PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Please let us know how we could make it better. To do so:

• For simple comments on specific passages:
  1. Make sure you are viewing the documentation in the *Multi-page HTML* format. In addition, ensure you see the **Feedback** button in the upper right corner of the document.
  2. Use your mouse cursor to highlight the part of text that you want to comment on.
  3. Click the **Add Feedback** pop-up that appears below the highlighted text.
  4. Follow the displayed instructions.

• For submitting more complex feedback, create a Bugzilla ticket:
  1. Go to the **Bugzilla** website.
  2. As the Component, use **Documentation**.
  3. Fill in the **Description** field with your suggestion for improvement. Include a link to the relevant part(s) of documentation.
  4. Click **Submit Bug**.
CHAPTER 1. CONNECTING RHEL SYSTEMS DIRECTLY TO AD USING SSSD

This section describes using the System Security Services Daemon (SSSD) to connect a RHEL system to Active Directory (AD). You need two components to connect a RHEL system to Active Directory (AD). One component, SSSD, interacts with the central identity and authentication source, and the other component, realmd, detects available domains and configures the underlying RHEL system services, in this case SSSD, to connect to the domain.

- Overview of direct integration using SSSD
- Supported Windows platforms for direct integration
- Connecting directly to AD
- How the AD provider handles trusted domains
- realm commands

1.1. OVERVIEW OF DIRECT INTEGRATION USING SSSD

You use SSSD to access a user directory for authentication and authorization through a common framework with user caching to permit offline logins. SSSD is highly configurable; it provides Pluggable Authentication Modules (PAM) and Name Switch Service (NSS) integration and a database to store local users as well as extended user data retrieved from a central server. SSSD is the recommended component to connect a RHEL system with one of the following types of identity server:

- Active Directory
- Identity Management (IdM) in RHEL
- Any generic LDAP or Kerberos server

NOTE

- Direct integration with SSSD works only within a single AD forest by default. For multi-forest setup, configure manual domain enumeration as described in this Knowledgebase solution: Joining SSSD to domains in different forests.

The most convenient way to configure SSSD to directly integrate a Linux system with AD is to use the realmd service. It allows callers to configure network authentication and domain membership in a standard way. The realmd service automatically discovers information about accessible domains and realms and does not require advanced configuration to join a domain or realm.

You can use SSSD for both direct and indirect integration with AD and it allows you to switch from one integration approach to another. Direct integration is a simple way to introduce RHEL systems to an AD environment. However, as the share of RHEL systems grows, your deployments usually need a better centralized management of the identity-related policies such as host-based access control, sudo, or SELinux user mappings. Initially, you can maintain the configuration of these aspects of the RHEL systems in local configuration files. However, with a growing number of systems, distribution and management of the configuration files is easier with a provisioning system such as Red Hat Satellite. When direct integration does not scale anymore, you should consider indirect integration. For more information on moving from direct integration (RHEL clients are in the AD domain) to indirect integration (IdM with trust to AD), see Moving RHEL clients from AD domain to IdM Server.
For more information on which type of integration fits your use case, see *Deciding between indirect and direct integration*.

Additional resources

- The `realm(8)` man page.
- The `sssd-ad(5)` man page.
- The `sssd(8)` man page.

### 1.2. SUPPORTED WINDOWS PLATFORMS FOR DIRECT INTEGRATION

You can directly integrate your RHEL system with Active Directory forests that use the following forest and domain functional levels:

Direct integration has been tested on the following supported operating systems:

- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2

**NOTE**

### 1.3. CONNECTING DIRECTLY TO AD

This section describes how to integrate directly with AD using either ID mapping or POSIX attributes.

- Connecting a RHEL system to an AD domain
- Options for integrating with AD: using ID mapping or POSIX attributes
- Connecting to AD using POSIX attributes defined in Active Directory
- Connecting to multiple domains in different AD forests with SSSD

#### 1.3.1. Connecting a RHEL system to an AD Domain

This procedure describes how to connect a RHEL system to an AD domain using SSSD.

**Prerequisites**

- Ensure that none of the following ports are blocked to the AD domain controllers.

<p>| Table 1.1. Ports Required for Direct Integration of Linux Systems into AD Using SSSD |</p>
<table>
<thead>
<tr>
<th>Service</th>
<th>Port</th>
<th>Protocol</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS</td>
<td>53</td>
<td>UDP and TCP</td>
<td></td>
</tr>
<tr>
<td>LDAP</td>
<td>389</td>
<td>UDP and TCP</td>
<td></td>
</tr>
<tr>
<td>Kerberos</td>
<td>88</td>
<td>UDP and TCP</td>
<td></td>
</tr>
<tr>
<td>Kerberos</td>
<td>464</td>
<td>UDP and TCP</td>
<td>Used by kadmin for setting and changing a password</td>
</tr>
<tr>
<td>LDAP Global Catalog</td>
<td>3268</td>
<td>TCP</td>
<td>If the id_provider = ad option is being used</td>
</tr>
<tr>
<td>NTP</td>
<td>123</td>
<td>UDP</td>
<td>Optional</td>
</tr>
</tbody>
</table>

- Ensure that you are using the AD domain controller server for DNS.
- Verify that the system time on both systems is synchronized. This ensures that Kerberos is able to work correctly.

**Procedure**

1. Install the following packages:

   ```bash
   # yum install realmd oddjob oddjob-mkhomedir sssd adcli krb5-workstation
   ```

2. Configure the local RHEL system with the `realm join` command. The `realmd` suite edits all required configuration files automatically. For example, for a domain named `ad.example.com`:

   ```bash
   # realm join ad.example.com
   ```

**Verification steps**

- Display an AD user details, such as the administrator user:

  ```bash
  # getent passwd administrator@ad.example.com
  administrator@ad.example.com:*:1450400500:1450400513:Administrator:/home/administrator@ad.example.com:/bin/bash
  ```

**Additional resources**

- See the `realm(8)` man page.
- See the `nmcli(1)` man page.
1.3.2. Options for integrating with AD: using ID mapping or POSIX attributes

Linux and Windows systems use different identifiers for users and groups:

- Linux uses user IDs (UID) and group IDs (GID). See Managing Users and Groups in Configuring Basic System Settings. Linux UIDs and GIDs are compliant with the POSIX standard.
- Windows use security IDs (SID).

**IMPORTANT**

Do not use the same user name in Windows and Linux.

To authenticate to a RHEL system as an AD user, you must have a UID and GID assigned. SSSD provides the option to integrate with AD either using ID mapping or POSIX attributes. The default is to use ID mapping.

### 1.3.2.1. Automatically generate new UIDs and GIDs for AD users

SSSD can use the SID of an AD user to algorithmically generate POSIX IDs in a process called ID mapping. ID mapping creates a map between SIDs in AD and IDs on Linux.

- When SSSD detects a new AD domain, it assigns a range of available IDs to the new domain.
- When an AD user logs in to an SSSD client machine for the first time, SSSD creates an entry for the user in the SSSD cache, including a UID based on the user’s SID and the ID range for that domain.
- Because the IDs for an AD user are generated in a consistent way from the same SID, the user has the same UID and GID when logging in to any Red Hat Enterprise Linux system.

See Connecting a RHEL system to an AD Domain using SSSD.

**NOTE**

When all client systems use SSSD to map SIDs to Linux IDs, the mapping is consistent. If some clients use different software, choose one of the following:

- Ensure that the same mapping algorithm is used on all clients.
- Use explicit POSIX attributes defined in AD.

### 1.3.2.2. Use POSIX attributes defined in AD

AD can create and store POSIX attributes, such as `uidNumber`, `gidNumber`, `unixHomeDirectory`, or `loginShell`.

When using ID mapping described above, SSSD creates new UIDs and GIDs, which overrides the values defined in AD. To keep the AD-defined values, you must disable ID mapping in SSSD.

See Connecting to AD using POSIX attributes defined in Active Directory.

### 1.3.3. Connecting to AD using POSIX attributes defined in Active Directory

For best performance, publish the POSIX attributes to the AD global catalog. If POSIX attributes are not present in the global catalog, SSSD connects to the individual domain controllers directly on the LDAP port.

**Prerequisites**

- Ensure that none of the following ports are blocked to the AD domain controllers.

<table>
<thead>
<tr>
<th>Table 1.2. Ports Required for Direct Integration of Linux Systems into AD Using SSSD</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Service</strong></td>
</tr>
<tr>
<td>DNS</td>
</tr>
<tr>
<td>LDAP</td>
</tr>
<tr>
<td>Kerberos</td>
</tr>
<tr>
<td>Kerberos</td>
</tr>
<tr>
<td>LDAP Global Catalog</td>
</tr>
<tr>
<td>NTP</td>
</tr>
</tbody>
</table>

- Ensure that you are using the AD domain controller server for DNS.
- Verify that the system time on both systems is synchronized. This ensures that Kerberos is able to work correctly.

**Procedure**

1. Install the following packages:

   ```
   # yum install realmd oddjob oddjob-mkhomedir sssd adcli krb5-workstation
   ```

2. Configure the local RHEL system with ID mapping disabled using the **realm join** command with the **--automatic-id-mapping=no** option. The **realm** suite edits all required configuration files automatically. For example, for a domain named **ad.example.com**:

   ```
   # realm join --automatic-id-mapping=no ad.example.com
   ```

3. If you already joined a domain, you can manually disable ID Mapping in SSSD:
   a. Open the **/etc/sssd/sssd.conf** file.
   b. In the AD domain section, add the **ldap_id_mapping = false** setting.
   c. Remove the SSSD caches:
**NOTE**
You must have the relevant POSIX attributes (*uidNumber*, *gidNumber*, *unixHomeDirectory*, and *loginShell*) configured for the users in AD.

**Verification steps**
- Display an AD user details, such as the administrator user:

```
# getent passwd administrator@ad.example.com
administrator@ad.example.com:*:10000:10000:Administrator:/home/Administrator:/bin/bash
```

**Additional resources**
- For further details about ID mapping and the `ldap_id_mapping` parameter, see the *sssd-ldap*(8) man page.

### 1.3.4. Connecting to multiple domains in different AD forests with SSSD

This procedure describes joining and authenticating to multiple Active Directory (AD) domains in different forests where there is no trust between them.

This example describes joining two domains, `addomain1.com` and `addomain2.com`. Use `realmd` to join the first domain and automatically configure SSSD, Kerberos, and other utilities for that domain. Use `adcli` to join additional domains, and manually edit configuration files to include those domains.

**Prerequisites**
- Ensure that none of the following ports are blocked to the AD domain controllers.

<table>
<thead>
<tr>
<th>Service</th>
<th>Port</th>
<th>Protocol</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS</td>
<td>53</td>
<td>UDP and TCP</td>
<td></td>
</tr>
<tr>
<td>LDAP</td>
<td>389</td>
<td>UDP and TCP</td>
<td></td>
</tr>
<tr>
<td>Kerberos</td>
<td>88</td>
<td>UDP and TCP</td>
<td></td>
</tr>
<tr>
<td>Kerberos</td>
<td>464</td>
<td>UDP and TCP</td>
<td>Used by kadmin for setting and changing a password</td>
</tr>
</tbody>
</table>
Ensure that you are using the AD domain controller server for DNS.

- Verify that the system time on both systems is synchronized. This ensures that Kerberos is able to work correctly.
- Ensure you have credentials for an AD administrator account in each AD domain which has rights to join machines to that domain

**Procedure**

1. Install required packages.
   ```bash
   # yum install sssd realmd adcli samba-common-tools oddjob oddjob-mkhomedir
   ```

2. Use `realmd` to join the first AD domain, `addomain1.com`.
   ```bash
   # realm join ADDOMAIN1.COM
   ```

3. Rename the system keytab to a unique name.
   ```bash
   # mv /etc/krb5.keytab /etc/addomain1.com.krb5.keytab
   ```

4. Use `adcli` to join the second AD domain, and any additional domains. Use the `-K` option to specify a unique path for the Kerberos keytab where host credentials will be written.
   ```bash
   # adcli join -D dc2.addomain2.com -K /etc/addomain2.com.krb5.keytab
   ```

5. Modify `/etc/krb5.conf`.
   - Add the `includedir` option to include SSSD configuration files.
   - Enable DNS lookups for AD Domain Controllers with the `dns_lookup_kdc` option.
   ```ini
   includedir /var/lib/sss/pubconf/krb5.include.d/
   
   [logging]
   default = FILE:/var/log/krb5libs.log
   kdc = FILE:/var/log/krb5kdc.log
   admin_server = FILE:/var/log/kadmind.log
   
   [libdefaults]
   default_realm = ADDOMAIN1.COM
   ```
6. Modify `/etc/sssd/sssd.conf` to include information about all AD domains in use.

```bash
[sssd]
services = nss, pam
config_file_version = 2
domains = addomain1.com, addomain2.com

[domain/addomain1.com]
id_provider = ad
access_provider = ad
krb5_keytab = /etc/addomain1.com.krb5.keytab
ldap_krb5_keytab = /etc/addomain1.com.krb5.keytab
ad_server = dc1.addomain1.com
ad_maximum_machine_account_password_age = 0
use_fully_qualified_names = true
default_shell=/bin/bash
override_homedir=/home/%d/%u

[domain/addomain2.com]
id_provider = ad
access_provider = ad
krb5_keytab = /etc/addomain2.com.krb5.keytab
ldap_krb5_keytab = /etc/addomain2.com.krb5.keytab
ad_server = dc2.addomain2.com
ad_maximum_machine_account_password_age = 0
use_fully_qualified_names = true
default_shell=/bin/bash
override_homedir=/home/%d/%u

[nss]
[pam]
```

- For each domain section, specify the path to the Kerberos keytab that corresponds to each domain with the `krb5_keytab` and `ldap_krb5_keytab` options.
  - Set `ad_maximum_machine_account_password_age = 0` to disable renewing host Kerberos keys.
  - Set `use_fully_qualified_names = true` to differentiate users from different domains.
  - Set `override_homedir = /home/%d/%u` so users (`%u`) from different domains (`%d`) each receive unique home directories. For example, the home directory for user `linuxuser@addomain1.com` is `/home/addomain1.com/linuxuser`

7. SSH retrieves host keys from the system keytab and provides single sign-on functionality through GSSAPI/Kerberos. If you would like to use single sign-on, copy all current Kerberos host keys to the `/etc/kbr5.keytab` system keytab.
8. Restart and enable the SSSD service.

```bash
# systemctl restart sssd
# systemctl enable sssd
```

**Verification steps**

1. Display user details for users from each AD domain:

```bash
# id administrator@addomain1.com
uid=1240800500(administrator@addomain1.com) gid=1240800513(domain users@addomain1.com) groups=1240800513(domain users@addomain1.com),1240800512(domain admins@addomain1.com),1240800518(schema admins@addomain1.com),1240800520(group policy creator owners@addomain1.com),1240800572(denied rodc password replication group@addomain1.com),1240800519(enterprise admins@addomain1.com)

# id administrator@addomain2.com
uid=1013800500(administrator@addomain2.com) gid=1013800500(administrator@addomain2.com) groups=1013800500(administrator@addomain2.com),1013800513(domain users@addomain2.com)
```

2. Log in as a user from each domain and verify the correct home directory is created for the user.

```bash
# ssh administrator@addomain1.com@localhost
Creating directory '/home/addomain1.com/administrator'.
$ pwd
/home/addomain1.com/administrator

# ssh administrator@addomain2.com@localhost
Creating directory '/home/addomain2.com/administrator'.
$ pwd
/home/addomain2.com/administrator
```

### 1.4. HOW THE AD PROVIDER HANDLES TRUSTED DOMAINS

This section describes how SSSD handles trusted domains if you set `id_provider = ad` in the `/etc/sssd/sssd.conf` file.

- SSSD only supports domains in a single AD forest. If SSSD requires access to multiple domains from multiple forests, consider using IPA with trusts (preferred) or the `winbindd` service instead of SSSD.
By default, SSSD discovers all domains in the forest and, if a request for an object in a trusted domain arrives, SSSD tries to resolve it.

If the trusted domains are not reachable or geographically distant, which makes them slow, you can set the `ad_enabled_domains` parameter in `/etc/sssd/sssd.conf` to limit from which trusted domains SSSD resolves objects.

By default, you must use fully-qualified user names to resolve users from trusted domains.

**Additional resources**

- The `sssd.conf(5)` man page.

# 1.5. REALM COMMANDS

The `realm` system has two major task areas:

- Managing system enrollment in a domain.
- Controlling which domain users are allowed to access local system resources.

In `realm` use the command line tool `realm` to run commands. Most `realm` commands require the user to specify the action that the utility should perform, and the entity, such as a domain or user account, for which to perform the action.

**Table 1.4. realmd Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Realm Commands</strong></td>
<td></td>
</tr>
<tr>
<td>discover</td>
<td>Run a discovery scan for domains on the network.</td>
</tr>
<tr>
<td>join</td>
<td>Add the system to the specified domain.</td>
</tr>
<tr>
<td>leave</td>
<td>Remove the system from the specified domain.</td>
</tr>
<tr>
<td>list</td>
<td>List all configured domains for the system or all discovered and configured domains.</td>
</tr>
<tr>
<td><strong>Login Commands</strong></td>
<td></td>
</tr>
<tr>
<td>permit</td>
<td>Enable access for specific users or for all users within a configured domain to access the local system.</td>
</tr>
<tr>
<td>deny</td>
<td>Restrict access for specific users or for all users within a configured domain to access the local system.</td>
</tr>
</tbody>
</table>

For more information about the `realm` commands, see the `realm(8)` man page.
CHAPTER 2. MANAGING DIRECT CONNECTIONS TO AD

This section describes how to modify and manage your connection to Active Directory.

Prerequisites

- You have connected your RHEL system to the Active Directory domain.

2.1. MODIFYING THE DEFAULT KERBEROS HOST KEYTAB RENEWAL INTERVAL

SSSD automatically renews the Kerberos host keytab file in an AD environment if the adcli package is installed. The daemon checks daily if the machine account password is older than the configured value and renews it if necessary.

The default renewal interval is 30 days. To change the default, follow the steps in this procedure.

Procedure

1. Add the following parameter to the AD provider in your /etc/sssd/sssd.conf file:

   ad_maximum_machine_account_password_age = value_in_days

2. Restart SSSD:

   # systemctl restart sssd

3. To disable the automatic Kerberos host keytab renewal, set

   ad_maximum_machine_account_password_age = 0.

Additional resources

- The adcli(8) man page.
- The sssd.conf(5) man page.

2.2. REMOVING A RHEL SYSTEM FROM AN AD DOMAIN

This procedure describes how to remove a RHEL system from an Active Directory (AD) domain.

Procedure

1. Remove a system from an identity domain using the realm leave command. The command removes the domain configuration from SSSD and the local system.

   # realm leave ad.example.com
NOTE

When a client leaves a domain, the account is not deleted from AD; the local client configuration is only removed. If you want to delete the AD account, run the command with the `--remove` option. You are prompted for your user password and you must have the rights to remove an account from Active Directory.

2. Use the `-U` option with the `realm leave` command to specify a different user to remove a system from an identity domain.

   By default, the `realm leave` command is executed as the default administrator. For AD, the administrator account is called `Administrator`. If a different user was used to join to the domain, it might be required to perform the removal as that user.

   ```
   # realm leave [ad.example.com] -U [AD.EXAMPLE.COM\user]
   ```

   The command first attempts to connect without credentials, but it prompts for a password if required.

Verification steps

- Verify the domain is no longer configured:

  ```
  # realm discover [ad.example.com]
  ad.example.com
  type: kerberos
  realm-name: EXAMPLE.COM
  domain-name: example.com
  configured: no
  server-software: active-directory
  client-software: sssd
  required-package: oddjob
  required-package: oddjob-mkhomedir
  required-package: sssd
  required-package: adcli
  required-package: samba-common-tools
  ```

Additional resources

- See the `realm(8)` man page.

2.3. MANAGING LOGIN PERMISSIONS FOR DOMAIN USERS

By default, domain-side access control is applied, which means that login policies for Active Directory (AD) users are defined in the AD domain itself. This default behavior can be overridden so that client-side access control is used. With client-side access control, login permission is defined by local policies only.

If a domain applies client-side access control, you can use the `realmd` to configure basic allow or deny access rules for users from that domain.

NOTE

Access rules either allow or deny access to all services on the system. More specific access rules must be set on a specific system resource or in the domain.
2.3.1. Enabling access to users within a domain

This section describes how to enable access to users within a domain.

**IMPORTANT**

It is safer to only allow access to specific users or groups than to deny access to some, while enabling it to everyone else. Therefore, it is not recommended to allow access to all by default while only denying it to specific users with realm permit -x. Instead, Red Hat recommends maintaining a default no access policy for all users and only grant access to selected users using realm permit.

**Prerequisites**

- Your RHEL system is a member of the Active Directory domain.

**Procedure**

1. Grant access to all users:

   `# realm permit --all`

2. Grant access to specific users:

   `$ realm permit aduser01@example.com`
   `$ realm permit 'AD.EXAMPLE.COM\aduser01'`

Currently, you can only allow access to users in primary domains and not to users in trusted domains. This is due to the fact that user login must contain the domain name and SSSD cannot currently provide `realmd` with information about available child domains.

**Verification steps**

1. Use SSH to log in to the server as the `aduser01@example.com` user:

   `$ ssh aduser01@example.com@server_name`
   `[aduser01@example.com@server_name ~]$`

2. Use the `ssh` command a second time to access the same server, this time as the `aduser02@example.com` user:

   `$ ssh aduser02@example.com@server_name`
   Authentication failed.

Notice how the `aduser02@example.com` is denied access to the system. You have granted the permission to log in to the system to the `aduser01@example.com` user only. All other users from that Active Directory domain are rejected because of the specified login policy.
NOTE

If you set `use_fully_qualified_names` to true in the `sssd.conf` file, all requests must use the fully qualified domain name. However, if you set `use_fully_qualified_names` to false, it is possible to use the fully-qualified name in the requests, but only the simplified version is displayed in the output.

Additional resources

- See the `realm(8)` man page.

2.3.2. Denying access to users within a domain

This section describes how to deny access to all users within a domain.

IMPORTANT

It is safer to only allow access to specific users or groups than to deny access to some, while enabling it to everyone else. Therefore, it is not recommended to allow access to all by default while only denying it to specific users with `realm permit -x`. Instead, Red Hat recommends maintaining a default no access policy for all users and only grant access to selected users using `realm permit`.

Prerequisites

- Your RHEL system is a member of the Active Directory domain.

Procedure

1. Deny access to all users within the domain:

   ```
   # realm deny --all
   ```

   This command prevents `realm` accounts from logging into the local machine. Use `realm permit` to restrict login to specific accounts.

2. Verify that the domain user’s `login-policy` is set to `deny-any-login`:

   ```
   [root@replica1 ~]# realm list
   example.net
   type: kerberos
   realm-name: EXAMPLE.NET
   domain-name: example.net
   configured: kerberos-member
   server-software: active-directory
   client-software: sssd
   required-package: oddjob
   required-package: oddjob-mkhomedir
   required-package: sssd
   required-package: adcli
   required-package: samba-common-tools
   login-formats: %U@example.net
   login-policy: deny-any-login
   ```
3. Deny access to specific users by using the `-x` option:

```
$ realm permit -x 'AD.EXAMPLE.COM\aduser02'
```

**Verification steps**

- Use SSH to log in to the server as the `aduser01@example.net` user.

```
$ ssh aduser01@example.net@server_name
Authentication failed.
```

**NOTE**

If you set `use_fully_qualified_names` to true in the `sssd.conf` file, all requests must use the fully qualified domain name. However, if you set `use_fully_qualified_names` to false, it is possible to use the fully-qualified name in the requests, but only the simplified version is displayed in the output.

**Additional resources**

- See the `realm(8)` man page.
