file /path/to/file/logging-playbook.yml
   ```

   Where: *inventory-file* is the inventory file. *logging-playbook.yml* is the playbook you use.

Verification

1. Test the syntax of the /etc/rsyslog.conf file:

   ```
   rsyslogd -N 1
   rsyslogd: version 8.1911.0-6.el8, config validation run (level 1), master config
   ```
2. Verify that the system sends messages to the log:
   a. Send a test message:

   ```
   # logger test
   ```

   b. View the `/var/log/messages` log, for example:

   ```
   # cat /var/log/messages
   Aug  5 13:48:31 hostname root[6778]: test
   ```

   Where `hostname` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

### 9.4. FILTERING LOGS IN A LOCAL LOGGING SYSTEM ROLE

You can deploy a logging solution which filters the logs based on the `rsyslog` property-based filter.

**Prerequisites**

- Access and permissions to one or more managed nodes, which are systems you want to configure with the Logging System Role.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Engine configures other systems.

On the control node:

- Red Hat Ansible Engine is installed
- The `rhel-system-roles` package is installed
- An inventory file which lists the managed nodes.

**NOTE**

You do not have to have the `rsyslog` package installed, because the system role installs `rsyslog` when deployed.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   ---
   - name: Deploying files input and configured files output
     hosts: all
     roles:
       - linux-system-roles.logging
     vars:
       logging_inputs:
         - name: files_input
           type: basics
   ```
logging_outputs:
- name: files_output0
type: files
property: msg
property_op: contains
property_value: error
path: /var/log/errors.log
- name: files_output1
type: files
property: msg
property_op: "!contains"
property_value: error
path: /var/log/others.log
logging_flows:
- name: flow0
  inputs: [files_input]
  outputs: [files_output0, files_output1]

Using this configuration, all messages that contain the error string are logged in /var/log/errors.log, and all other messages are logged in /var/log/others.log.

You can replace the error property value with the string by which you want to filter.

You can modify the variables according to your preferences.

2. Optional: Verify playbook syntax.

   # ansible-playbook --syntax-check playbook.yml

3. Run the playbook on your inventory file:

   # ansible-playbook -i inventory_file /path/to/file/playbook.yml

Verification

1. Test the syntax of the /etc/rsyslog.conf file:

   # rsyslogd -N 1
   rsyslogd: version 8.1911.0-6.el8, config validation run (level 1), master config /etc/rsyslog.conf

2. Verify that the system sends messages that contain the error string to the log:

   a. Send a test message:

      # logger error

   b. View the /var/log/errors.log log, for example:

      # cat /var/log/errors.log
      Aug  5 13:48:31 hostname root[6778]: error
Where `hostname` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

Additional resources

- Documentation installed with the `rhel-system-roles` package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`

### 9.5. APPLYING A REMOTE LOGGING SOLUTION USING THE LOGGING SYSTEM ROLE

Follow these steps to prepare and apply a Red Hat Ansible Engine playbook to configure a remote logging solution. In this playbook, one or more clients take logs from `systemd-journal` and forward them to a remote server. The server receives remote input from `remote_rsyslog` and `remote_files` and outputs the logs to local files in directories named by remote host names.

**Prerequisites**

- Access and permissions to one or more *managed nodes*, which are systems you want to configure with the Logging System Role.

- Access and permissions to a *control node*, which is a system from which Red Hat Ansible Engine configures other systems. On the control node:
  - Red Hat Ansible Engine is installed.
  - The `rhel-system-roles` package is installed.
  - An inventory file which lists the managed nodes.

**NOTE**

You do not have to have the `rsyslog` package installed, because the system role installs `rsyslog` when deployed.

**Procedure**

1. Create a playbook that defines the required role:
   a. Create a new YAML file and open it in a text editor, for example:

   ```yaml
   # vi logging-playbook.yml
   ```

   b. Insert the following content into the file:

   ```yaml
   ---
   - name: Deploying remote input and remote_files output
     hosts: server
     roles:
     - rhel-system-roles.logging
     vars:
     logging_inputs:
     - name: remote_udp_input
   ```
type: remote
udp_ports: [ 601 ]
- name: remote_tcp_input
type: remote
tcp_ports: [ 601 ]
logging_outputs:
- name: remote_files_output
type: remote_files
logging_flows:
- name: flow_0
  inputs: [remote_udp_input, remote_tcp_input]
  outputs: [remote_files_output]

- name: Deploying basics input and forwards output
  hosts: clients
  roles:
  - rhel-system-roles.logging
  vars:
    logging_inputs:
    - name: basic_input
type: basics
    logging_outputs:
    - name: forward_output0
type: forwards
      severity: info
      target: _host1.example.com_
      udp_port: 601
    - name: forward_output1
type: forwards
      facility: mail
      target: _host1.example.com_
      tcp_port: 601
    logging_flows:
    - name: flows0
      inputs: [basic_input]
      outputs: [forward_output0, forward_output1]

[basic_input]
[forward_output0, forward_output1]

Where host1.example.com is the logging server.

NOTE

You can modify the parameters in the playbook to fit your needs.
2. Create an inventory file that lists your servers and clients:
   a. Create a new file and open it in a text editor, for example:
      ```
      # vi inventory.ini
      ```
   b. Insert the following content into the inventory file:
      ```ini
      [servers]
      server ansible_host=host1.example.com
      [clients]
      client ansible_host=host2.example.com
      ```
      Where:
      - `host1.example.com` is the logging server.
      - `host2.example.com` is the logging client.

3. Run the playbook on your inventory.
   ```
   # ansible-playbook -i /path/to/file/inventory.ini /path/to/file/_logging-playbook.yml
   ```
   Where:
   - `inventory.ini` is the inventory file.
   - `logging-playbook.yml` is the playbook you created.

Verification

1. On both the client and the server system, test the syntax of the `/etc/rsyslog.conf` file:
   ```
   # rsyslogd -N 1
   rsyslogd: version 8.1911.0-6.el8, config validation run (level 1), master config
   /etc/rsyslog.conf
   ```

2. Verify that the client system sends messages to the server:
   a. On the client system, send a test message:
      ```
      ```
b. On the server system, view the /var/log/messages log, for example:

```bash
# cat /var/log/messages
Aug  5 13:48:31 host2.example.com root[6778]: test
```

Where `host2.example.com` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

### Additional resources

- Documentation installed with the `rhel-system-roles` package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`
- RHEL System Roles KB article

#### 9.6. USING THE LOGGING SYSTEM ROLE WITH TLS

Transport Layer Security (TLS) is a cryptographic protocol designed to securely communicate over the computer network.

As an administrator, you can use the Logging System Role on RHEL to configure secure transfer of logs using Red Hat Ansible Automation Platform.

### 9.6.1. Configuring client logging with TLS

You can use the Logging System Role to configure logging in RHEL systems that are logged on a local machine and can transfer logs to the remote logging system with TLS by running an Ansible playbook.

This procedure configures TLS on all hosts in the clients group in the Ansible inventory. The TLS protocol encrypts the message transmission for secure transfer of logs over the network.

**Prerequisites**

- You have permissions to run playbooks on managed nodes on which you want to configure TLS.
- The managed nodes are listed in the inventory file on the control node.
- The `ansible` and `rhel-system-roles` packages are installed on the control node.

**Procedure**

1. Create a `playbook.yml` file with the following content:

```yaml
---
- name: Deploying files input and forwards output with certs
  hosts: clients
  roles:
    - rhel-system-roles.logging
  vars:
    logging_pki_files:
```

---
The playbook uses the following parameters:

**logging_pki_files**

Using this parameter you can configure TLS and has to pass `ca_cert_src`, `cert_src`, and `private_key_src` parameters.

**ca_cert**

Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

**cert**

Represents the path to cert. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

**private_key**

Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

**ca_cert_src**

Represents local CA cert file path which is copied to the target host. If `ca_cert` is specified, it is copied to the location.

**cert_src**

Represents the local cert file path which is copied to the target host. If `cert` is specified, it is copied to the location.

**private_key_src**

Represents the local key file path which is copied to the target host. If `private_key` is specified, it is copied to the location.

**tls**

Using this parameter ensures secure transfer of logs over the network. If you do not want a secure wrapper, you can set `tls: true`.

2. Verify playbook syntax:

```
# ansible-playbook --syntax-check playbook.yml
```
3. Run the playbook on your inventory file:

   ```
   # ansible-playbook -i inventory_file playbook.yml
   ```

9.6.2. Configuring server logging with TLS

You can use the Logging System Role to configure logging in RHEL systems as a server and can receive logs from the remote logging system with TLS by running an Ansible playbook.

This procedure configures TLS on all hosts in the server group in the Ansible inventory.

Prerequisites

- You have permissions to run playbooks on managed nodes on which you want to configure TLS.
- The managed nodes are listed in the inventory file on the control node.
- The `ansible` and `rhel-system-roles` packages are installed on the control node.

Procedure

1. Create a `playbook.yml` file with the following content:

   ```yaml
   ---
   - name: Deploying remote input and remote_files output with certs
     hosts: server
     roles:
     - rhel-system-roles.logging
     vars:
     logging_pki_files:
     - ca_cert_src: /local/path/to/ca_cert.pem
       cert_src: /local/path/to/cert.pem
       private_key_src: /local/path/to/key.pem
     logging_inputs:
     - name: input_name
       type: remote
       tcp_ports: 514
       tls: true
       permitted_clients: ['clients.example.com']
     logging_outputs:
     - name: output_name
       type: remote_files
       remote_log_path: /var/log/remote/%FROMHOST%/%PROGRAMNAME:::secpath-replace%.log
       async_writing: true
       client_count: 20
       io_buffer_size: 8192
     logging_flows:
     - name: flow_name
       inputs: [input_name]
       outputs: [output_name]
   ```

The playbook uses the following parameters:

- **logging_pki_files**
Using this parameter you can configure TLS and has to pass `ca_cert_src`, `cert_src`, and `private_key_src` parameters.

**ca_cert**

Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

**cert**

Represents the path to cert. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

**private_key**

Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

**ca_cert_src**

Represents local CA cert file path which is copied to the target host. If `ca_cert` is specified, it is copied to the location.

**cert_src**

Represents the local cert file path which is copied to the target host. If `cert` is specified, it is copied to the location.

**private_key_src**

Represents the local key file path which is copied to the target host. If `private_key` is specified, it is copied to the location.

**tls**

Using this parameter ensures secure transfer of logs over the network. If you do not want a secure wrapper, you can set `tls: true`.

2. Verify playbook syntax:

   ```shell
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```shell
   # ansible-playbook -i inventory_file playbook.yml
   ```

# 9.7. USING THE LOGGING SYSTEM ROLES WITH RELP

Reliable Event Logging Protocol (RELP) is a networking protocol for data and message logging over the TCP network. It ensures reliable delivery of event messages and you can use it in environments that do not tolerate any message loss.

The RELP sender transfers log entries in form of commands and the receiver acknowledges them once they are processed. To ensure consistency, RELP stores the transaction number to each transferred command for any kind of message recovery.

You can consider a remote logging system in between the RELP Client and RELP Server. The RELP Client transfers the logs to the remote logging system and the RELP Server receives all the logs sent by the remote logging system.

Administrators can use the Logging System Role to configure the logging system to reliably send and receive log entries.
9.7.1. Configuring client logging with RELP

You can use the Logging System Role to configure logging in RHEL systems that are logged on a local machine and can transfer logs to the remote logging system with RELP by running an Ansible playbook.

This procedure configures RELP on all hosts in the clients group in the Ansible inventory. The RELP configuration uses Transport Layer Security (TLS) to encrypt the message transmission for secure transfer of logs over the network.

Prerequisites

- You have permissions to run playbooks on managed nodes on which you want to configure RELP.
- The managed nodes are listed in the inventory file on the control node.
- The ansible and rhel-system-roles packages are installed on the control node.

Procedure

1. Create a playbook.yml file with the following content:

```yaml
---
- name: Deploying basic input and relp output
  hosts: clients
  roles:
    - rhel-system-roles.logging
  vars:
    logging_inputs:
      - name: basic_input
        type: basics
    logging_outputs:
      - name: relp_client
        type: relp
        target: _logging.server.com_
        port: 20514
        tls: true
        ca_cert: _/etc/pki/tls/certs/ca.pem_
        cert: _/etc/pki/tls/certs/client-cert.pem_
        private_key: _/etc/pki/tls/private/client-key.pem_
        pki_authmode: name
        permitted_servers:
          - '*.server.example.com'
    logging_flows:
      - name: _example_flow_
        inputs: [basic_input]
        outputs: [relp_client]
```

The playbooks uses following settings:

- **target**: This is a required parameter that specifies the host name where the remote logging system is running.
- **port**: Port number the remote logging system is listening.
- **tls**: Ensures secure transfer of logs over the network. If you do not want a secure wrapper
you can set the **tls** variable to **false**. By default **tls** parameter is set to true while working with RELP and requires key/certificates and triplets `{ca_cert, cert, private_key}` and/or `{ca_cert_src, cert_src, private_key_src}`.

- If `{ca_cert_src, cert_src, private_key_src}` triplet is set, the default locations `/etc/pki/tls/certs` and `/etc/pki/tls/private` are used as the destination on the managed node to transfer files from control node. In this case, the file names are identical to the original ones in the triplet.

- If `{ca_cert, cert, private_key}` triplet is set, files are expected to be on the default path before the logging configuration.

- If both the triplets are set, files are transferred from local path from control node to specific path of the managed node.

  - **ca_cert**: Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

  - **cert**: Represents the path to cert. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

  - **private_key**: Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

  - **ca_cert_src**: Represents local CA cert file path which is copied to the target host. If ca_cert is specified, it is copied to the location.

  - **cert_src**: Represents the local cert file path which is copied to the target host. If cert is specified, it is copied to the location.

  - **private_key_src**: Represents the local key file path which is copied to the target host. If private_key is specified, it is copied to the location.

  - **pki_authmode**: Accepts the authentication mode as **name** or **fingerprint**.

  - **permitted_servers**: List of servers that will be allowed by the logging client to connect and send logs over TLS.

  - **inputs**: List of logging input dictionary.

  - **outputs**: List of logging output dictionary.

2. Optional: Verify playbook syntax.

   ```
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook:

   ```
   # ansible-playbook -i inventory_file playbook.yml
   ```

### 9.7.2. Configuring server logging with RELP

You can use the Logging System Role to configure logging in RHEL systems as a server and can receive logs from the remote logging system with RELP by running an Ansible playbook.
This procedure configures RELP on all hosts in the server group in the Ansible inventory. The RELP configuration uses TLS to encrypt the message transmission for secure transfer of logs over the network.

Prerequisites

- You have permissions to run playbooks on managed nodes on which you want to configure RELP.
- The managed nodes are listed in the inventory file on the control node.
- The ansible and rhel-system-roles packages are installed on the control node.

Procedure

1. Create a playbook.yml file with the following content:

```yaml
---
- name: Deploying remote input and remote_files output
  hosts: server
  roles:
    - rhel-system-roles.logging
  vars:
    logging_inputs:
      - name: relp_server
        type: relp
        port: 20514
        tls: true
        ca_cert: /etc/pki/tls/certs/ca.pem
        cert: /etc/pki/tls/certs/server-cert.pem
        private_key: /etc/pki/tls/private/server-key.pem
        pki_authmode: name
        permitted_clients:
          - '*example.client.com'
    logging_outputs:
      - name: __remote_files_output__
        type: __remote_files__
    logging_flows:
      - name: __example_flow__
        inputs: __relp_server__
        outputs: __remote_files_output__
```

The playbooks uses following settings:

- **port**: Port number the remote logging system is listening.
- **tls**: Ensures secure transfer of logs over the network. If you do not want a secure wrapper you can set the tls variable to false. By default tls parameter is set to true while working with RELP and requires key/certificates and triplets {ca_cert, cert, private_key} and/or {ca_cert_src, cert_src, private_key_src}.
  - If {ca_cert_src, cert_src, private_key_src} triplet is set, the default locations /etc/pki/tls/certs and /etc/pki/tls/private are used as the destination on the managed node to transfer files from control node. In this case, the file names are identical to the original ones in the triplet.
If \{ca_cert, cert, private_key\} triplet is set, files are expected to be on the default path before the logging configuration.

If both the triplets are set, files are transferred from local path from control node to specific path of the managed node.

- **ca_cert**: Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

- **cert**: Represents the path to cert. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

- **private_key**: Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

- **ca_cert_src**: Represents local CA cert file path which is copied to the target host. If `ca_cert` is specified, it is copied to the location.

- **cert_src**: Represents the local cert file path which is copied to the target host. If `cert` is specified, it is copied to the location.

- **private_key_src**: Represents the local key file path which is copied to the target host. If `private_key` is specified, it is copied to the location.

- **pki_authmode**: Accepts the authentication mode as **name** or **fingerprint**.

- **permitted_clients**: List of clients that will be allowed by the logging server to connect and send logs over TLS.

- **inputs**: List of logging input dictionary.

- **outputs**: List of logging output dictionary.

2. Optional: Verify playbook syntax.

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook:

   ```bash
   # ansible-playbook -i inventory_file playbook.yml
   ```

### 9.8. ADDITIONAL RESOURCES

- **Getting started with RHEL System Roles**

- Documentation installed with the **rhel-system-roles** package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`.

- **RHEL System Roles**

- **ansible-playbook(1) man page**.
CHAPTER 10. CONFIGURING SECURE COMMUNICATION WITH THE SSH SYSTEM ROLES

As an administrator, you can use the SSHD System Role to configure SSH servers and the SSH System Role to configure SSH clients consistently on any number of RHEL systems at the same time by using Red Hat Ansible Automation Platform.

10.1. SSHD SYSTEM ROLE VARIABLES

In an SSHD System Role playbook, you can define the parameters for the SSH configuration file according to your preferences and limitations.

If you do not configure these variables, the system role produces an `sshd_config` file that matches the RHEL defaults.

In all cases, Booleans correctly render as `yes` and `no` in `sshd` configuration. You can define multi-line configuration items using lists. For example:

```
sshd_ListenAddress:
  - 0.0.0.0
  - '::'
```

renders as:

```
ListenAddress 0.0.0.0
ListenAddress ::
```

Variables for the SSHD System Role

**sshd_enable**

If set to `False`, the role is completely disabled. Defaults to `True`.

**sshd_skip_defaults**

If set to `True`, the system role does not apply default values. Instead, you specify the complete set of configuration defaults by using either the `sshd` dict, or `sshd_Key` variables. Defaults to `False`.

**sshd_manage_service**

If set to `False`, the service is not managed, which means it is not enabled on boot and does not start or reload. Defaults to `True` except when running inside a container or AIX, because the Ansible service module does not currently support `enabled` for AIX.

**sshd_allow_reload**

If set to `False`, `sshd` does not reload after a change of configuration. This can help with troubleshooting. To apply the changed configuration, reload `sshd` manually. Defaults to the same value as `sshd_manage_service` except on AIX, where `sshd_manage_service` defaults to `False` but `sshd_allow_reload` defaults to `True`.

**sshd_install_service**

If set to `True`, the role installs service files for the `sshd` service. This overrides files provided in the operating system. Do not set to `True` unless you are configuring a second instance and you also change the `sshd_service` variable. Defaults to `False`.

The role uses the files pointed by the following variables as templates:
sshd_service

This variable changes the `sshd` service name, which is useful for configuring a second `sshd` service instance.

sshd

A dict that contains configuration. For example:

```
sshd:
    Compression: yes
    ListenAddress:
- 0.0.0.0
```

sshd_OptionName

You can define options by using simple variables consisting of the `sshd_` prefix and the option name instead of a dict. The simple variables override values in the `sshd` dict. For example:

```
sshd_Compression: no
```

sshd_match and sshd_match_1 to sshd_match_9

A list of dicts or just a dict for a Match section. Note that these variables do not override match blocks as defined in the `sshd` dict. All of the sources will be reflected in the resulting configuration file.

Secondary variables for the SSHD System Role

You can use these variables to override the defaults that correspond to each supported platform.

sshd_packages

You can override the default list of installed packages using this variable.

sshd_config_owner, sshd_config_group, and sshd_config_mode

You can set the ownership and permissions for the `openssh` configuration file that this role produces using these variables.

sshd_config_file

The path where this role saves the `openssh` server configuration produced.

sshd_config_namespace

The default value of this variable is null, which means that the role defines the entire content of the configuration file including system defaults. Alternatively, you can use this variable to invoke this role from other roles or from multiple places in a single playbook on systems that do not support drop-in directory. The `sshd_skip_defaults` variable is ignored and no system defaults are used in this case. When this variable is set, the role places the configuration that you specify to configuration snippets in an existing configuration file under the given namespace. If your scenario requires applying the role several times, you need to select a different namespace for each application.
NOTE

Limitations of the openssh configuration file still apply. For example, only the first option specified in a configuration file is effective for most of the configuration options.

Technically, the role places snippets in "Match all" blocks, unless they contain other match blocks, to ensure they are applied regardless of the previous match blocks in the existing configuration file. This allows configuring any non-conflicting options from different roles invocations.

**sshd_binary**

The path to the sshd executable of openssh.

**sshd_service**

The name of the sshd service. By default, this variable contains the name of the sshd service that the target platform uses. You can also use it to set the name of the custom sshd service when the role uses the sshd_install_service variable.

**sshd_verify_hostkeys**

Defaults to auto. When set to auto, this lists all host keys that are present in the produced configuration file, and generates any paths that are not present. Additionally, permissions and file owners are set to default values. This is useful if the role is used in the deployment stage to make sure the service is able to start on the first attempt. To disable this check, set this variable to an empty list [].

**sshd_hostkey_owner**, **sshd_hostkey_group**, **sshd_hostkey_mode**

Use these variables to set the ownership and permissions for the host keys from sshd_verify_hostkeys.

**sshd_sysconfig**

On RHEL-based systems, this variable configures additional details of the sshd service. If set to true, this role manages also the /etc/sysconfig/sshd configuration file based on the following configuration. Defaults to false.

**sshd_sysconfig_override_crypto_policy**

In RHEL, when set to true, this variable overrides the system-wide crypto policy. Defaults to false.

**sshd_sysconfig_use_strong_rng**

On RHEL-based systems, this variable can force sshd to reseed the openssl random number generator with the number of bytes given as the argument. The default is 0, which disables this functionality. Do not turn this on if the system does not have a hardware random number generator.

### 10.2. CONFIGURING OPENSSH SERVERS USING THE SSHD SYSTEM ROLE

You can use the SSHD System Role to configure multiple SSH servers by running an Ansible playbook.

NOTE

You can use the SSHD System Role with other system roles that change SSH and SSHD configuration, for example the Identity Management RHEL System Roles. To prevent the configuration from being overwritten, make sure that the SSHD role uses namespaces (RHEL 8 and earlier versions) or a drop-in directory (RHEL 9).

Prerequisites
• Access and permissions to one or more managed nodes, which are systems you want to configure with the SSHD System Role.

• Access and permissions to a control node, which is a system from which Red Hat Ansible Engine configures other systems.

  On the control node:
  
  o Red Hat Ansible Engine is installed.
  
  o The **rhel-system-roles** package is installed.
  
  o An inventory file which lists the managed nodes.

**Procedure**

1. Copy the example playbook for the SSHD System Role:

   ```
   # cp /usr/share/doc/rhel-system-roles/sshd/example-root-login-playbook.yml path/custom-playbook.yml
   ```

2. Open the copied playbook by using a text editor, for example:

   ```
   # vim path/custom-playbook.yml
   ```
   
   ```yaml
   ---
   - hosts: all
     tasks:
       - name: Configure sshd to prevent root and password login except from particular subnet
         include_role:
           name: rhel-system-roles.sshd
         vars:
           sshd:
             # root login and password login is enabled only from a particular subnet
             PermitRootLogin: no
             PasswordAuthentication: no
             Match:
               - Condition: "Address 192.0.2.0/24"
                 PermitRootLogin: yes
                 PasswordAuthentication: yes
   ```

   The playbook configures the managed node as an SSH server configured so that:

   • password and **root** user login is disabled

   • password and **root** user login is enabled only from the subnet **192.0.2.0/24**

   You can modify the variables according to your preferences. For more details, see **SSHD System Role variables**.

3. Optional: Verify playbook syntax.

   ```
   # ansible-playbook --syntax-check path/custom-playbook.yml
   ```

4. Run the playbook on your inventory file:
# ansible-playbook -i inventory_file path/custom-playbook.yml

...  

PLAY RECAP  
**************************************************  
localhost : ok=12 changed=2 unreachable=0 failed=0  
skipped=10 rescued=0 ignored=0

Verification

1. Log in to the SSH server:

   $ ssh user1@10.1.1.1

   Where:

   - **user1** is a user on the SSH server.
   - **10.1.1.1** is the IP address of the SSH server.

2. Check the contents of the `sshd_config` file on the SSH server:

   $ vim /etc/ssh/sshd_config

   # Ansible managed  
   HostKey /etc/ssh/ssh_host_rsa_key  
   HostKey /etc/ssh/ssh_host_ecdsa_key  
   HostKey /etc/ssh/ssh_host_ed25519_key  
   AcceptEnv LANG LC_CTYPE LC_NUMERIC LC_TIME LC_COLLATE LC_MONETARY LC_MESSAGES  
   AcceptEnv LC_PAPER LC_NAME LC_ADDRESS LC_TELEPHONE LC_MEASUREMENT  
   AcceptEnv LC_IDENTIFICATION LC_ALL LANGUAGE  
   AcceptEnv XMODIFIERS  
   AuthorizedKeysFile .ssh/authorized_keys  
   ChallengeResponseAuthentication no  
   GSSAPIAuthentication yes  
   GSSAPICleanupCredentials no  
   PasswordAuthentication no  
   PermitRootLogin no  
   PrintMotd no  
  Subsystem sftp /usr/libexec/openssh/sftp-server  
   SyslogFacility AUTHPRIV  
   UsePAM yes  
   X11Forwarding yes  
   Match Address 192.0.2.0/24  
   PasswordAuthentication yes  
   PermitRootLogin yes

3. Check that you can connect to the server as root from the **192.0.2.0/24** subnet:
   
   a. Determine your IP address:
$ hostname -I
192.0.2.1

If the IP address is within the 192.0.2.1 - 192.0.2.254 range, you can connect to the server.

b. Connect to the server as root:

$ ssh root@10.1.1.1

Additional resources

- ansible-playbook(1) man page.

10.3. SSH SYSTEM ROLE VARIABLES

In an SSH System Role playbook, you can define the parameters for the client SSH configuration file according to your preferences and limitations.

If you do not configure these variables, the system role produces a global ssh_config file that matches the RHEL defaults.

In all cases, booleans correctly render as yes or no in ssh configuration. You can define multi-line configuration items using lists. For example:

```
LocalForward:
  - 22 localhost:2222
  - 403 localhost:4003
```

renders as:

```
LocalForward 22 localhost:2222
LocalForward 403 localhost:4003
```

**NOTE**

The configuration options are case sensitive.

Variables for the SSH System Role

**ssh_user**

You can define an existing user name for which the system role modifies user-specific configuration. The user-specific configuration is saved in ~/.ssh/config of the given user. The default value is null, which modifies global configuration for all users.

**ssh_skip_defaults**

Defaults to auto. If set to auto, the system role writes the system-wide configuration file /etc/ssh/sshd_config and keeps the RHEL defaults defined there. Creating a drop-in configuration file, for example by defining the ssh_drop_in_name variable, automatically disables the ssh_skip_defaults variable.

**ssh_drop_in_name**
Defines the name for the drop-in configuration file, which is placed in the system-wide drop-in directory. The name is used in the template /etc/ssh/ssh_config.d/{ssh_drop_in_name}.conf to reference the configuration file to be modified. If the system does not support drop-in directory, the default value is null. If the system supports drop-in directories, the default value is 00-ansible.

**WARNING**

If the system does not support drop-in directories, setting this option will make the play fail.

The suggested format is **NN-name**, where **NN** is a two-digit number used for ordering the configuration files and **name** is any descriptive name for the content or the owner of the file.

**ssh**

A dict that contains configuration options and their respective values.

**ssh**\_OptionName

You can define options by using simple variables consisting of the **ssh** prefix and the option name instead of a dict. The simple variables override values in the **ssh** dict.

**ssh\_additional\_packages**

This role automatically installs the **openssh** and **openssh-clients** packages, which are needed for the most common use cases. If you need to install additional packages, for example, **openssh-keysign** for host-based authentication, you can specify them in this variable.

**ssh\_config\_file**

The path to which the role saves the configuration file produced. Default value:

- If the system has a drop-in directory, the default value is defined by the template /etc/ssh/ssh_config.d/{ssh_drop_in_name}.conf.

- If the system does not have a drop-in directory, the default value is /etc/ssh/ssh_config.

- If the **ssh\_user** variable is defined, the default value is ~/.ssh/config.

**ssh\_config\_owner, ssh\_config\_group, ssh\_config\_mode**

The owner, group and modes of the created configuration file. By default, the owner of the file is **root:root**, and the mode is **0644**. If **ssh\_user** is defined, the mode is **0600**, and the owner and group are derived from the user name specified in the **ssh\_user** variable.

### 10.4. CONFIGURING OPENSSH CLIENTS USING THE SSH SYSTEM ROLE

You can use the SSH System Role to configure multiple SSH clients by running an Ansible playbook.
NOTE

You can use the SSH System Role with other system roles that change SSH and SSHD configuration, for example the Identity Management RHEL System Roles. To prevent the configuration from being overwritten, make sure that the SSH role uses a drop-in directory (default from RHEL 8).

Prerequisites

- Access and permissions to one or more managed nodes, which are systems you want to configure with the SSH System Role.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Engine configures other systems.

On the control node:

- Red Hat Ansible Engine is installed.
- The rhel-system-roles package is installed.
- An inventory file which lists the managed nodes.

Procedure

1. Create a new playbook.yml file with the following content:

```yaml
---
- hosts: all
  tasks:
  - name: "Configure ssh clients"
    include_role:
      name: rhel-system-roles.ssh
    vars:
      ssh_user: root
      ssh:
        Compression: true
        GSSAPIAuthentication: no
        ControlMaster: auto
        ControlPath: ~/.ssh/.cm%C
        Host:
        - Condition: example
          Hostname: example.com
          User: user1
          ssh_ForwardX11: no
```

This playbook configures the root user’s SSH client preferences on the managed nodes with the following configurations:

- Compression is enabled.
- ControlMaster multiplexing is set to auto.
- The example alias for connecting to the example.com host is user1.
- The example host alias is created, which represents a connection to the example.com host the with user1 user name.
- X11 forwarding is disabled.

Optionally, you can modify these variables according to your preferences. For more details, see [SSH System Role variables](#).

2. Optional: Verify playbook syntax.

   ```
   # ansible-playbook --syntax-check path/custom-playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```
   # ansible-playbook -i inventory_file path/custom-playbook.yml
   ```

**Verification**

- Verify that the managed node has the correct configuration by opening the SSH configuration file in a text editor, for example:

  ```
  # vi ~root/.ssh/config
  ```

After application of the example playbook shown above, the configuration file should have the following content:

```
# Ansible managed
Compression yes
ControlMaster auto
ControlPath ~/.ssh/.cm%C
ForwardX11 no
GSSAPIAuthentication no
Host example
Hostname example.com
User user1
```

**10.5. USING THE SSH SERVER SYSTEM ROLE FOR NON-EXCLUSIVE CONFIGURATION**

Normally, applying the SSHD System Role overwrites the entire configuration. This may be problematic if you have previously adjusted the configuration, for example with a different system role or playbook. To apply the SSHD System Role for only selected configuration options while keeping other options in place, you can use the non-exclusive configuration.

In RHEL 8 and earlier, you can apply the non-exclusive configuration with a configuration snippet.

**Prerequisites**

- Access and permissions to one or more managed nodes, which are systems you want to configure with the SSHD System Role.

- Access and permissions to a control node, which is a system from which Red Hat Ansible Engine configures other systems.
  On the control node:
  - Red Hat Ansible Engine is installed.
The `rhel-system-roles` package is installed.

- An inventory file which lists the managed nodes.
- A playbook for a different RHEL System Role. For additional information, see Applying a role.

**Procedure**

1. Add a configuration snippet with the `sshd_config_namespace` variable to the playbook:

```yaml
---
- hosts: all
  tasks:
    - name: <Configure SSHD to accept some useful environment variables>
      include_role:
        name: rhel-system-roles.sshd
      vars:
        sshd_config_namespace: <my-application>
        sshd:
          # Environment variables to accept
          AcceptEnv:
            LANG
            LS_COLORS
            EDITOR
```

When you apply the playbook to the inventory, the role adds the following snippet, if not already present, to the `/etc/ssh/sshd_config` file.

```bash
# BEGIN sshd system role managed block: namespace <my-application>
Match all
  AcceptEnv LANG LS_COLORS EDITOR
# END sshd system role managed block: namespace <my-application>
```

**Verification**

- Optional: Verify playbook syntax.

```bash
# ansible-playbook --syntax-check playbook.yml -i inventory_file
```

**Additional resources**

- `ansible-playbook(1)` man page.
CHAPTER 11. CONFIGURING VPN CONNECTIONS WITH IPSEC BY USING THE RHEL VPN SYSTEM ROLE

With the VPN System Role, you can configure VPN connections on RHEL systems by using Red Hat Ansible Automation Platform. You can use it to set up host-to-host, network-to-network, VPN Remote Access Server, and mesh configurations.

For host-to-host connections, the role sets up a VPN tunnel between each pair of hosts in the list of `vpn_connections` using the default parameters, including generating keys as needed. Alternatively, you can configure it to create an opportunistic mesh configuration between all hosts listed. The role assumes that the names of the hosts under `hosts` are the same as the names of the hosts used in the Ansible inventory, and that you can use those names to configure the tunnels.

### NOTE

The VPN RHEL System Role currently supports only Libreswan, which is an IPsec implementation, as the VPN provider.

### 11.1. CREATING A HOST-TO-HOST VPN WITH IPSEC USING THE VPN SYSTEM ROLE

You can use the VPN System Role to configure host-to-host connections by running an Ansible playbook on the control node, which will configure all the managed nodes listed in an inventory file.

#### Prerequisites

- Access and permissions to one or more `managed nodes`, which are systems you want to configure with the VPN System Role.
- Access and permissions to a `control node`, which is a system from which Red Hat Ansible Engine configures other systems.

  On the control node:

  - Red Hat Ansible Engine is installed.
  - The `rhel-system-roles` package is installed.
  - An inventory file which lists the managed nodes.

#### Procedure

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   - name: Host to host VPN
     hosts: managed_node1, managed_node2
     roles:
       - rhel-system-roles.vpn
     vars:
       vpn_connections:
         - hosts:
             managed_node1:
             managed_node2:
   ```
This playbook configures the connection `managed_node1-to-managed_node2` using pre-shared key authentication with keys auto-generated by the system role.

2. Optional: Configure connections from managed hosts to external hosts that are not listed in the inventory file by adding the following section to the `vpn_connections` list of hosts:

   ```yaml
   vpn_connections:
   - hosts:
     managed_node1:
     managed_node2:
     external_node:
       hostname: 192.0.2.2
   ``

   This configures two additional connections: `managed_node1-to-external_node` and `managed_node2-to-external_node`.

   **NOTE**
   
   The connections are configured only on the managed nodes and not on the external node.

1. Optional: You can specify multiple VPN connections for the managed nodes by using additional sections within `vpn_connections`, for example a control plane and a data plane:

   ```yaml
   - name: Multiple VPN
     hosts: managed_node1, managed_node2
     roles:
       - rhel-system-roles.vpn
     vars:
       vpn_connections:
       - name: control_plane_vpn
         hosts:
           managed_node1:
             hostname: 192.0.2.0 # IP for the control plane
           managed_node2:
             hostname: 192.0.2.1
       - name: data_plane_vpn
         hosts:
           managed_node1:
             hostname: 10.0.0.1 # IP for the data plane
           managed_node2:
             hostname: 10.0.0.2
   ``

2. Optional: You can modify the variables according to your preferences. For more details, see the `/usr/share/doc/rhel-system-roles/vpn/README.md` file.

3. Optional: Verify playbook syntax.

   ```bash
   # ansible-playbook --syntax-check /path/to/file/playbook.yml -i /path/to/file/inventory_file
   ``

4. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i /path/to/file/inventory_file /path/to/file/playbook.yml
   ```
1. On the managed nodes, confirm that the connection is successfully loaded:

```
# ipsec status | grep connection.name
```

Replace `connection.name` with the name of the connection from this node, for example `managed_node1-to-managed_node2`.

**NOTE**

By default, the role generates a descriptive name for each connection it creates from the perspective of each system. For example, when creating a connection between `managed_node1` and `managed_node2`, the descriptive name of this connection on `managed_node1` is `managed_node1-to-managed_node2` but on `managed_node2` the connection is named `managed_node2-to-managed_node1`.

1. On the managed nodes, confirm that the connection is successfully started:

```
# ipsec trafficstatus | grep connection.name
```

2. Optional: If a connection did not successfully load, manually add the connection by entering the following command. This will provide more specific information indicating why the connection failed to establish:

```
# ipsec auto --add connection.name
```

**NOTE**

Any errors that may have occurred during the process of loading and starting the connection are reported in the logs, which can be found in `/var/log/pluto.log`. Because these logs are hard to parse, try to manually add the connection to obtain log messages from the standard output instead.

11.2. CREATING AN OPPORTUNISTIC MESH VPN CONNECTION WITH IPSEC BY USING THE VPN SYSTEM ROLE

You can use the VPN System Role to configure an opportunistic mesh VPN connection that uses certificates for authentication by running an Ansible playbook on the control node, which will configure all the managed nodes listed in an inventory file.

Authentication with certificates is configured by defining the `auth_method: cert` parameter in the playbook. The VPN System Role assumes that the IPsec Network Security Services (NSS) crypto library, which is defined in the `/etc/ipsec.d` directory, contains the necessary certificates. By default, the node name is used as the certificate nickname. In this example, this is `managed_node1`. You can define different certificate names by using the `cert_name` attribute in your inventory.

In the following example procedure, the control node, which is the system from which you will run the Ansible playbook, shares the same classless inter-domain routing (CIDR) number as both of the managed nodes (192.0.2.0/24) and has the IP address 192.0.2.7. Therefore, the control node falls under the private policy which is automatically created for CIDR 192.0.2.0/24.

To prevent SSH connection loss during the play, a clear policy for the control node is included in the list...
of policies. Note that there is also an item in the policies list where the CIDR is equal to default. This is because this playbook overrides the rule from the default policy to make it private instead of private-or-clear.

Prerequisites

- Access and permissions to one or more managed nodes, which are systems you want to configure with the VPN System Role.
  - On all the managed nodes, the NSS database in the `/etc/ipsec.d` directory contains all the certificates necessary for peer authentication. By default, the node name is used as the certificate nickname.

- Access and permissions to a control node, which is a system from which Red Hat Ansible Engine configures other systems.

  On the control node:
  - Red Hat Ansible Engine is installed.
  - The `rhel-system-roles` package is installed.
  - An inventory file which lists the managed nodes.

Procedure

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   - name: Mesh VPN
     hosts: managed_node1, managed_node2, managed_node3
     roles:
       - rhel-system-roles.vpn
     vars:
       vpn_connections:
         - opportunistic: true
           auth_method: cert
           policies:
             - policy: private
               cidr: default
             - policy: private-or-clear
               cidr: 198.51.100.0/24
             - policy: private
               cidr: 192.0.2.0/24
             - policy: clear
               cidr: 192.0.2.7/32
   ```

2. Optional: You can modify the variables according to your preferences. For more details, see the `/usr/share/doc/rhel-system-roles/vpn/README.md` file.

3. Optional: Verify playbook syntax.

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

4. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i inventory_file /path/to/file/playbook.yml
   ```
11.3. ADDITIONAL RESOURCES

- For details about the parameters used in the VPN System Role and additional information about the VPN System Role, see the /usr/share/doc/rhel-system-roles/vpn/README.md file.

- For details about the ansible-playbook command, see the ansible-playbook(1) man page.
CHAPTER 12. SETTING A CUSTOM CRYPTOGRAPHIC POLICY ACROSS SYSTEMS

As an administrator, you can use the Crypto Policies System Role on RHEL to quickly and consistently configure custom cryptographic policies across many different systems using Red Hat Ansible Automation Platform.

12.1. CRYPTO POLICIES SYSTEM ROLE VARIABLES AND FACTS

In a Crypto Policies System Role playbook, you can define the parameters for the crypto policies configuration file according to your preferences and limitations.

If you do not configure any variables, the system role does not configure the system and only reports the facts.

Selected variables for the Crypto Policies System Role

- **crypto_policies_policy**
  Determines the cryptographic policy the system role applies to the managed nodes. For details about the different crypto policies, see [System-wide cryptographic policies](#).

- **crypto_policies_reload**
  If set to `yes`, the affected services, currently the `ipsec`, `bind`, and `sshd` services, reload after applying a crypto policy. Defaults to `yes`.

- **crypto_policies_reboot_ok**
  If set to `yes`, and a reboot is necessary after the system role changes the crypto policy, it sets `crypto_policies_reboot_required` to `yes`. Defaults to `no`.

Facts set by the Crypto Policies System Role

- **crypto_policies_active**
  Lists the currently selected policy.

- **crypto_policies_available_policies**
  Lists all available policies available on the system.

- **crypto_policies_available_subpolicies**
  Lists all available subpolicies available on the system.

Additional resources

- [Creating and setting a custom system-wide cryptographic policy](#).

12.2. SETTING A CUSTOM CRYPTOGRAPHIC POLICY USING THE CRYPTO POLICIES SYSTEM ROLE

You can use the Crypto Policies System Role to configure a large number of managed nodes consistently from a single control node.

Prerequisites
Access and permissions to one or more **managed nodes**, which are systems you want to configure with the Crypto Policies System Role.

Access and permissions to a **control node**, which is a system from which Red Hat Ansible Engine configures other systems.

On the control node:

- Red Hat Ansible Engine is installed
- The **rhel-system-roles** package is installed
- An inventory file which lists the managed nodes.

Procedure

1. Create a new **playbook.yml** file with the following content:

   ```yaml
   ---
   - hosts: all
     tasks:
     - name: Configure crypto policies
       include_role:
         name: rhel-system-roles.crypto_policies
       vars:
         - crypto_policies_policy: FUTURE
         - crypto_policies_reboot_ok: true
   
   You can replace the `FUTURE` value with your preferred crypto policy, for example: **DEFAULT**, **LEGACY**, and **FIPS:OSPP**.

   The `crypto_policies_reboot_ok: true` variable causes the system to reboot after the system role changes the crypto policy.

   For more details, see Crypto Policies System Role variables and facts.

2. Optional: Verify playbook syntax.

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   
   # ansible-playbook -i inventory_file playbook.yml
   ```

Verification

1. On the control node, create another playbook named, for example, **verify_playbook.yml**:

   ```yaml
   - hosts: all
     tasks:
     - name: Verify active crypto policy
       include_role:
         name: rhel-system-roles.crypto_policies
     - debug:
       var: crypto_policies_active
   ```
This playbook does not change any configurations on the system, only reports the active policy on the managed nodes.

2. Run the playbook on the same inventory file:

```bash
# ansible-playbook -i inventory_file verify_playbook.yml
```

```
TASK [debug] **************************
ok: [host] => {
  "crypto_policies_active": "FUTURE"
}
```

The "crypto_policies_active" variable shows the policy active on the managed node.

### 12.3. ADDITIONAL RESOURCES

- `/usr/share/ansible/roles/rhel-system-roles.crypto_policies/README.md` file.
- `ansible-playbook(1)` man page.
- Installing RHEL System Roles...
- Applying a system role.
CHAPTER 13. USING THE CLEVIS AND TANG SYSTEM ROLES

13.1. INTRODUCTION TO THE CLEVIS AND TANG SYSTEM ROLES

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems.

RHEL 8.3 introduced Ansible roles for automated deployments of Policy-Based Decryption (PBD) solutions using Clevis and Tang. The `rhel-system-roles` package contains these system roles, the related examples, and also the reference documentation.

The `nbde_client` System Role enables you to deploy multiple Clevis clients in an automated way. Note that the `nbde_client` role supports only Tang bindings, and you cannot use it for TPM2 bindings at the moment.

The `nbde_client` role requires volumes that are already encrypted using LUKS. This role supports to bind a LUKS-encrypted volume to one or more Network-Bound (NBDE) servers - Tang servers. You can either preserve the existing volume encryption with a passphrase or remove it. After removing the passphrase, you can unlock the volume only using NBDE. This is useful when a volume is initially encrypted using a temporary key or password that you should remove after the system you provision the system.

If you provide both a passphrase and a key file, the role uses what you have provided first. If it does not find any of these valid, it attempts to retrieve a passphrase from an existing binding.

PBD defines a binding as a mapping of a device to a slot. This means that you can have multiple bindings for the same device. The default slot is slot 1.

The `nbde_client` role provides also the `state` variable. Use the `present` value for either creating a new binding or updating an existing one. Contrary to a `clevis luks bind` command, you can use `state: present` also for overwriting an existing binding in its device slot. The `absent` value removes a specified binding.

Using the `nbde_server` System Role, you can deploy and manage a Tang server as part of an automated disk encryption solution. This role supports the following features:

- Rotating Tang keys
- Deploying and backing up Tang keys

Additional resources

- For a detailed reference on Network-Bound Disk Encryption (NBDE) role variables, install the `rhel-system-roles` package, and see the `README.md` and `README.html` files in the `/usr/share/doc/rhel-system-roles/nbde_client/` and `/usr/share/doc/rhel-system-roles/nbde_server/` directories.

- For example system-roles playbooks, install the `rhel-system-roles` package, and see the `/usr/share/ansible/roles/rhel-system-roles.nbde_server/examples/` directories.

- For more information on RHEL System Roles, see Introduction to RHEL System Roles

13.2. USING THE NBDE_SERVER SYSTEM ROLE FOR SETTING UP MULTIPLE TANG SERVERS
Follow the steps to prepare and apply an Ansible playbook containing your Tang server settings.

**Prerequisites**

- Access and permissions to one or more *managed nodes*, which are systems you want to configure with the `nbde_server` System Role.

- Access and permissions to a *control node*, which is a system from which Red Hat Ansible Engine configures other systems.

  On the control node:

  - Red Hat Ansible Engine is installed.
  - The `rhel-system-roles` package is installed.
  - An inventory file which lists the managed nodes.

**Procedure**

1. Prepare your playbook containing settings for Tang servers. You can either start from the scratch, or use one of the example playbooks from the `/usr/share/ansible/roles/rhel-system-roles.nbde_server/examples/` directory.

   ```bash
   # cp /usr/share/ansible/roles/rhel-system-roles.nbde_server/examples/simple_deploy.yml .my-tang-playbook.yml
   ```

2. Edit the playbook in a text editor of your choice, for example:

   ```bash
   # vi my-tang-playbook.yml
   ```

3. Add the required parameters. The following example playbook ensures deploying of your Tang server and a key rotation:

   ```yaml
   ---
   - hosts: all
     vars:
      nbde_server_rotate_keys: yes
     roles:
      - rhel-system-roles.nbde_server
   ```

4. Apply the finished playbook:

   ```bash
   # ansible-playbook -i host1,host2,host3 my-tang-playbook.yml
   ```

**IMPORTANT**

To ensure that networking for a Tang pin is available during early boot by using the `grubby` tool on the systems where Clevis is installed:

```bash
# grubby --update-kernel=ALL --args="rd.neednet=1"
```
13.3. USING THE NBDE_CLIENT SYSTEM ROLE FOR SETTING UP MULTIPLE CLEVIS CLIENTS

Follow the steps to prepare and apply an Ansible playbook containing your Clevis client settings.

NOTE

The nbde_client System Role supports only Tang bindings. This means that you cannot use it for TPM2 bindings at the moment.

Prerequisites

- Access and permissions to one or more managed nodes, which are systems you want to configure with the nbde_client System Role.

- Access and permissions to a control node, which is a system from which Red Hat Ansible Engine configures other systems.

On the control node:

- Red Hat Ansible Engine is installed.

- The rhel-system-roles package is installed.

- An inventory file which lists the managed nodes.

- Your volumes are already encrypted by LUKS.

Procedure

1. Prepare your playbook containing settings for Clevis clients. You can either start from the scratch, or use one of the example playbooks from the /usr/share/ansible/roles/rhel-system-roles.nbde_client/examples/ directory.

   ```
   # cp /usr/share/ansible/roles/rhel-system-roles.nbde_client/examples/high_availability.yml ./my-clevis-playbook.yml
   ```

2. Edit the playbook in a text editor of your choice, for example:

   ```
   # vi my-clevis-playbook.yml
   ```

3. Add the required parameters. The following example playbook configures Clevis clients for automated unlocking of two LUKS-encrypted volumes by when at least one of two Tang servers is available:

   ```
   ---
   - hosts: all

   vars:
   ```
nbde_client_bindings:
  - device: /dev/rhel/root
    encryption_key_src: /etc/luks/keyfile
  servers:
    - http://server1.example.com
    - http://server2.example.com

roles:
  - rhel-system-roles.nbde_client

4. Apply the finished playbook:

```bash
# ansible-playbook -i host1,host2,host3 my-clevis-playbook.yml
```

**IMPORTANT**

To ensure that networking for a Tang pin is available during early boot by using the `grubby` tool on the system where Clevis is installed:

```bash
# grubby --update-kernel=ALL --args="rd.neednet=1"
```

**Additional resources**

- For details about the parameters and additional information about the `nbde_client` System Role, install the `rhel-system-roles` package, and see the `/usr/share/doc/rhel-system-roles/nbde_client/` and `/usr/share/ansible/roles/rhel-system-roles.nbde_client/` directories.
CHAPTER 14. REQUESTING CERTIFICATES USING RHEL SYSTEM ROLES

With the Certificate System Role, you can use Red Hat Ansible Engine to issue and manage certificates.

This chapter covers the following topics:

- The Certificate System Role
- Requesting a new self-signed certificate using the Certificate System Role
- Requesting a new certificate from IdM CA using the Certificate System Role

14.1. THE CERTIFICATE SYSTEM ROLE

Using the Certificate System Role, you can manage issuing and renewing TLS and SSL certificates using Red Hat Ansible Engine.

The role uses certmonger as the certificate provider, and currently supports issuing and renewing self-signed certificates and using the IdM integrated certificate authority (CA).

You can use the following variables in your Ansible playbook with the Certificate System Role:

- **certificate_wait**
  
  to specify if the task should wait for the certificate to be issued.

- **certificate_requests**
  
  to represent each certificate to be issued and its parameters.

Additional resources

- See the `/usr/share/ansible/roles/rhel-system-roles.certificate/README.md` file.
- See Getting started with RHEL System Roles.

14.2. REQUESTING A NEW SELF-SIGNED CERTIFICATE USING THE CERTIFICATE SYSTEM ROLE

With the Certificate System Role, you can use Red Hat Ansible Engine to issue self-signed certificates.

This process uses the certmonger provider and requests the certificate through the `getcert` command.

**NOTE**

By default, certmonger automatically tries to renew the certificate before it expires. You can disable this by setting the `auto_renew` parameter in the Ansible playbook to `no`.

Prerequisites

- You have Red Hat Ansible Engine installed on the system from which you want to run the playbook.
NOTE

You do not have to have Ansible installed on the systems on which you want to deploy the certificate solution.

- You have the rhel-system-roles package installed on the system from which you want to run the playbook.
  For details about RHEL System Roles and how to apply them, see Getting started with RHEL System Roles.

Procedure

1. Optional: Create an inventory file, for example inventory.file:

```bash
$ touch inventory.file
```

2. Open your inventory file and define the hosts on which you want to request the certificate, for example:

```yaml
[webserver]
server.idm.example.com
```

3. Create a playbook file, for example request-certificate.yml:

   - Set **hosts** to include the hosts on which you want to request the certificate, such as webserver.

   - Set the **certificate_requests** variable to include the following:
     - Set the **name** parameter to the desired name of the certificate, such as mycert.
     - Set the **dns** parameter to the domain to be included in the certificate, such as *.example.com.
     - Set the **ca** parameter to self-sign.

   - Set the **rhel-system-roles.certificate** role under **roles**.

This is the playbook file for this example:

```yaml
---
- hosts: webserver

  vars:
    certificate_requests:
      - name: mycert
dns: "*.example.com"
ca: self-sign

  roles:
    - rhel-system-roles.certificate
```

4. Save the file.

5. Run the playbook:
$ ansible-playbook -i inventory.file request-certificate.yml

Additional resources

- See the /usr/share/ansible/roles/rhel-system-roles.certificate/README.md file.
- See the ansible-playbook(1) man page.

14.3. REQUESTING A NEW CERTIFICATE FROM IDM CA USING THE CERTIFICATE SYSTEM ROLE

With the Certificate System Role, you can use Red Hat Ansible Engine to issue certificates while using an IdM server with an integrated certificate authority (CA). Therefore, you can efficiently and consistently manage the certificate trust chain for multiple systems when using IdM as the CA.

This process uses the certmonger provider and requests the certificate through the getcert command.

NOTE

By default, certmonger automatically tries to renew the certificate before it expires. You can disable this by setting the auto_renew parameter in the Ansible playbook to no.

Prerequisites

- You have Red Hat Ansible Engine installed on the system from which you want to run the playbook.

NOTE

You do not have to have Ansible installed on the systems on which you want to deploy the certificate solution.

- You have the rhel-system-roles package installed on the system from which you want to run the playbook.
For details about RHEL System Roles and how to apply them, see Getting started with RHEL System Roles.

Procedure

1. Optional: Create an inventory file, for example inventory.file:

   $ touch inventory.file

2. Open your inventory file and define the hosts on which you want to request the certificate, for example:

   [webserver]
   server.idm.example.com

3. Create a playbook file, for example request-certificate.yml:
Set **hosts** to include the hosts on which you want to request the certificate, such as `webserver`

- Set the **certificate_requests** variable to include the following:
  - Set the **name** parameter to the desired name of the certificate, such as `mycert`
  - Set the **dns** parameter to the domain to be included in the certificate, such as `www.example.com`
  - Set the **principal** parameter to specify the Kerberos principal, such as `HTTP/www.example.com@EXAMPLE.COM`
  - Set the **ca** parameter to `ipa`

- Set the **rhel-system-roles.certificate** role under **roles**.

```
---
- hosts: webserver
  vars:
    certificate_requests:
      - name: mycert
dns: www.example.com
principal: HTTP/www.example.com@EXAMPLE.COM
ca: ipa
roles:
  - rhel-system-roles.certificate
```

4. Save the file.
5. Run the playbook:

```
$ ansible-playbook -i inventory.file request-certificate.yml
```

Additional resources

- See the `/usr/share/ansible/roles/rhel-system-roles.certificate/README.md` file.
- See the `ansible-playbook(1)` man page.

### 14.4. SPECIFYING COMMANDS TO RUN BEFORE OR AFTER CERTIFICATE ISSUANCE USING THE CERTIFICATE SYSTEM ROLE

With the Certificate System Role, you can use Red Hat Ansible Engine to execute a command before and after a certificate is issued or renewed.

In the following example, the administrator ensures stopping the `httpd` service before a self-signed certificate for `www.example.com` is issued or renewed, and restarting it afterwards.
NOTE

By default, certmonger automatically tries to renew the certificate before it expires. You can disable this by setting the `auto_renew` parameter in the Ansible playbook to `no`.

Prerequisites

- You have Red Hat Ansible Engine installed on the system from which you want to run the playbook.

NOTE

You do not have to have Ansible installed on the systems on which you want to deploy the certificate solution.

- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.
  For details about RHEL System Roles and how to apply them, see Getting started with RHEL System Roles.

Procedure

1. Optional: Create an inventory file, for example `inventory.file`:

   ```bash
   $ touch inventory.file
   ```

2. Open your inventory file and define the hosts on which you want to request the certificate, for example:

   ```yaml
   [webserver]
   server.idm.example.com
   ```

3. Create a playbook file, for example `request-certificate.yml`:

   - Set `hosts` to include the hosts on which you want to request the certificate, such as `webserver`.

   - Set the `certificate_requests` variable to include the following:
     - Set the `name` parameter to the desired name of the certificate, such as `mycert`.
     - Set the `dns` parameter to the domain to be included in the certificate, such as `www.example.com`.
     - Set the `ca` parameter to the CA you want to use to issue the certificate, such as `self-sign`.
     - Set the `run_before` parameter to the command you want to execute before this certificate is issued or renewed, such as `systemctl stop httpd.service`.
     - Set the `run_after` parameter to the command you want to execute after this certificate is issued or renewed, such as `systemctl start httpd.service`.

   - Set the `rhel-system-roles.certificate` role under `roles`.

This is the playbook file for this example:
---
- hosts: webserver
  vars:
    certificate_requests:
      - name: mycert
dns: www.example.com
      ca: self-sign
    run_before: systemctl stop httpd.service
    run_after: systemctl start httpd.service
  roles:
    - rhel-system-roles.certificate

4. Save the file.

5. Run the playbook:

   ```bash
   $ ansible-playbook -i inventory.file request-certificate.yml
   ```

Additional resources

- See the `/usr/share/ansible/roles/rhel-system-roles.certificate/README.md` file.
- See the `ansible-playbook(1)` man page.
CHAPTER 15. CONFIGURING KDUMP USING RHEL SYSTEM ROLES

To manage kdump using Ansible, you can use the kdump role, which is one of the RHEL System Roles available in RHEL 8.

Using the kdump enables you to specify where to save the contents of the system’s memory for later analysis.

For more information about RHEL System Roles and how to apply them, see Introduction to RHEL System Roles.

15.1. THE KDUMP RHEL SYSTEM ROLE

The kdump System Role enables you to set basic kernel dump parameters on multiple systems.

15.2. KDUMP ROLE PARAMETERS

The parameters used for the kdump RHEL System Roles are:

<table>
<thead>
<tr>
<th>Role Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kdump_path</td>
<td>The path to which vmcore is written. If kdump_target is not null, path is relative to that dump target. Otherwise, it must be an absolute path in the root file system.</td>
</tr>
</tbody>
</table>

Additional resources

- The makedumpfile(8) man page.
- For details about the parameters used in kdump and additional information about the kdump System Role, see the /usr/share/ansible/roles/rhel-system-roles.tlog/README.md file.

15.3. CONFIGURING KDUMP USING RHEL SYSTEM ROLES

You can set basic kernel dump parameters on multiple systems using the kdump System Role by running an Ansible playbook.

WARNING

The kdump role replaces the kdump configuration of the managed hosts entirely by replacing the /etc/kdump.conf file. Additionally, if the kdump role is applied, all previous kdump settings are also replaced, even if they are not specified by the role variables, by replacing the /etc/sysconfig/kdump file.
Prerequisites

- You have Red Hat Ansible Engine installed on the system from which you want to run the playbook.

**NOTE**

You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to deploy the `kdump` solution.

- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.

- You have an inventory file which lists the systems on which you want to deploy `kdump`.

Procedure

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   ---
   - hosts: kdump-test
     vars:
       kdump_path: /var/crash
     roles:
       - rhel-system-roles.kdump
   ```

2. Optional: Verify playbook syntax.

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i inventory_file /path/to/file/playbook.yml
   ```

Additional resources

- For a detailed reference on `kdump` role variables, see the README.md or README.html files in the `/usr/share/doc/rhel-system-roles/kdump` directory.

- See Applying a system role.

- Documentation installed with the `rhel-system-roles` package `/usr/share/ansible/roles/rhel-system-roles.kdump/README.html`
CHAPTER 16. MANAGING LOCAL STORAGE USING RHEL SYSTEM ROLES

To manage LVM and local file systems (FS) using Ansible, you can use the `storage` role, which is one of the RHEL System Roles available in RHEL 8.

Using the `storage` role enables you to automate administration of file systems on disks and logical volumes on multiple machines and across all versions of RHEL starting with RHEL 7.7.

For more information about RHEL System Roles and how to apply them, see Introduction to RHEL System Roles.

16.1. INTRODUCTION TO THE STORAGE ROLE

The `storage` role can manage:

- File systems on disks which have not been partitioned
- Complete LVM volume groups including their logical volumes and file systems

With the `storage` role you can perform the following tasks:

- Create a file system
- Remove a file system
- Mount a file system
- Unmount a file system
- Create LVM volume groups
- Remove LVM volume groups
- Create logical volumes
- Remove logical volumes
- Create RAID volumes
- Remove RAID volumes
- Create LVM pools with RAID
- Remove LVM pools with RAID

16.2. PARAMETERS THAT IDENTIFY A STORAGE DEVICE IN THE STORAGE SYSTEM ROLE

Your `storage` role configuration affects only the file systems, volumes, and pools that you list in the following variables.

`storage_volumes`

List of file systems on all unpartitioned disks to be managed.
Partitions are currently unsupported.
storage_pools

List of pools to be managed.
Currently the only supported pool type is LVM. With LVM, pools represent volume groups (VGs).
Under each pool there is a list of volumes to be managed by the role. With LVM, each volume
corresponds to a logical volume (LV) with a file system.

16.3. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AN XFS FILE SYSTEM ON A BLOCK DEVICE

This section provides an example Ansible playbook. This playbook applies the storage role to create an
XFS file system on a block device using the default parameters.

WARNING
The storage role can create a file system only on an unpartitioned, whole disk or a
logical volume (LV). It cannot create the file system on a partition.

Example 16.1. A playbook that creates XFS on /dev/sdb

---
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
        disks:
          - sdb
        fs_type: xfs
        roles:
          - rhel-system-roles.storage

- The volume name (barefs in the example) is currently arbitrary. The storage role identifies
  the volume by the disk device listed under the disks: attribute.
- You can omit the fs_type: xfs line because XFS is the default file system in RHEL 8.
- To create the file system on an LV, provide the LVM setup under the disks: attribute,
  including the enclosing volume group. For details, see Example Ansible playbook to manage
  logical volumes.
  Do not provide the path to the LV device.

Additional resources
- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.
16.4. EXAMPLE ANSIBLE PLAYBOOK TO PERSISTENTLY MOUNT A FILE SYSTEM

This section provides an example Ansible playbook. This playbook applies the `storage` role to immediately and persistently mount an XFS file system.

Example 16.2. A playbook that mounts a file system on `/dev/sdb` to `/mnt/data`

```yaml
---
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
        disks:
          - sdb
        fs_type: xfs
        mount_point: /mnt/data
    roles:
      - rhel-system-roles.storage

  - This playbook adds the file system to the `/etc/fstab` file, and mounts the file system immediately.

  - If the file system on the `/dev/sdb` device or the mount point directory do not exist, the playbook creates them.

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

16.5. EXAMPLE ANSIBLE PLAYBOOK TO MANAGE LOGICAL VOLUMES

This section provides an example Ansible playbook. This playbook applies the `storage` role to create an LVM logical volume in a volume group.

Example 16.3. A playbook that creates a mylv logical volume in the myvg volume group

```yaml
- hosts: all
  vars:
    storage_pools:
      - name: myvg
        disks:
          - sda
          - sdb
          - sdc
        volumes:
          - name: mylv
            size: 2G
            fs_type: ext4
```
The `myvg` volume group consists of the following disks:

- `/dev/sda`
- `/dev/sdb`
- `/dev/sdc`

- If the `myvg` volume group already exists, the playbook adds the logical volume to the volume group.
- If the `myvg` volume group does not exist, the playbook creates it.
- The playbook creates an Ext4 file system on the `mylv` logical volume, and persistently mounts the file system at `/mnt`.

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

### 16.6. EXAMPLE ANSIBLE PLAYBOOK TO ENABLE ONLINE BLOCK DISCARD

This section provides an example Ansible playbook. This playbook applies the `storage` role to mount an XFS file system with online block discard enabled.

#### Example 16.4. A playbook that enables online block discard on `/mnt/data/`

```yaml
---
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
disks:
    - sdb
  fs_type: xfs
  mount_point: /mnt/data
  mount_options: discard
roles:
- rhel-system-roles.storage
```

Additional resources

- Example Ansible playbook to persistently mount a file system
- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.
16.7. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AND MOUNT AN EXT4 FILE SYSTEM

This section provides an example Ansible playbook. This playbook applies the `storage` role to create and mount an Ext4 file system.

Example 16.5. A playbook that creates Ext4 on /dev/sdb and mounts it at /mnt/data

---
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
        disks:
          - sdb
        fs_type: ext4
        fs_label: label-name
        mount_point: /mnt/data
    roles:
      - rhel-system-roles.storage

- The playbook creates the file system on the /dev/sdb disk.
- The playbook persistently mounts the file system at the /mnt/data directory.
- The label of the file system is `label-name`.

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

16.8. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AND MOUNT AN EXT3 FILE SYSTEM

This section provides an example Ansible playbook. This playbook applies the `storage` role to create and mount an Ext3 file system.

Example 16.6. A playbook that creates Ext3 on /dev/sdb and mounts it at /mnt/data

---
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
        disks:
          - sdb
        fs_type: ext3
        fs_label: label-name
mount_point: /mnt/data
roles:
- rhel-system-roles.storage

- The playbook creates the file system on the /dev/sdb disk.
- The playbook persistently mounts the file system at the /mnt/data directory.
- The label of the file system is label-name.

Additional resources
- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.

16.9. EXAMPLE ANSIBLE PLAYBOOK TO RESIZE AN EXISTING EXT4 OR EXT3 FILE SYSTEM USING THE STORAGE RHEL SYSTEM ROLE

This section provides an example Ansible playbook. This playbook applies the storage role to resize an existing Ext4 or Ext3 file system on a block device.

Example 16.7. A playbook that set up a single volume on a disk

```yaml
---
- name: Create a disk device mounted on /opt/barefs
- hosts: all
vars:
  storage_volumes:
  - name: barefs
type: disk
disks:
  - /dev/sdb
size: 12 GiB
  fs_type: ext4
  mount_point: /opt/barefs
roles:
- rhel-system-roles.storage
```

- If the volume in the previous example already exists, to resize the volume, you need to run the same playbook, just with a different value for the parameter size. For example:

Example 16.8. A playbook that resizes ext4 on /dev/sdb

```yaml
---
- name: Create a disk device mounted on /opt/barefs
- hosts: all
vars:
  storage_volumes:
  - name: barefs
type: disk
disks:
  - /dev/sdb
```

```
size: 10 GiB
  fs_type: ext4
  mount_point: /opt/barefs
roles:
  - rhel-system-roles.storage

- The volume name (barefs in the example) is currently arbitrary. The storage role identifies the volume by the disk device listed under the disks: attribute.

NOTE
Using the **Resizing** action in other file systems can destroy the data on the device you are working on.

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

16.10. EXAMPLE ANSIBLE PLAYBOOK TO RESIZE AN EXISTING FILE SYSTEM ON LVM USING THE STORAGE RHEL SYSTEM ROLE

This section provides an example Ansible playbook. This playbook applies the storage RHEL System Role to resize an LVM logical volume with a file system.

---

- hosts: all
  vars:
    storage_pools:
      - name: myvg
        disks:
          - /dev/sda
          - /dev/sdb
          - /dev/sdc
        volumes:
          - name: mylv1
            size: 10 GiB
            fs_type: ext4
            mount_point: /opt/mount1

WARNING
Using the **Resizing** action in other file systems can destroy the data on the device you are working on.

Example 16.9. A playbook that resizes existing mylv1 and myvl2 logical volumes in the myvg volume group
- name: mylv2
  size: 50 GiB
  fs_type: ext4
  mount_point: /opt/mount2

- name: Create LVM pool over three disks
  include_role:
    name: rhel-system-roles.storage

  - This playbook resizes the following existing file systems:

    - The Ext4 file system on the **mylv1** volume, which is mounted at /opt/mount1, resizes to 10 GiB.
    - The Ext4 file system on the **mylv2** volume, which is mounted at /opt/mount2, resizes to 50 GiB.

Additional resources

- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.

16.11. EXAMPLE ANSIBLE PLAYBOOK TO CREATE A SWAP PARTITION USING THE STORAGE RHEL SYSTEM ROLE

This section provides an example Ansible playbook. This playbook applies the **storage** role to create a swap partition, if it does not exist, or to modify the swap partition, if it already exist, on a block device using the default parameters.

Example 16.10. A playbook that creates or modify an existing XFS on /dev/sdb

```yaml
---
- name: Create a disk device with swap
  - hosts: all
    vars:
      storage_volumes:
        - name: swap_fs
          type: disk
          disks:
            - /dev/sdb
          size: 15 GiB
          fs_type: swap
          roles:
            - rhel-system-roles.storage

- name: Create LVM pool over three disks
  include_role:
    name: rhel-system-roles.storage

- This playbook resizes the following existing file systems:

  - The Ext4 file system on the **mylv1** volume, which is mounted at /opt/mount1, resizes to 10 GiB.
  - The Ext4 file system on the **mylv2** volume, which is mounted at /opt/mount2, resizes to 50 GiB.

Additional resources

- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.
16.12. CONFIGURING A RAID VOLUME USING THE STORAGE SYSTEM ROLE

With the storage System Role, you can configure a RAID volume on RHEL using Red Hat Ansible Automation Platform. In this section you will learn how to set up an Ansible playbook with the available parameters to configure a RAID volume to suit your requirements.

Prerequisites

- You have Red Hat Ansible Engine installed on the system from which you want to run the playbook.

  NOTE
  You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to deploy the storage solution.

- You have the rhel-system-roles package installed on the system from which you want to run the playbook.

- You have an inventory file detailing the systems on which you want to deploy a RAID volume using the storage System Role.

Procedure

1. Create a new playbook.yml file with the following content:

```yaml
- hosts: all
  vars:
    storage_safe_mode: false
    storage_volumes:
    - name: data
      type: raid
      disks: [sdd, sde, sdf, sdg]
      raid_level: raid0
      raid_chunk_size: 32 KiB
      mount_point: /mnt/data
      state: present
  roles:
    - name: rhel-system-roles.storage
```

   WARNING

   Device names can change in certain circumstances; for example, when you add a new disk to a system. Therefore, to prevent data loss, we do not recommend using specific disk names in the playbook.

3. Run the playbook on your inventory file:

   # ansible-playbook -i inventory_file /path/to/file/playbook.yml

**Additional resources**

- Managing RAID.

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

## 16.13. CONFIGURING AN LVM POOL WITH RAID USING THE STORAGE SYSTEM ROLE

With the `storage` System Role, you can configure an LVM pool with RAID on RHEL using Red Hat Ansible Automation Platform. In this section you will learn how to set up an Ansible playbook with the available parameters to configure an LVM pool with RAID.

**Prerequisites**

- You have Red Hat Ansible Engine installed on the system from which you want to run the playbook.

  **NOTE**

  You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to deploy the `storage` solution.

- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.

- You have an inventory file detailing the systems on which you want to configure an LVM pool with RAID using the `storage` System Role.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   - hosts: all
     vars:
       storage_safe_mode: false
       storage_pools:
         - name: my_pool
           type: lvm
           disks: [sdh, sdi]
           raid_level: raid1
           volumes:
             - name: my_pool
               size: "1 GiB"
               mount_point: "/mnt/app/shared"
               fs_type: xfs
   ```
state: present
roles:
- name: rhel-system-roles.storage

NOTE
To create an LVM pool with RAID, you must specify the RAID type using the `raid_level` parameter.

```
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```
# ansible-playbook -i inventory.file /path/to/file/playbook.yml
```

Additional resources

- Managing RAID.

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

16.14. EXAMPLE ANSIBLE PLAYBOOK TO COMPRESS AND DEDUPLICATE A VDO VOLUME ON LVM USING THE STORAGE RHEL SYSTEM ROLE

This section provides an example Ansible playbook. This playbook applies the storage RHEL System Role to enable compression and deduplication to a Logical Manager Volumes (LVM) using the Virtual Data Optimizer (VDO) volume.

Example 16.11. A playbook that creates a `mylv1` LVM VDO volume in the `myvg` volume group

```yaml
---
- name: Create LVM VDO volume under volume group 'myvg'
  hosts: all
  roles:
  - rhel-system-roles.storage
  vars:
    storage_pools:
    - name: myvg
disks:
    - /dev/sdb
volumes:
  - name: mylv1
    compression: true
deduplication: true
    vdo_pool_size: 10 GiB
    size: 30 GiB
    mount_point: /mnt/app/shared
In this example, the compression and deduplication pools are set to true, which specifies that the VDO is used. The following describes the usage of these parameters:

- The deduplication is used to deduplicate the duplicated data stored on the storage volume.
- The compression is used to compress the data stored on the storage volume, which results in more storage capacity.
- The vdo_pool_size specifies the actual size the volume takes on the device. The virtual size of VDO volume is set by the size parameter. NOTE: Because of the storage role use of LVM VDO, only one volume per pool can use the compression and deduplication.

16.15. CREATING A LUKS ENCRYPTED VOLUME USING THE STORAGE ROLE

You can use the storage role to create and configure a volume encrypted with LUKS by running an Ansible playbook.

Prerequisites

- You have Red Hat Ansible Engine installed on the system from which you want to run the playbook.

  NOTE

  You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to create the volume.

- You have the rhel-system-roles package installed on the Ansible controller.
- You have an inventory file detailing the systems on which you want to deploy a LUKS encrypted volume using the storage System Role.

Procedure

1. Create a new playbook.yml file with the following content:

   ```yaml
   - hosts: all
     vars:
       storage_volumes:
         - name: barefs
           type: disk
           disks:
             - sdb
           fs_type: xfs
           fs_label: label-name
           mount_point: /mnt/data
           encryption: true
           encryption_password: your-password
         roles:
           - rhel-system-roles.storage
   ```

2. Optional: Verify playbook syntax:
# ansible-playbook --syntax-check playbook.yml

3. Run the playbook on your inventory file:

```bash
# ansible-playbook -i inventory.file /path/to/file/playbook.yml
```

Additional resources

- Encrypting block devices using LUKS
- `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file

## 16.16. EXAMPLE ANSIBLE PLAYBOOK TO EXPRESS POOL VOLUME SIZES AS PERCENTAGE USING THE STORAGE RHEL SYSTEM ROLE

This section provides an example Ansible playbook. This playbook applies the storage RHEL System Role to enable you to express Logical Manager Volumes (LVM) volume sizes as a percentage of the pool’s total size.

**Example 16.12. A playbook that express volume sizes as a percentage of the pool’s total size**

```yaml
---
- name: Express volume sizes as a percentage of the pool's total size
  hosts: all
  roles
  - rhel-system-roles.storage
  vars:
    storage_pools:
      - name: myvg
disks:
        - /dev/sdb
  volumes:
    - name: data
      size: 60%
      mount_point: /opt/mount/data
    - name: web
      size: 30%
      mount_point: /opt/mount/web
    - name: cache
      size: 10%
      mount_point: /opt/cache/mount
```

This example specifies the size of LVM volumes as a percentage of the pool size, for example: "60%". Additionally, you can also specify the size of LVM volumes as a percentage of the pool size in a human-readable size of the file system, for example, "10g" or "50 GiB".

## 16.17. ADDITIONAL RESOURCES

- `/usr/share/doc/rhel-system-roles/storage/`
- `/usr/share/ansible/roles/rhel-system-roles.storage/`
CHAPTER 17. CONFIGURING TIME SYNCHRONIZATION USING RHEL SYSTEM ROLES

With the timesync RHEL System Role, you can manage time synchronization on multiple target machines on RHEL using Red Hat Ansible Automation Platform.

17.1. THE TIMESYNC SYSTEM ROLE

You can manage time synchronization on multiple target machines using the timesync RHEL System Role.

The timesync role installs and configures an NTP or PTP implementation to operate as an NTP client or PTP replica in order to synchronize the system clock with NTP servers or grandmasters in PTP domains.

Note that using the timesync role also facilitates the migration to chrony, because you can use the same playbook on all versions of Red Hat Enterprise Linux starting with RHEL 6 regardless of whether the system uses ntp or chrony to implement the NTP protocol.

17.2. APPLYING THE TIMESYNC SYSTEM ROLE FOR A SINGLE POOL OF SERVERS

The following example shows how to apply the timesync role in a situation with just one pool of servers.

WARNING

The timesync role replaces the configuration of the given or detected provider service on the managed host. Previous settings are lost, even if they are not specified in the role variables. The only preserved setting is the choice of provider if the timesync_ntp_provider variable is not defined.

Prerequisites

- You have Red Hat Ansible Engine installed on the system from which you want to run the playbook.

NOTE

You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to deploy the timesync solution.

- You have the rhel-system-roles package installed on the system from which you want to run the playbook.

- You have an inventory file which lists the systems on which you want to deploy timesync System Role.

Procedure
1. Create a new `playbook.yml` file with the following content:

```yaml
---
- hosts: timesync-test
  vars:
    timesync_ntp_servers:
      - hostname: 2.rhel.pool.ntp.org
        pool: yes
        iburst: yes
  roles:
    - rhel-system-roles.timesync
```

2. Optional: Verify playbook syntax.

```bash
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```bash
# ansible-playbook -i inventory_file /path/to/file/playbook.yml
```

### 17.3. APPLYING THE TIMESYNC SYSTEM ROLE ON CLIENT SERVERS

You can use the `timesync` role to enable Network Time Security (NTS) on NTP clients. Network Time Security (NTS) is an authentication mechanism specified for Network Time Protocol (NTP). It verifies that NTP packets exchanged between the server and client are not altered.

**WARNING**

The `timesync` role replaces the configuration of the given or detected provider service on the managed host. Previous settings are lost even if they are not specified in the role variables. The only preserved setting is the choice of provider if the `timesync_ntp_provider` variable is not defined.

**Prerequisites**

- You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to deploy the `timesync` solution.
- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.
- You have an inventory file which lists the systems on which you want to deploy the `timesync` System Role.
- The `chrony` NTP provider version is 4.0 or later.

**Procedure**

1. Create a `playbook.yml` file with the following content:
---

- hosts: timesync-test
  vars:
    timesync_ntp_servers:
      - hostname: ptbtime1.ptb.de
        iburst: yes
        nts: yes
        roles:
          - rhel-system-roles.timesync

ptbtime1.ptb.de is an example of public server. You may want to use a different public server or your own server.

2. Optional: Verify playbook syntax.

  # ansible-playbook --syntax-check playbook.yml

3. Run the playbook on your inventory file:

  # ansible-playbook -i inventory_file /path/to/file/playbook.yml

Verification

1. Perform a test on the client machine:

  # chronyc -N authdata

  Name/IP address Mode KeyID Type KLen Last Atmp  NAK Cook CLen
  ==========================================================================
  ptbtime1.ptb.de   NTS 1 15 256 157 0 0 8 100

2. Check that the number of reported cookies is larger than zero.

Additional resources

  - chrony.conf(5) man page

17.4. TIMESYNC SYSTEM ROLES VARIABLES

You can pass the following variable to the timesync role:

  - timesync_ntp_servers:

<table>
<thead>
<tr>
<th>Role variable settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname: host.example.com</td>
<td>Hostname or address of the server</td>
</tr>
<tr>
<td>minpoll: number</td>
<td>Minimum polling interval. Default: 6</td>
</tr>
<tr>
<td>maxpoll: number</td>
<td>Maximum polling interval. Default: 10</td>
</tr>
<tr>
<td>Role variable settings</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>iburst: yes</td>
<td>Flag enabling fast initial synchronization. Default: no</td>
</tr>
<tr>
<td>pool: yes</td>
<td>Flag indicating that each resolved address of the hostname is a separate NTP server. Default: no</td>
</tr>
<tr>
<td>nts: yes</td>
<td>Flag to enable Network Time Security (NTS). Default: no. Supported only with chrony &gt;= 4.0.</td>
</tr>
</tbody>
</table>

**Additional resources**

- For a detailed reference on timesync role variables, install the rhel-system-roles package, and see the README.md or README.html files in the `/usr/share/doc/rhel-system-roles/timesync` directory.
CHAPTER 18. MONITORING PERFORMANCE USING RHEL SYSTEM ROLES

As a system administrator, you can use the metrics RHEL System Role with any Ansible Automation Platform control node to monitor the performance of a system.

18.1. INTRODUCTION TO THE METRICS SYSTEM ROLE

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems. The metrics System Role configures performance analysis services for the local system and, optionally, includes a list of remote systems to be monitored by the local system. The metrics System Role enables you to use `pcp` to monitor your systems performance without having to configure `pcp` separately, as the set-up and deployment of `pcp` is handled by the playbook.

Table 18.1. Metrics system role variables

<table>
<thead>
<tr>
<th>Role variable</th>
<th>Description</th>
<th>Example usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics_monitored_hosts</td>
<td>List of remote hosts to be analyzed by the target host. These hosts will have metrics recorded on the target host, so ensure enough disk space exists below <code>/var/log</code> for each host.</td>
<td><code>metrics_monitored_hosts: [&quot;webserver.example.com&quot;, &quot;database.example.com&quot;]</code></td>
</tr>
<tr>
<td>metrics_retention_days</td>
<td>Configures the number of days for performance data retention before deletion.</td>
<td><code>metrics_retention_days: 14</code></td>
</tr>
<tr>
<td>metrics_graph_service</td>
<td>A boolean flag that enables the host to be set up with services for performance data visualization via <code>pcp</code> and <code>grafana</code>. Set to false by default.</td>
<td><code>metrics_graph_service: no</code></td>
</tr>
<tr>
<td>metrics_query_service</td>
<td>A boolean flag that enables the host to be set up with time series query services for querying recorded <code>pcp</code> metrics via <code>redis</code>. Set to false by default.</td>
<td><code>metrics_query_service: no</code></td>
</tr>
<tr>
<td>metrics_provider</td>
<td>Specifies which metrics collector to use to provide metrics. Currently, <code>pcp</code> is the only supported metrics provider.</td>
<td><code>metrics_provider: &quot;pcp&quot;</code></td>
</tr>
</tbody>
</table>

NOTE

For details about the parameters used in `metrics_connections` and additional information about the metrics System Role, see the `/usr/share/ansible/roles/rhel-system-roles.metrics/README.md` file.
18.2. USING THE METRICS SYSTEM ROLE TO MONITOR YOUR LOCAL SYSTEM WITH VISUALIZATION

This procedure describes how to use the metrics RHEL System Role to monitor your local system while simultaneously provisioning data visualization via Grafana.

Prerequisites

- You have Red Hat Ansible Engine installed on the machine you want to monitor.
- You have the `rhel-system-roles` package installed on the machine you want to monitor.

Procedure

1. Configure `localhost` in the the `/etc/ansible/hosts` Ansible inventory by adding the following content to the inventory:
   ```
   localhost ansible_connection=local
   ```

2. Create an Ansible playbook with the following content:

   ```
   ---
   - hosts: localhost
     vars:
       metrics_graph_service: yes
     roles:
       - rhel-system-roles.metrics
   ```

3. Run the Ansible playbook:
   ```
   # ansible-playbook name_of_your_playbook.yml
   ```

   **NOTE**

   Since the `metrics_graph_service` boolean is set to value="yes", Grafana is automatically installed and provisioned with `pcp` added as a data source.

4. To view visualization of the metrics being collected on your machine, access the grafana web interface as described in Accessing the Grafana web UI.

18.3. USING THE METRICS SYSTEM ROLE TO SETUP A FLEET OF INDIVIDUAL SYSTEMS TO MONITOR THEMSELVES

This procedure describes how to use the metrics System Role to set up a fleet of machines to monitor themselves.

Prerequisites

- You have Red Hat Ansible Engine installed on the machine you want to use to run the playbook.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.
You have the SSH connection established.

Procedure

1. Add the name or IP of the machines you wish to monitor via the playbook to the `/etc/ansible/hosts` Ansible inventory file under an identifying group name enclosed in brackets:

   [remotes]
   webserver.example.com
database.example.com

2. Create an Ansible playbook with the following content:

   ```yaml
   ---
   - hosts: remotes
     vars:
       metrics_retention_days: 0
     roles:
       - rhel-system-roles.metrics
   ```

3. Run the Ansible playbook:

   ```bash
   # ansible-playbook name_of_your_playbook.yml -k
   ```

   Where the `-k` prompt for password to connect to remote system.

18.4. USING THE METRICS SYSTEM ROLE TO MONITOR A FLEET OF MACHINES CENTRALLY VIA YOUR LOCAL MACHINE

This procedure describes how to use the metrics System Role to set up your local machine to centrally monitor a fleet of machines while also provisioning visualization of the data via grafana and querying of the data via redis.

Prerequisites

- You have Red Hat Ansible Engine installed on the machine you want to use to run the playbook.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.

Procedure

1. Create an Ansible playbook with the following content:

   ```yaml
   ---
   - hosts: localhost
     vars:
       metrics_graph_service: yes
       metrics_query_service: yes
       metrics_retention_days: 10
     roles:
       - rhel-system-roles.metrics
   ```
2. Run the Ansible playbook:

```bash
# ansible-playbook name_of_your_playbook.yml
```

**NOTE**

Since the `metrics_graph_service` and `metrics_query_service` booleans are set to value="yes", `grafana` is automatically installed and provisioned with `pcp` added as a data source with the `pcp` data recording indexed into `redis`, allowing the `pcp` querying language to be used for complex querying of the data.

3. To view graphical representation of the metrics being collected centrally by your machine and to query the data, access the `grafana` web interface as described in Accessing the Grafana web UI.

### 18.5. SETTING UP AUTHENTICATION WHILE MONITORING A SYSTEM USING THE METRICS SYSTEM ROLE

PCP supports the `scram-sha-256` authentication mechanism through the Simple Authentication Security Layer (SASL) framework. The metrics RHEL System Role automates the steps to setup authentication using the `scram-sha-256` authentication mechanism. This procedure describes how to setup authentication using the metrics RHEL System Role.

**Prerequisites**

- You have Red Hat Ansible Engine installed on the machine you want to use to run the playbook.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.

**Procedure**

1. Include the following variables in the Ansible playbook you want to setup authentication for:

```yaml
---
vars:
  metrics_username: your_username
  metrics_password: your_password
```

2. Run the Ansible playbook:

```bash
# ansible-playbook name_of_your_playbook.yml
```

**Verification steps**

- Verify the `sasl` configuration:

```bash
# pminfo -f -h "pcp://ip_adress?username=your_username" disk.dev.read
Password: disk.dev.read
inst [0 or "sda"] value 19540
```

*`ip_adress` should be replaced by the IP adress of the host.*
18.6. USING THE METRICS SYSTEM ROLE TO CONFIGURE AND ENABLE METRICS COLLECTION FOR SQL SERVER

This procedure describes how to use the metrics RHEL System Role to automate the configuration and enabling of metrics collection for Microsoft SQL Server via `pcp` on your local system.

**Prerequisites**

- You have Red Hat Ansible Engine installed on the machine you want to monitor.
- You have the `rhel-system-roles` package installed on the machine you want to monitor.
- You have installed Microsoft SQL Server for Red Hat Enterprise Linux and established a 'trusted' connection to an SQL server.
- You have installed the Microsoft ODBC driver for SQL Server for Red Hat Enterprise Linux.

**Procedure**

1. Configure `localhost` in the the `/etc/ansible/hosts` Ansible inventory by adding the following content to the inventory:

   ```
   localhost ansible_connection=local
   ```

2. Create an Ansible playbook that contains the following content:

   ```
   ---
   - hosts: localhost
     roles:
     - role: rhel-system-roles.metrics
       vars:
         metrics_from_mssql: yes
   ```

3. Run the Ansible playbook:

   ```
   # ansible-playbook name_of_your_playbook.yml
   ```

**Verification steps**

- Use the `pcp` command to verify that SQL Server PMDA agent (mssql) is loaded and running:

  ```
  # pcp
  platform: Linux rhel82-2.local 4.18.0-167.el8.x86_64 #1 SMP Sun Dec 15 01:24:23 UTC 2019 x86_64
  hardware: 2 cpus, 1 disk, 1 node, 2770MB RAM
  timezone: PDT+7
  services: pmcd pmproxy
    pmcd: Version 5.0.2-1, 12 agents, 4 clients
    pmda: root pmcd proc pmproxy xfs linux nfsclient kvm mssql jbd2 dm
  pmlogger: primary logger: /var/log/pcp/pmlogger/rhel82-2.local/20200326.16.31
  pmie: primary engine: /var/log/pcp/pmie/rhel82-2.local/pmie.log
  ```
Additional resources

- For more information about using Performance Co-Pilot for Microsoft SQL Server, see this Red Hat Developers Blog post.
CHAPTER 19. CONFIGURING MICROSOFT SQL SERVER USING MICROSOFT.SQL.SERVER ANSIBLE ROLE

As an administrator, you can use the `microsoft.sql.server` Ansible role to install, configure, and start Microsoft SQL Server (SQL Server). The `microsoft.sql.server` Ansible role optimizes your operating system to improve performance and throughput for the SQL Server. The role simplifies and automates the configuration of your RHEL host with recommended settings to run the SQL Server workloads.

19.1. PREREQUISITES

- 2 GB of RAM
- `root` access to the managed node where you want to configure SQL Server
- Pre-configured firewall
  You must enable the connection on the SQL Server TCP port set with the `mssql_tcp_port` variable. If you do not define this variable, the role defaults to the TCP port number `1443`.

To add a new port, use:

```
# firewall-cmd --add-port=xxxx/tcp --permanent
# firewall-cmd --reload
```

Replace `xxxx` with the TCP port number then reload the firewall rules.

- Optional: Create a file with the `.sql` extension containing the SQL statements and procedures to input them to SQL Server.

19.2. INSTALLING MICROSOFT.SQL.SERVER ANSIBLE ROLE

The `microsoft.sql.server` Ansible role is part of the `ansible-collection-microsoft-sql` package. For more information, see [How do I Download and Install Red Hat Ansible Engine?](#).

If you do not have the Red Hat Ansible Engine Subscription, you can use the limited supported version of Ansible Engine provided with your Red Hat Enterprise Linux subscription.

To enable the limited supported version of Ansible Engine and install `microsoft.sql.server` Ansible roles, follow the steps outlined in the procedure below using the command line.

**Prerequisites**

- `root` access

**Procedure**

1. Refresh your subscriptions:

```
# subscription-manager refresh
```

2. Enable the RHEL Ansible subscription:

```
# subscription-manager repos --enable ansible-2-for-rhel-8-x86_64-rpms
```
3. Install Ansible:

   # yum install ansible

4. Install `microsoft.sql.server` Ansible role:

   # yum install ansible-collection-microsoft-sql

### 19.3. INSTALLING AND CONFIGURING SQL SERVER USING MICROSOFT.SQL.SERVER ANSIBLE ROLE

You can use the `microsoft.sql.server` Ansible role to install and configure SQL server.

**Prerequisites**

- The Ansible inventory is created

**Procedure**

1. Create a file with the `.yml` extension. For example, `mssql-server.yml`.

2. Add the following content to your `.yml` file:

   ```yaml
   ---
   - hosts: all
     vars:
       mssql_accept_microsoft_odbc_driver_17_for_sql_server_eula: true
       mssql_accept_microsoft_cli_utilities_for_sql_server_eula: true
       mssql_accept_microsoft_sql_server_standard_eula: true
       mssql_password: <password>
       mssql_edition: Developer
       mssql_tcp_port: 1443
     roles:
       - microsoft.sql.server
   
   Replace `<password>` with your SQL Server password.

3. Run the `mssql-server.yml` ansible playbook:

   # ansible-playbook mssql-server.yml

### 19.4. TLS VARIABLES

The following variables are available for configuring the Transport Level Security (TLS).

**Table 19.1. TLS role variables**

<table>
<thead>
<tr>
<th>Role variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### mssql_tls_enable

This variable enables or disables TLS encryption.

The **microsoft.sql.server** Ansible role performs following tasks when the variable is set to **true**:

- Copies TLS certificate to `/etc/pki/tls/certs/` on the SQL Server
- Copies private key to `/etc/pki/tls/private/` on the SQL Server
- Configures SQL Server to use TLS certificate and private key to encrypt connections

**NOTE**

You must have the TLS certificate and private key on the Ansible control node.

When set to **false**, the TLS encryption is disabled. The role does not remove the existing certificate and private key files.

### mssql_tls_cert

To define this variable, enter the path to the TLS certificate file.

### mssql_tls_private_key

To define this variable, enter the path to the private key file.

### mssql_tls_version

Define this variable to select which TSL version to use.

The default is **1.2**

### mssql_tls_force

Set this variable to **true** to replace the certificate and private key files on the host. The files must exist under `/etc/pki/tls/certs/` and `/etc/pki/tls/private/` directories.

The default is **false**.

---

### 19.5. ACCEPTING EULA FOR MLSERVICES

You must accept all the EULA for the open-source distributions of Python and R packages to install the required SQL Server Machine Learning Services (MLServices).

See `/usr/share/doc/mssql-server` for the license terms.

**Table 19.2. SQL Server Machine Learning Services EULA variables**
19.6. ACCEPTING EULAS FOR MICROSOFT ODBC 17

You must accept all the EULAs to install the Microsoft Open Database Connectivity (ODBC) driver.

See `/usr/share/doc/msodbcsql17/LICENSE.txt` and `/usr/share/doc/mssql-tools/LICENSE.txt` for the license terms.

Table 19.3. Microsoft ODBC 17 EULA variables

<table>
<thead>
<tr>
<th>Role variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mssql_accept_microsoft_sql_server_standard_eula</td>
<td>This variable determines whether to accept the terms and conditions for installing the <code>mssql-conf</code> package. To accept the terms and conditions set this variable to <code>true</code>. The default is <code>false</code>.</td>
</tr>
<tr>
<td>mssql_accept_microsoft_odbc_driver_17_for_sql_server_eula</td>
<td>This variable determines whether to accept the terms and conditions for installing the <code>msodbcsql17</code> package. To accept the terms and conditions set this variable to <code>true</code>. The default is <code>false</code>.</td>
</tr>
<tr>
<td>mssql_accept_microsoft_cli_utilities_for_sql_server_eula</td>
<td>This variable determines whether to accept the terms and conditions for installing the <code>mssql-tools</code> package. To accept the terms and conditions set this variable to <code>true</code>. The default is <code>false</code>.</td>
</tr>
</tbody>
</table>
CHAPTER 20. CONFIGURING A SYSTEM FOR SESSION RECORDING USING THE TLOG RHEL SYSTEM ROLES

With the tlog RHEL System Role, you can configure a system for terminal session recording on RHEL using Red Hat Ansible Automation Platform.

20.1. THE TLOG SYSTEM ROLE

You can configure a RHEL system for terminal session recording on RHEL using the tlog RHEL System Role.

You can configure the recording to take place per user or user group via the SSSD service.

Additional resources

- For more details on session recording in RHEL, see Recording Sessions

20.2. COMPONENTS AND PARAMETERS OF THE TLOG SYSTEM ROLES

The Session Recording solution has the following components:

- The tlog utility
- System Security Services Daemon (SSSD)
- Optional: The web console interface

The parameters used for the tlog RHEL System Roles are:

<table>
<thead>
<tr>
<th>Role Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tlog_use_sssd (default: yes)</td>
<td>Configure session recording with SSSD, the preferred way of managing recorded users or groups</td>
</tr>
<tr>
<td>tlog_scope_sssd (default: none)</td>
<td>Configure SSSD recording scope - all / some / none</td>
</tr>
<tr>
<td>tlog_users_sssd (default: [])</td>
<td>YAML list of users to be recorded</td>
</tr>
<tr>
<td>tlog_groups_sssd (default: [])</td>
<td>YAML list of groups to be recorded</td>
</tr>
</tbody>
</table>

- For details about the parameters used in tlog and additional information about the tlog System Role, see the /usr/share/ansible/roles/rhel-system-roles.tlog/README.md file.

20.3. DEPLOYING THE TLOG RHEL SYSTEM ROLE

Follow these steps to prepare and apply an Ansible playbook to configure a RHEL system to log session recording data to the systemd journal.

Prerequisites
- You have set SSH keys for access from the control node to the target system where the **tlog** System Role will be configured.

- You have one control node, which is a system from which the Ansible Engine configures the other systems.

- You have Red Hat Ansible Engine installed on the control node, from which you want to run the playbook.

- You have the **rhel-system-roles** package installed on the control node from which you want to run the playbook.

- You have at least one system that you want to configure the **tlog** System Role. You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to deploy the **tlog** solution.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

```yaml
---
- name: Deploy session recording
  hosts: all
  vars:
    tlog_scope_sssd: some
    tlog_users_sssd:
      - recordeduser
  roles:
    - rhel-system-roles.tlog
```

Where,

- **tlog_scope_sssd**:  
  - **some** specifies you want to record only certain users and groups, not **all** or **none**.

- **tlog_users_sssd**:  
  - **recordeduser** specifies the user you want to record a session from. Note that this does not add the user for you. You must set the user by yourself.

2. Optionally, verify the playbook syntax.

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i IP_Address /path/to/file/playbook.yml -v
   ```

As a result, the playbook installs the **tlog** role on the system you specified. It also creates an SSSD configuration drop file that can be used by the users and groups that you define. SSSD parses and reads these users and groups to overlay **tlog** session as the shell user. Additionally, if the **cockpit** package is installed on the system, the playbook also installs the **cockpit-session-recording** package, which is a **Cockpit** module that allows you to view and play recordings in the web console interface.
Verification steps

To verify that the SSSD configuration drop file is created in the system, perform the following steps:

1. Navigate to the folder where the SSSD configuration drop file is created:

   ```
   # cd /etc/sssd/conf.d
   ```

2. Check the file content:

   ```
   # cat /etc/sssd/conf.d/sssd-session-recording.conf
   ```

You can see that the file contains the parameters you set in the playbook.

### 20.4. DEPLOYING THE TLOG RHEL SYSTEM ROLE FOR EXCLUDING LISTS OF GROUPS OR USERS

You can use the `tlog` System Role to support the SSSD session recording configuration options `exclude_users` and `exclude_groups`. Follow these steps to prepare and apply an Ansible playbook to configure a RHEL system to exclude users or groups from having their sessions recorded and logged in the systemd journal.

#### Prerequisites

- You have set SSH keys for access from the control node to the target system on which you want to configure the tlog System Role.
- You have one control node, which is a system from which the Red Hat Ansible Engine configures the other systems.
- You have Red Hat Ansible Engine installed on the control node, from which you want to run the playbook.
- You have the `rhel-system-roles` package installed on the control node.
- You have at least one system on which you want to configure the tlog System Role. You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to deploy the tlog solution.

#### Procedure

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   ---
   - name: Deploy session recording excluding users and groups
     hosts: all
     vars:
       tlog_scope_sssd: all
       tlog_exclude_users_sssd:
         - jeff
         - james
       tlog_exclude_groups_sssd:
         - admins
   ```
roles:
- rhel-system-roles.tlog

Where,

- **tlog_scope_sssd**:  
  - `all`: specifies that you want to record all users and groups.

- **tlog_exclude_users_sssd**:  
  - `user names`: specifies the user names of the users you want to exclude from the session recording.

- **tlog_exclude_groups_sssd**:  
  - `admins`: specifies the group you want to exclude from the session recording.

2. Optionally, verify the playbook syntax;

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i IP_Address /path/to/file/playbook.yml -v
   ```

As a result, the playbook installs the **tlog** package on the system you specified. It also creates an `/etc/sssd/conf.d/sssd-session-recording.conf` SSSD configuration drop file that can be used by users and groups except those that you defined as excluded. SSSD parses and reads these users and groups to overlap **tlog** session as the shell user. Additionally, if the **cockpit** package is installed on the system, the playbook also installs the **cockpit-session-recording** package, which is a **Cockpit** module that allows you to view and play recordings in the web console interface.

**Verification steps**

To verify that the SSSD configuration drop file is created in the system, perform the following steps:

1. Navigate to the folder where the SSSD configuration drop file is created:

   ```bash
   # cd /etc/sssd/conf.d
   ```

2. Check the file content:

   ```bash
   # cat sssd-session-recording.conf
   ```

You can see that the file contains the parameters you set in the playbook.

**Additional resources**

- See the `/usr/share/doc/rhel-system-roles/tlog/` and `/usr/share/ansible/roles/rhel-system-roles.tlog/` directories.

- The [Recording a session using the deployed tlog system role in the CLI](#) .
20.5. RECORDING A SESSION USING THE DEPLOYED TLOG SYSTEM ROLE IN THE CLI

Once you have deployed the tlog System Role in the system you have specified, you are able to record a user terminal session using the command-line interface (CLI).

Prerequisites

- You have deployed the tlog System Role in the target system.
- The SSSD configuration drop file was created in the /etc/sssd/conf.d directory. See Deploying the tlog RHEL System Role.

Procedure

1. Create a user and assign a password for this user:
   
   ```
   # useradd recorded-user
   # passwd recorded-user
   ```

2. Log in to the system as the user you just created:
   
   ```
   # ssh recorded-user@localhost
   ```

3. Type "yes" when the system prompts you to type yes or no to authenticate.

4. Insert the recorded-user’s password.
   The system displays a message about your session being recorded.

   ```
   ATTENTION! Your session is being recorded!
   ```

5. Once you have finished recording the session, type:
   
   ```
   # exit
   ```
   
   The system logs out from the user and closes the connection with the localhost.

As a result, the user session is recorded, stored and you can play it using a journal.

Verification steps

To view your recorded session in the journal, do the following steps:

1. Run the command below:
   
   ```
   # journalctl -o verbose -r
   ```

2. Search for the MESSAGE field of the tlog-rec recorded journal entry.
   
   ```
   # journalctl -xel _EXE=/usr/bin/tlog-rec-session
   ```

20.6. WATCHING A RECORDED SESSION USING THE CLI
You can play a user session recording from a journal using the command-line interface (CLI).

**Prerequisites**

- You have recorded a user session. See Recording a session using the deployed tlog system role in the CLI.

**Procedure**

1. On the CLI terminal, play the user session recording:
   
   ```bash
   # journalctl -o verbose -r
   ```

2. Search for the *tlog* recording:

   ```bash
   $ /tlog-rec
   ```

   You can see details such as:
   
   - The username for the user session recording
   - The *out_txt* field, a raw output encode of the recorded session
   - The identifier number TLOG_REC=ID_number

3. Copy the identifier number TLOG_REC=ID_number.

4. Playback the recording using the identifier number TLOG_REC=ID_number.

   ```bash
   # tlog-play -r journal -M TLOG_REC=ID_number
   ```

As a result, you can see the user session recording terminal output being played back.
CHAPTER 21. CONFIGURING A HIGH-AVAILABILITY CLUSTER USING SYSTEM ROLES

With the `ha_cluster` system role, you can configure and manage a high-availability cluster that uses the Pacemaker high availability cluster resource manager.

**NOTE**

The High Availability Cluster (HA Cluster) role is available as a Technology Preview.

The HA system role does not currently support constraints. Running the role after constraints are configured manually will remove the constraints, as well as any configuration not supported by the role.

The HA system role does not currently support SBD.

21.1. HA_CLUSTER SYSTEM ROLE VARIABLES

In an `ha_cluster` system role playbook, you define the variables for a high availability cluster according to the requirements of your cluster deployment.

The variables you can set for an `ha_cluster` system role are as follows.

- **ha_cluster_enable_repos**
  A boolean flag that enables the repositories containing the packages that are needed by the `ha_cluster` system role. When this is set to `yes`, the default value of this variable, you must have active subscription coverage for RHEL and the RHEL High Availability Add-On on the systems that you will use as your cluster members or the system role will fail.

- **ha_cluster_cluster_present**
  A boolean flag which, if set to `yes`, determines that HA cluster will be configured on the hosts according to the variables passed to the role. Any cluster configuration not specified in the role and not supported by the role will be lost.
  If `ha_cluster_cluster_present` is set to `no`, all HA cluster configuration will be removed from the target hosts.

  The default value of this variable is `yes`.

  The following example playbook removes all cluster configuration on `node1` and `node2`:

  ```yaml
  - hosts: node1 node2
    vars:
      ha_cluster_cluster_present: no
    roles:
      - rhel-system-roles.ha_cluster
  ```

- **ha_cluster_start_on_boot**
  A boolean flag that determines whether cluster services will be configured to start on boot. The default value of this variable is `yes`.

- **ha_cluster_fence_agent_packages**
  List of fence agent packages to install. The default value of this variable is `fence-agents-all, fence-virt`. 

129
**ha_cluster_extra_packages**

List of additional packages to be installed. The default value of this variable is no packages. This variable can be used to install additional packages not installed automatically by the role, for example custom resource agents.

It is possible to specify fence agents as members of this list. However, **ha_cluster_fence_agent_packages** is the recommended role variable to use for specifying fence agents, so that its default value is overridden.

**ha_cluster_hacluster_password**

A string value that specifies the password of the **hacluster** user. The **hacluster** user has full access to a cluster. It is recommended that you vault encrypt the password, as described in Encrypting content with Ansible Vault. There is no default password value, and this variable must be specified.

**ha_cluster_corosync_key_src**

The path to Corosync **authkey** file, which is the authentication and encryption key for Corosync communication. It is highly recommended that you have a unique **authkey** value for each cluster. The key should be 256 bytes of random data.

If you specify a key for this variable, it is recommended that you vault encrypt the key, as described in Encrypting content with Ansible Vault.

If no key is specified, a key already present on the nodes will be used. If nodes do not have the same key, a key from one node will be distributed to other nodes so that all nodes have the same key. If no node has a key, a new key will be generated and distributed to the nodes.

If this variable is set, **ha_cluster_regenerate_keys** is ignored for this key.

The default value of this variable is null.

**ha_cluster_pacemaker_key_src**

The path to the Pacemaker **authkey** file, which is the authentication and encryption key for Pacemaker communication. It is highly recommended that you have a unique **authkey** value for each cluster. The key should be 256 bytes of random data.

If you specify a key for this variable, it is recommended that you vault encrypt the key, as described in Encrypting content with Ansible Vault.

If no key is specified, a key already present on the nodes will be used. If nodes do not have the same key, a key from one node will be distributed to other nodes so that all nodes have the same key. If no node has a key, a new key will be generated and distributed to the nodes.

If this variable is set, **ha_cluster_regenerate_keys** is ignored for this key.

The default value of this variable is null.

**ha_cluster_fence_virt_key_src**

The path to the **fence-virt** or **fence-xvm** pre-shared key file, which is the location of the authentication key for the **fence-virt** or **fence-xvm** fence agent.

If you specify a key for this variable, it is recommended that you vault encrypt the key, as described in Encrypting content with Ansible Vault.

If no key is specified, a key already present on the nodes will be used. If nodes do not have the same key, a key from one node will be distributed to other nodes so that all nodes have the same key. If no node has a key, a new key will be generated and distributed to the nodes. If the **ha_cluster** system...
A boolean flag which, when set to `yes`, determines that pre-shared keys and TLS certificates will be regenerated. For more information on when keys and certificates will be regenerated, see the descriptions of the `ha_cluster_corosync_key_src`, `ha_cluster_pacemaker_key_src`, `ha_cluster_fence_virt_key_src`, `ha_cluster_pcsd_public_key_src`, and `ha_cluster_pcsd_private_key_src` variables. The default value of this variable is `no`.

`ha_cluster_pcs_permission_list` Configures permissions to manage a cluster using `pcsd`. The items you configure with this variable are as follows:

- **type** - user or group
- **name** - user or group name
- **allow_list** - Allowed actions for the specified user or group:
  - **read** - View cluster status and settings
  - **write** - Modify cluster settings except permissions and ACLs
  - **grant** - Modify cluster permissions and ACLs
  - **full** - Unrestricted access to a cluster including adding and removing nodes and access to keys and certificates

The structure of the `ha_cluster_pcs_permission_list` variable and its default values are as follows:

```
ha_cluster_pcs_permission_list:
- type: group
  name: hacluster
  allow_list:
    - grant
    - read
    - write
```
**ha_cluster_cluster_name**

The name of the cluster. This is a string value with a default of `my-cluster`.

**ha_cluster_cluster_properties**

List of sets of cluster properties for Pacemaker cluster-wide configuration. Only one set of cluster properties is supported.

The structure of a set of cluster properties is as follows:

```yaml
ha_cluster_cluster_properties:
  - attrs:
    - name: property1_name
      value: property1_value
    - name: property2_name
      value: property2_value
```

By default, no properties are set.

The following example playbook configures a cluster consisting of `node1` and `node2` and sets the `stonith-enabled` and `no-quorum-policy` cluster properties.

```yaml
- hosts: node1 node2
  vars:
    ha_cluster_cluster_name: my-new-cluster
    ha_cluster_hacluster_password: password
    ha_cluster_cluster_properties:
      - attrs:
        - name: stonith-enabled
          value: 'true'
        - name: no-quorum-policy
          value: stop

  roles:
    - rhel-system-roles.ha_cluster
```

**ha_cluster_resource_primitives**

This variable defines pacemaker resources configured by the system role, including stonith resources, including stonith resources. The items you can configure for each resource are as follows:

- **id** (mandatory) - ID of a resource.

- **agent** (mandatory) - Name of a resource or stonith agent, for example `ocf:pacemaker:Dummy` or `stonith:fence_xvm`. It is mandatory to specify `stonith:` for stonith agents. For resource agents, it is possible to use a short name, such as `Dummy`, instead of `ocf:pacemaker:Dummy`. However, if several agents with the same short name are installed, the role will fail as it will be unable to decide which agent should be used. Therefore, it is recommended that you use full names when specifying a resource agent.

- **instance_attrs** (optional) - List of sets of the resource’s instance attributes. Currently, only one set is supported. The exact names and values of attributes, as well as whether they are mandatory or not, depend on the resource or stonith agent.

- **meta_attrs** (optional) - List of sets of the resource’s meta attributes. Currently, only one set is supported.

- **operations** (optional) - List of the resource’s operations.
- action (mandatory) - Operation action as defined by pacemaker and the resource or stonith agent.

- attrs (mandatory) - Operation options, at least one option must be specified.

The structure of the resource definition that you configure with the **ha_cluster** system role is as follows.

```
- id: resource-id
  agent: resource-agent
  instance_attrs:
    - attrs:
      - name: attribute1_name
        value: attribute1_value
      - name: attribute2_name
        value: attribute2_value
  meta_attrs:
    - attrs:
      - name: meta_attribute1_name
        value: meta_attribute1_value
      - name: meta_attribute2_name
        value: meta_attribute2_value
  operations:
    - action: operation1-action
      attrs:
        - name: operation1_attribute1_name
          value: operation1_attribute1_value
        - name: operation1_attribute2_name
          value: operation1_attribute2_value
    - action: operation2-action
      attrs:
        - name: operation2_attribute1_name
          value: operation2_attribute1_value
        - name: operation2_attribute2_name
          value: operation2_attribute2_value
```

By default, no resources are defined.

For an example **ha_cluster** system role system role playbook that includes resource configuration, see *Configuring a high availability cluster with fencing and resources*.

**ha_cluster_resource_groups**

This variable defines pacemaker resource groups configured by the system role. The items you can configure for each resource group are as follows:

- **id** (mandatory) - ID of a group.

- **resources** (mandatory) - List of the group’s resources. Each resource is referenced by its ID and the resources must be defined in the **ha_cluster_resource_primitives** variable. At least one resource must be listed.

- **meta_attrs** (optional) - List of sets of the group’s meta attributes. Currently, only one set is supported.
The structure of the resource group definition that you configure with the `ha_cluster` system role is as follows.

```
ha_cluster_resource_groups:
  - id: group-id
    resource_ids:
      - resource1-id
      - resource2-id
    meta_attrs:
      - attrs:
          - name: group_meta_attribute1_name
            value: group_meta_attribute1_value
          - name: group_meta_attribute2_name
            value: group_meta_attribute2_value
```

By default, no resource groups are defined.

For an example `ha_cluster` system role system role playbook that includes resource group configuration, see `Configuring a high availability cluster with fencing and resources`.

**ha_cluster_resource_clones**

This variable defines pacemaker resource clones configured by the system role. The items you can configure for a resource clone are as follows:

- **resource_id** (mandatory) - Resource to be cloned. The resource must be defined in the `ha_cluster_resource_primitives` variable or the `ha_cluster_resource_groups` variable.
- **promotable** (optional) - Indicates whether the resource clone to be created is a promotable clone, indicated as `yes` or `no`.
- **id** (optional) - Custom ID of the clone. If no ID is specified, it will be generated. A warning will be displayed if this option is not supported by the cluster.
- **meta_attrs** (optional) - List of sets of the clone’s meta attributes. Currently, only one set is supported.

The structure of the resource clone definition that you configure with the `ha_cluster` system role is as follows.

```
ha_cluster_resource_clones:
  - resource_id: resource-to-be-cloned
    promotable: yes
    id: custom-clone-id
    meta_attrs:
      - attrs:
          - name: clone_meta_attribute1_name
            value: clone_meta_attribute1_value
          - name: clone_meta_attribute2_name
            value: clone_meta_attribute2_value
```

By default, no resource clones are defined.

For an example `ha_cluster` system role system role playbook that includes resource clone configuration, see `Configuring a high availability cluster with fencing and resources`.
21.2. SPECIFYING AN INVENTORY FOR THE HA_CLUSTER SYSTEM ROLE

When configuring an HA cluster using the `ha_cluster` system role playbook, you configure the names and addresses of the nodes for the cluster in an inventory.

For each node in an inventory, you can optionally specify the following items:

- **node_name** - the name of a node in a cluster.
- **pcs_address** - an address used by `pcs` to communicate with the node. It can be a name, FQDN or an IP address and it can include a port number.
- **corosync_addresses** - list of addresses used by Corosync. All nodes which form a particular cluster must have the same number of addresses and the order of the addresses matters.

The following example shows an inventory with targets `node1` and `node2`. `node1` and `node2` must be either fully qualified domain names or must otherwise be able to connect to the nodes as when, for example, the names are resolvable through the `/etc/hosts` file.

```yaml
all:
  hosts:
    node1:
      ha_cluster:
        node_name: node-A
        pcs_address: node1-address
        corosync_addresses:
          - 192.168.1.11
          - 192.168.2.11
    node2:
      ha_cluster:
        node_name: node-B
        pcs_address: node2-address:2224
        corosync_addresses:
          - 192.168.1.12
          - 192.168.2.12
```

21.3. CONFIGURING A HIGH AVAILABILITY CLUSTER RUNNING NO RESOURCES

The following procedure uses the `ha_cluster` system role, to create a high availability cluster with no fencing configured and which runs no resources.

**Prerequisites**

- You have Red Hat Ansible Engine installed on the node from which you want to run the playbook.

**NOTE**

You do not have to have Ansible installed on the cluster member nodes.
You have the **rhel-system-roles** package installed on the system from which you want to run the playbook. For details about RHEL System Roles and how to apply them, see Getting started with RHEL System Roles.

The systems running RHEL that you will use as your cluster members must have active subscription coverage for RHEL and the RHEL High Availability Add-On.

**NOTE**

The **ha_cluster** system role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

**Procedure**

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the ha_cluster system role.

2. Create a playbook file, for example **new-cluster.yml**.
   The following example playbook file configures a cluster with no fencing configured and which runs no resources. When creating your playbook file for production, it is recommended that you vault encrypt the password, as described in Encrypting content with Ansible Vault.

```
- hosts: node1 node2
  vars:
    ha_cluster_cluster_name: my-new-cluster
    ha_cluster_hacluster_password: password
  roles:
    - rhel-system-roles.ha_cluster
```

3. Save the file.

4. Run the playbook:

```
$ ansible-playbook -i inventory new-cluster.yml
```

### 21.4. CONFIGURING A HIGH AVAILABILITY CLUSTER WITH FENCING AND RESOURCES

The following procedure uses the **ha_cluster** system role to create a high availability cluster that includes a fencing device, cluster resources, resource groups, and a cloned resource.

**Prerequisites**

- You have Red Hat Ansible Engine installed on the node from which you want to run the playbook.

**NOTE**

You do not have to have Ansible Engine installed on the cluster member nodes.
- You have the **rhel-system-roles** package installed on the system from which you want to run the playbook. For details about RHEL System Roles and how to apply them, see Getting started with RHEL System Roles.

- The systems running RHEL that you will use as your cluster members must have active subscription coverage for RHEL and the RHEL High Availability Add-On.

**NOTE**

The **ha_cluster** system role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

**Procedure**

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the ha_cluster system role.

2. Create a playbook file, for example **new-cluster.yml**:

   The following example playbook file configures a cluster that includes fencing, several resources, and a resource group. It also includes a resource clone for the resource group. When creating your playbook file for production, it is recommended that you vault encrypt the password, as described in Encrypting content with Ansible Vault.

   ```yaml
   - hosts: node1 node2
     vars:
       ha_cluster_cluster_name: my-new-cluster
       ha_cluster_hacluster_password: password
       ha_cluster_resource_primitives:
         - id: xvm-fencing
           agent: 'stonith:fence_xvm'
           instanceAttrs:
             - name: pcmk_host_list
               value: node1 node2
         - id: simple-resource
           agent: 'ocf:pacemaker:Dummy'
         - id: resource-with-options
           agent: 'ocf:pacemaker:Dummy'
           instanceAttrs:
             - name: fake
               value: fake-value
             - name: passwd
               value: passwd-value
       meta_attrs:
         - attrs:
             - name: target-role
               value: Started
             - name: is-managed
               value: true
       operations:
         - action: start
           attrs:
             - name: timeout
   ```
value: '30s'
  - action: monitor
    attrs:
    - name: timeout
      value: '5'
    - name: interval
      value: '1min'
  - id: dummy-1
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-2
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-3
    agent: 'ocf:pacemaker:Dummy'
  - id: simple-clone
    agent: 'ocf:pacemaker:Dummy'
  - id: clone-with-options
    agent: 'ocf:pacemaker:Dummy'

ha_cluster_resource_groups:
  - id: simple-group
    resource_ids:
    - dummy-1
    - dummy-2
    meta_attrs:
    - attrs:
      - name: target-role
        value: Started
      - name: is-managed
        value: 'true'
  - id: cloned-group
    resource_ids:
    - dummy-3

ha_cluster_resource_clones:
  - resource_id: simple-clone
  - resource_id: clone-with-options
    promotable: yes
  - resource_id: cloned-group
    promotable: yes

roles:
  - rhel-system-roles.ha_cluster

3. Save the file.

4. Run the playbook:

   $ ansible-playbook -i inventory new-cluster.yml
This procedure configures an active/passive Apache HTTP server in a two-node Red Hat Enterprise Linux High Availability Add-On cluster using the `ha_cluster` system role.

### Prerequisites

- You have Red Hat Ansible Engine installed on the node from which you want to run the playbook.

  **NOTE**
  
  You do not have to have Ansible Engine installed on the cluster member nodes.

- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook. For details about RHEL System Roles and how to apply them, see [Getting started with RHEL System Roles](#).

- The systems running RHEL that you will use as your cluster members must have active subscription coverage for RHEL and the RHEL High Availability Add-On.

- Your system includes a public virtual IP address, required for Apache.

- Your system includes shared storage for the nodes in the cluster, using iSCSI, Fibre Channel, or other shared network block device.

- You have configured an LVM logical volume with an ext4 file system, as described in [Configuring an LVM volume with an ext4 file system in a Pacemaker cluster](#).

- You have configured an Apache HTTP server, as described in [Configuring an Apache HTTP Server](#).

- Your system includes an APC power switch that will be used to fence the cluster nodes.

  **NOTE**
  
  The `ha_cluster` system role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

### Procedure

1. Create an inventory file specifying the nodes in the cluster, as described in [Specifying an inventory for the ha_cluster system role](#).

2. Create a playbook file, for example `http-cluster.yml`:

   The following example playbook file configures a previously-created Apache HTTP server in an active/passive two-node HA cluster

   This example uses an APC power switch with a host name of `zapc.example.com`. If the cluster does not use any other fence agents, you can optionally list only the fence agents your cluster requires when defining the `ha_cluster_fence_agent_packages` variable, as in this example.
When creating your playbook file for production, it is recommended that you vault encrypt the password, as described in Encrypting content with Ansible Vault.

- hosts: z1.example.com z2.example.com
  roles:
  - rhel-system-roles.ha_cluster
  vars:
    ha_cluster_hacluster_password: password
    ha_cluster_cluster_name: my_cluster
    ha_cluster_fence_agent_packages:
    - fence-agents-apc-snmp
    ha_cluster_resource_primitives:
      - id: myapc
        agent: stonith:fence_apc_snmp
        instance_attrs:
          - name: ipaddr
            value: zapc.example.com
          - name: pcmk_host_map
            value: z1.example.com:1;z2.example.com:2
          - name: login
            value: apc
          - name: passwd
            value: apc
      - id: my_lvm
        agent: ocf:heartbeat:LVM-activate
        instance_attrs:
          - name: vgname
            value: my_vg
          - name: vg_access_mode
            value: system_id
      - id: my_fs
        agent: Filesystem
        instance_attrs:
          - name: device
            value: /dev/my_vg/my_lv
          - name: directory
            value: /var/www
          - name: fstype
            value: ext4
      - id: VirtualIP
        agent: IPaddr2
        instance_attrs:
          - name: ip
            value: 198.51.100.3
          - name: cidr_netmask
            value: 24
      - id: Website
        agent: apache
        instance_attrs:
          - name: configfile
            value: /etc/httpd/conf/httpd.conf
- name: statusurl
  value: http://127.0.0.1/server-status

ha_cluster_resource_groups:
  - id: apachegroup
    resource_ids:
      - my_lvm
      - my_fs
      - VirtualIP
      - Website

3. Save the file.

4. Run the playbook:

   $ ansible-playbook -i inventory http-cluster.yml

Verification steps

1. From one of the nodes in the cluster, check the status of the cluster. Note that all four resources are running on the same node, z1.example.com. If you find that the resources you configured are not running, you can run the `pcs resource debug-start resource` command to test the resource configuration.

   [root@z1 ~]# pcs status
   Cluster name: my_cluster
   Last updated: Wed Jul 31 16:38:51 2013
   Last change: Wed Jul 31 16:42:14 2013 via crm_attribute on z1.example.com
   Stack: corosync
   Current DC: z2.example.com (2) - partition with quorum
   Version: 1.1.10-5.el7-9abe687
   2 Nodes configured
   6 Resources configured

   Online: [ z1.example.com z2.example.com ]

   Full list of resources:
   myapc (stonith:fence_apc_snmp):       Started z1.example.com
   Resource Group: apachegroup
       my_lvm (ocf::heartbeat:LVM):   Started z1.example.com
       my_fs (ocf::heartbeat:Filesystem):    Started z1.example.com
   VirtualIP (ocf::heartbeat:IPaddr2):       Started z1.example.com
   Website (ocf::heartbeat:apache):        Started z1.example.com

2. Once the cluster is up and running, you can point a browser to the IP address you defined as the IPaddr2 resource to view the sample display, consisting of the simple word "Hello".

   Hello

3. To test whether the resource group running on z1.example.com fails over to node z2.example.com, put node z1.example.com in standby mode, after which the node will no longer be able to host resources.

   [root@z1 ~]# pcs node standby z1.example.com
4. After putting node **z1** in **standby** mode, check the cluster status from one of the nodes in the cluster. Note that the resources should now all be running on **z2**.

```bash
[root@z1 ~]# pcs status
Cluster name: my_cluster
Last updated: Wed Jul 31 17:16:17 2013
Last change: Wed Jul 31 17:18:34 2013 via crm_attribute on z1.example.com
Stack: corosync
Current DC: z2.example.com (2) - partition with quorum
Version: 1.1.10-5.el7-9abe687
2 Nodes configured
6 Resources configured

Node z1.example.com (1): standby
Online: [ z2.example.com ]

Full list of resources:

myapc (stonith:fence_apc_snmp): Started z1.example.com
Resource Group: apachegroup
  my_lvm (ocf::heartbeat:LVM): Started z2.example.com
  my_fs (ocf::heartbeat:Filesystem): Started z2.example.com
VirtualIP (ocf::heartbeat:IPaddr2): Started z2.example.com
Website (ocf::heartbeat:apache): Started z2.example.com

The web site at the defined IP address should still display, without interruption.

5. To remove **z1** from **standby** mode, enter the following command.

```bash
[root@z1 ~]# pcs node unstandby z1.example.com
```

**NOTE**

Removing a node from **standby** mode does not in itself cause the resources to fail back over to that node. This will depend on the **resource-stickiness** value for the resources. For information on the **resource-stickiness** meta attribute, see Configuring a resource to prefer its current node.
