Abstract

This document provides the users and administrators with necessary information about configuring their workstations on the Linux kernel level. Such adjustments bring performance enhancements, easier troubleshooting or optimized system.
# Table of Contents

PROVIDING FEEDBACK ON RED HAT DOCUMENTATION ........................................ 6

CHAPTER 1. THE LINUX KERNEL RPM .............................................................. 7
  1.1. WHAT AN RPM IS ................................................................................. 7
     Types of RPM packages ............................................................................ 7
  1.2. THE LINUX KERNEL RPM PACKAGE OVERVIEW ............................ 7

CHAPTER 6. APPLYING KERNEL PATCHES WITH KPATCH .................................. 39

6.1. ACCESS TO KERNEL PATCHES                                             39
6.2. COMPONENTS OF KPATCH                                                39
6.3. HOW KPATCH WORKS                                                    40
6.4. INSTALLING KPATCH MODULES                                           40
   Prerequisites                                                          40
   Procedure                                                              41
6.5. REMOVING KPATCH MODULES                                             42
   Procedure                                                              42
6.6. KPATCH SUPPORT                                                      42
6.7. SUPPORT FOR THIRD-PARTY LIVE PATCHING                              43
6.8. LIMITATIONS OF KPATCH                                               43

CHAPTER 7. SETTING LIMITS FOR APPLICATIONS ........................................ 44

7.1. WHAT ARE CONTROL GROUPS                                              44
    7.1.1. Control groups version 1                                        44
    7.1.2. Control groups version 2                                        44
       Additional resources                                                45
7.2. WHAT ARE KERNEL RESOURCE CONTROLLERS                                 45
   Additional resources                                                  46
7.3. WHAT ARE NAMESPACES                                                  46
   Additional resources                                                  47
7.4. USING CONTROL GROUPS THROUGH A VIRTUAL FILE SYSTEM                  47
    7.4.1. Setting memory limits to applications through cgroups-v1      47
       Prerequisites                                                       47
       Procedure                                                           47
       Additional resources                                                48

CHAPTER 8. ANALYZING SYSTEM PERFORMANCE WITH BPF COMPILER COLLECTION ....... 50

8.1. BCC                                                                 50
   Additional resources                                                  50
8.2. INSTALLING BCC                                                      50
   Prerequisites                                                          50
   Procedure                                                              50
8.3. USING SELECTED BCC-TOOLS FOR PERFORMANCE ANALYSES                    51
   Prerequisites                                                          51
   Using execsnoop to examine the system processes                        51
   Using opensnoop to track what files a command opens                    52
Using biotop to examine the I/O operations on the disk
Using xfsslower to expose unexpectedly slow file system operations
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Please let us know how we could make it better. To do so:

- For simple comments on specific passages, make sure you are viewing the documentation in the Multi-page HTML format. Highlight the part of text that you want to comment on. Then, click the Add Feedback pop-up that appears below the highlighted text, and follow the displayed instructions.

- For submitting more complex feedback, create a Bugzilla ticket:
  1. Go to the Bugzilla website.
  2. As the Component, use Documentation.
  3. Fill in the Description field with your suggestion for improvement. Include a link to the relevant part(s) of documentation.
  4. Click Submit Bug.
CHAPTER 1. THE LINUX KERNEL RPM

The following sections describe the Linux kernel RPM package provided and maintained by Red Hat.

1.1. WHAT AN RPM IS

An RPM package is a file containing other files and their metadata (information about the files that are needed by the system).

Specifically, an RPM package consists of the cpio archive.

The cpio archive contains:

- Files
- RPM header (package metadata)
  The rpm package manager uses this metadata to determine dependencies, where to install files, and other information.

Types of RPM packages

There are two types of RPM packages. Both types share the file format and tooling, but have different contents and serve different purposes:

- Source RPM (SRPM)
  An SRPM contains source code and a SPEC file, which describes how to build the source code into a binary RPM. Optionally, the patches to source code are included as well.

- Binary RPM
  A binary RPM contains the binaries built from the sources and patches.

1.2. THE LINUX KERNEL RPM PACKAGE OVERVIEW

The kernel RPM is a meta package that does not contain any files, but rather ensures that the following sub-packages are properly installed:

- kernel-core - contains a minimal number of kernel modules needed for core functionality. This sub-package alone could be used in virtualized and cloud environments to provide a Red Hat Enterprise Linux 8 kernel with a quick boot time and a small disk size footprint.

- kernel-modules - contains further kernel modules.

- kernel-modules-extra - contains kernel modules for rare hardware.

The smaller number of kernel sub-packages aims to provide a reduced maintenance surface to system administrators especially in virtualized and cloud environments.

1.3. DISPLAYING CONTENTS OF THE KERNEL PACKAGE

The following procedure describes how to view the contents of the kernel package and its sub-packages without installing them using the rpm command.

Prerequisites

- Obtained kernel, kernel-core, kernel-modules, kernel-modules-extra RPM packages for your CPU architecture
Procedure

- List modules for `kernel`

  $$\texttt{rpm -qlp <kernel\_rpm> (contains no files)}$$

- List modules for `kernel-core`

  $$\texttt{rpm -qlp <kernel-core\_rpm> ($lib/modules/4.18.0-80.el8.x86_64/kernel/fs/udf/udf.ko.xz)}$$

- List modules for `kernel-modules`

  $$\texttt{rpm -qlp <kernel-modules\_rpm> ($lib/modules/4.18.0-80.el8.x86_64/kernel/drivers/infiniband/hw/mlx4/mlx4_ib.ko.xz)}$$

- List modules for `kernel-modules-extra`

  $$\texttt{rpm -qlp <kernel-modules-extra\_rpm> ($lib/modules/4.18.0-80.el8.x86_64/extra/net/sched/sch_gred.ko.xz)}$$

Additional resources

- For information on how to use the `rpm` command on already installed `kernel` RPM, including its sub-packages, see the `rpm(8)` manual page.

- Introduction to `RPM packages`

- The Linux kernel RPM package overview
CHAPTER 2. UPDATING KERNEL WITH YUM

The following sections bring information about the Linux kernel provided and maintained by Red Hat (Red Hat kernel), and how to keep the Red Hat kernel updated. As a consequence, the operating system will have all the latest bug fixes, performance enhancements, and patches ensuring compatibility with new hardware.

2.1. WHAT IS KERNEL

A kernel is a core part of a Linux operating system, which manages the system resources, and provides interface between hardware and software applications. The Red Hat kernel is custom-build and based on the upstream Linux kernel, with focus on stability and compatibility with the latest technologies and hardware.

Before Red Hat releases a new kernel version, the kernel needs to pass a set of rigorous quality assurance tests.

The Red Hat kernels are packaged in the RPM format so that they are easy to upgrade and verify by the yum package manager.

![WARNING]

Custom kernels are not supported by Red Hat.

2.2. WHAT IS YUM

This section refers to description of the yum package manager.

Additional resources

- For more information on yum see the relevant sections of Configuring basic system settings.

2.3. UPDATING KERNEL

The following procedure describes how to update the kernel using the yum package manager.

Procedure

1. To update the kernel, use the following:

   ```
   # yum update kernel
   ```

   This command updates the kernel along with all dependencies to the latest available version.

2. Reboot your system for the changes to take effect.
When upgrading from Red Hat Enterprise Linux 7 to Red Hat Enterprise Linux 8, Red Hat strongly recommends that you reinstall the whole OS. While it is theoretically possible to update all necessary packages, it could easily result in the system being unusable.

2.4. INSTALLING KERNEL

The following procedure describes how to update or install the kernel using the **yum** package manager.

**Procedure**

- To install a specific kernel version, use the following:

  ```bash
  # yum install kernel-{version}
  ```

**NOTE**

The **yum** package manager always **installs** a new kernel instead of replacing the current one, which could potentially leave your system unbootable.

**Additional resources**

- For a list of available kernels, refer to this [Red Hat labs page](https://www.redhat.com/en/labs).
- For a list of release dates of specific kernel versions, see [this article](https://example.com).
CHAPTER 3. CONFIGURING KERNEL COMMAND LINE PARAMETERS

As a system administrator, you can configure the kernel command line parameters to ensure that they are set and loaded as soon as possible. Also, certain kernel command line parameters are only adjustable in this way.

**IMPORTANT**

Be careful when configuring kernel command line parameters on a production system. Haphazard changes may render the kernel unstable, and could cause the system to fail to boot on reboot for all kernels. For this reason, be knowledgeable and sure that you are using the valid options before attempting to change any values.

### 3.1. WHAT ARE BOOT ENTRIES

A boot entry is a collection of options forming together a configuration file, which is usually tied to a particular kernel version. In practice, you have at least as many boot entries as your system has installed kernels. The boot entry configuration file is located in the `/boot/loader/entries/` directory and can look like this:

```bash
6f9cc9cb7d7845d49698c9537337cedc-4.18.0-5.el8.x86_64.conf
```

The file name above consists of a machine ID stored in the `/etc/machine-id` file, and a kernel version.

The boot entry configuration file carries, among others, information about kernel version, initial ramdisk image, and the `kernelopts` variable, which contains kernel command line parameters. The contents of a boot entry config can be seen below:

```
title Red Hat Enterprise Linux (4.18.0-74.el8.x86_64) 8.0 (Ootpa)
version 4.18.0-74.el8.x86_64
linux /vmlinuz-4.18.0-74.el8.x86_64
initrd /initramfs-4.18.0-74.el8.x86_64.img $tuned_initrd
options $kernelopts $tuned_params
id rhel-20190227183418-4.18.0-74.el8.x86_64
grub_users $grub_users
grub_arg --unrestricted
grub_class kernel
```

### 3.2. WHAT ARE KERNEL COMMAND LINE PARAMETERS

This module explains the concept of kernel command line parameters and their role in the system administration.

The kernel command line parameters, also known as kernel arguments, are used for boot time configuration of:

- The Linux kernel
- The initial RAM disk
- The user space features
The kernel command line parameters are often used to overwrite the default values and for informing
the kernel about hardware parameters where the kernel would have problems to obtain such
information.

By default, the kernel command line parameters for systems using the GRUB2 bootloader are defined in
the kernelopts variable of the /boot/grub2/grubenv file for all kernel boot entries.

NOTE

For IBM Z, the kernel command line parameters are stored in the boot entry config file
because the zipl bootloader does not support environment variables. Thus kernelopts
cannot be used.

Additional resources

- For more information about what kernel command line parameters you can modify, install the
  man-pages package and see kernel-command-line(7), bootparam(7) and dracut.cmdline(7)
  manual pages.

3.3. WHAT IS GRUBBY

grubby is a utility for manipulating bootloader-specific configuration files.

You can use grubby also for changing the default boot entry, and for adding/removing arguments from
a GRUB2 menu entry.

For more details see the grubby(8) manual page.

3.4. SETTING KERNEL COMMAND LINE PARAMETERS

This section explains how to change kernel command line parameters on the AMD64 and Intel 64
architectures, the 64-bit ARM architectures, and the little-endian variant of IBM Power Systems.

3.4.1. Changing kernel command line parameters for all boot entries

This procedure describes how to change kernel command line parameters for all boot entries on your
system.

Prerequisites

- Introduction to kernel command line parameters.

Procedure

1. To add a new parameter, use the grub2-editenv command as in the following example:

   ```
   # grub2-editenv - set "$(grub2-editenv - list | grep kernelopts) <NEW_PARAMETER>
   ```

   This command appends an extra argument to the entire parameter list in the global variable
   kernelopts. As a result, the kernel command line parameter NEW_PARAMETER is set for all
   boot entries on your system.

2. To remove a parameter, use the following command:
3. Reboot your system for the changes to take effect.

As a result, the boot loader is reconfigured, and the kernel command line parameters that you specified are applied.

NOTE

The alternative way to update the kernel command line parameters is to edit the \texttt{GRUB\_CMDLINE\_LINUX} parameter in the /\texttt{etc/default/grub}\ file and execute the \texttt{# grub2-mkconfig -o /boot/grub2/grub.cfg} command to update the GRUB2 configuration file.

Additional resources

- For more information on how to modify the kernel parameters using the GRUB2 configuration file, see \textit{Editing a Menu Entry}.

3.4.2. Changing kernel command line parameters for a single boot entry

This procedure describes how to change kernel command line parameters for a single boot entry on your system.

Prerequisites

- Introduction to \texttt{kernel command line parameters}.

- \texttt{grubby(8)} manual page.

Procedure

- To add a parameter execute the following:

  \texttt{# grubby --update-kernel=/boot/vmlinuz-$\{uname -r\} --args="<NEW\_PARAMETER>"}

- To remove a parameter use the following:

  \texttt{# grubby --update-kernel=/boot/vmlinuz-$\{uname -r\} --remove-args="<PARAMETER\_TO\_REMOVE>"}

NOTE

By default, there is the \texttt{options} parameter for each kernel boot entry, which is set to the \texttt{kernelopts} variable. This variable is defined in the \texttt{/boot/grub2/grubenv} configuration file.
IMPORTANT

When you modify a specific boot entry, the contents of the edited `kernelopts` are stored in the relevant kernel boot entry in 
`/boot/loader/entries/<RELEVANTKERNEL_BOOT_ENTRY.conf>` and have their own command line now. As a result, any additional changes to `kernelopts` have no affect on that specific kernel boot entry.

Additional resources

- For further examples on how to use `grubby` see [grubby tool](#).
CHAPTER 4. CONFIGURING KERNEL TUNABLES

As a system administrator, you can configure kernel tunables for various reasons, such as improving system performance. This section describes how to configure kernel tunables by using the `sysctl` command and by modifying the configuration files in the `/etc/sysctl.d/` and `/proc/sys/` directories.

4.1. WHAT ARE KERNEL TUNABLES

Kernel tunables are kernel parameters, which are addressed by the `sysctl` command or through the virtual file system mounted at the `/proc/sys/` directory. It is also possible to use the configuration files in the `/etc/sysctl.d/` directory to adjust the tunables. Kernel parameters can be adjusted while the system is running. There is no requirement to reboot or recompile the kernel for changes to take effect.

Tunables are divided into classes by the kernel subsystem. Red Hat Enterprise Linux has the following classes of tunables:

<table>
<thead>
<tr>
<th>Tunable class</th>
<th>Subsystem</th>
</tr>
</thead>
<tbody>
<tr>
<td>abi</td>
<td>Execution domains and personalities</td>
</tr>
<tr>
<td>crypto</td>
<td>Cryptographic interfaces</td>
</tr>
<tr>
<td>debug</td>
<td>Kernel debugging interfaces</td>
</tr>
<tr>
<td>dev</td>
<td>Device-specific information</td>
</tr>
<tr>
<td>fs</td>
<td>Global and specific file system tunables</td>
</tr>
<tr>
<td>kernel</td>
<td>Global kernel tunables</td>
</tr>
<tr>
<td>net</td>
<td>Network tunables</td>
</tr>
<tr>
<td>sunrpc</td>
<td>Sun Remote Procedure Call (NFS)</td>
</tr>
<tr>
<td>user</td>
<td>User Namespace limits</td>
</tr>
<tr>
<td>vm</td>
<td>Tuning and management of memory, buffers, and cache</td>
</tr>
</tbody>
</table>

**Additional resources**

- For more information about `sysctl`, see `sysctl(8)` manual pages.
- For more information about `/etc/sysctl.d/` see, `sysctl.d(5)` manual pages.

4.2. SETTING KERNEL TUNABLES
**IMPORTANT**

Configuring kernel tunables on a production system requires careful planning. Unplanned changes may render the kernel unstable, requiring a system reboot. Verify that you are using valid options before changing any kernel values.

### 4.2.1. Configuring kernel tunables temporarily with sysctl

The following procedure describes how to use the `sysctl` command to temporarily set kernel tunables. The command is also useful for listing and filtering tunables.

**Prerequisites**

- Kernel tunables introduction
- Root permissions

**Procedure**

1. To list all tunables, use the following:
   
   ```bash
   # sysctl -a
   ```

   **NOTE**

   # sysctl -a displays kernel tunables, which can be adjusted at runtime and at boot time.

2. To configure a tunable temporarily, use the command as in the following example:

   ```bash
   # sysctl <TUNABLE_CLASS>.<TUNABLE>=<TARGET_VALUE>
   ```

   The sample command above changes the tunable value while the system is running. The changes take effect immediately, without a need for restart.

   **NOTE**

   The changes return back to default after your system reboots.

**Additional resources**

- For more information about `sysctl`, see `sysctl(8)` manual pages.
- To permanently modify kernel tunables, either use the `sysctl` command to write the values to the `/etc/sysctl.conf` file or make manual changes to the configuration files in the `/etc/sysctl.d/` directory.

### 4.2.2. Configuring kernel tunables permanently with sysctl

The following procedure describes how to use the `sysctl` command to permanently set kernel tunables.

**Prerequisites**

- Kernel tunables introduction
Root permissions

Procedure

1. To list all tunables, use the following:

   ```
   # sysctl -a
   ```

   The command displays all kernel tunables that can be configured at runtime.

2. To configure a tunable permanently:

   ```
   # sysctl -w <TUNABLE_CLASS>.<TUNABLE>=<TARGET_VALUE> /etc/sysctl.conf
   ```

   The sample command changes the tunable value and writes it to the `/etc/sysctl.conf` file, which overrides the default values of kernel tunables. The changes take effect immediately and persistently, without a need for restart.

   **NOTE**

   To permanently modify kernel tunables you can also make manual changes to the configuration files in the `/etc/sysctl.d/` directory.

Additional resources

- For more information about `sysctl`, see `sysctl(8)` and `sysctl.conf(5)` manual pages.
- For more information about using the configuration files in the `/etc/sysctl.d/` directory to make permanent changes to kernel tunables, see the `Using configuration files in /etc/sysctl.d/ to adjust kernel tunables` section.

4.2.3. Using configuration files in `/etc/sysctl.d/` to adjust kernel tunables

The following procedure describes how to manually modify configuration files in the `/etc/sysctl.d/` directory to permanently set kernel tunables.

Prerequisites

- Kernel tunables introduction
- Root permissions

Procedure

1. Create a new configuration file in `/etc/sysctl.d/`:

   ```
   # vim /etc/sysctl.d/<some_file.conf>
   ```

2. Include kernel tunables, one per line, as follows:

   ```
   <TUNABLE_CLASS>.<TUNABLE>=<TARGET_VALUE>
   <TUNABLE_CLASS>.<TUNABLE>=<TARGET_VALUE>
   ```

3. Save the configuration file.
4. Reboot the machine for the changes to take effect.
   
   • Alternatively, to apply changes without rebooting, execute:

   ```
   # sysctl -p /etc/sysctl.d/<some_file.conf>
   ```

   The command enables you to read values from the configuration file, which you created earlier.

Additional resources

• For more information about `sysctl`, see `sysctl(8)` manual pages.

• For more information about `/etc/sysctl.d/` see, `sysctl.d(5)` manual pages.

4.2.4. Configuring kernel tunables temporarily through `/proc/sys/`

The following procedure describes how to set kernel tunables temporarily through the files in the virtual file system `/proc/sys/` directory.

Prerequisites

• Kernel tunables introduction

• Root permissions

Procedure

1. Identify a kernel tunable you want to configure:

   ```
   # ls -l /proc/sys/<TUNABLE_CLASS>/
   ```

   The writable files returned by the command can be used to configure the kernel. The files with read-only permissions provide feedback on the current settings.

2. Assign a target value to the kernel tunable:

   ```
   # echo <TARGET_VALUE> > /proc/sys/<TUNABLE_CLASS>/<TUNABLE>
   ```

   The command makes configuration changes that will disappear once the system is restarted.

3. Optionally, verify the value of the newly set kernel tunable:

   ```
   # cat /proc/sys/<TUNABLE_CLASS>/<TUNABLE>
   ```

Additional resources

• To permanently modify kernel tunables, either use the `sysctl` command or make manual changes to the configuration files in the `/etc/sysctl.d/` directory.
5.1. WHAT IS KDUMP

kdump is a service providing a crash dumping mechanism. The service enables you to save the contents of the system’s memory for later analysis. kdump uses the kexec system call to boot into the second kernel (a capture kernel) without rebooting; and then captures the contents of the crashed kernel’s memory (a crash dump or a vmcore) and saves it. The second kernel resides in a reserved part of the system memory.

IMPORTANT

A kernel crash dump can be the only information available in the event of a system failure (a critical bug). Therefore, ensuring that kdump is operational is important in mission-critical environments. Red Hat advise that system administrators regularly update and test kexec-tools in your normal kernel update cycle. This is especially important when new kernel features are implemented.

5.2. INSTALLING KDUMP

In many cases, the kdump service is installed and activated by default on the new Red Hat Enterprise Linux installations. The Anaconda installer provides a screen for kdump configuration when performing an interactive installation using the graphical or text interface. The installer screen is titled Kdump and is available from the main Installation Summary screen, and only allows limited configuration - you can only select whether kdump is enabled and how much memory is reserved.

Some installation options, such as custom Kickstart installations, in some cases do not install or enable kdump by default. If this is the case on your system, follow the procedure below to install kdump.

Prerequisites

- An active Red Hat Enterprise Linux subscription.
- A repository containing the kexec-tools package for your system CPU architecture.
- Fulfilled kdump requirements.

Procedure

1. Execute the following command to check whether kdump is installed on your system:
$ rpm -q kexec-tools
Output if the package is installed:

kexec-tools-2.0.17-11.el8.x86_64

Output if the package is not installed:

package kexec-tools is not installed

2. Install **kdump** and other necessary packages by:

   # yum install kexec-tools

**IMPORTANT**

Starting with Red Hat Enterprise Linux 7.4 (kernel-3.10.0-693.el7) the **Intel IOMMU**
driver is supported with **kdump**. For prior versions, Red Hat Enterprise Linux 7.3 (kernel-
3.10.0-514[.XYZ].el7) and earlier, it is advised that **Intel IOMMU** support is disabled,
otherwise **kdump** kernel is likely to become unresponsive.

Additional resources

- Information about memory requirements for **kdump** is available in Section 5.5.1, "Memory
  requirements for **kdump**".

### 5.3. CONFIGURING KDUMP ON THE COMMAND LINE

#### 5.3.1. Configuring kdump memory usage

The memory reserved for the **kdump** feature is always reserved during the system boot. The amount of
memory is specified in the system’s Grand Unified Bootloader (GRUB) 2 configuration. The procedure
below describes how to configure the memory reserved for **kdump** through the command line.

**Prerequisites**

- **Fulfilled** **kdump** requirements.

**Procedure**

1. Edit the `/etc/default/grub` file using the root permissions.

2. Set the `crashkernel=` option to the required value.
   For example, to reserve 128 MB of memory, use the following:

   crashkernel=128M

   Alternatively, you can set the amount of reserved memory to a variable depending on the total
   amount of installed memory. The syntax for memory reservation into a variable is
   `crashkernel=<range1>:<size1>,<range2>:<size2>`. For example:

   crashkernel=512M-2G:64M,2G-:128M
The above example reserves 64 MB of memory if the total amount of system memory is 512 MB or higher and lower than 2 GB. If the total amount of memory is more than 2 GB, 128 MB is reserved for **kdump** instead.

- Offset the reserved memory.
  Some systems require to reserve memory with a certain fixed offset since crashkernel reservation is very early, and it wants to reserve some area for special usage. If the offset is set, the reserved memory begins there. To offset the reserved memory, use the following syntax:

  crashkernel=128M@16M

  The example above means that **kdump** reserves 128 MB of memory starting at 16 MB (physical address 0x01000000). If the offset parameter is set to 0 or omitted entirely, **kdump** offsets the reserved memory automatically. This syntax can also be used when setting a variable memory reservation as described above; in this case, the offset is always specified last (for example, crashkernel=512M-2G:64M,2G-:128M@16M).

3. Use the following command to update the GRUB2 configuration file:

   ```
   # grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

   **NOTE**
   The alternative way to configure memory for **kdump** is to append the `crashkernel=\<SOME_VALUE>\` parameter to the `kernelopts` variable with the `grub2-editenv` which will update all of your boot entries. Or you can use the `grubby` utility to update kernel command line parameters of just one entry.

**Additional resources**

- The `crashkernel=` option can be defined in multiple ways. The `auto` value enables automatic configuration of reserved memory based on the total amount of memory in the system, following the guidelines described in Section 5.5.1, “Memory requirements for kdump”.

- For more information on boot entries, `kernelopts`, and how to work with `grub2-editenv` and `grubby` see Chapter 3, Configuring kernel command line parameters.

### 5.3.2. Configuring the kdump target

When a kernel crash is captured, the core dump can be either stored as a file in a local file system, written directly to a device, or sent over a network using the NFS (Network File System) or SSH (Secure Shell) protocol. Only one of these options can be set at a time, and the default behavior is to store the vmcore file in the `/var/crash/` directory of the local file system.

**Prerequisites**

- Fulfilled **kdump** requirements.

**Procedure**

To change the local directory in which the core dump is to be saved, as root, edit the `/etc/kdump.conf` configuration file as described below.

1. Remove the hash sign ("#") from the beginning of the `#path /var/crash` line.
2. Replace the value with the intended directory path. For example:

```
path /usr/local/cores
```

**IMPORTANT**

In Red Hat Enterprise Linux 8, the directory defined as the kdump target using the `path` directive must exist when the `kdump` systemd service is started - otherwise the service fails. This behavior is different from earlier releases of Red Hat Enterprise Linux, where the directory was being created automatically if it did not exist when starting the service.

To write the file to a different partition, as `root`, edit the `/etc/kdump.conf` configuration file as described below.

1. Remove the hash sign ("#") from the beginning of the `#ext4` line, depending on your choice.
   - device name (the `#ext4 /dev/vg/lv_kdump` line)
   - file system label (the `#ext4 LABEL=/boot` line)
   - UUID (the `#ext4 UUID=03138356-5e61-4ab3-b58e-27507ac41937` line)
2. Change the file system type as well as the device name, label or UUID to the desired values. For example:

```
ext4 UUID=03138356-5e61-4ab3-b58e-27507ac41937
```

**IMPORTANT**

It is recommended to specify storage devices using a `LABEL=` or `UUID=`. Disk device names such as `/dev/sda3` are not guaranteed to be consistent across reboot.

**IMPORTANT**

When dumping to Direct Access Storage Device (DASD) on IBM Z hardware, it is essential that the dump devices are correctly specified in `/etc/dasd.conf` before proceeding.

To write the dump directly to a device:

1. Remove the hash sign ("#") from the beginning of the `#raw /dev/vg/lv_kdump` line.
2. Replace the value with the intended device name. For example:

```
raw /dev/sdb1
```

To store the dump to a remote machine using the `NFS` protocol:

1. Remove the hash sign ("#") from the beginning of the `#nfs my.server.com:/export/tmp` line.
2. Replace the value with a valid hostname and directory path. For example:
To store the dump to a remote machine using the SSH protocol:

1. Remove the hash sign ("#") from the beginning of the `#ssh user@my.server.com` line.
2. Replace the value with a valid username and hostname.
3. Include your SSH key in the configuration.
   - Remove the hash sign from the beginning of the `#sshkey /root/.ssh/kdump_id_rsa` line.
   - Change the value to the location of a key valid on the server you are trying to dump to. For example:

```
ssh john@penguin.example.com
sshkey /root/.ssh/mykey
```

Additional resources

- For a complete list of currently supported and unsupported targets sorted by type, see Section 5.5.3, “Supported kdump targets”.
- For information on how to configure an SSH server and set up a key-based authentication, see Configuring basic system settings in Red Hat Enterprise Linux.

5.3.3. Configuring the core collector

kdump uses a program specified as `core collector` to capture the vmcore. Currently, the only fully supported `core collector` is the `makedumpfile` utility. It has several configurable options, which affect the collection process. For example the extent of collected data, or whether the resulting vmcore should be compressed.

To enable and configure the `core collector`, follow the procedure below.

**Prerequisites**

- Fulfilled kdump requirements.

**Procedure**

1. As `root`, edit the `/etc/kdump.conf` configuration file and remove the hash sign ("#") from the beginning of the `#core_collector makedumpfile -l --message-level 1 -d 31`.

2. Add the `-c` parameter. For example:

```
core_collector makedumpfile -c
```

The command above enables the dump file compression.

3. Add the `-d value` parameter. For example:

```
core_collector makedumpfile -d 17 -c
```

The command above removes both zero and free pages from the dump. The value represents a bitmask, where each bit is associated with a certain type of memory pages and determines
whether that type of pages will be collected. For description of respective bits see Section 5.5.4, “Supported kdump filtering levels”.

Additional resources

- See the `makedumpfile(8)` man page for a complete list of available options.

5.3.4. Configuring the kdump default failure responses

By default, when kdump fails to create a vmcore dump file at the target location specified in Section 5.3.2, “Configuring the kdump target”, the system reboots, and the dump is lost in the process. To change this behavior, follow the procedure below.

Prerequisites

- Fulfilled kdump requirements.

Procedure

1. As root, remove the hash sign (“#”) from the beginning of the `#default shell` line in the `/etc/kdump.conf` configuration file.

2. Replace the value with a desired action as described in Section 5.5.5, “Supported default failure responses”. For example:

   ```
   default poweroff
   ```

5.3.5. Enabling and disabling the kdump service

To start the kdump service at boot time, follow the procedure below.

Prerequisites

- Fulfilled kdump requirements.
- All configuration is set up according to your needs.

Procedure

1. To enable the kdump service, use the following command:

   ```
   # systemctl enable kdump.service
   ```

   This enables the service for `multi-user.target`.

2. To start the service in the current session, use the following command:

   ```
   # systemctl start kdump.service
   ```

3. To stop the kdump service, type the following command:

   ```
   # systemctl stop kdump.service
   ```

4. To disable the kdump service, execute the following command:
# systemctl disable kdump.service

Additional resources

- For more information on **systemd** and configuring services in general, see *Configuring basic system settings* in Red Hat Enterprise Linux.

5.4. CONFIGURING KDUMP IN THE WEB CONSOLE

The following sections provide an overview of how to setup and test the **kdump** configuration through the Red Hat Enterprise Linux web console. The web console is part of a default installation of Red Hat Enterprise Linux 8 and enables or disables the **kdump** service at boot time. Further, the web console conveniently enables you to configure the reserved memory for **kdump**; or to select the **vmcore** saving location in an uncompressed or compressed format.

Prerequisites

- See *Red Hat Enterprise Linux web console* for further details.

5.4.1. Configuring kdump memory usage and target location in web console

The procedure below shows you how to use the **Kernel Dump** tab in the Red Hat Enterprise Linux web console interface to configure the amount of memory that is reserved for the kdump kernel. The procedure also describes how to specify the target location of the vmcore dump file and how to test your configuration.

Prerequisites

- Introduction to operating the **web console**.

Procedure

1. Open the **Kernel Dump** tab and start the **kdump** service.

2. Configure the **kdump** memory usage through the **command line**.

3. Click the link next to the **Crash dump location** option.

4. Select the **Local Filesystem** option from the drop-down and specify the directory you want to save the dump in.
Alternatively, select the **Remote over SSH** option from the drop-down to send the vmcore to a remote machine using the SSH protocol. Fill the **Server**, **ssh key**, and **Directory** fields with the remote machine address, ssh key location, and a target directory.

Another choice is to select the **Remote over NFS** option from the drop-down and fill the **Mount** field to send the vmcore to a remote machine using the NFS protocol.

**NOTE**

Tick the **Compression** check box to reduce the size of the vmcore file.

5. Test your configuration by crashing the kernel.

**WARNING**

This step disrupts execution of the kernel and results in a system crash and loss of data.
**5.5. SUPPORTED KDUMP CONFIGURATIONS AND TARGETS**

### 5.5.1. Memory requirements for kdump

In order for **kdump** to be able to capture a kernel crash dump and save it for further analysis, a part of the system memory has to be permanently reserved for the capture kernel. When reserved, this part of the system memory is not available to the main kernel.

The memory requirements vary based on certain system parameters. One of the major factors is the system’s hardware architecture. To find out the exact machine architecture (such as Intel 64 and AMD64, also known as x86_64) and print it to standard output, use the following command:

```bash
$ uname -m
```

The table below contains a list of minimum memory requirements to automatically reserve a memory size for **kdump**. The size changes according to the system’s architecture and total available physical memory.

**Table 5.1. Minimum Amount of Reserved Memory Required for kdump**

<table>
<thead>
<tr>
<th>Architecture</th>
<th>Available Memory</th>
<th>Minimum Reserved Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMD64 and Intel 64 (x86_64)</td>
<td>1 GB to 64 GB</td>
<td>160 MB of RAM.</td>
</tr>
<tr>
<td></td>
<td>64 GB to 1 TB</td>
<td>256 MB of RAM.</td>
</tr>
<tr>
<td></td>
<td>1 TB and more</td>
<td>512 MB of RAM.</td>
</tr>
<tr>
<td>64-bit ARM architecture (arm64)</td>
<td>2 GB and more</td>
<td>512 MB of RAM.</td>
</tr>
<tr>
<td>IBM Power Systems (ppc64le)</td>
<td>2 GB to 4 GB</td>
<td>384 MB of RAM.</td>
</tr>
<tr>
<td></td>
<td>4 GB to 16 GB</td>
<td>512 MB of RAM.</td>
</tr>
<tr>
<td></td>
<td>16 GB to 64 GB</td>
<td>1 GB of RAM.</td>
</tr>
<tr>
<td></td>
<td>64 GB to 128 GB</td>
<td>2 GB of RAM.</td>
</tr>
<tr>
<td></td>
<td>128 GB and more</td>
<td>4 GB of RAM.</td>
</tr>
<tr>
<td>IBM Z (s390x)</td>
<td>4 GB to 64 GB</td>
<td>160 MB of RAM.</td>
</tr>
<tr>
<td></td>
<td>64 GB to 1 TB</td>
<td>256 MB of RAM.</td>
</tr>
</tbody>
</table>
On many systems, `kdump` is able to estimate the amount of required memory and reserve it automatically. This behavior is enabled by default, but only works on systems that have more than a certain amount of total available memory, which varies based on the system architecture.

**IMPORTANT**

The automatic configuration of reserved memory based on the total amount of memory in the system is a best effort estimation. The actual required memory may vary due to other factors such as I/O devices. Using not enough of memory might cause that a debug kernel is not able to boot as a capture kernel in case of a kernel panic. To avoid this problem, sufficiently increase the crash kernel memory.

Additional resources

- For information on how to change memory settings on the command line, see Section 5.3.1, "Configuring kdump memory usage".
- For instructions on how to set up the amount of reserved memory through the web console, see Section 5.4.1, "Configuring kdump memory usage and target location in web console".
- For more information about various Red Hat Enterprise Linux technology capabilities and limits, see the technology capabilities and limits tables.

### 5.5.2. Minimum threshold for automatic memory reservation

On some systems, it is possible to allocate memory for `kdump` automatically, either by using the `crashkernel=auto` parameter in the boot loader configuration file, or by enabling this option in the graphical configuration utility. For this automatic reservation to work, however, a certain amount of total memory needs to be available in the system. The amount differs based on the system’s architecture.

The table below lists the thresholds for automatic memory allocation. If the system has less memory than specified in the table, the memory needs to be reserved manually.

**Table 5.2. Minimum Amount of Memory Required for Automatic Memory Reservation**

<table>
<thead>
<tr>
<th>Architecture</th>
<th>Required Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMD64 and Intel 64 (x86_64)</td>
<td>2 GB</td>
</tr>
<tr>
<td>IBM Power Systems (ppc64le)</td>
<td>2 GB</td>
</tr>
<tr>
<td>IBM Z (s390x)</td>
<td>4 GB</td>
</tr>
</tbody>
</table>

Additional resources

- For information on how to manually change these settings on the command line, see Section 5.3.1, “Configuring kdump memory usage”.

---

**Architecture** | **Available Memory** | **Minimum Reserved Memory**
---|---|---
1 TB and more | 512 MB of RAM. |
5.5.3. Supported kdump targets

When a kernel crash is captured, the vmcore dump file can be either written directly to a device, stored as a file on a local file system, or sent over a network. The table below contains a complete list of dump targets that are currently supported or explicitly unsupported by kdump.

<table>
<thead>
<tr>
<th>Type</th>
<th>Supported Targets</th>
<th>Unsupported Targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw device</td>
<td>All locally attached raw disks and partitions.</td>
<td>Any local file system not explicitly listed as supported in this table, including the auto type (automatic file system detection).</td>
</tr>
<tr>
<td>Local file system</td>
<td>ext2, ext3, ext4, and xfs file systems on directly attached disk drives, hardware RAID logical drives, LVM devices, and mdraid arrays.</td>
<td></td>
</tr>
<tr>
<td>Remote directories</td>
<td>Remote directories accessed using the iSCSI protocol on be2iscsi hardware.</td>
<td>Multipath-based storages.</td>
</tr>
<tr>
<td>accessed using the iSCSI</td>
<td></td>

<td>initiators.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Remote directories</td>
<td></td>
<td></td>
</tr>
<tr>
<td>accessed over IPv6.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Remote directories</td>
<td></td>
<td></td>
</tr>
<tr>
<td>accessed using the SMB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>or CIFS protocol.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Remote directories</td>
<td></td>
<td></td>
</tr>
<tr>
<td>accessed using the FCoE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(Fibre Channel over Ethernet) protocol.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Remote directories</td>
<td></td>
<td></td>
</tr>
<tr>
<td>accessed using wireless</td>
<td></td>
<td></td>
</tr>
<tr>
<td>network interfaces.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Additional resources

- For information on how to configure the target type on the command line, see Section 5.3.2, “Configuring the kdump target”.
- For information on how to configure the target through the web console, see Section 5.4.1, “Configuring kdump memory usage and target location in web console”.

For instructions on how to manually change the amount of reserved memory through the web console, see Section 5.4.1, “Configuring kdump memory usage and target location in web console”.
5.5.4. Supported kdump filtering levels

To reduce the size of the dump file, kdump uses the makedumpfile core collector to compress the data and optionally to omit unwanted information. The table below contains a complete list of filtering levels that are currently supported by the makedumpfile utility.

Table 5.4. Supported Filtering Levels

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Zero pages</td>
</tr>
<tr>
<td>2</td>
<td>Cache pages</td>
</tr>
<tr>
<td>4</td>
<td>Cache private</td>
</tr>
<tr>
<td>8</td>
<td>User pages</td>
</tr>
<tr>
<td>16</td>
<td>Free pages</td>
</tr>
</tbody>
</table>

**NOTE**

The makedumpfile command supports removal of transparent huge pages and hugetlbfs pages. Consider both these types of hugepages User Pages and remove them using the -8 level.

Additional resources

- For instructions on how to configure the core collector on the command line, see Section 5.3.3, "Configuring the core collector".

5.5.5. Supported default failure responses

By default, when kdump fails to create a core dump, the operating system reboots. You can, however, configure kdump to perform a different operation in case it fails to save the core dump to the primary target. The table below lists all default actions that are currently supported.

Table 5.5. Supported Default Actions

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dump_to_rootfs</td>
<td>Attempt to save the core dump to the root file system. This option is especially useful in combination with a network target: if the network target is unreachable, this option configures kdump to save the core dump locally. The system is rebooted afterwards.</td>
</tr>
<tr>
<td>reboot</td>
<td>Reboot the system, losing the core dump in the process.</td>
</tr>
</tbody>
</table>
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>halt</td>
<td>Halt the system, losing the core dump in the process.</td>
</tr>
<tr>
<td>poweroff</td>
<td>Power off the system, losing the core dump in the process.</td>
</tr>
<tr>
<td>shell</td>
<td>Run a shell session from within the initramfs, allowing the user to record the core dump manually.</td>
</tr>
</tbody>
</table>

**Additional resources**

- For detailed information on how to set up the default failure responses on the command line, see Section 5.3.4, “Configuring the kdump default failure responses”.

### 5.5.6. Estimating kdump size

When planning and building your kdump environment, it is necessary to know how much space is required for the dump file before one is produced.

The `makedumpfile --mem-usage` command provides a useful report about excludable pages, and can be used to determine which dump level you want to assign. Run this command when the system is under representative load, otherwise `makedumpfile --mem-usage` returns a smaller value than is expected in your production environment.

```bash
[root@hostname ~]# makedumpfile --mem-usage /proc/kcore
```

<table>
<thead>
<tr>
<th>TYPE</th>
<th>PAGES</th>
<th>EXCLUDABLE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZERO</td>
<td>501635</td>
<td>yes</td>
<td>Pages filled with zero</td>
</tr>
<tr>
<td>CACHE</td>
<td>51657</td>
<td>yes</td>
<td>Cache pages</td>
</tr>
<tr>
<td>CACHE_PRIVATE</td>
<td>5442</td>
<td>yes</td>
<td>Cache pages + private</td>
</tr>
<tr>
<td>USER</td>
<td>16301</td>
<td>yes</td>
<td>User process pages</td>
</tr>
<tr>
<td>FREE</td>
<td>77738211</td>
<td>yes</td>
<td>Free pages</td>
</tr>
<tr>
<td>KERN_DATA</td>
<td>1333192</td>
<td>no</td>
<td>Dumpable kernel data</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The `makedumpfile --mem-usage` command reports in pages. This means that you have to calculate the size of memory in use against the kernel page size. By default the Red Hat Enterprise Linux kernel uses 4 KB sized pages for AMD64 and Intel 64 architectures, and 64 KB sized pages for IBM POWER architectures.

### 5.6. TESTING THE KDUMP CONFIGURATION

The following procedure describes how to test that the kernel dump process works and is valid before the machine enters production.
WARNING
The commands below cause the kernel to crash. Use caution when following these steps, and never carelessly use them on active production system.

Procedure

1. Reboot the system with kdump enabled.

2. Make sure that kdump is running:

   ```
   ~]# systemctl is-active kdump
   active
   ```

3. Force the Linux kernel to crash:

   ```
   echo 1 > /proc/sys/kernel/sysrq
   echo c > /proc/sysrq-trigger
   ```

   WARNING
   The command above crashes the kernel and a reboot is required.

Once booted again, the `address-YYYY-MM-DD-HH:MM:SS/vmcore` file is created at the location you have specified in `/etc/kdump.conf` (by default to `/var/crash/`).

NOTE
In addition to confirming the validity of the configuration, it is possible to use this action to record how long it takes for a crash dump to complete, while a representative load was running.

5.7. ANALYZING A CORE DUMP

To determine the cause of the system crash, you can use the crash utility, which provides an interactive prompt very similar to the GNU Debugger (GDB). This utility allows you to interactively analyze a core dump created by kdump, netdump, diskdump or xendump as well as a running Linux system. Alternatively, you have the option to use the Kdump Helper or Kernel Oops Analyzer.

5.7.1. Installing the crash utility

The following procedure describes how to install the crash analyzing tool.

Procedure
1. Enable the relevant **baseos** and **appstream** repositories:

   # subscription-manager repos --enable baseos repository
   # subscription-manager repos --enable appstream repository

2. Install the **crash** package:

   # yum install crash

3. Install the **kernel-debuginfo** package:

   # yum install kernel-debuginfo

   The package corresponds to your running kernel and provides the data necessary for the dump analysis.

Additional resources

- For more information about how to work with repositories using the **subscription-manager** utility, see *Configuring basic system settings*.

**5.7.2. Running and exiting the crash utility**

The following procedure describes how to start the crash utility for analyzing the cause of the system crash.

**Prerequisites**

- Find out which kernel you are currently running (for example **4.18.0-5.el8.x86_64**).

**Procedure**

1. To start the **crash** utility, two necessary parameters need to be passed to the command:

   - The debug-info (a decompressed vmlinuz image), for example 
     `/usr/lib/debug/lib/modules/4.18.0-5.el8.x86_64/vmlinux` provided through a specific
     **kernel-debuginfo** package.

   - The actual vmcore file, for example `/var/crash/127.0.0.1-2018-10-06-14:05:33/vmcore`

   The resulting **crash** command then looks like this:

   ```
   # crash /usr/lib/debug/lib/modules/4.18.0-5.el8.x86_64/vmlinux /var/crash/127.0.0.1-2018-10-06-14:05:33/vmcore
   ```

   Use the same `<kernel>` version that was captured by **kdump**.

**Example 5.1. Running the crash utility**

The following example shows analyzing a core dump created on October 6 2018 at 14:05 PM, using the 4.18.0-5.el8.x86_64 kernel.

```... WARNING: kernel relocated [202MB]: patching 90160 gdb minimal_symbol values...```
2. To exit the interactive prompt and terminate crash, type exit or q.

Example 5.2. Exiting the crash utility

```
crash> exit
~]#
```

NOTE

The crash command can also be used as a powerful tool for debugging a live system. However use it with caution so as not to break your system.

5.7.3. Displaying message buffer, backtrace, and other indicators in the crash utility

The following procedures describe how to use the crash utility and display various indicators, such as a kernel message buffer, a backtrace, a process status, virtual memory information and open files.

Displaying the message buffer

- To display the kernel message buffer, type the log command at the interactive prompt as displayed in the example below:

Example 5.3. Displaying the kernel message buffer

```
crash> log
... several lines omitted ...
EIP: 0060:[<c068124f>] EFLAGS: 00010096 CPU: 2
EIP is at sysrq_handle_crash+0xf/0x20

EIP: [c068124f] sysrq_handle_crash+0xf/0x20 SS:ESP 0068:ef4dbf24
CR2: 0000000000000000

Type help log for more information on the command usage.

NOTE

The kernel message buffer includes the most essential information about the
system crash and, as such, it is always dumped first in to the vmcore-dmesg.txt
file. This is useful when an attempt to get the full vmcore file failed, for example
because of lack of space on the target location. By default, vmcore-dmesg.txt is
located in the /var/crash/ directory.

5.7.3.1. Displaying a backtrace

- To display the kernel stack trace, use the bt command.

Example 5.4. Displaying the kernel stack trace

```
crash> bt
PID: 5591 TASK: f196d560 CPU: 2 COMMAND: "bash"
#0 [ef4dbd2c] crash_kexec at c0494922

#12 [ef4dbf0] system_call at c0409ad5
```
5.7.3.2. Displaying a process status

To display the status of processes in the system, use the `ps` command.

**Example 5.5. Displaying the status of processes in the system**

```
crash> ps
    PID  PPID  CPU TASK ST  %MEM  VSZ  RSS  COMM
>  0   0   0  c09dc560 RU   0.0       0      0  [swapper]
>  0   0   1  f7072030 RU   0.0       0      0  [swapper]
0   0   2  f70a3a90 RU   0.0       0      0  [swapper]
>  0   0   3  f70ac560 RU   0.0       0      0  [swapper]
  1   0   1  f705ba90 IN   0.0    2828   1424  init
... several lines omitted ...
  5566  5567   1  f2592560 IN   0.0   12876    784  auditd
  5567  5587  5132  f196d030 IN   0.0   11064   3184  sshd
>  5591  5587  5132  f196d560 RU   0.0   5084   1648  bash
```

Use `ps <pid>` to display the status of a single specific process. Use `help ps` for more information on `ps` usage.

5.7.3.3. Displaying virtual memory information

To display basic virtual memory information, type the `vm` command at the interactive prompt.

**Example 5.6. Displaying virtual memory information of the current context**

```
crash> vm
    PID: 5591   TASK: f196d560   CPU: 2   COMMAND: "bash"
    MM   PGD   RSS   TOTAL_VM
f19b5900 ef9c6000  1648k   5084k
  VMA   START   END   FLAGS   FILE
f1bb0310    242000   260000 8000875  /lib/ld-2.12.so
f26af0b8    260000   261000 8100871  /lib/ld-2.12.so
efbc275c    261000   262000 8100873  /lib/ld-2.12.so
efbc2a18    268000   3ed000 8000075  /lib/libc-2.12.so
efbc23d8    3ed000    3e0000 8000070  /lib/libc-2.12.so
efbc2888    3ee000    3f0000 8100071  /lib/libdl-2.12.so
efbc2cd4    3f0000    3f1000 8100073  /lib/libc-2.12.so
efbc243c    3f1000    3f4000 100073
efbc28ec    3f6000    3f9000 8000075  /lib/libdl-2.12.so
efbc2568    3f9000    3fa000 8100071  /lib/libc-2.12.so
efbc2f2c    3fa000    3f0000 8100073  /lib/libdl-2.12.so
f26af888    7e6000   7fc000 8000075  /lib/libtinfo.so.5.7
```
5.7.3.4. Displaying open files

- To display information about open files, use the `files` command.

```
Example 5.7. Displaying information about open files of the current context

crash> files
PID: 5591   TASK: f196d560  CPU: 2  COMMAND: "bash"
ROOT: /    CWD: /root
FD   FILE     DENTRY    INODE    TYPE  PATH
 0  f734f640  eedc2c6c  eecd6048  CHR   /pts/0
 1  efade5c0  eee14090  f00431d4  REG   /proc/sysrq-trigger
 2  f734f640  eedc2c6c  eecd6048  CHR   /pts/0
 10 f734f640  eedc2c6c  eecd6048  CHR   /pts/0
255 f734f640  eedc2c6c  eecd6048  CHR   /pts/0

Use `files <pid>` to display files opened by only one selected process, or use `help files` for more information on `files` usage.
```

5.7.4. Using Kernel Oops Analyzer

The Kernel Oops Analyzer is a tool that analyzes the crash dump by comparing the oops messages with known issues in the knowledge base.

**Prerequisites**

- Secure an oops message to feed the Kernel Oops Analyzer by following instructions in Red Hat Labs.

**Procedure**

1. Follow the Kernel Oops Analyzer link to access the tool.
2. Browse for the oops message by hitting the Browse button.
Choose and upload the **kernel oops log** generated from a vmcore.

Maximum file size for uploaded kernel oops log is 10 MB.

3. Click the **DETECT** button to compare the oops message based on information from **makedumpfile** against known solutions.

Additional resources

- **kdump.conf**(5) – a manual page for the `/etc/kdump.conf` configuration file containing the full documentation of available options.
- **zipl.conf**(5) – a manual page for the `/etc/zipl.conf` configuration file.
- **zipl**(8) – a manual page for the **zipl** boot loader utility for IBM System z.
- **makedumpfile**(8) – a manual page for the **makedumpfile** core collector.
- **kexec**(8) – a manual page for **kexec**.
- **crash**(8) – a manual page for the **crash** utility.
- **/usr/share/doc/kexec-tools/kexec-kdump-howto.txt** – an overview of the **kdump** and **kexec** installation and usage.
- For more information about the **kexec** and **kdump** configuration see the *Red Hat Knowledgebase article*.
- For more information about the supported **kdump** targets see the *Red Hat Knowledgebase article*. 
CHAPTER 6. APPLYING KERNEL PATCHES WITH KPATCH

The `kpatch` live kernel patching solution allows you to patch a running kernel without rebooting or restarting any processes. `kpatch` enables system administrators to apply critical security patches to the kernel immediately, without having to wait for long-running tasks to complete, for users to log off, or for scheduled downtime. It gives more control over uptime without sacrificing security or stability.

### 6.1. ACCESS TO KERNEL PATCHES

Live kernel patching capability is implemented as a kernel module (`kmod`) that is delivered as an RPM package. The `kpatch` utility is used to install and remove the kernel modules for live kernel patching.

Customers with Premium subscriptions are eligible to request a live kernel patch as part of an accelerated fix solution from Red Hat Support.

Eligible customers who typically used 'hotfix' kernels which required a reboot can now request a kpatch patch that requires no down time. The kpatch patch will be supported 30 days after the erratum that contains the released fix.

Customers who require accelerated fix options should open a support case Red Hat Customer Portal and discuss appropriate accelerated fix options. For fastest support, include the CVE id or Bug number as well as the precise kernel version(s) to be patched. Obtain the kernel version by using the `uname -r` command.

### 6.2. COMPONENTS OF KPATCH

The components of `kpatch` are as follows:

**kpatch.service**

- A `systemd` service required by `multiuser.target` which loads the `kpatch` modules at boot time.

**Patch Module**

- The delivery mechanism for new kernel code.
- This is another kernel module that matches the patch being applied.
- The patch module contains the code of the desired hotfixes for the kernel.
- The patch modules register with the `livepatch` kernel subsystem and provide information about original functions to be replaced, with corresponding pointers to the replacement functions.

**The kpatch Utility**

- A command-line tool which allows you to manage patch modules.
### 6.3. HOW KPATCH WORKS

The **kpatch** kernel patching solution uses the **livepatch** kernel subsystem to redirect old functions to new ones. When a live kernel patch is applied to a system, the following things happen:

1. The new compiled code in the module is copied to the `/var/lib/kpatch/` directory and registered for re-application to the kernel via `systemd` on next boot.

2. The kpatch module is loaded into the running kernel and the new functions are registered to the `ftrace` mechanism with a pointer to the location in memory of the new code.

3. When the kernel accesses the patched function, it is redirected by the `ftrace` mechanism which bypasses the original functions and redirects the kernel to patched version of the function.

![Figure 6.1. How kpatch Works](image)

### 6.4. INSTALLING KPATCH MODULES

This procedure describes how to install kpatch modules through the **kpatch** utility.

**WARNING**

Red Hat strongly discourages from using any kpatch modules, which were not provided for your specific usage by Red Hat itself.

**Prerequisites**

- An installed **kpatch** utility. To install **kpatch**, run the following:

  ```bash
  # yum install kpatch
  ```
- RPM package with a **kpatch** module.

  To get a kpatch module, open a support case. In the support case indicate that you want a kpatch patch. Also inform about kernel version as returned by command:

  ```
  $ uname -r
  ```

  You can also indicate the Bugzilla issues which should be corrected by **kpatch**.

  For more information about how to create a support case see How do I open and manage a support case on the Customer Portal?

**Procedure**

1. List installed kpatch modules to see if the patch is installed:

   ```
   # kpatch list
   Loaded patch modules:
   kpatch_4_18_0_100_1_1
   Installed patch modules:
   kpatch_4_18_0_100_1_1 (4.18.0-100.el8.x86_64)
   kpatch_4_18_0_200_1_1 (4.18.0-200.el8.x86_64)
   ```

   The output shows that the module has been loaded into the kernel, meaning the kernel is now patched with the latest hotfixes in the **kpatch-patch-4_18_0_100-1-1.el8.x86_64.rpm** package. It also shows that it has been saved to the `/var/lib/kpatch/` directory to be loaded by **systemd** during future reboots into kernel versions 4.18.0-100 and 4.18.0-200.

2. Install a kpatch module:

   - If the kpatch module is not installed, install the RPM package with **yum**. For example, to install **kpatch-patch-4_18_0_100-1-1.el8.x86_64.rpm**, issue the following command:

     ```
     # yum install kpatch-patch-4_18_0_100-1-1.el8.x86_64.rpm
     ```

     The example command above installs and loads the kpatch module.

   - If an older version of the kpatch module is installed, update it using **yum**. For example, to upgrade to **kpatch-patch-4_18_0_100-1-2.el8.x86_64.rpm** run:

     ```
     # yum update kpatch-patch-4_18_0_100-1-2.el8.x86_64.rpm
     ```

     Upgrading the RPM package automatically replaces the relevant kernel module in the running kernel and updates the `/var/lib/kpatch/` structures.

     **NOTE**

     The kpatch modules in the RPM packages are cumulative. Consequently, you could skip installing kpatch-patch-4_18_0_100-1-1 and instead start with installing kpatch-patch-4_18_0_100-1-2 if it were available.

3. Load the kpatch module:

   ```
   # kpatch load kpatch_4_18_0_200_1_1
   ```
The example command above shows how to load the installed kpatch modules.

4. Verify whether the kpatch module was loaded by running the following command:

```
# kpatch list
```

### 6.5. REMOVING KPATCH MODULES

This procedure describes how to remove installed kpatch modules through the `kpatch` utility.

**Procedure**

1. List the installed kpatch modules:

```
# kpatch list
Loaded patch modules:
kpatch_4_18_0_100_1_1
Installed patch modules:
kpatch_4_18_0_100_1_1 (4.18.0-100.el8.x86_64)
kpatch_4_18_0_200_1_1 (4.18.0-200.el8.x86_64)
```

The example output above shows that there are `kpatch_4_18_0_100_1_1` and `kpatch_4_18_0_200_1_1` kpatch modules installed.

2. Unload the relevant kpatch module:

```
# kpatch unload kpatch-4_18_0_100-1-2
```

3. Uninstall the kpatch module:

   - Using kpatch:

     ```
     # kpatch uninstall kpatch-4_18_0_100-1-2
     ```

     The command above uninstalls the kpatch module from the `/var/lib/kpatch/` directory.

     The default behavior of this command is to uninstall `kpatch` from the kernel corresponding to the current kernel version. However, you can specify a different kernel version by the `kernel-version` option:

     ```
     # kpatch uninstall --kernel-version 4.18.0-200.el8.x86_64 kpatch-4_18_0_200-1-1
     ```

   - Using yum:

     ```
     # yum erase kpatch-patch-4_18_0_100-1-1.el8.x86_64
     ```

     The command above uninstalls the kpatch RPM package and also removes the patch module from `/var/lib/kpatch/`.

### 6.6. KPATCH SUPPORT

- Live kernel is supported for customers who have a Premium SLA subscription.
Live kernel patching is only supported on the active Red Hat Enterprise Linux 8 maintenance stream that is within the current async errata phase. See Red Hat Enterprise Linux Life Cycle for information about current support phases.

Live kernel patching is not available on the Extended Update Support (EUS) at this time.

Live kernel patching is not supported on the Red Hat Enterprise Linux for Real Time (RT) kernel.

Red Hat supports one RPM containing a kernel module per one kernel version. For example, if the customer requests more than one patch for one kernel version, the patches are combined into one RPM.

Not all issues may be covered under live kernel patching, including hardware enablement.

6.7. SUPPORT FOR THIRD-PARTY LIVEPATCHING

kpatch is the only live kernel patching utility supported by Red Hat with the RPM modules supplied through your Red Hat support contract. Red Hat will not support any live kernel patches which were not provided by Red Hat itself.

If you require support for an issue that arises with a third-party live patch, Red Hat recommends that you open a case with the live kernel patching vendor at the outset of any investigation in which a root cause determination is necessary. This allows the source code to be supplied if the vendor allows, and for their support organization to provide assistance in root cause determination prior to escalating the investigation to Red Hat Support.

For any system running with third-party live kernel patches, Red Hat reserves the right to ask for reproduction with Red Hat shipped and supported software. In the event that this is not possible, we require a similar system and workload be deployed on your test environment without live patches applied, to confirm if the same behavior is observed.

For more information about third-party software support policies, see How does Red Hat Global Support Services handle third-party software, drivers, and/or uncertified hardware/hypervisors or guest operating systems?

6.8. LIMITATIONS OF KPATCH

- kpatch is not a general-purpose kernel upgrade mechanism. It is used for applying simple security and bug fix updates when rebooting the system is not immediately possible.

- Do not use the SystemTap or kprobe tools during or after loading a patch. The patch could fail to take effect until after such probes have been removed.

- Do not suspend or hibernate the system when using kpatch. This can result in a patch being temporarily disabled.
CHAPTER 7. SETTING LIMITS FOR APPLICATIONS

As a system administrator, use the control groups kernel functionality to set limits, prioritize or isolate the hardware resources of processes so that applications on your system are stable and do not run out of memory.

7.1. WHAT ARE CONTROL GROUPS

Control groups is a Linux kernel feature that enables you to organize processes into hierarchically ordered groups - cgroups. The hierarchy (control groups tree) is defined by providing structure to cgroups virtual file system, mounted by default on the /sys/fs/cgroup/ directory. It is done manually by creating and removing sub-directories in /sys/fs/cgroup/. Alternatively, by using the systemd system and service manager.

The resource controllers (a kernel component) then modify the behavior of processes in cgroups by limiting, prioritizing or allocating system resources, (such as CPU time, memory, network bandwidth, or various combinations) of those processes.

The added value of cgroups is process aggregation which enables division of hardware resources among applications and users. Thereby an increase in overall efficiency, stability and security of users' environment can be achieved.

7.1.1. Control groups version 1

Control groups version 1 (cgroups-v1) provide a per-resource controller hierarchy. It means that each resource, such as CPU, memory, I/O, and so on, has its own control group hierarchy. It is possible to combine different control group hierarchies in a way that one controller can coordinate with another one in managing their respective resources. However, the two controllers may belong to different process hierarchies, which does not permit their proper coordination.

The cgroups-v1 controllers were developed across a large time span and as a result, the behavior and naming of their control files is not uniform.

This sub-section was based on a Devconf.cz 2019 presentation.[1]

7.1.2. Control groups version 2

The problems with controller coordination, which stemmed from hierarchy flexibility, led to the development of control groups version 2.

Control groups version 2 (cgroups-v2) provides a single control group hierarchy against which all resource controllers are mounted.

The control file behavior and naming is consistent among different controllers.

This sub-section was based on a Devconf.cz 2019 presentation.[2]
Additional resources

- For more information about resource controllers, see What are kernel resource controllers section and cgroups(7) manual pages.
- For more information about cgroups hierarchies and cgroups versions, refer to cgroups(7) manual pages.

7.2. WHAT ARE KERNEL RESOURCE CONTROLLERS

This section explains the concept of resource controllers in the Linux kernel and also lists supported controllers for control groups version 1 (cgroups-v1) and control groups version 2 (cgroups-v2) in Red Hat Enterprise Linux 8.

A resource controller, also called a cgroup subsystem, represents a single resource, such as CPU time, memory, network bandwidth or disk I/O. The Linux kernel provides a range of resource controllers that are mounted automatically by the systemd system and service manager. Find a list of currently mounted resource controllers in the /proc/cgroups entry.

The following controllers are available for cgroups-v1:

- **blkio** - sets limits on input/output access to and from block devices.
- **cpu** - uses the CPU scheduler to provide the control group tasks with an access to the CPU. It is mounted together with the cpuacct controller on the same mount.
- **cpuacct** - creates automatic reports on CPU resources used by tasks in a control group. It is mounted together with the cpu controller on the same mount.
- **cpuset** - assigns individual CPUs on a multicore system and memory nodes to tasks in a control group.
- **devices** - grants or denies access to devices for tasks in a control group.
- **freezer** - suspends or resumes tasks in a control group.
- **memory** - sets limits on memory use by tasks in a control group and generates automatic reports on memory resources used by those tasks.
- **net_cls** - tags network packets with a class identifier (classid) that enables the Linux traffic controller (the tc command) to identify packets originating from a particular control group task. A subsystem of net_cls, the net_filter (iptables), can also use this tag to perform actions on such packets. The net_filter tags network sockets with a firewall identifier (fwid) that allows the Linux firewall (the iptables command) to identify packets originating from a particular control group task.
- net_prio - sets the priority of network traffic.
- pids - sets limits on number of processes and their children in a control group.
- perf_event - enables monitoring cgroups with the perf tool.
- rdma - sets limits on Remote Direct Memory Access/InfiniBand specific resources in a control group.
- hugetlb - enables to use virtual memory pages of large sizes and to enforce resource limits on these pages.

The following controllers are available for cgroups-v2:
- io - follow-up to blkio of cgroups-v1
- memory - follow-up to memory of cgroups-v1
- pids - same as pids in cgroups-v1
- rdma - same as rdma in cgroups-v1
- cpu - follow-up to cpu and cpuacct of cgroups-v1

**IMPORTANT**

A given resource controller can be employed either in a cgroups-v1 hierarchy or a cgroups-v2 hierarchy, not simultaneously in both.

Additional resources
- For more information about resource controllers in general, refer to the cgroups(7) manual page.
- For detailed descriptions of specific resource controllers, see the documentation in the /usr/share/doc/kernel-doc-<kernel_version>/Documentation/cgroups-v1/ directory.
- For more information about cgroups-v2, refer to the cgroups(7) manual page.

### 7.3. WHAT ARE NAMESPACES

This section explains the concept of namespaces, their connection to control groups and resource management.

Namespaces are a kernel feature that enables a virtual view of isolated system resources through the /proc/self/ns/cgroup interface. By isolating a process from system resources, you can specify and control what a process is able to interact with.

The purpose is to prevent leakage of privileged data from the global namespaces to cgroup and to enable other features, such as container migration.

The following namespaces are supported:
- Mount
The mount namespace isolates file system mount points, enabling each process to have a distinct filesystem space within which to operate.

- **UTS**
  - Hostname and NIS domain name
- **IPC**
  - System V IPC, POSIX message queues
- **PID**
  - Process IDs
- **Network**
  - Network devices, stacks, ports, etc.
- **User**
  - User and group IDs
- **Control groups**
  - Isolates cgroups

**Additional resources**
- For more information about namespaces, see the *namespaces(7)* and *cgroup_namespaces(7)* manual pages.
- For more information about *cgroups*, see *What are control groups*.

### 7.4. USING CONTROL GROUPS THROUGH A VIRTUAL FILE SYSTEM

The following sections provide an overview of tasks related to creation, modification and removal of control groups (*cgroups*) using the */sys/fs/* virtual file system.

#### 7.4.1. Setting memory limits to applications through cgroups-v1

This procedure describes how to use the */sys/fs/* virtual file system to configure a memory limit to an application through control groups version 1 (*cgroups-v1*).

**Prerequisites**
- Application to restrict
- Root permissions
- Control groups basic concept

**Procedure**

1. Create a sub-directory in the memory resource controller directory:

   ```bash
   # mkdir /sys/fs/cgroup/memory/example/
   ```
The directory above represents a control group, where you can place specific processes and apply certain memory limits to the processes.

2. Optionally, investigate the newly created control group:

```bash
# ll /sys/fs/cgroup/memory/example/
-rw-r--r- 1 root root 0 Apr 25 16:34 cgroup.clone_children
--w--w--w- 1 root root 0 Apr 25 16:34 cgroup.event_control
-rw-r--r- 1 root root 0 Apr 25 16:42 cgroup.procs
...
```

The example output shows files that the `example` control group inherited from its parent resource controller. By default, the newly created control group inherited access to the system’s entire memory without a limit.

3. Configure a memory limit of the control group:

```bash
# echo 700000 > /sys/fs/cgroup/memory/example/memory.limit_in_bytes
```

The example command sets the memory limit to 700 Kilobytes.

4. Verify the limit:

```bash
# cat /sys/fs/cgroup/memory/example/memory.limit_in_bytes
696320
```

The example output displays the memory limit value as a multiple of 4096 bytes - one kernel page size.

5. Add the application’s PID to the control group:

```bash
# echo 23453 > /sys/fs/cgroup/memory/example/cgroup.procs
```

The example command ensures that a desired application does not exceed a memory limit configured in the control group. Your PID should come from an existing process in the system, `PID 23453` here is fictional.

6. Verify that the application runs in the specified control group:

```bash
# ps -o cgroup 23453
CGROUP
11:memory:/example,5:devices:/system.slice/example.service,4:pids:/system.slice/example.service,1:name=systemd:/system.slice/example.service
```

The example output above shows that the process of the desired application runs in the `example` control group, which applies a memory limit to the application’s process.

**Additional resources**

- For more information about resource controllers, see the [What are kernel resource controllers](#) section and the [cgroups(7)](#) manual page.

- For more information about `/sys/fs/`, see the [sysfs(5)](#) manual page.
CHAPTER 8. ANALYZING SYSTEM PERFORMANCE WITH BPF COMPILER COLLECTION

As a system administrator, use the BPF Compiler Collection (BCC) library to create tools for analyzing the performance of your Linux operating system and gathering information, which could be difficult to obtain through other interfaces.

IMPORTANT

The BCC library is a Technology Preview in Red Hat Enterprise Linux 8. See Technology Preview Features Support Scope for more details.

8.1. BCC

BPF Compiler Collection (BCC) is a library, which facilitates the creation of the extended Berkeley Packet Filter (eBPF) programs. Their main utility is analyzing OS performance and network performance without experiencing overhead or security issues.

BCC removes the need for users to know deep technical details of eBPF, and provides many out-of-the-box starting points, such as the bcc-tools package with pre-created eBPF programs.

NOTE

The eBPF programs are triggered on events, such as disk I/O, TCP connections, and process creations. It is unlikely that the programs should cause the kernel to crash, loop or become unresponsive because they run in a safe virtual machine in the kernel.

Additional resources

- For more information about BCC, see the /usr/share/doc/bcc/README.md file.

8.2. INSTALLING BCC

This section describes how to install the bcc-tools package, which contains the BPF Compiler Collection (BCC) library.

Prerequisites

- An active Red Hat Enterprise Linux subscription
- An enabled repository containing the bcc-tools package
- Introduction to yum package manager
- Updated kernel

Procedure

1. Install bcc-tools:

```bash
# yum install bcc-tools
```

Once installed, the tools are placed in the /usr/share/bcc/tools/ directory.
2. Optionally, inspect the tools:

```bash
# ll /usr/share/bcc/tools/
... 
-rwxr-xr-x. 1 root root  4198 Dec 14 17:53 dcsnoop 
-rwxr-xr-x. 1 root root  3931 Dec 14 17:53 dcstat 
-rwxr-xr-x. 1 root root 20040 Dec 14 17:53 deadlock_detector 
-rw-r--r--. 1 root root  7105 Dec 14 17:53 deadlock_detector.c 
-drwxr-xr-x. 3 root root  8192 Mar 11 10:28 doc 
-rwxr-xr-x. 1 root root  7588 Dec 14 17:53 execsnoop 
-rwxr-xr-x. 1 root root  6373 Dec 14 17:53 ext4dist 
-rwxr-xr-x. 1 root root 10401 Dec 14 17:53 ext4slower 
...
```

The `doc` directory in the listing above contains documentation for each tool.

### 8.3. USING SELECTED BCC-TOOLS FOR PERFORMANCE ANALYSES

This section describes how to use certain pre-created programs from the BPF Compiler Collection (BCC) library to efficiently and securely analyze the system performance on the per-event basis. The set of pre-created programs in the BCC library can serve as examples for creation of additional programs.

#### Prerequisites

- Introduction to BCC
- Installed BCC library
- Root permissions

#### Using `execsnoop` to examine the system processes

1. Execute the `execsnoop` program in one terminal:

   ```bash
   # /usr/share/bcc/tools/execsnoop
   ```

2. In another terminal execute for example:

   ```bash
   $ ls /usr/share/bcc/tools/doc/
   ```

   The above creates a short-lived process of the `ls` command.

3. The terminal running `execsnoop` shows the output similar to the following:

   ```
   PCOMM PID PPID RET ARGS
   ls 8382 8287 0 /usr/bin/ls --color=auto /usr/share/bcc/tools/doc/ 
   sed 8385 8383 0 /usr/bin/sed s/^ *[0-9]\+ */
   ...
   ```

   The `execsnoop` program prints a line of output for each new process, which consumes system resources. It even detects processes of programs that run very shortly, such as `ls`, and most monitoring tools would not register them.

   The result above shows a parent process name (`ls`), its process ID (5076), parent process ID...
(2931), the return value of the exec() system call (0), which loads program code into new processes. Finally, the output displays a location of the started program with arguments (/usr/bin/ls --color=auto /usr/share/bcc/tools/doc/).

To see more details, examples, and options for execsnoop, refer to the /usr/share/bcc/tools/doc/execsnoop_example.txt file.

For more information about exec(), see exec(3) manual pages.

Using opensnoop to track what files a command opens

1. Execute the opensnoop program in one terminal:
   
   # /usr/share/bcc/tools/opensnoop -n uname
   
   The above prints output for files, which are opened only by the process of the uname command.

2. In another terminal execute:
   
   $ uname
   
   The command above opens certain files, which are captured in the next step.

3. The terminal running opensnoop shows the output similar to the following:

<table>
<thead>
<tr>
<th>PID</th>
<th>COMM</th>
<th>FD</th>
<th>ERR</th>
<th>PATH</th>
</tr>
</thead>
<tbody>
<tr>
<td>8596</td>
<td>uname</td>
<td>3</td>
<td>0</td>
<td>/etc/ld.so.cache</td>
</tr>
<tr>
<td>8596</td>
<td>uname</td>
<td>3</td>
<td>0</td>
<td>/lib64/libc.so.6</td>
</tr>
<tr>
<td>8596</td>
<td>uname</td>
<td>3</td>
<td>0</td>
<td>/usr/lib/locale/locale-archive</td>
</tr>
</tbody>
</table>
   ...

   The opensnoop program watches the open() system call across the whole system, and prints a line of output for each file that uname tried to open along the way.

   The result above shows a process ID (PID), a process name (COMM), and a file descriptor (FD) - a value that open() returns to refer to the open file. Finally, the output displays a column for errors (ERR) and a location of files that open() tries to open (PATH).

   If a command tries to read a non-existent file, then the FD column returns -1 and the ERR column prints a value corresponding to the relevant error. As a result, opensnoop can help you identify an application that does not behave properly.

To see more details, examples, and options for opensnoop, refer to the /usr/share/bcc/tools/doc/opensnoop_example.txt file.

For more information about open(), see open(2) manual pages.

Using biotop to examine the I/O operations on the disk

1. Execute the biotop program in one terminal:

   # /usr/share/bcc/tools/biotop 30

   The command enables you to monitor the top processes, which perform I/O operations on the disk. The argument ensures that the command will produce a 30 second summary.
When no argument provided, the output screen by default refreshes every 1 second.

2. In another terminal execute for example:

```
# dd if=/dev/vda of=/dev/zero
```

The command above reads the content from the local hard disk device and writes the output to the /dev/zero file. This step generates certain I/O traffic to illustrate `biotop`.

3. The terminal running `biotop` shows the output similar to the following:

```
PID    COMM             D MAJ MIN DISK       I/O  Kbytes     AVGms
9568   dd               R 252 0   vda      16294 14440636.0  3.69
48     kswapd0          W 252 0   vda       1763 120696.0    1.65
7571   gnome-shell      R 252 0   vda        834 83612.0     0.33
1891   gnome-shell      R 252 0   vda       1379 19792.0     0.15
7515   Xorg             R 252 0   vda        280  9940.0     0.28
7579   llvmpipe-1       R 252 0   vda       228  6928.0     0.19
9515   gnome-control-c  R 252 0   vda         62  6444.0     0.43
5815   gnome-terminal-  R 252 0   vda        228  6928.0     0.19
7587   gnome-software   R 252 0   vda         31  2336.0     0.73
9578   awk              R 252 0   vda         17  2228.0     0.66
7578   llvmpipe-0       R 252 0   vda        58  1748.0     0.42
7531   InputThread      R 252 0   vda        30  1200.0     0.48
7504   gdbus            R 252 0   vda          3  1164.0     0.30
1983   llvmpipe-1       R 252 0   vda         39  724.0     0.08
1982   llvmpipe-0       R 252 0   vda         36  652.0     0.06
...
```

The results shows that the `dd` process, with the process ID 9568, performed 16,294 read operations from the `vda` disk. The read operations reached total of 14,440,636 Kbytes with an average I/O time 3.69 ms.

To see more details, examples, and options for `biotop`, refer to the `/usr/share/bcc/tools/doc/biotop_example.txt` file.

For more information about `dd`, see `dd(1)` manual pages.

**Using xfsslower to expose unexpectedly slow file system operations**

1. Execute the `xfsslower` program in one terminal:

```
# /usr/share/bcc/tools/xfsslower 1
```

The command above measures the time the XFS file system spends in performing read, write, open or sync (`fsync`) operations. The 1 argument ensures that the program shows only the operations that are slower than 1 ms.
NOTE

When no arguments provided, `xfsslower` by default displays operations slower than 10 ms.

2. In another terminal execute, for example, the following:

```bash
$ vim text
```

The command above creates a text file in the `vim` editor to initiate certain interaction with the XFS file system.

3. The terminal running `xfsslower` shows something similar upon saving the file from the previous step:

```
<table>
<thead>
<tr>
<th>TIME</th>
<th>COMM</th>
<th>PID</th>
<th>T</th>
<th>BYTES</th>
<th>OFF_KB</th>
<th>LAT(ms)</th>
<th>FILENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>13:07:14</td>
<td>b'bash'</td>
<td>4754</td>
<td>R</td>
<td>256</td>
<td>0</td>
<td>7.11</td>
<td>b'vim'</td>
</tr>
<tr>
<td>13:07:14</td>
<td>b'vim'</td>
<td>4754</td>
<td>R</td>
<td>832</td>
<td>0</td>
<td>4.03</td>
<td>b'libgpm.so.2.1.0'</td>
</tr>
<tr>
<td>13:07:14</td>
<td>b'vim'</td>
<td>4754</td>
<td>R</td>
<td>32</td>
<td>20</td>
<td>1.04</td>
<td>b'libgpm.so.2.1.0'</td>
</tr>
<tr>
<td>13:07:14</td>
<td>b'vim'</td>
<td>4754</td>
<td>R</td>
<td>1982</td>
<td>0</td>
<td>2.30</td>
<td>b'vimrc'</td>
</tr>
<tr>
<td>13:07:14</td>
<td>b'vim'</td>
<td>4754</td>
<td>R</td>
<td>1393</td>
<td>0</td>
<td>2.52</td>
<td>b'getscriptPlugin.vim'</td>
</tr>
<tr>
<td>13:07:45</td>
<td>b'vim'</td>
<td>4754</td>
<td>S</td>
<td>0</td>
<td>0</td>
<td>6.71</td>
<td>b'text'</td>
</tr>
<tr>
<td>13:07:45</td>
<td>b'pool'</td>
<td>2588</td>
<td>R</td>
<td>16</td>
<td>0</td>
<td>5.58</td>
<td>b'text'</td>
</tr>
</tbody>
</table>
```

Each line above represents an operation in the file system, which took more time than a certain threshold. `xfsslower` is good at exposing possible file system problems, which can take form of unexpectedly slow operations.

The `T` column represents operation type (Read/Write/Sync), `OFF_KB` is a file offset in KB. `FILENAME` is the file the process (`COMM`) is trying to read, write, or sync.

To see more details, examples, and options for `xfsslower`, refer to the `/usr/share/bcc/tools/doc/xfsslower_example.txt` file.

For more information about `fsync`, see `fsync(2)` manual pages.
