Red Hat Enterprise Linux 8

Configuring InfiniBand and RDMA networks

Configuring and managing high-speed network protocols and RDMA hardware
Red Hat Enterprise Linux 8 Configuring InfiniBand and RDMA networks

Configuring and managing high-speed network protocols and RDMA hardware
Abstract

You can configure and manage Remote Directory Memory Access (RDMA) networks and InfiniBand hardware at an enterprise level by using various protocols. These include RDMA over Converged Ethernet (RoCE), the software implementation of RoCE (Soft-RoCE), the IP networks protocol such as iWARP, the software implementation of iWARP (Soft-iWARP), and the Network File System over RDMA (NFSoRDMA) protocol as a native support on RDMA-supported hardware. For low-latency and high-throughput connections, you can configure IP over InfiniBand (IPoIB) and Open Subnet Manager (OpenSM).

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your feedback on our documentation. Let us know how we can improve it.

Submitting feedback through Jira (account required)

1. Log in to the Jira website.

2. Click **Create** in the top navigation bar.

3. Enter a descriptive title in the **Summary** field.

4. Enter your suggestion for improvement in the **Description** field. Include links to the relevant parts of the documentation.

5. Click **Create** at the bottom of the dialogue.
CHAPTER 1. UNDERSTANDING INFINIBAND AND RDMA

InfiniBand refers to two distinct things:

- The physical link-layer protocol for InfiniBand networks
- The InfiniBand Verbs API, an implementation of the remote direct memory access (RDMA) technology

RDMA provides access between the main memory of two computers without involving an operating system, cache, or storage. Using RDMA, data transfers with high-throughput, low-latency, and low CPU utilization.

In a typical IP data transfer, when an application on one machine sends data to an application on another machine, the following actions happen on the receiving end:

1. The kernel must receive the data.
2. The kernel must determine that the data belongs to the application.
3. The kernel wakes up the application.
4. The kernel waits for the application to perform a system call into the kernel.
5. The application copies the data from the internal memory space of the kernel into the buffer provided by the application.

This process means that most network traffic is copied across the main memory of the system if the host adapter uses direct memory access (DMA) or otherwise at least twice. Additionally, the computer executes some context switches to switch between the kernel and application. These context switches can cause a higher CPU load with high traffic rates while slowing down the other tasks.

Unlike traditional IP communication, RDMA communication bypasses the kernel intervention in the communication process. This reduces the CPU overhead. The RDMA protocol enables the host adapter to decide after a packet enters the network which application should receive it and where to store it in the memory space of that application. Instead of sending the packet for processing to the kernel and copying it into the memory of the user application, the host adapter directly places the packet contents in the application buffer. This process requires a separate API, the InfiniBand Verbs API, and applications need to implement the InfiniBand Verbs API to use RDMA.

Red Hat Enterprise Linux supports both the InfiniBand hardware and the InfiniBand Verbs API. Additionally, it supports the following technologies to use the InfiniBand Verbs API on non-InfiniBand hardware:

- Internet Wide Area RDMA Protocol (iWARP): A network protocol that implements RDMA over IP networks
- RDMA over Converged Ethernet (RoCE), which is also known as InfiniBand over Ethernet (IBoE): A network protocol that implements RDMA over Ethernet networks

Additional resources

- Configuring RoCE
CHAPTER 2. CONFIGURING ROCE

Remote Direct Memory Access (RDMA) provides remote execution for Direct Memory Access (DMA). RDMA over Converged Ethernet (RoCE) is a network protocol that utilizes RDMA over an Ethernet network. For configuration, RoCE requires specific hardware and some of the hardware vendors are Mellanox, Broadcom, and QLogic.

2.1. OVERVIEW OF ROCE PROTOCOL VERSIONS

RoCE is a network protocol that enables remote direct memory access (RDMA) over Ethernet.

The following are the different RoCE versions:

RoCE v1
The RoCE version 1 protocol is an Ethernet link layer protocol with ethertype 0x8915 that enables the communication between any two hosts in the same Ethernet broadcast domain.

RoCE v2
The RoCE version 2 protocol exists on the top of either the UDP over IPv4 or the UDP over IPv6 protocol. For RoCE v2, the UDP destination port number is 4791.

The RDMA_CM sets up a reliable connection between a client and a server for transferring data. RDMA_CM provides an RDMA transport-neutral interface for establishing connections. The communication uses a specific RDMA device and message-based data transfers.

IMPORTANT
Using different versions like RoCE v2 on the client and RoCE v1 on the server is not supported. In such a case, configure both the server and client to communicate over RoCE v1.

Additional resources
- Temporarily changing the default RoCE version

2.2. TEMPORARILY CHANGING THE DEFAULT ROCE VERSION

Using the RoCE v2 protocol on the client and RoCE v1 on the server is not supported. If the hardware in your server supports RoCE v1 only, configure your clients for RoCE v1 to communicate with the server. For example, you can configure a client that uses the mlx5_0 driver for the Mellanox ConnectX-5 InfiniBand device that only supports RoCE v1.

NOTE
Changes described here will remain effective until you reboot the host.

Prerequisites
- The client uses an InfiniBand device with RoCE v2 protocol.
- The server uses an InfiniBand device that only supports RoCE v1.

Procedure
1. Create the `/sys/kernel/config/rdma_cm/mlx5_0` directory:
   ```
   # mkdir /sys/kernel/config/rdma_cm/mlx5_0
   ```

2. Display the default RoCE mode:
   ```
   # cat /sys/kernel/config/rdma_cm/mlx5_0/ports/1/default_roce_mode
   RoCE v2
   ```

3. Change the default RoCE mode to version 1:
   ```
   # echo "IB/RoCE v1" > /sys/kernel/config/rdma_cm/mlx5_0/ports/1/default_roce_mode
   ```

### 2.3. CONFIGURING SOFT-ROCE

Soft-RoCE is a software implementation of remote direct memory access (RDMA) over Ethernet, which is also called RXE. Use Soft-RoCE on hosts without RoCE host channel adapters (HCA).

**IMPORTANT**

The Soft-RoCE feature is provided as a Technology Preview only. Technology Preview features are not supported with Red Hat production Service Level Agreements (SLAs), might not be functionally complete, and Red Hat does not recommend using them for production. These previews provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

See Technology Preview Features Support Scope on the Red Hat Customer Portal for information about the support scope for Technology Preview features.

**Prerequisites**

- An Ethernet adapter is installed

**Procedure**

1. Install the `iproute`, `libibverbs`, `libibverbs-utils`, and `infiniband-diags` packages:
   ```
   # yum install iproute libibverbs libibverbs-utils infiniband-diags
   ```

2. Display the RDMA links:
   ```
   # rdma link show
   ```

3. Load the `rdma_rxe` kernel module and add a new `rxe` device named `rxe0` that uses the `enp0s1` interface:
   ```
   # rdma link add rxe0 type rxe netdev enp0s1
   ```

**Verification**

1. View the state of all RDMA links:
# rdma link show

link rxe0/1 state ACTIVE physical_state LINK_UP netdev enp1s0

2. List the available RDMA devices:

```bash
# ibv_devices

<table>
<thead>
<tr>
<th>device</th>
<th>node GUID</th>
</tr>
</thead>
<tbody>
<tr>
<td>rxe0</td>
<td>505400fffed5e0fb</td>
</tr>
</tbody>
</table>
```

3. You can use the `ibstat` utility to display a detailed status:

```bash
# ibstat rxe0

CA 'rxe0'
CA type:
Number of ports: 1
Firmware version:
Hardware version:
Node GUID: 0x505400fffed5e0fb
System image GUID: 0x0000000000000000
Port 1:
  State: Active
  Physical state: LinkUp
  Rate: 100
  Base lid: 0
  LMC: 0
  SM lid: 0
  Capability mask: 0x00890000
  Port GUID: 0x505400fffed5e0fb
  Link layer: Ethernet
```
CHAPTER 3. CONFIGURING SOFT-IWARP

Remote Direct Memory Access (RDMA) uses several libraries and protocols over an Ethernet such as iWARP, Soft-iWARP for performance improvement and aided programming interface.

3.1. OVERVIEW OF IWARP AND SOFT-IWARP

Remote direct memory access (RDMA) uses the Internet Wide-area RDMA Protocol (iWARP) over Ethernet for converged and low latency data transmission over TCP. Using standard Ethernet switches and the TCP/IP stack, iWARP routes traffic across the IP subnets. This provides flexibility to efficiently use the existing infrastructure. In Red Hat Enterprise Linux, multiple providers implement iWARP in their hardware network interface cards. For example, cxgb4, irdma, qedr, and so on.

Soft-iWARP (siw) is a software-based iWARP kernel driver and user library for Linux. It is a software-based RDMA device that provides a programming interface to RDMA hardware when attached to network interface cards. It provides an easy way to test and validate the RDMA environment.

3.2. CONFIGURING SOFT-IWARP

Soft-iWARP (siw) implements the Internet Wide-area RDMA Protocol (iWARP) Remote direct memory access (RDMA) transport over the Linux TCP/IP network stack. It enables a system with a standard Ethernet adapter to interoperate with an iWARP adapter or with another system running the Soft-iWARP driver or a host with the hardware that supports iWARP.

IMPORTANT

The Soft-iWARP feature is provided as a Technology Preview only. Technology Preview features are not supported with Red Hat production Service Level Agreements (SLAs), might not be functionally complete, and Red Hat does not recommend using them for production. These previews provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

See Technology Preview Features Support Scope on the Red Hat Customer Portal for information about the support scope for Technology Preview features.

To configure Soft-iWARP, you can use this procedure in a script to run automatically when the system boots.

Prerequisites

- An Ethernet adapter is installed

Procedure

1. Install the iproute, libibverbs, libibverbs-utils, and infiniband-diags packages:

   ```
   # yum install iproute libibverbs libibverbs-utils infiniband-diags
   ```

2. Display the RDMA links:

   ```
   # rdma link show
   ```

3. Load the siw kernel module:
4. Add a new `siw` device named `siw0` that uses the `enp0s1` interface:

```
# rdma link add siw0 type siw netdev enp0s1
```

**Verification**

1. View the state of all RDMA links:

```
# rdma link show
```

   link siw0/1 state ACTIVE physical_state LINK_UP netdev enp0s1

2. List the available RDMA devices:

```
# ibv_devices
```

<table>
<thead>
<tr>
<th>device</th>
<th>node GUID</th>
</tr>
</thead>
<tbody>
<tr>
<td>siw0</td>
<td>0250:b6ff:fea1:9d61</td>
</tr>
</tbody>
</table>

3. You can use the `ibv_devinfo` utility to display a detailed status:

```
# ibv_devinfo siw0
```

```plaintext
hca_id: siw0
transport: iWARP (1)
fw_ver: 0.0.0
node_guid: 0250:b6ff:fea1:9d61
sys_image_guid: 0250:b6ff:fea1:9d61
vendor_id: 0x626d74
vendor_part_id: 1
hw_ver: 0x0
phys_port_cnt: 1
port:
  1
    state: PORT_ACTIVE (4)
    max_mtu: 1024 (3)
    active_mtu: 1024 (3)
    sm_lid: 0
    port_lid: 0
    port_lmc: 0x00
    link_layer: Ethernet
```
CHAPTER 4. CONFIGURING THE CORE RDMA SUBSYSTEM

The rdma service configuration manages the network protocols and communication standards such as InfiniBand, iWARP, and RoCE.

4.1. RENAMING IPOIB DEVICES

By default, the kernel names Internet Protocol over InfiniBand (IPoIB) devices, for example, ib0, ib1, and so on. To avoid conflicts, Red Hat recommends creating a rule in the udev device manager to create persistent and meaningful names such as mlx4_ib0.

Prerequisites

- You have installed an InfiniBand device.

Procedure

1. Display the hardware address of the device ib0:

   ```
   # ip link show ib0
   8: ib0: >BROADCAST,MULTICAST,UP,LOWER_UP< mtu 65520 qdisc pfifo_fast state UP
   mode DEFAULT qlen 256
   link/infiniband 80:00:02:00:fe:80:00:00:00:00:00:00:00:00:02:c9:03:00:31:78:f2 brd 00:ff:ff:ff:ff:12:40:1b:ff:ff:00:00:00:00:00:00:ff:ff:ff:ff
   ```

   The last eight bytes of the address are required to create a udev rule in the next step.

2. To configure a rule that renames the device with the 00:02:c9:03:00:31:78:f2 hardware address to mlx4_ib0, edit the /etc/udev/rules.d/70-persistent-ipoib.rules file and add an ACTION rule:

   ```
   ACTION="add", SUBSYSTEM="net", DRIVERS="?*", ATTR{type}="32",
   ATTR{address}="?00:02:c9:03:00:31:78:f2", NAME="mlx4_ib0"
   ```

3. Reboot the host:

   ```
   # reboot
   ```

Additional resources

- udev(7) man page
- Understanding IPoIB hardware addresses

4.2. INCREASING THE AMOUNT OF MEMORY THAT USERS ARE ALLOWED TO PIN IN THE SYSTEM

Remote direct memory access (RDMA) operations require the pinning of physical memory. As a consequence, the kernel is not allowed to write memory into the swap space. If a user pins too much memory, the system can run out of memory, and the kernel terminates processes to free up more memory. Therefore, memory pinning is a privileged operation.

If non-root users need to run large RDMA applications, it is necessary to increase the amount of memory to maintain pages in primary memory pinned all the time.
Procedure

- As the root user, create the file `/etc/security/limits.conf` with the following contents:

  @rdma soft memlock unlimited
  @rdma hard memlock unlimited

Verification

1. Log in as a member of the rdma group after editing the `/etc/security/limits.conf` file. Note that Red Hat Enterprise Linux applies updated `ulimit` settings when the user logs in.

2. Use the `ulimit -l` command to display the limit:

   $ ulimit -l
   unlimited

   If the command returns `unlimited`, the user can pin an unlimited amount of memory.

Additional resources

- `limits.conf(5)` man page

4.3. CONFIGURING THE RDMA SERVICE

With the Remote Direct Memory Access (RDMA) protocol, you can transfer data between the RDMA enabled systems over the network by using the main memory. The RDMA protocol provides low latency and high throughput. To manage supported network protocols and communication standards, you need to configure the `rdma` service. This configuration includes high speed network protocols such as RoCE and iWARP, and communication standards such as Soft-RoCE and Soft-iWARP. When Red Hat Enterprise Linux detects InfiniBand, iWARP, or RoCE devices and their configuration files residing at the `/etc/rdma/modules/*` directory, the udev device manager instructs systemd to start the `rdma` service. Configuration of modules in the `/etc/rdma/modules/rdma.conf` file remains persistent after reboot. You need to restart the `rdma-load-modules@rdma.service` configuration service to apply changes.

Procedure

1. Edit the `/etc/rdma/modules/rdma.conf` file and uncomment the modules that you want to enable:

   # These modules are loaded by the system if any RDMA devices is installed
   # iSCSI over RDMA client support
   ib_iser
   # iSCSI over RDMA target support
   ib_isert
   # SCSI RDMA Protocol target driver
   ib_srpt
   # User access to RDMA verbs (supports libibverbs)
   ib_uverbs
4.4. ENABLING NFS OVER RDMA ON AN NFS SERVER

Remote Direct Memory Access (RDMA) is a protocol that enables a client system to directly transfer data from the memory of a storage server into its own memory. This enhances storage throughput, decreases latency in data transfer between the server and client, and reduces CPU load on both ends. If both the NFS server and clients are connected over RDMA, clients can use NFSoRDMA to mount an exported directory.

Prerequisites

- The NFS service is running and configured
- An InfiniBand or RDMA over Converged Ethernet (RoCE) device is installed on the server.
- IP over InfiniBand (IPoIB) is configured on the server, and the InfiniBand device has an IP address assigned.

Procedure

1. Install the `rdma-core` package:

   ```
   # dnf install rdma-core
   ```

2. If the package was already installed, verify that the `xprtrdma` and `svcrdma` modules in the `/etc/rdma/modules/rdma.conf` file are uncommented:

   ```
   # NFS over RDMA client support
   xprtrdma
   # NFS over RDMA server support
   svcrdma
   ```
3. Optional. By default, NFS over RDMA uses port 20049. If you want to use a different port, set the `rdma-port` setting in the `[nfsd]` section of the `/etc/nfs.conf` file:

```bash
rdma-port=<port>
```

4. Open the NFSoRDMA port in `firewalld`:

```bash
# firewall-cmd --permanent --add-port={20049/tcp,20049/udp}
# firewall-cmd --reload
```

Adjust the port numbers if you set a different port than 20049.

5. Restart the `nfs-server` service:

```bash
# systemctl restart nfs-server
```

Verification

1. On a client with InfiniBand hardware, perform the following steps:

   a. Install the following packages:

   ```bash
   # dnf install nfs-utils rdma-core
   ```

   b. Mount an exported NFS share over RDMA:

   ```bash
   # mount -o rdma server.example.com:/nfs/projects/ /mnt/
   ```

   If you set a port number other than the default (20049), pass `port=<port_number>` to the command:

   ```bash
   # mount -o rdma,port=<port_number> server.example.com:/nfs/projects/ /mnt/
   ```

   c. Verify that the share was mounted with the `rdma` option:

   ```bash
   # mount | grep "^/mnt" server.example.com:/nfs/projects/ on /mnt type nfs (...,proto=rdma, ...)
   ```

Additional resources

- Configuring InfiniBand and RDMA networks
CHAPTER 5. CONFIGURING AN INFINIBAND SUBNET MANAGER

All InfiniBand networks must have a subnet manager running for the network to function. This is true even if two machines are connected directly with no switch involved.

It is possible to have more than one subnet manager. In that case, one acts as a master and another subnet manager acts as a slave that will take over in case the master subnet manager fails.

Most InfiniBand switches contain an embedded subnet manager. However, if you need a more up-to-date subnet manager or if you require more control, use the **OpenSM** subnet manager provided by Red Hat Enterprise Linux.

### 5.1. INSTALLING THE OPENSM SUBNET MANAGER

**OpenSM** is a subnet manager and administrator that follows the InfiniBand specifications to initialize InfiniBand hardware where at least one instance of **OpenSM** service always runs.

**Procedure**

1. Install the `opensm` package:
   ```
   # yum install opensm
   ```

2. Configure OpenSM in case the default installation does not match your environment. With only one InfiniBand port, the host acts as the master subnet manager that does not require any custom changes. The default configuration works without any modification.

3. Enable and start the `opensm` service:
   ```
   # systemctl enable --now opensm
   ```

**Additional resources**

- `opensm(8)` man page

### 5.2. CONFIGURING OPENSM USING THE SIMPLE METHOD

**OpenSM** is an InfiniBand specification-based subnet manager and administrator that configures the InfiniBand fabric, a network topology to interconnect the InfiniBand nodes.

**Prerequisites**

- One or more InfiniBand ports are installed on the server

**Procedure**

1. Obtain the GUIDs for the ports using the `ibstat` utility:
   ```
   # ibstat -d mlx4_0
   CA 'mlx4_0'
   ```
CA type: MT4099
Number of ports: 2
Firmware version: 2.42.5000
Hardware version: 1
Node GUID: 0xf4521403007be130
System image GUID: 0xf4521403007be133
Port 1:
  State: Active
  Physical state: LinkUp
  Rate: 56
  Base lid: 3
  LMC: 0
  SM lid: 1
  Capability mask: 0x02594868
  Port GUID: 0xf4521403007be131
  Link layer: InfiniBand
Port 2:
  State: Down
  Physical state: Disabled
  Rate: 10
  Base lid: 0
  LMC: 0
  SM lid: 0
  Capability mask: 0x04010000
  Port GUID: 0xf65214fffe7be132
  Link layer: Ethernet

NOTE
Some InfiniBand adapters use the same GUID for the node, system, and port.

2. Edit the `/etc/sysconfig/opensm` file and set the GUIDs in the `GUIDS` parameter:

   GUIDS="GUID_1 GUID_2"

3. You can set the `PRIORITY` parameter if multiple subnet managers are available in your subnet. For example:

   PRIORITY=15

Additional resources
- `/etc/sysconfig/opensm`

5.3. CONFIGURING OPENSM BY EDITING THE OPENSMSM.CONF FILE

OpenSM performance depends on the number of available InfiniBand ports on the device. You can customize it by editing `/etc/rdma/opensm.conf` file.

Prerequisites
- Only one InfiniBand port is installed on the server.
Procedure

1. Edit the `/etc/rdma/opensm.conf` file and customize the settings to match your environment. After updating an `opensm` package, the `yum` utility overrides the `/etc/rdma/opensm.conf` and creates a copy which is the new OpenSM configuration file `/etc/rdma/opensm.conf.rpmnew`. So, you can compare the previous and new files to identify changes and incorporate them manually in file `opensm.conf`.

2. Restart the `opensm` service:

```
# systemctl restart opensm
```

### 5.4. CONFIGURING MULTIPLE OPENSM INSTANCES

**OpenSM** is an InfiniBand constrained subnet manager and administrator. To provide high performance, **OpenSM** uses switched fabric network topology that interconnects with InfiniBand network nodes.

**Prerequisites**

- One or more InfiniBand ports are installed on the server.

**Procedure**

1. Copy the `/etc/rdma/opensm.conf` file to `/etc/rdma/opensm.conf.orig` file:

```
# cp /etc/rdma/opensm.conf /etc/rdma/opensm.conf.orig
```

When you install an updated `opensm` package, the `yum` utility overrides the `/etc/rdma/opensm.conf`. With the copy created in this step, compare the previous and new files to identify changes and incorporate them manually in the instance-specific `opensm.conf` files.

2. Create a copy of the `/etc/rdma/opensm.conf` file:

```
# cp /etc/rdma/opensm.conf /etc/rdma/opensm.conf.1
```

For each instance, create and append a unique and continuous number to a copy of the configuration file.

After updating the `opensm` package, the `yum` utility stores the new OpenSM configuration file as `/etc/rdma/opensm.conf.rpmnew`. Compare this file with your customized `/etc/rdma/opensm.conf.*` files, and manually incorporate the changes.

3. Edit the copy you created in the previous step, and customize the settings for the instance to match your environment. For example, set the `guid`, `subnet_prefix`, and `logdir` parameters.

4. Optionally, create a `partitions.conf` file with a unique name specifically for this subnet and reference that file in the `partition_config_file` parameter in the corresponding copy of the `opensm.conf` file.

5. Repeat the previous steps for each instance you want to create.

6. Start the `opensm` service:

```
# systemctl start opensm
```
The opensm service automatically starts a unique instance for each opensm.conf.* file in the /etc/rdma/ directory. If multiple opensm.conf.* files exist, the service ignores settings in the /etc/sysconfig/opensm file as well as in the base /etc/rdma/opensm.conf file.

5.5. CREATING A PARTITION CONFIGURATION

Partitions enable administrators to create subnets on InfiniBand similar to Ethernet VLANs.

**IMPORTANT**

If you define a partition with a specific speed such as 40 Gbps, all hosts within this partition must support this speed minimum. If a host does not meet the speed requirements, it cannot join the partition. Therefore, set the speed of a partition to the lowest speed supported by any host with permission to join the partition.

**Prerequisites**

- One or more InfiniBand ports are installed on the server

**Procedure**

1. Edit the /etc/rdma/partitions.conf file to configure the partitions as follows:

```
# For reference:
# IPv4 IANA reserved multicast addresses:
#   http://www.iana.org/assignments/multicast-addresses/multicast-addresses.txt
# IPv6 IANA reserved multicast addresses:
#   http://www.iana.org/assignments/ipv6-multicast-addresses/ipv6-multicast-addresses.xml
#
# mtu =
#   1 = 256
#   2 = 512
#   3 = 1024
#   4 = 2048
#   5 = 4096
#
# rate =
#   2  = 2.5 GBit/s
#   3  = 10 GBit/s
#   4  = 30 GBit/s
#   5  = 50 GBit/s
#   6  = 20 GBit/s
#   7  = 100 GBit/s
#   8  = 60 GBit/s
#   9  = 80 GBit/s
#  10  = 120 GBit/s
```

Add the following content to the file to create the 0x7fff default partition at a reduced speed of 10 Gbps, and a partition 0x0002 with a speed of 40 Gbps:
Default=0x7fff, rate=3, mtu=4, scope=2, defmember=full:
   ALL, ALL_SWITCHES=full;
Default=0x7fff, ipoib, rate=3, mtu=4, scope=2:
   mgid=ff12:401b::ffff:ffff   # IPv4 Broadcast address
   mgid=ff12:401b::1           # IPv4 All Hosts group
   mgid=ff12:401b::2           # IPv4 All Routers group
   mgid=ff12:401b::16          # IPv4 IGMP group
   mgid=ff12:401b::fb          # IPv4 mDNS group
   mgid=ff12:401b::fc          # IPv4 Multicast Link Local Name Resolution group
   mgid=ff12:401b::101         # IPv4 NTP group
   mgid=ff12:401b::202         # IPv4 Sun RPC
   mgid=ff12:601b::1           # IPv6 All Hosts group
   mgid=ff12:601b::2           # IPv6 All Routers group
   mgid=ff12:601b::16          # IPv6 MLDv2-capable Routers group
   mgid=ff12:601b::fb          # IPv6 mDNS group
   mgid=ff12:601b::101         # IPv6 NTP group
   mgid=ff12:601b::202         # IPv6 Sun RPC group
   mgid=ff12:601b::1:3         # IPv6 Multicast Link Local Name Resolution group
   ALL=full, ALL_SWITCHES=full;

ib0_2=0x0002, rate=7, mtu=4, scope=2, defmember=full:
   ALL, ALL_SWITCHES=full;
ib0_2=0x0002, ipoib, rate=7, mtu=4, scope=2:
   mgid=ff12:401b::ffff:ffff   # IPv4 Broadcast address
   mgid=ff12:401b::1           # IPv4 All Hosts group
   mgid=ff12:401b::2           # IPv4 All Routers group
   mgid=ff12:401b::16          # IPv4 IGMP group
   mgid=ff12:401b::fb          # IPv4 mDNS group
   mgid=ff12:401b::fc          # IPv4 Multicast Link Local Name Resolution group
   mgid=ff12:401b::101         # IPv4 NTP group
   mgid=ff12:401b::202         # IPv4 Sun RPC
   mgid=ff12:601b::1           # IPv6 All Hosts group
   mgid=ff12:601b::2           # IPv6 All Routers group
   mgid=ff12:601b::16          # IPv6 MLDv2-capable Routers group
   mgid=ff12:601b::fb          # IPv6 mDNS group
   mgid=ff12:601b::101         # IPv6 NTP group
   mgid=ff12:601b::202         # IPv6 Sun RPC group
   mgid=ff12:601b::1:3         # IPv6 Multicast Link Local Name Resolution group
   ALL=full, ALL_SWITCHES=full;
CHAPTER 6. CONFIGURING IPOIB

By default, InfiniBand does not use the internet protocol (IP) for communication. However, IP over InfiniBand (IPoIB) provides an IP network emulation layer on top of InfiniBand remote direct memory access (RDMA) networks. This allows existing unmodified applications to transmit data over InfiniBand networks, but the performance is lower than if the application would use RDMA natively.

**NOTE**

The Mellanox devices, starting from ConnectX-4 and above, on RHEL 8 and later use Enhanced IPoIB mode by default (datagram only). Connected mode is not supported on these devices.

6.1. THE IPOIB COMMUNICATION MODES

An IPoIB device is configurable in either **Datagram** or **Connected** mode. The difference is the type of queue pair the IPoIB layer attempts to open with the machine at the other end of the communication:

- **In the Datagram mode**, the system opens an unreliable, disconnected queue pair. This mode does not support packages larger than Maximum Transmission Unit (MTU) of the InfiniBand link layer. During transmission of data, the IPoIB layer adds a 4-byte IPoIB header on top of the IP packet. As a result, the IPoIB MTU is 4 bytes less than the InfiniBand link-layer MTU. As 2048 is a common InfiniBand link-layer MTU, the common IPoIB device MTU in **Datagram** mode is 2044.

- **In the Connected mode**, the system opens a reliable, connected queue pair. This mode allows messages larger than the InfiniBand link-layer MTU. The host adapter handles packet segmentation and reassembly. As a result, in the **Connected** mode, the messages sent from Infiniband adapters have no size limits. However, there are limited IP packets due to the data field and TCP/IP header field. For this reason, the IPoIB MTU in the **Connected** mode is 65520 bytes.

The **Connected** mode has a higher performance but consumes more kernel memory.

Though a system is configured to use the **Connected** mode, a system still sends multicast traffic using the **Datagram** mode because InfiniBand switches and fabric cannot pass multicast traffic in the **Connected** mode. Also, when the host is not configured to use the **Connected** mode, the system falls back to the **Datagram** mode.

While running an application that sends multicast data up to MTU on the interface, configures the interface in **Datagram** mode or configure the application to cap the send size of a packet that will fit in datagram-sized packets.

6.2. UNDERSTANDING IPOIB HARDWARE ADDRESSES

IPoIB devices have a 20 byte hardware address that consists of the following parts:

- The first 4 bytes are flags and queue pair numbers

- The next 8 bytes are the subnet prefix
  The default subnet prefix is **0xfe:80:00:00:00:00:00:00**. After the device connects to the subnet manager, the device changes this prefix to match with the configured subnet manager.

- The last 8 bytes are the Globally Unique Identifier (GUID) of the InfiniBand port that attaches to the IPoIB device
NOTE
As the first 12 bytes can change, do not use them in the udev device manager rules.

6.3. CONFIGURING AN IPOIB CONNECTION USING NMCLI COMMANDS

The nmcli command-line utility controls the NetworkManager and reports network status using CLI.

Prerequisites
- An InfiniBand device is installed on the server
- The corresponding kernel module is loaded

Procedure
1. Create the InfiniBand connection to use the mlx4_ib0 interface in the Connected transport mode and the maximum MTU of 65520 bytes:

   ```
   # nmcli connection add type infiniband con-name mlx4_ib0 ifname mlx4_ib0 transport-mode Connected mtu 65520
   ```

2. You can also set 0x8002 as a P_Key interface of the mlx4_ib0 connection:

   ```
   # nmcli connection modify mlx4_ib0 infiniband.p-key 0x8002
   ```

3. To configure the IPv4 settings set a static IPv4 address, network mask, default gateway, and DNS server of the mlx4_ib0 connection:

   ```
   # nmcli connection modify mlx4_ib0 ipv4.addresses 192.0.2.1/24
   # nmcli connection modify mlx4_ib0 ipv4.gateway 192.0.2.254
   # nmcli connection modify mlx4_ib0 ipv4.dns 192.0.2.253
   # nmcli connection modify mlx4_ib0 ipv4.method manual
   ```

4. To configure the IPv6 settings set a static IPv6 address, network mask, default gateway, and DNS server of the mlx4_ib0 connection:

   ```
   # nmcli connection modify mlx4_ib0 ipv6.addresses 2001:db8:1::1/32
   # nmcli connection modify mlx4_ib0 ipv6.gateway 2001:db8:1::ffe
   # nmcli connection modify mlx4_ib0 ipv6.dns 2001:db8:1::fffd
   # nmcli connection modify mlx4_ib0 ipv6.method manual
   ```

5. To activate the mlx4_ib0 connection:

   ```
   # nmcli connection up mlx4_ib0
   ```

6.4. CONFIGURING AN IPOIB CONNECTION BY USING THE NETWORK RHEL SYSTEM ROLE
You can use the network RHEL system role to remotely create NetworkManager connection profiles for IP over InfiniBand (IPoIB) devices. For example, remotely add an InfiniBand connection for the mlx4_ib0 interface with the following settings by running an Ansible playbook:

- An IPoIB device - `mlx4_ib0.8002`
- A partition key `p_key` - `0x8002`
- A static IPv4 address - `192.0.2.1` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- An InfiniBand device named `mlx4_ib0` is installed in the managed nodes.
- The managed nodes use NetworkManager to configure the network.

Procedure

1. Create a playbook file, for example `~/playbook.yml`, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure IPoIB
      ansible.builtin.include_role:
        name: rhel-system-roles.network
      vars:
        network_connections:
          # InfiniBand connection mlx4_ib0
          - name: mlx4_ib0
            interface_name: mlx4_ib0
            type: infiniband

          # IPoIB device mlx4_ib0.8002 on top of mlx4_ib0
          - name: mlx4_ib0.8002
            type: infiniband
            autoconnect: yes
            infiniband:
              p_key: 0x8002
              transport_mode: datagram
            parent: mlx4_ib0
            ip:
              address:
```

Red Hat Enterprise Linux 8 Configuring InfiniBand and RDMA networks
- 192.0.2.1/24
- 2001:db8:1::1/64
state: up

If you set a `p_key` parameter as in this example, do not set an `interface_name` parameter on the IPoIB device.

2. Validate the playbook syntax:

   ```bash
   $ ansible-playbook --syntax-check ~/playbook.yml
   ```

   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

   ```bash
   $ ansible-playbook ~/playbook.yml
   ```

**Verification**

1. On the `managed-node-01.example.com` host, display the IP settings of the `mlx4_ib0.8002` device:

   ```bash
   # ip address show mlx4_ib0.8002
   ...
   inet 192.0.2.1/24 brd 192.0.2.255 scope global noprefixroute ib0.8002
   valid_lft forever preferred_lft forever
   inet6 2001:db8:1::1/64 scope link tentative noprefixroute
   valid_lft forever preferred_lft forever
   
   state: up
   ```

2. Display the partition key (P_Key) of the `mlx4_ib0.8002` device:

   ```bash
   # cat /sys/class/net/mlx4_ib0.8002/pkey
   0x8002
   ```

3. Display the mode of the `mlx4_ib0.8002` device:

   ```bash
   # cat /sys/class/net/mlx4_ib0.8002mode
   datagram
   ```

**Additional resources**

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
- `/usr/share/doc/rhel-system-roles/network/` directory

### 6.5. CONFIGURING AN IPOIB CONNECTION USING NM-CONNECTION-EDITOR

The `nmcli-connection-editor` application configures and manages network connections stored by NetworkManager using the management console.
Prerequisites

- An InfiniBand device is installed on the server.
- Corresponding kernel module is loaded
- The nm-connection-editor package is installed.

Procedure

1. Enter the command:

   ```
   $ nm-connection-editor
   ```

2. Click the + button to add a new connection.

3. Select the InfiniBand connection type and click Create.

4. On the InfiniBand tab:
   a. Change the connection name if you want to.
   b. Select the transport mode.
   c. Select the device.
   d. Set an MTU if needed.

5. On the IPv4 Settings tab, configure the IPv4 settings. For example, set a static IPv4 address, network mask, default gateway, and DNS server:
6. On the **IPv6 Settings** tab, configure the IPv6 settings. For example, set a static IPv6 address, network mask, default gateway, and DNS server:

<table>
<thead>
<tr>
<th>Connection name:</th>
<th>mlx4_ib0</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>General</th>
<th>InfiniBand</th>
<th>Proxy</th>
<th>IPv4 Settings</th>
<th>IPv6 Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Method:</td>
<td>Manual</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Addresses

<table>
<thead>
<tr>
<th>Address</th>
<th>Prefix</th>
<th>Gateway</th>
</tr>
</thead>
<tbody>
<tr>
<td>2001:db8::1</td>
<td>32</td>
<td>2001:db8::ffe</td>
</tr>
</tbody>
</table>

| DNS servers: | 2001:db8::fffd |

7. Click **Save** to save the team connection.

8. Close **nm-connection-editor**.

9. You can set a **P_Key** interface. As this setting is not available in **nm-connection-editor**, you must set this parameter on the command line.

   For example, to set **0x8002** as **P_Key** interface of the **mlx4_ib0** connection:

   ```
   # nmcli connection modify mlx4_ib0 infiniband.p-key 0x8002
   ```
CHAPTER 7. TESTING INFINIBAND NETWORKS

7.1. TESTING EARLY INFINIBAND RDMA OPERATIONS

InfiniBand provides low latency and high performance for Remote Direct Memory Access (RDMA).

NOTE

Apart from InfiniBand, if you use IP-based devices such as Internet Wide-area Remote Protocol (iWARP) or RDMA over Converged Ethernet (RoCE) or InfiniBand over Ethernet (IBoE) devices, see:

- Testing an IPoIB using the ping utility
- Testing an RDMA network using qperf after IPoIB is configured

Prerequisites

- You have configured the rdma service.
- You have installed the libibverbs-utils and infiniband-diags packages.

Procedure

1. List the available InfiniBand devices:

   ```
   # ibv_devices
   device                node GUID
   ------              ----------------
   mlx4_0              0002c903003178f0
   mlx4_1              f4521403007bcba0
   ```

2. Display the information of the mlx4_1 device:

   ```
   # ibv_devinfo -d mlx4_1
   hca_id: mlx4_1
   transport: InfiniBand (0)
   fw_ver: 2.30.8000
   node_guid: f452:1403:007b:cba0
   sys_image_guid: f452:1403:007b:cba3
   vendor_id: 0x02c9
   vendor_part_id: 4099
   hw_ver: 0x0
   board_id: MT_1090120019
   phys_port_cnt: 2
   port: 1
   state: PORT_ACTIVE (4)
   max_mtu: 4096 (5)
   active_mtu: 2048 (4)
   sm_lid: 2
   port_lid: 2
   port_lmc: 0x01
   ```
3. Display the status of the `mlx4_1` device:

```
# ibstat mlx4_1

CA 'mlx4_1'
  CA type: MT4099
  Number of ports: 2
  Firmware version: 2.30.8000
  Hardware version: 0
  Node GUID: 0xf4521403007bcba0
  System image GUID: 0xf4521403007bcba3

Port 1:
  State: Active
  Physical state: LinkUp
  Rate: 56
  Base lid: 2
  LMC: 1
  SM lid: 2
  Capability mask: 0x0251486a
  Port GUID: 0xf4521403007bcba1
  Link layer: InfiniBand

Port 2:
  State: Active
  Physical state: LinkUp
  Rate: 40
  Base lid: 0
  LMC: 0
  SM lid: 0
  Capability mask: 0x04010000
  Port GUID: 0xf65214fffe7bcba2
  Link layer: Ethernet
```

4. The `ibping` utility pings an InfiniBand address and runs as a client/server.

   a. To start server mode on a host, use the `-S` parameter on port number `-P` with `-C` InfiniBand certificate authority (CA) name:

      ```
      # ibping -S -C mlx4_1 -P 1
      ```

   b. To start client mode on another host, send some packets `-c` on port number `-P` using `-C` InfiniBand certificate authority (CA) name with `-L` Local Identifier (LID):

      ```
      # ibping -c 50 -C mlx4_0 -P 1 -L 2
      ```
Additional resources

- ibping(8) man page

### 7.2. TESTING AN IPOIB USING THE PING UTILITY

After you configured IP over InfiniBand (IPoIB), use the `ping` utility to send ICMP packets to test the IPoIB connection.

**Prerequisites**

- The two RDMA hosts are connected in the same InfiniBand fabric with RDMA ports
- The IPoIB interfaces in both hosts are configured with IP addresses within the same subnet

**Procedure**

- Use the `ping` utility to send five ICMP packets to the remote host’s InfiniBand adapter:
  
  ```bash
  # ping -c5 192.0.2.1
  ```

### 7.3. TESTING AN RDMA NETWORK USING QPERF AFTER IPOIB IS CONFIGURED

The `qperf` utility measures RDMA and IP performance between two nodes in terms of bandwidth, latency, and CPU utilization.

**Prerequisites**

- You have installed the `qperf` package on both hosts.
- IPoIB is configured on both hosts.

**Procedure**

1. Start `qperf` on one of the hosts without any options to act as a server:

   ```bash
   # qperf
   ```

2. Use the following commands on the client. The commands use port 1 of the mlx4_0 host channel adapter in the client to connect to IP address 192.0.2.1 assigned to the InfiniBand adapter in the server.

   a. Display the configuration of the host channel adapter:

   ```bash
   # qperf -v -i mlx4_0:1 192.0.2.1 conf
   ```

   ```bash
   conf:
   loc_node  = rdma-dev-01.lab.bos.redhat.com
   loc_cpu   = 12 Cores: Mixed CPUs
   loc_os    = Linux 4.18.0-187.el8.x86_64
   loc_qperf = 0.4.11
   rem_node  = rdma-dev-00.lab.bos.redhat.com
   ```
### Additional resources

- **qperf(1) man page**
