Red Hat Enterprise Linux 8

Monitoring and managing system status and performance

Optimizing system throughput, latency, and power consumption
Red Hat Enterprise Linux 8 Monitoring and managing system status and performance

Optimizing system throughput, latency, and power consumption
Abstract

Monitor and optimize the throughput, latency, and power consumption of Red Hat Enterprise Linux 8 in different scenarios.

## Chapter 1. Overview of Performance Monitoring Options ................................. 12

## Chapter 2. Getting Started with Tuned ......................................................... 14
  2.1. The Purpose of Tuned ..............................
  2.2. Tuned Profiles ................
    Syntax of profile configuration ............................
  2.3. The Default Tuned Profile ........................
  2.4. Merged Tuned Profiles ................
  2.5. The Location of Tuned Profiles ..............
  2.6. Tuned Profiles Distributed with RHEL ........
  2.7. Tuned CPU-Partitioning Profile .............
  2.8. Using the Tuned CPU-Partitioning Profile for Low-Latency Tuning ........
  2.9. Customizing the Tuned CPU-Partitioning Profile ............................
  2.10. Real-Time Tuned Profiles Distributed with RHEL .....................
  2.11. Static and Dynamic Tuning in Tuned ........
  2.12. Tuned No-Daemon Mode ......................
  2.13. Installing and Enabling Tuned .................
  2.14. Listing Available Tuned Profiles ...........
  2.15. Setting a Tuned Profile .......................
  2.16. Disabling Tuned ....................

## Chapter 3. Customizing Tuned Profiles ....................................................... 26
  3.1. Tuned Profiles ................
    Syntax of profile configuration ............................
  3.2. The Default Tuned Profile ........................
  3.3. Merged Tuned Profiles ................
  3.4. The Location of Tuned Profiles ..............
  3.5. Inheritance Between Tuned Profiles ........
  3.6. Static and Dynamic Tuning in Tuned ........
  3.7. Tuned Plug-Ins ..................
    Syntax for plug-ins in TuneD profiles .................
    Short plug-in syntax ...........................
    Conflicting plug-in definitions in a profile ..........
  3.8. Available Tuned Plug-Ins ..................
    Monitoring plug-ins ...........................
    Tuning plug-ins ............................
  3.9. Functionalities of the Scheduler Tuned Plugin ..................
  3.10. Variables in Tuned Profiles ...............
  3.11. Built-In Functions in Tuned Profiles ....
  3.12. Built-In Functions Available in Tuned Profiles ........
  3.13. Creating New Tuned Profiles ................
  3.14. Modifying Existing Tuned Profiles ...........
  3.15. Setting the Disk Scheduler Using Tuned ........

## Chapter 4. Reviewing a System Using Tuna Interface .................................... 48
  4.1. Installing Tuna Tool ....................
  4.2. Viewing the System Status Using Tuna Tool ...........
  4.3. Tuning CPUs Using Tuna Tool ..........
# Chapter 4.4: Tuning IRQs Using TUNA Tool

## Chapter 5: Monitoring Performance Using RHEL System Roles

### 5.1. Preparing a Control Node and Managed Nodes to Use RHEL System Roles

#### 5.1.1. Preparing a control node on RHEL 8

#### 5.1.2. Preparing a managed node

### 5.2. Introduction to the Metrics System Role

### 5.3. Using the Metrics System Role to Monitor Your Local System with Visualization

### 5.4. Using the Metrics System Role to Set Up a Fleet of Individual Systems to Monitor Themselves

### 5.5. Using the Metrics System Role to Monitor a Fleet of Machines Centrally Via Your Local Machine

### 5.6. Setting Up Authentication While Monitoring a System Using the Metrics System Role

### 5.7. Using the Metrics System Role to Configure and Enable Metrics Collection for SQL Server

## Chapter 6: Setting Up PCP

### 6.1. Overview of PCP

### 6.2. Installing and Enabling PCP

### 6.3. Deploying a Minimal PCP Setup

### 6.4. System Services Distributed with PCP

### 6.5. Tools Distributed with PCP

### 6.6. PCP Deployment Architectures

### 6.7. Recommended Deployment Architecture

### 6.8. Sizing Factors

### 6.9. Configuration Options for PCP Scaling

### 6.10. Example: Analyzing the Centralized Logging Deployment

### 6.11. Example: Analyzing the Federated Setup Deployment

### 6.12. Troubleshooting High Memory Usage

## Chapter 7: Logging Performance Data with PMLogger

### 7.1. Modifying the PMLogger Configuration File with PMLOGCONF

### 7.2. Editing the PMLogger Configuration File Manually

### 7.3. Enabling the PMLogger Service

### 7.4. Setting Up a Client System for Metrics Collection

### 7.5. Setting Up a Central Server to Collect Data

### 7.6. Replaying the PCP Log Archives with PMREP

## Chapter 8: Monitoring Performance with Performance Co-Pilot

### 8.1. Monitoring Postfix with PMDA-POSTFIX

### 8.2. Visually Tracing PCP Log Archives with the PCP Charts Application

### 8.3. Collecting Data from SQL Server Using PCP

## Chapter 9: Performance Analysis of XFS with PCP

### 9.1. Installing XFS PMDA Manually

### 9.2. Examining XFS Performance Metrics with PMINFO

### 9.3. Resetting XFS Performance Metrics with PMSTORE

### 9.4. PCP Metric Groups for XFS

### 9.5. Per-Device PCP Metric Groups for XFS

## Chapter 10: Setting Up Graphical Representation of PCP Metrics

### 10.1. Setting Up PCP with PCP-ZEROCONF

### 10.2. Setting Up a Grafana-Server

### 10.3. Accessing the Grafana Web UI

  16.6.2. The powertop2tuned utility  ......................................... 160
  16.6.3. Optimizing power consumption using the powertop2tuned utility  ............................................... 160
  16.6.4. Comparison of powertop.service and powertop2tuned  .... 161

### CHAPTER 17. TUNING CPU FREQUENCY TO OPTIMIZE ENERGY CONSUMPTION
17.1. SUPPORTED CPUPOWER TOOL COMMANDS  .......................... 162
17.2. CPU IDLE STATES  .............................................................. 163
17.3. OVERVIEW OF CPufreq  ...................................................... 164
  17.3.1. CPufreq drivers  ......................................................... 164
  17.3.2. Core CPufreq governors  .......................................... 165
  17.3.3. Intel P–state CPufreq governors  .................................. 166
  17.3.4. Setting up CPufreq governor  .................................... 167

### CHAPTER 18. GETTING STARTED WITH PERF
18.1. INTRODUCTION TO PERF  .................................................... 169
18.2. INSTALLING PERF  ............................................................... 169
18.3. COMMON PERF COMMANDS  .............................................. 169

### CHAPTER 19. PROFILING CPU USAGE IN REAL TIME WITH PERF TOP
19.1. THE PURPOSE OF PERF TOP  ............................................... 171
19.2. PROFILING CPU USAGE WITH PERF TOP  ............................ 171
19.3. INTERPRETATION OF PERF TOP OUTPUT  ............................ 172
19.4. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES  ............................................... 172
19.5. ENABLING DEBUG AND SOURCE REPOSITORIES  .................. 172
19.6. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB  ............................................... 173

### CHAPTER 20. COUNTING EVENTS DURING PROCESS EXECUTION WITH PERF STAT
20.1. THE PURPOSE OF PERF STAT  .............................................. 175
20.2. COUNTING EVENTS WITH PERF STAT  .................................. 175
20.3. INTERPRETATION OF PERF STAT OUTPUT  ............................ 176
20.4. ATTACHING PERF STAT TO A RUNNING PROCESS  .................. 177

### CHAPTER 21. RECORDING AND ANALYZING PERFORMANCE PROFILES WITH PERF
21.1. THE PURPOSE OF PERF RECORD  ......................................... 178
# Table of Contents

21.2. RECORDING A PERFORMANCE PROFILE WITHOUT ROOT ACCESS .......................... 178
21.3. RECORDING A PERFORMANCE PROFILE WITH ROOT ACCESS ...................... 178
21.4. RECORDING A PERFORMANCE PROFILE IN PER-CPU MODE ......................... 179
21.5. CAPTURING CALL GRAPH DATA WITH PERF RECORD ................................. 179
21.6. ANALYZING PERF.DATA WITH PERF REPORT ........................................... 180
21.7. INTERPRETATION OF PERF REPORT OUTPUT ............................................ 181
21.8. GENERATING A PERF.DATA FILE THAT IS READABLE ON A DIFFERENT DEVICE .. 181
21.9. ANALYZING A PERF.DATA FILE THAT WAS CREATED ON A DIFFERENT DEVICE 182
21.10. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES .. 183
21.11. ENABLING DEBUG AND SOURCE REPOSITORIES ..................................... 183
21.12. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB 184

CHAPTER 22. INVESTIGATING BUSY CPUS WITH PERF ........................................... 186
22.1. DISPLAYING WHICH CPU EVENTS WERE COUNTED ON WITH PERF STAT ........ 186
22.2. DISPLAYING WHICH CPU SAMPLES WERE TAKEN ON WITH PERF REPORT ....... 186
22.3. DISPLAYING SPECIFIC CPUS DURING PROFILING WITH PERF TOP .............. 187
22.4. MONITORING SPECIFIC CPUS WITH PERF RECORD AND PERF REPORT ......... 187

CHAPTER 23. MONITORING APPLICATION PERFORMANCE WITH PERF ....................... 189
23.1. ATTACHING PERF RECORD TO A RUNNING PROCESS .................................. 189
23.2. CAPTURING CALL GRAPH DATA WITH PERF RECORD ............................... 189
23.3. ANALYZING PERF.DATA WITH PERF REPORT ........................................... 190

CHAPTER 24. CREATING UPROBES WITH PERF ..................................................... 192
24.1. CREATING UPROBES AT THE FUNCTION LEVEL WITH PERF ...................... 192
24.2. CREATING UPROBES ON LINES WITHIN A FUNCTION WITH PERF ............ 192
24.3. PERF SCRIPT OUTPUT OF DATA RECORDED OVER UPROBES .................... 193

CHAPTER 25. PROFILING MEMORY ACCESSES WITH PERF MEM ............................ 194
25.1. THE PURPOSE OF PERF MEM ................................................................. 194
25.2. SAMPLING MEMORY ACCESS WITH PERF MEM ....................................... 194
25.3. INTERPRETATION OF PERF MEM REPORT OUTPUT ................................. 196

CHAPTER 26. DETECTING FALSE SHARING ............................................................. 198
26.1. THE PURPOSE OF PERF C2C ..................................................................... 198
26.2. DETECTING CACHE-LINE CONTENTION WITH PERF C2C ......................... 198
26.3. VISUALIZING A PERF.DATA FILE RECORDED WITH PERF C2C RECORD .... 199
26.4. INTERPRETATION OF PERF C2C REPORT OUTPUT .................................. 201
26.5. DETECTING FALSE SHARING WITH PERF C2C ...................................... 202

CHAPTER 27. GETTING STARTED WITH FLAMEGRAPHS ........................................... 205
27.1. INSTALLING FLAMEGRAPHS ................................................................. 205
27.2. CREATING FLAMEGRAPHS OVER THE ENTIRE SYSTEM ....................... 205
27.3. CREATING FLAMEGRAPHS OVER SPECIFIC PROCESSES .................... 206
27.4. INTERPRETING FLAMEGRAPHS ............................................................. 207

CHAPTER 28. MONITORING PROCESSES FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS .............................................................. 209
28.1. CIRCULAR BUFFERS AND EVENT-SPECIFIC SNAPSHOTS WITH PERF ...... 209
28.2. COLLECTING SPECIFIC DATA TO MONITOR FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS ........................................... 209

CHAPTER 29. ADDING AND REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF ........................................... 211
29.1. ADDING TRACEPOINTS TO A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF ............................................................. 211
29.2. REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

CHAPTER 30. PROFILING MEMORY ALLOCATION WITH NUMASTAT .......................... 213
30.1. DEFAULT NUMASTAT STATISTICS ..................................................... 213
30.2. VIEWING MEMORY ALLOCATION WITH NUMASTAT .......................... 213

CHAPTER 31. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE CPU UTILIZATION .............. 215
31.1. TOOLS FOR MONITORING AND DIAGNOSING PROCESSOR ISSUES .................. 215
31.2. TYPES OF SYSTEM TOPOLOGY ....................................................... 216
   31.2.1. Displaying system topologies ................................................. 216
31.3. CONFIGURING KERNEL TICK TIME ............................................... 218
31.4. OVERVIEW OF AN INTERRUPT REQUEST ........................................... 220
   31.4.1. Balancing interrupts manually ................................................ 220
   31.4.2. Setting the smp_affinity mask ............................................... 221

CHAPTER 32. TUNING SCHEDULING POLICY .................................................. 223
32.1. CATEGORIES OF SCHEDULING POLICIES ............................................ 223
32.2. STATIC PRIORITY SCHEDULING WITH SCHED_FIFO ............................... 223
32.3. ROUND ROBIN PRIORITY SCHEDULING WITH SCHED_RR ....................... 224
32.4. NORMAL SCHEDULING WITH SCHED_OTHER ...................................... 224
32.5. SETTING SCHEDULER POLICIES .................................................... 224
32.6. POLICY OPTIONS FOR THE CHRT COMMAND .................................... 225
32.7. CHANGING THE PRIORITY OF SERVICES DURING THE BOOT PROCESS ............ 226
32.8. PRIORITY MAP ........................................................................... 227
32.9. TUNED CPU-PARTITIONING PROFILE .............................................. 228
32.10. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING .......... 229
32.11. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE ....................... 230

CHAPTER 33. FACTORS AFFECTING I/O AND FILE SYSTEM PERFORMANCE ......................... 232
33.1. TOOLS FOR MONITORING AND DIAGNOSING I/O AND FILE SYSTEM ISSUES ............ 232
33.2. AVAILABLE TUNING OPTIONS FOR FORMATTING A FILE SYSTEM ................. 234
33.3. AVAILABLE TUNING OPTIONS FOR MOUNTING A FILE SYSTEM .................. 235
33.4. TYPES OF DISCARDING UNUSED BLOCKS .......................................... 236
33.5. SOLID-STATE DISKS TUNING CONSIDERATIONS ................................... 236
33.6. GENERIC BLOCK DEVICE TUNING PARAMETERS .................................... 237

CHAPTER 34. TUNING THE NETWORK PERFORMANCE ......................................... 239
34.1. TUNING NETWORK ADAPTER SETTINGS ............................................ 239
   34.1.1. Increasing the ring buffers to reduce a high packet drop rate .................. 239
   34.1.2. Tuning the network device backlog queue to avoid packet drops ............. 240
   34.1.3. Increasing the transmit queue length of a NIC to reduce the number of transmit errors 242
34.2. TUNING IRQ BALANCING ............................................................... 243
   34.2.1. Interrupts and interrupt handlers ............................................... 243
   34.2.2. Software interrupt requests ....................................................... 243
   34.2.3. NAPI Polling ........................................................................ 244
   34.2.4. The irqbalance service .............................................................. 244
   34.2.5. Increasing the time SoftIRQs can run on the CPU .............................. 245
34.3. IMPROVING THE NETWORK LATENCY .............................................. 246
   34.3.1. How the CPU power states influence the network latency .................... 246
   34.3.2. C-state settings in the EFI firmware .......................................... 247
   34.3.3. Disabling C-states by using a custom TuneD profile ......................... 247
   34.3.4. Disabling C-states by using a kernel command line option ................. 248
34.4. IMPROVING THE THROUGHPUT OF LARGE AMOUNTS OF CONTIGUOUS DATA STREAMS 250
34.4.1. Considerations before configuring jumbo frames
34.4.2. Configuring the MTU in an existing NetworkManager connection profile
34.5. TUNING TCP CONNECTIONS FOR HIGH THROUGHPUT
34.5.1. Testing the TCP throughput using iperf3
34.5.2. The system-wide TCP socket buffer settings
34.5.3. Increasing the system-wide TCP socket buffers
34.5.4. TCP Window Scaling
34.5.5. How TCP SACK reduces the packet drop rate
34.6. TUNING UDP CONNECTIONS
34.6.1. Detecting packet drops
34.6.2. Testing the UDP throughput using iperf3
34.6.3. Impact of the MTU size on UDP traffic throughput
34.6.4. Impact of the CPU speed on UDP traffic throughput
34.6.5. Increasing the system-wide UDP socket buffers
34.7. IDENTIFYING APPLICATION READ SOCKET BUFFER BOTTLENECKS
34.7.1. Identifying receive buffer collapsing and pruning
34.8. TUNING APPLICATIONS WITH A LARGE NUMBER OF INCOMING REQUESTS
34.8.1. Tuning the TCP listen backlog to process a high number of TCP connection attempts
34.9. AVOIDING LISTEN QUEUE LOCK CONTENTION
34.9.1. Avoiding RX queue lock contention: The SO_REUSEPORT and SO_REUSEPORT_BPF socket options
34.9.2. Avoiding TX queue lock contention: Transmit packet steering
34.9.3. Disabling the Generic Receive Offload feature on servers with high UDP traffic
34.10. TUNING THE DEVICE DRIVER AND NIC
34.10.1. Configuring custom NIC driver parameters
34.11. CONFIGURING NETWORK ADAPTER OFFLOAD SETTINGS
34.11.1. Temporarily setting an offload feature
34.11.2. Permanently setting an offload feature
34.12. TUNING INTERRUPT COALESCENCE SETTINGS
34.12.1. Optimizing RHEL for latency or throughput-sensitive services
34.13. BENEFITS OF TCP TIMESTAMPS
34.14. FLOW CONTROL FOR ETHERNET NETWORKS

CHAPTER 35. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE MEMORY ACCESS
35.1. TOOLS FOR MONITORING AND DIAGNOSING SYSTEM MEMORY ISSUES
35.2. OVERVIEW OF A SYSTEM’S MEMORY
35.3. VIRTUAL MEMORY PARAMETERS
35.4. FILE SYSTEM PARAMETERS
35.5. KERNEL PARAMETERS
35.6. SETTING MEMORY-RELATED KERNEL PARAMETERS

CHAPTER 36. CONFIGURING HUGE PAGES
36.1. AVAILABLE HUGE PAGE FEATURES
36.2. PARAMETERS FOR RESERVING HUGETLB PAGES AT BOOT TIME
36.3. CONFIGURING HUGETLB AT BOOT TIME
36.4. PARAMETERS FOR RESERVING HUGETLB PAGES AT RUN TIME
36.5. CONFIGURING HUGETLB AT RUN TIME
36.6. ENABLING TRANSPARENT HUGEPAGES
36.7. DISABLING TRANSPARENT HUGEPAGES
36.8. IMPACT OF PAGE SIZE ON TRANSLATION LOOKASIDE BUFFER SIZE

CHAPTER 37. GETTING STARTED WITH SYSTEMTAP
37.1. THE PURPOSE OF SYSTEMTAP
37.2. INSTALLING SYSTEMTAP

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your feedback on our documentation. Let us know how we can improve it.

Submitting comments on specific passages

1. View the documentation in the Multi-page HTML format and ensure that you see the Feedback button in the upper right corner after the page fully loads.

2. Use your cursor to highlight the part of the text that you want to comment on.

3. Click the Add Feedback button that appears near the highlighted text.

4. Add your feedback and click Submit.

Submitting feedback through Jira (account required)

1. Log in to the Jira website.

2. Click Create in the top navigation bar

3. Enter a descriptive title in the Summary field.

4. Enter your suggestion for improvement in the Description field. Include links to the relevant parts of the documentation.

5. Click Create at the bottom of the dialogue.
CHAPTER 1. OVERVIEW OF PERFORMANCE MONITORING OPTIONS

The following are some of the performance monitoring and configuration tools available in Red Hat Enterprise Linux 8:

- **Performance Co-Pilot** (*pcp*) is used for monitoring, visualizing, storing, and analyzing system-level performance measurements. It allows the monitoring and management of real-time data, and logging and retrieval of historical data.

- Red Hat Enterprise Linux 8 provides several tools that can be used from the command line to monitor a system outside run level 5. The following are the built-in command line tools:
  - **top** is provided by the *procps-ng* package. It gives a dynamic view of the processes in a running system. It displays a variety of information, including a system summary and a list of tasks currently being managed by the Linux kernel.
  - **ps** is provided by the *procps-ng* package. It captures a snapshot of a select group of active processes. By default, the examined group is limited to processes that are owned by the current user and associated with the terminal where the **ps** command is executed.
  - Virtual memory statistics (**vmstat**) is provided by the *procps-ng* package. It provides instant reports of your system’s processes, memory, paging, block input/output, interrupts, and CPU activity.
  - System activity reporter (**sar**) is provided by the *sysstat* package. It collects and reports information about system activity that has occurred so far on the current day.
  - **perf** uses hardware performance counters and kernel trace-points to track the impact of other commands and applications on a system.
  - **bcc-tools** is used for BPF Compiler Collection (BCC). It provides over 100 eBPF scripts that monitor kernel activities. For more information about each of this tool, see the man page describing how to use it and what functions it performs.
  - **turbostat** is provided by the *kernel-tools* package. It reports on processor topology, frequency, idle power-state statistics, temperature, and power usage on the Intel 64 processors.
  - **iostat** is provided by the *sysstat* package. It monitors and reports on system IO device loading to help administrators make decisions about how to balance IO load between physical disks.
  - **irqbalance** distributes hardware interrupts across processors to improve system performance.
  - **ss** prints statistical information about sockets, allowing administrators to assess device performance over time. Red Hat recommends using **ss** over **netstat** in Red Hat Enterprise Linux 8.
  - **numastat** is provided by the *numactl* package. By default, **numastat** displays per-node NUMA hit and miss system statistics from the kernel memory allocator. Optimal performance is indicated by high **numa_hit** values and low **numa_miss** values.
  - **numad** is an automatic NUMA affinity management daemon. It monitors NUMA topology and resource usage within a system that dynamically improves NUMA resource allocation, management, and therefore system performance.
  - **SystemTap** monitors and analyzes operating system activities, especially the kernel activities.
valgrind analyzes applications by running it on a synthetic CPU and instrumenting existing application code as it is executed. It then prints commentary that clearly identifies each process involved in application execution to a user-specified file, file descriptor, or network socket. It is also useful for finding memory leaks.

pqos is provided by the intel-cmt-cat package. It monitors and controls CPU cache and memory bandwidth on recent Intel processors.

CHAPTER 2. GETTING STARTED WITH TUNED

As a system administrator, you can use the TuneD application to optimize the performance profile of your system for a variety of use cases.

2.1. THE PURPOSE OF TUNED

TuneD is a service that monitors your system and optimizes the performance under certain workloads. The core of TuneD are profiles, which tune your system for different use cases.

TuneD is distributed with a number of predefined profiles for use cases such as:

- High throughput
- Low latency
- Saving power

It is possible to modify the rules defined for each profile and customize how to tune a particular device. When you switch to another profile or deactivate TuneD, all changes made to the system settings by the previous profile revert back to their original state.

You can also configure TuneD to react to changes in device usage and adjusts settings to improve performance of active devices and reduce power consumption of inactive devices.

2.2. TUNED PROFILES

A detailed analysis of a system can be very time-consuming. TuneD provides a number of predefined profiles for typical use cases. You can also create, modify, and delete profiles.

The profiles provided with TuneD are divided into the following categories:

- Power-saving profiles
- Performance-boosting profiles

The performance-boosting profiles include profiles that focus on the following aspects:

- Low latency for storage and network
- High throughput for storage and network
- Virtual machine performance
- Virtualization host performance

Syntax of profile configuration
The tuned.conf file can contain one [main] section and other sections for configuring plug-in instances. However, all sections are optional.

Lines starting with the hash sign (#) are comments.

Additional resources
- tuned.conf(5) man page.
2.3. THE DEFAULT TUNED PROFILE

During the installation, the best profile for your system is selected automatically. Currently, the default profile is selected according to the following customizable rules:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Default profile</th>
<th>Goal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute nodes</td>
<td><strong>throughput-performance</strong></td>
<td>The best throughput performance</td>
</tr>
<tr>
<td>Virtual machines</td>
<td><strong>virtual-guest</strong></td>
<td>The best performance. If you are not interested in the best performance, you can change it to the balanced or powersave profile.</td>
</tr>
<tr>
<td>Other cases</td>
<td><strong>balanced</strong></td>
<td>Balanced performance and power consumption</td>
</tr>
</tbody>
</table>

Additional resources

- tuned.conf(5) man page.

2.4. MERGED TUNED PROFILES

As an experimental feature, it is possible to select more profiles at once. TuneD will try to merge them during the load.

If there are conflicts, the settings from the last specified profile takes precedence.

Example 2.1. Low power consumption in a virtual guest

The following example optimizes the system to run in a virtual machine for the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

# tuned-adm profile virtual-guest powersave

**WARNING**

Merging is done automatically without checking whether the resulting combination of parameters makes sense. Consequently, the feature might tune some parameters the opposite way, which might be counterproductive: for example, setting the disk for high throughput by using the throughput-performance profile and concurrently setting the disk spindown to the low value by the spindown-disk profile.

Additional resources
2.5. THE LOCATION OF TUNED PROFILES

TunedD stores profiles in the following directories:

/usr/lib/tuned/

Distribution-specific profiles are stored in the directory. Each profile has its own directory. The profile consists of the main configuration file called tuned.conf, and optionally other files, for example helper scripts.

/etc/tuned/

If you need to customize a profile, copy the profile directory into the directory, which is used for custom profiles. If there are two profiles of the same name, the custom profile located in /etc/tuned/ is used.

Additional resources

- tuned.conf(5) man page.

2.6. TUNED PROFILES DISTRIBUTED WITH RHEL

The following is a list of profiles that are installed with TunedD on Red Hat Enterprise Linux.

**NOTE**

There might be more product-specific or third-party TunedD profiles available. Such profiles are usually provided by separate RPM packages.

**balanced**

The default power-saving profile. It is intended to be a compromise between performance and power consumption. It uses auto-scaling and auto-tuning whenever possible. The only drawback is the increased latency. In the current TunedD release, it enables the CPU, disk, audio, and video plugins, and activates the conservative CPU governor. The radeon_powersave option uses the dpm-balanced value if it is supported, otherwise it is set to auto. It changes the energy_performance_preference attribute to the normal energy setting. It also changes the scaling_governor policy attribute to either the conservative or powersave CPU governor.

**powersave**

A profile for maximum power saving performance. It can throttle the performance in order to minimize the actual power consumption. In the current TunedD release it enables USB autosuspend, WiFi power saving, and Aggressive Link Power Management (ALPM) power savings for SATA host adapters. It also schedules multi-core power savings for systems with a low wakeup rate and activates the ondemand governor. It enables AC97 audio power saving or, depending on your system, HDA-Intel power savings with a 10 seconds timeout. If your system contains a supported Radeon graphics card with enabled KMS, the profile configures it to automatic power saving. On ASUS Eee PCs, a dynamic Super Hybrid Engine is enabled. It changes the energy_performance_preference attribute to the powersave or power energy setting. It also changes the scaling_governor policy attribute to either the ondemand or powersave CPU governor.
NOTE

In certain cases, the **balanced** profile is more efficient compared to the **powersave** profile.

Consider there is a defined amount of work that needs to be done, for example a video file that needs to be transcoded. Your machine might consume less energy if the transcoding is done on the full power, because the task is finished quickly, the machine starts to idle, and it can automatically step-down to very efficient power save modes. On the other hand, if you transcode the file with a throttled machine, the machine consumes less power during the transcoding, but the process takes longer and the overall consumed energy can be higher.

That is why the **balanced** profile can be generally a better option.

**throughput-performance**

A server profile optimized for high throughput. It disables power savings mechanisms and enables **sysctl** settings that improve the throughput performance of the disk and network IO. CPU governor is set to **performance**.

It changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

**accelerator-performance**

The **accelerator-performance** profile contains the same tuning as the **throughput-performance** profile. Additionally, it locks the CPU to low C states so that the latency is less than 100us. This improves the performance of certain accelerators, such as GPUs.

**latency-performance**

A server profile optimized for low latency. It disables power savings mechanisms and enables **sysctl** settings that improve latency. CPU governor is set to **performance** and the CPU is locked to the low C states (by PM QoS).

It changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

**network-latency**

A profile for low latency network tuning. It is based on the **latency-performance** profile. It additionally disables transparent huge pages and NUMA balancing, and tunes several other network-related **sysctl** parameters.

It inherits the **latency-performance** profile which changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

**hpc-compute**

A profile optimized for high-performance computing. It is based on the **latency-performance** profile.

**network-throughput**

A profile for throughput network tuning. It is based on the **throughput-performance** profile. It additionally increases kernel network buffers.

It inherits either the **latency-performance** or **throughput-performance** profile, and changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

**virtual-guest**
A profile designed for Red Hat Enterprise Linux 8 virtual machines and VMWare guests based on the throughput-performance profile that, among other tasks, decreases virtual memory swappiness and increases disk readahead values. It does not disable disk barriers. It inherits the throughput-performance profile and changes the energy_performance_preference and scaling_governor attribute to the performance profile.

virtual-host
A profile designed for virtual hosts based on the throughput-performance profile that, among other tasks, decreases virtual memory swappiness, increases disk readahead values, and enables a more aggressive value of dirty pages writeback. It inherits the throughput-performance profile and changes the energy_performance_preference and scaling_governor attribute to the performance profile.

oracle
A profile optimized for Oracle databases loads based on throughput-performance profile. It additionally disables transparent huge pages and modifies other performance-related kernel parameters. This profile is provided by the tuned-profiles-oracle package.

desktop
A profile optimized for desktops, based on the balanced profile. It additionally enables scheduler autogroups for better response of interactive applications.

optimize-serial-console
A profile that tunes down I/O activity to the serial console by reducing the printk value. This should make the serial console more responsive. This profile is intended to be used as an overlay on other profiles. For example:

```
# tuned-adm profile throughput-performance optimize-serial-console
```

mssql
A profile provided for Microsoft SQL Server. It is based on the throughput-performance profile.

intel-sst
A profile optimized for systems with user-defined Intel Speed Select Technology configurations. This profile is intended to be used as an overlay on other profiles. For example:

```
# tuned-adm profile cpu-partitioning intel-sst
```

2.7. TUNED CPU-PARTITIONING PROFILE

For tuning Red Hat Enterprise Linux 8 for latency-sensitive workloads, Red Hat recommends to use the cpu-partitioning TuneD profile.

Prior to Red Hat Enterprise Linux 8, the low-latency Red Hat documentation described the numerous low-level steps needed to achieve low-latency tuning. In Red Hat Enterprise Linux 8, you can perform low-latency tuning more efficiently by using the cpu-partitioning TuneD profile. This profile is easily customizable according to the requirements for individual low-latency applications.

The following figure is an example to demonstrate how to use the cpu-partitioning profile. This example uses the CPU and node layout.
You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the following configuration options:

**Isolated CPUs with load balancing**

In the cpu-partitioning figure, the blocks numbered from 4 to 23, are the default isolated CPUs. The kernel scheduler’s process load balancing is enabled on these CPUs. It is designed for low-latency processes with multiple threads that need the kernel scheduler load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the `isolated_cores=cpu-list` option, which lists CPUs to isolate that will use the kernel scheduler load balancing.

The list of isolated CPUs is comma-separated or you can specify a range using a dash, such as `3-5`. This option is mandatory. Any CPU missing from this list is automatically considered a housekeeping CPU.

**Isolated CPUs without load balancing**

In the cpu-partitioning figure, the blocks numbered 2 and 3, are the isolated CPUs that do not provide any additional kernel scheduler process load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the `no_balance_cores=cpu-list` option, which lists CPUs to isolate that will not use the kernel scheduler load balancing.

Specifying the `no_balance_cores` option is optional, however any CPUs in this list must be a subset of the CPUs listed in the `isolated_cores` list.

Application threads using these CPUs need to be pinned individually to each CPU.

**Housekeeping CPUs**

Any CPU not isolated in the `cpu-partitioning-variables.conf` file is automatically considered a housekeeping CPU. On the housekeeping CPUs, all services, daemons, user processes, movable kernel threads, interrupt handlers, and kernel timers are permitted to execute.

**Additional resources**

- `tuned-profiles-cpu-partitioning(7)` man page

**2.8. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING**
This procedure describes how to tune a system for low-latency using the TuneD’s `cpu-partitioning` profile. It uses the example of a low-latency application that can use `cpu-partitioning` and the CPU layout as mentioned in the `cpu-partitioning` figure.

The application in this case uses:

- One dedicated reader thread that reads data from the network will be pinned to CPU 2.
- A large number of threads that process this network data will be pinned to CPUs 4-23.
- A dedicated writer thread that writes the processed data to the network will be pinned to CPU 3.

Prerequisites

- You have installed the `cpu-partitioning` TuneD profile by using the `yum install tuned-profiles-cpu-partitioning` command as root.

Procedure

1. Edit `/etc/tuned/cpu-partitioning-variables.conf` file and add the following information:

   ```
   # All isolated CPUs:
   isolated_cores=2-23
   # Isolated CPUs without the kernel’s scheduler load balancing:
   no_balance_cores=2,3
   ```

2. Set the `cpu-partitioning` TuneD profile:

   ```
   # tuned-adm profile cpu-partitioning
   ```

3. Reboot

   After rebooting, the system is tuned for low-latency, according to the isolation in the `cpu-partitioning` figure. The application can use `taskset` to pin the reader and writer threads to CPUs 2 and 3, and the remaining application threads on CPUs 4-23.

Additional resources

- `tuned-profiles-cpu-partitioning(7)` man page

2.9. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE

You can extend the TuneD profile to make additional tuning changes.

For example, the `cpu-partitioning` profile sets the CPUs to use `cstate=1`. In order to use the `cpu-partitioning` profile but to additionally change the CPU cstate from cstate1 to cstate0, the following procedure describes a new TuneD profile named `my_profile`, which inherits the `cpu-partitioning` profile and then sets C state-0.

Procedure

1. Create the `/etc/tuned/my_profile` directory:

   ```
   # mkdir /etc/tuned/my_profile
   ```
2. Create a `tuned.conf` file in this directory, and add the following content:

```bash
# vi /etc/tuned/my_profile/tuned.conf
[main]
summary=Customized tuning on top of cpu-partitioning
include=cpu-partitioning
[cpu]
force_latency=cstate.id:0|1
```

3. Use the new profile:

```bash
# tuned-adm profile my_profile
```

**NOTE**

In the shared example, a reboot is not required. However, if the changes in the `my_profile` profile require a reboot to take effect, then reboot your machine.

Additional resources

- `tuned-profiles-cpu-partitioning(7)` man page

### 2.10. REAL-TIME TUNED PROFILES DISTRIBUTED WITH RHEL

Real-time profiles are intended for systems running the real-time kernel. Without a special kernel build, they do not configure the system to be real-time. On RHEL, the profiles are available from additional repositories.

The following real-time profiles are available:

- **realtime**
  
  Use on bare-metal real-time systems.
  Provided by the `tuned-profiles-realtime` package, which is available from the RT or NFV repositories.

- **realtime-virtual-host**
  
  Use in a virtualization host configured for real-time.
  Provided by the `tuned-profiles-nfv-host` package, which is available from the NFV repository.

- **realtime-virtual-guest**
  
  Use in a virtualization guest configured for real-time.
  Provided by the `tuned-profiles-nfv-guest` package, which is available from the NFV repository.

### 2.11. STATIC AND DYNAMIC TUNING IN TUNED

Understanding the difference between the two categories of system tuning that **TuneD** applies, **static** and **dynamic**, is important when determining which one to use for a given situation or purpose.

**Static tuning**

Mainly consists of the application of predefined `sysctl` and `sysfs` settings and one-shot activation of several configuration tools such as `ethtool`. 

Dynamic tuning

Watches how various system components are used throughout the uptime of your system. **TuneD** adjusts system settings dynamically based on that monitoring information. For example, the hard drive is used heavily during startup and login, but is barely used later when the user might mainly work with applications such as web browsers or email clients. Similarly, the CPU and network devices are used differently at different times. **TuneD** monitors the activity of these components and reacts to the changes in their use.

By default, dynamic tuning is disabled. To enable it, edit the `/etc/tuned/tuned-main.conf` file and change the `dynamic_tuning` option to `1`. **TuneD** then periodically analyzes system statistics and uses them to update your system tuning settings. To configure the time interval in seconds between these updates, use the `update_interval` option.

Currently implemented dynamic tuning algorithms try to balance the performance and powersave, and are therefore disabled in the performance profiles. Dynamic tuning for individual plug-ins can be enabled or disabled in the **TuneD** profiles.

Example 2.2. Static and dynamic tuning on a workstation

On a typical office workstation, the Ethernet network interface is inactive most of the time. Only a few emails go in and out or some web pages might be loaded.

For those kinds of loads, the network interface does not have to run at full speed all the time, as it does by default. **TuneD** has a monitoring and tuning plug-in for network devices that can detect this low activity and then automatically lower the speed of that interface, typically resulting in a lower power usage.

If the activity on the interface increases for a longer period of time, for example because a DVD image is being downloaded or an email with a large attachment is opened, **TuneD** detects this and sets the interface speed to maximum to offer the best performance while the activity level is high.

This principle is used for other plug-ins for CPU and disks as well.

2.12. TUNED NO-DAEMON MODE

You can run **TuneD** in no-daemon mode, which does not require any resident memory. In this mode, **TuneD** applies the settings and exits.

By default, no-daemon mode is disabled because a lot of **TuneD** functionality is missing in this mode, including:

- D-Bus support
- Hot-plug support
- Rollback support for settings

To enable no-daemon mode, include the following line in the `/etc/tuned/tuned-main.conf` file:

```
demon = 0
```

2.13. INSTALLING AND ENABLING TUNED
This procedure installs and enables the Tuned application, installs Tuned profiles, and presets a default Tuned profile for your system.

**Procedure**

1. Install the Tuned package:
   
   ```
   # yum install tuned
   ```

2. Enable and start the Tuned service:
   
   ```
   # systemctl enable --now tuned
   ```

3. Optionally, install Tuned profiles for real-time systems:
   For the Tuned profiles for real-time systems enable rhel-8 repository.
   
   ```
   # subscription-manager repos --enable=rhel-8-for-x86_64-nfv-beta-rpms
   Install it.
   ```

   ```
   # yum install tuned-profiles-realtime tuned-profiles-nfv
   ```

4. Verify that a Tuned profile is active and applied:
   
   ```
   $ tuned-adm active
   ```

   Current active profile: *throughput-performance*

   **NOTE**

   The active profile Tuned automatically presets differs based on your machine type and system settings.

   ```
   $ tuned-adm verify
   ```

   Verification succeeded, current system settings match the preset profile. See tuned log file (‘/var/log/tuned/tuned.log’) for details.

### 2.14. LISTING AVAILABLE TUNED PROFILES

This procedure lists all Tuned profiles that are currently available on your system.

**Procedure**

- To list all available Tuned profiles on your system, use:

  ```
  $ tuned-adm list
  ```

  Available profiles:
  - accelerator-performance - Throughput performance based tuning with disabled higher latency STOP states
- balanced - General non-specialized TuneD profile
- desktop - Optimize for the desktop use-case
- latency-performance - Optimize for deterministic performance at the cost of increased power consumption
- network-latency - Optimize for deterministic performance at the cost of increased power consumption, focused on low latency network performance
- network-throughput - Optimize for streaming network throughput, generally only necessary on older CPUs or 40G+ networks
- powersave - Optimize for low power consumption
- throughput-performance - Broadly applicable tuning that provides excellent performance across a variety of common server workloads
- virtual-guest - Optimize for running inside a virtual guest
- virtual-host - Optimize for running KVM guests

Current active profile: balanced

- To display only the currently active profile, use:

```
$tuned-adm active
```

Current active profile: throughput-performance

### Additional resources
- **tuned-adm(8) man page.**

### 2.15. SETTING A TUNED PROFILE

This procedure activates a selected TuneD profile on your system.

#### Prerequisites
- The TuneD service is running. See Installing and Enabling TuneD for details.

#### Procedure

1. Optionally, you can let TuneD recommend the most suitable profile for your system:

   ```bash
   # tuned-adm recommend
   throughput-performance
   ``

2. Activate a profile:

   ```bash
   # tuned-adm profile selected-profile
   ``

   Alternatively, you can activate a combination of multiple profiles:

   ```bash
   # tuned-adm profile selected-profile1 selected-profile2
   ```

Example 2.3. A virtual machine optimized for low power consumption
The following example optimizes the system to run in a virtual machine with the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

```bash
# tuned-adm profile virtual-guest powersave
```

3. View the current active TuneD profile on your system:

```bash
# tuned-adm active
Current active profile: selected-profile
```

4. Reboot the system:

```bash
# reboot
```

**Verification steps**

- Verify that the TuneD profile is active and applied:

```bash
$ tuned-adm verify
Verification succeeded, current system settings match the preset profile. See tuned log file ('/var/log/tuned/tuned.log') for details.
```

**Additional resources**

- `tuned-adm(8)` man page

## 2.16. DISABLING TUNE

This procedure disables TuneD and resets all affected system settings to their original state before TuneD modified them.

**Procedure**

- To disable all tunings temporarily:

```bash
# tuned-adm off
```

The tunings are applied again after the TuneD service restarts.

- Alternatively, to stop and disable the TuneD service permanently:

```bash
# systemctl disable --now tuned
```

**Additional resources**

- `tuned-adm(8)` man page
CHAPTER 3. CUSTOMIZING TUNED PROFILES

You can create or modify TuneD profiles to optimize system performance for your intended use case.

Prerequisites

- Install and enable TuneD as described in Installing and Enabling TuneD for details.

3.1. TUNED PROFILES

A detailed analysis of a system can be very time-consuming. TuneD provides a number of predefined profiles for typical use cases. You can also create, modify, and delete profiles.

The profiles provided with TuneD are divided into the following categories:

- Power-saving profiles
- Performance-boosting profiles

The performance-boosting profiles include profiles that focus on the following aspects:

- Low latency for storage and network
- High throughput for storage and network
- Virtual machine performance
- Virtualization host performance

Syntax of profile configuration

The tuned.conf file can contain one [main] section and other sections for configuring plug-in instances. However, all sections are optional.

Lines starting with the hash sign (#) are comments.

Additional resources

- tuned.conf(5) man page.

3.2. THE DEFAULT TUNED PROFILE

During the installation, the best profile for your system is selected automatically. Currently, the default profile is selected according to the following customizable rules:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Default profile</th>
<th>Goal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute nodes</td>
<td>throughput-performance</td>
<td>The best throughput performance</td>
</tr>
<tr>
<td>Virtual machines</td>
<td>virtual-guest</td>
<td>The best performance. If you are not interested in the best performance, you can change it to the balanced or powersave profile.</td>
</tr>
</tbody>
</table>
3.3. MERGED TUNED PROFILES

As an experimental feature, it is possible to select more profiles at once. TuneD will try to merge them during the load.

If there are conflicts, the settings from the last specified profile takes precedence.

Example 3.1. Low power consumption in a virtual guest

The following example optimizes the system to run in a virtual machine for the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

```
# tuned-adm profile virtual-guest powersave
```

WARNING

Merging is done automatically without checking whether the resulting combination of parameters makes sense. Consequently, the feature might tune some parameters the opposite way, which might be counterproductive: for example, setting the disk for high throughput by using the `throughput-performance` profile and concurrently setting the disk spindown to the low value by the `spindown-disk` profile.

Additional resources

- `tuned-adm` man page.
- `tuned.conf(5)` man page.

3.4. THE LOCATION OF TUNED PROFILES

TuneD stores profiles in the following directories:

```
/usr/lib/tuned/
```

Distribution-specific profiles are stored in the directory. Each profile has its own directory. The profile consists of the main configuration file called `tuned.conf`, and optionally other files, for example helper scripts.
/etc/tuned/

If you need to customize a profile, copy the profile directory into the directory, which is used for custom profiles. If there are two profiles of the same name, the custom profile located in /etc/tuned/ is used.

Additional resources

- tuned.conf(5) man page.

3.5. INHERITANCE BETWEEN TUNED PROFILES

TuneD profiles can be based on other profiles and modify only certain aspects of their parent profile.

The [main] section of TuneD profiles recognizes the include option:

```
[main]
include=parent
```

All settings from the parent profile are loaded in this child profile. In the following sections, the child profile can override certain settings inherited from the parent profile or add new settings not present in the parent profile.

You can create your own child profile in the /etc/tuned/ directory based on a pre-installed profile in /usr/lib/tuned/ with only some parameters adjusted.

If the parent profile is updated, such as after a TuneD upgrade, the changes are reflected in the child profile.

Example 3.2. A power-saving profile based on balanced

The following is an example of a custom profile that extends the balanced profile and sets Aggressive Link Power Management (ALPM) for all devices to the maximum powersaving.

```
[main]
include=balanced

[scsi_host]
alpm=min_power
```

Additional resources

- tuned.conf(5) man page

3.6. STATIC AND DYNAMIC TUNING IN TUNED

Understanding the difference between the two categories of system tuning that TuneD applies, static and dynamic, is important when determining which one to use for a given situation or purpose.

Static tuning

Mainly consists of the application of predefined sysctl and sysfs settings and one-shot activation of several configuration tools such as ethtool.
Dynamic tuning

Watches how various system components are used throughout the uptime of your system. TuneD adjusts system settings dynamically based on that monitoring information.

For example, the hard drive is used heavily during startup and login, but is barely used later when the user might mainly work with applications such as web browsers or email clients. Similarly, the CPU and network devices are used differently at different times. TuneD monitors the activity of these components and reacts to the changes in their use.

By default, dynamic tuning is disabled. To enable it, edit the `/etc/tuned/tuned-main.conf` file and change the `dynamic_tuning` option to 1. TuneD then periodically analyzes system statistics and uses them to update your system tuning settings. To configure the time interval in seconds between these updates, use the `update_interval` option.

Currently implemented dynamic tuning algorithms try to balance the performance and powersave, and are therefore disabled in the performance profiles. Dynamic tuning for individual plug-ins can be enabled or disabled in the TuneD profiles.

Example 3.3. Static and dynamic tuning on a workstation

On a typical office workstation, the Ethernet network interface is inactive most of the time. Only a few emails go in and out or some web pages might be loaded.

For those kinds of loads, the network interface does not have to run at full speed all the time, as it does by default. TuneD has a monitoring and tuning plug-in for network devices that can detect this low activity and then automatically lower the speed of that interface, typically resulting in a lower power usage.

If the activity on the interface increases for a longer period of time, for example because a DVD image is being downloaded or an email with a large attachment is opened, TuneD detects this and sets the interface speed to maximum to offer the best performance while the activity level is high.

This principle is used for other plug-ins for CPU and disks as well.

3.7. TUNED PLUG-INS

Plug-ins are modules in TuneD profiles that TuneD uses to monitor or optimize different devices on the system.

TuneD uses two types of plug-ins:

Monitoring plug-ins

Monitoring plug-ins are used to get information from a running system. The output of the monitoring plug-ins can be used by tuning plug-ins for dynamic tuning.

Monitoring plug-ins are automatically instantiated whenever their metrics are needed by any of the enabled tuning plug-ins. If two tuning plug-ins require the same data, only one instance of the monitoring plug-in is created and the data is shared.

Tuning plug-ins

Each tuning plug-in tunes an individual subsystem and takes several parameters that are populated from the TuneD profiles. Each subsystem can have multiple devices, such as multiple CPUs or network cards, that are handled by individual instances of the tuning plug-ins. Specific settings for individual devices are also supported.
Syntax for plug-ins in TuneD profiles
Sections describing plug-in instances are formatted in the following way:

```
[NAME]
type=TYPE
devices=DEVICES
```

**NAME**

is the name of the plug-in instance as it is used in the logs. It can be an arbitrary string.

**TYPE**

is the type of the tuning plug-in.

**DEVICES**

is the list of devices that this plug-in instance handles.

The `devices` line can contain a list, a wildcard (`*`), and negation (`!`). If there is no `devices` line, all devices present or later attached on the system of the `TYPE` are handled by the plug-in instance. This is same as using the `devices=*` option.

**Example 3.4. Matching block devices with a plug-in**

The following example matches all block devices starting with `sd`, such as `sda` or `sdb`, and does not disable barriers on them:

```
[data_disk]
type=disk
devices=sd*
disable_barriers=false
```

The following example matches all block devices except `sda1` and `sda2`:

```
[data_disk]
type=disk
devices=!sda1, !sda2
disable_barriers=false
```

If no instance of a plug-in is specified, the plug-in is not enabled.

If the plug-in supports more options, they can be also specified in the plug-in section. If the option is not specified and it was not previously specified in the included plug-in, the default value is used.

**Short plug-in syntax**

If you do not need custom names for the plug-in instance and there is only one definition of the instance in your configuration file, TuneD supports the following short syntax:

```
[TYPE]
devices=DEVICES
```

In this case, it is possible to omit the `type` line. The instance is then referred to with a name, same as the type. The previous example could be then rewritten into:

**Example 3.5. Matching block devices using the short syntax**
Conflicting plug-in definitions in a profile
If the same section is specified more than once using the `include` option, the settings are merged. If they cannot be merged due to a conflict, the last conflicting definition overrides the previous settings. If you do not know what was previously defined, you can use the `replace` Boolean option and set it to `true`. This causes all the previous definitions with the same name to be overwritten and the merge does not happen.

You can also disable the plug-in by specifying the `enabled=false` option. This has the same effect as if the instance was never defined. Disabling the plug-in is useful if you are redefining the previous definition from the `include` option and do not want the plug-in to be active in your custom profile.

NOTE
Tuned includes the ability to run any shell command as part of enabling or disabling a tuning profile. This enables you to extend Tuned profiles with functionality that has not been integrated into Tuned yet.
You can specify arbitrary shell commands using the `script` plug-in.

Additional resources
- `tuned.conf(5)` man page

3.8. AVAILABLE TUNED PLUG-INS

Monitoring plug-ins
Currently, the following monitoring plug-ins are implemented:

- **disk**
  Gets disk load (number of IO operations) per device and measurement interval.

- **net**
  Gets network load (number of transferred packets) per network card and measurement interval.

- **load**
  Gets CPU load per CPU and measurement interval.

Tuning plug-ins
Currently, the following tuning plug-ins are implemented. Only some of these plug-ins implement dynamic tuning. Options supported by plug-ins are also listed:

- **cpu**
  Sets the CPU governor to the value specified by the `governor` option and dynamically changes the Power Management Quality of Service (PM QoS) CPU Direct Memory Access (DMA) latency according to the CPU load.
  If the CPU load is lower than the value specified by the `load_threshold` option, the latency is set to the value specified by the `latency_high` option, otherwise it is set to the value specified by `latency_low`. 
You can also force the latency to a specific value and prevent it from dynamically changing further. To do so, set the `force_latency` option to the required latency value.

**eeepc_she**

Dynamically sets the front-side bus (FSB) speed according to the CPU load. This feature can be found on some netbooks and is also known as the ASUS Super Hybrid Engine (SHE).

If the CPU load is lower or equal to the value specified by the `load_threshold_powersave` option, the plug-in sets the FSB speed to the value specified by the `she_powersave` option. If the CPU load is higher or equal to the value specified by the `load_threshold_normal` option, it sets the FSB speed to the value specified by the `she_normal` option.

Static tuning is not supported and the plug-in is transparently disabled if TuneD does not detect the hardware support for this feature.

**net**

Configures the Wake-on-LAN functionality to the values specified by the `wake_on_lan` option. It uses the same syntax as the `ethtool` utility. It also dynamically changes the interface speed according to the interface utilization.

**sysctl**

Sets various `sysctl` settings specified by the plug-in options. The syntax is `name=value`, where `name` is the same as the name provided by the `sysctl` utility.

Use the `sysctl` plug-in if you need to change system settings that are not covered by other plug-ins available in TuneD. If the settings are covered by some specific plug-ins, prefer these plug-ins.

**usb**

Sets autosuspend timeout of USB devices to the value specified by the `autosuspend` parameter. The value 0 means that autosuspend is disabled.

**vm**

Enables or disables transparent huge pages depending on the value of the `transparent_hugepages` option.

Valid values of the `transparent_hugepages` option are:

- "always"
- "never"
- "madvise"

**audio**

Sets the autosuspend timeout for audio codecs to the value specified by the `timeout` option. Currently, the `snd_hda_intel` and `snd_ac97_codec` codecs are supported. The value 0 means that the autosuspend is disabled. You can also enforce the controller reset by setting the Boolean option `reset_controller` to true.

**disk**

Sets the disk elevator to the value specified by the `elevator` option. It also sets:
- APM to the value specified by the `apm` option
- Scheduler quantum to the value specified by the `scheduler_quantum` option
- Disk spindown timeout to the value specified by the `spindown` option
- Disk readahead to the value specified by the `readahead` parameter
- The current disk readahead to a value multiplied by the constant specified by the `readahead_multiply` option

In addition, this plug-in dynamically changes the advanced power management and spindown timeout setting for the drive according to the current drive utilization. The dynamic tuning can be controlled by the Boolean option `dynamic` and is enabled by default.

**scsi_host**

Tunes options for SCSI hosts.

It sets Aggressive Link Power Management (ALPM) to the value specified by the `alpm` option.

**mounts**

Enables or disables barriers for mounts according to the Boolean value of the `disable_barriers` option.

**script**

Executes an external script or binary when the profile is loaded or unloaded. You can choose an arbitrary executable.

**IMPORTANT**

The `script` plug-in is provided mainly for compatibility with earlier releases. Prefer other TuneD plug-ins if they cover the required functionality.

TuneD calls the executable with one of the following arguments:

- **start** when loading the profile
- **stop** when unloading the profile

You need to correctly implement the **stop** action in your executable and revert all settings that you changed during the **start** action. Otherwise, the roll-back step after changing your TuneD profile will not work.

Bash scripts can import the `/usr/lib/tuned/functions` Bash library and use the functions defined there. Use these functions only for functionality that is not natively provided by TuneD. If a function name starts with an underscore, such as `_wifi_set_power_level`, consider the function private and do not use it in your scripts, because it might change in the future.

Specify the path to the executable using the `script` parameter in the plug-in configuration.

### Example 3.6. Running a Bash script from a profile

To run a Bash script named `script.sh` that is located in the profile directory, use:

```
[script]
script=${i:PROFILE_DIR}/script.sh
```
sysfs

Sets various syfs settings specified by the plug-in options. The syntax is **name=value**, where *name* is the syfs path to use.

Use this plugin in case you need to change some settings that are not covered by other plug-ins. Prefer specific plug-ins if they cover the required settings.

video

Sets various powersave levels on video cards. Currently, only the Radeon cards are supported. The powersave level can be specified by using the **raiden_powersave** option. Supported values are:

- default
- auto
- low
- mid
- high
- dynpm
- dpm-battery
- dpm-balanced
- dpm-performance

For details, see [www.x.org](http://www.x.org). Note that this plug-in is experimental and the option might change in future releases.

bootloader

Adds options to the kernel command line. This plug-in supports only the GRUB 2 boot loader. Customized non-standard location of the GRUB 2 configuration file can be specified by the **grub2_cfg_file** option.

The kernel options are added to the current GRUB configuration and its templates. The system needs to be rebooted for the kernel options to take effect.

Switching to another profile or manually stopping the TuneD service removes the additional options. If you shut down or reboot the system, the kernel options persist in the **grub.cfg** file.

The kernel options can be specified by the following syntax:

```
cmdline=arg1 arg2 ... argN
```

**Example 3.7. Modifying the kernel command line**

For example, to add the **quiet** kernel option to a TuneD profile, include the following lines in the **tuned.conf** file:
The following is an example of a custom profile that adds the `isolcpus=2` option to the kernel command line:

```
[bootloader]
cmdline=quiet
```

```
[bootloader]
cmdline=isolcpus=2
```

**service**

Handles various `sysvinit`, `sysv-rc`, `openrc`, and `systemd` services specified by the plug-in options. The syntax is `service.service_name=command[,file:file]`.

Supported service-handling commands are:

- `start`
- `stop`
- `enable`
- `disable`

Separate multiple commands using either a comma (,) or a semicolon (;). If the directives conflict, the `service` plugin uses the last listed one.

Use the optional `file:file` directive to install an overlay configuration file, `file`, for `systemd` only. Other init systems ignore this directive. The `service` plugin copies overlay configuration files to `/etc/systemd/system/service_name.service.d/` directories. Once profiles are unloaded, the `service` plugin removes these directories if they are empty.

**NOTE**

The `service` plugin only operates on the current runlevel with non-`systemd` init systems.

**Example 3.8. Starting and enabling the sendmail service with an overlay file**

```
[service]
service.sendmail=start,enable,file:${i:PROFILE_DIR}/tuned-sendmail.conf
```

The internal variable `${i:PROFILE_DIR}` points to the directory the plugin loads the profile from.

**scheduler**

Offers a variety of options for the tuning of scheduling priorities, CPU core isolation, and process, thread, and IRQ affinities.

For specifics of the different options available, see Functionalities of the `scheduler` TuneD plug-in.
### 3.9. FUNCTIONALITIES OF THE SCHEDULER TUNED PLUGIN

Use the scheduler TuneD plugin to control and tune scheduling priorities, CPU core isolation, and process, thread, and IRQ affinities.

#### CPU isolation

To prevent processes, threads, and IRQs from using certain CPUs, use the `isolated_cores` option. It changes process and thread affinities, IRQ affinities, and sets the `default_smp_affinity` parameter for IRQs.

The CPU affinity mask is adjusted for all processes and threads matching the `ps_whitelist` option, subject to success of the `sched_setaffinity()` system call. The default setting of the `ps_whitelist` regular expression is `.*` to match all processes and thread names. To exclude certain processes and threads, use the `ps_blacklist` option. The value of this option is also interpreted as a regular expression. Process and thread names are matched against that expression. Profile rollback enables all matching processes and threads to run on all CPUs, and restores the IRQ settings prior to the profile application.

Multiple regular expressions separated by `;` for the `ps_whitelist` and `ps_blacklist` options are supported. Escaped semicolon `\;` is taken literally.

#### Example 3.9. Isolate CPUs 2-4

The following configuration isolates CPUs 2-4. Processes and threads that match the `ps_blacklist` regular expression can use any CPUs regardless of the isolation:

```ini
[scheduler]
isolated_cores=2-4
ps_blacklist=.*pmd.*;.*PMD.*;^DPDK;.*qemu-kvm.*
```

#### IRQ SMP affinity

The `/proc/irq/default_smp_affinity` file contains a bitmask representing the default target CPU cores on a system for all inactive interrupt request (IRQ) sources. Once an IRQ is activated or allocated, the value in the `/proc/irq/default_smp_affinity` file determines the IRQ’s affinity bitmask.

The `default_irq_smp_affinity` parameter controls what TuneD writes to the `/proc/irq/default_smp_affinity` file. The `default_irq_smp_affinity` parameter supports the following values and behaviors:

- **calc**
  - Calculates the content of the `/proc/irq/default_smp_affinity` file from the `isolated_cores` parameter. An inversion of the `isolated_cores` parameter calculates the non-isolated cores. The intersection of the non-isolated cores and the previous content of the `/proc/irq/default_smp_affinity` file is then written to the `/proc/irq/default_smp_affinity` file.
  - This is the default behavior if the `default_irq_smp_affinity` parameter is omitted.

- **ignore**
  - TuneD does not modify the `/proc/irq/default_smp_affinity` file.

- **A CPU list**
  - Takes the form of a single number such as 1, a comma separated list such as 1,3, or a range such as 3-5.
Unpacks the CPU list and writes it directly to the `/proc/irq/default_smp_affinity` file.

Example 3.10. Setting the default IRQ SMP affinity using an explicit CPU list

The following example uses an explicit CPU list to set the default IRQ SMP affinity to CPUs 0 and 2:

```
[scheduler]
iisolated_cores=1,3
default_irq_smp_affinity=0,2
```

Scheduling policy

To adjust scheduling policy, priority and affinity for a group of processes or threads, use the following syntax:

```
group.groupname=rule_prio:sched:prio:affinity:regex
```

where `rule_prio` defines internal TuneD priority of the rule. Rules are sorted based on priority. This is needed for inheritance to be able to reorder previously defined rules. Equal `rule_prio` rules should be processed in the order they were defined. However, this is Python interpreter dependent. To disable an inherited rule for `groupname`, use:

```
group.groupname=
```

`sched` must be one of the following:

- `f` for first in, first out (FIFO)
- `b` for batch
- `r` for round robin
- `o` for other
- `*` for do not change

`affinity` is CPU affinity in hexadecimal. Use `*` for no change.

`prio` is scheduling priority (see `chrt -m`).

`regex` is Python regular expression. It is matched against the output of the `ps -eo cmd` command.

Any given process name can match more than one group. In such cases, the last matching `regex` determines the priority and scheduling policy.

Example 3.11. Setting scheduling policies and priorities

The following example sets the scheduling policy and priorities to kernel threads and watchdog:
The scheduler plugin uses a perf event loop to identify newly created processes. By default, it listens to perf.RECORD_COMM and perf.RECORD_EXIT events.

Setting the perf_process_fork parameter to true tells the plug-in to also listen to perf.RECORD_FORK events, meaning that child processes created by the fork() system call are processed.

NOTE
Processing perf events can pose a significant CPU overhead.

The CPU overhead of the scheduler plugin can be mitigated by using the scheduler runtime option and setting it to 0. This completely disables the dynamic scheduler functionality and the perf events are not monitored and acted upon. The disadvantage of this is that the process and thread tuning will be done only at profile application.

Example 3.12. Disabling the dynamic scheduler functionality

The following example disables the dynamic scheduler functionality while also isolating CPUs 1 and 3:

```
[scheduler]
runtime=0
isolated_cores=1,3
```

The mmapped buffer is used for perf events. Under heavy loads, this buffer might overflow and as a result the plugin might start missing events and not processing some newly created processes. In such cases, use the perf_mmap_pages parameter to increase the buffer size. The value of the perf_mmap_pages parameter must be a power of 2. If the perf_mmap_pages parameter is not manually set, a default value of 128 is used.

Confinement using cgroups

The scheduler plugin supports process and thread confinement using cgroups v1.

The cgroup_mount_point option specifies the path to mount the cgroup file system, or, where TuneD expects it to be mounted. If it is unset, /sys/fs/cgroup/cpuset is expected.

If the cgroup_groups_init option is set to 1, TuneD creates and removes all cgroups defined with the cgroup* options. This is the default behavior. If the cgroup_mount_point option is set to 0, the cgroups must be preset by other means.

If the cgroup_mount_point_init option is set to 1, TuneD creates and removes the cgroup mount point. It implies cgroup_groups_init = 1. If the cgroup_mount_point_init option is set to 0, you must preset the cgroups mount point by other means. This is the default behavior.

The cgroup_for_isolated_cores option is the cgroup name for the isolated_cores option functionality. For example, if a system has 4 CPUs, isolated_cores=1 means that Tuned moves all processes and threads to CPUs 0, 2, and 3. The scheduler plug-in isolates the specified core by writing
the calculated CPU affinity to the `cpuset.cpus` control file of the specified cgroup and moves all the matching processes and threads to this group. If this option is unset, classic cpuset affinity using `sched_setaffinity()` sets the CPU affinity.

The `cgroup.cgroup_name` option defines affinities for arbitrary cgroups. You can even use hierarchic cgroups, but you must specify the hierarchy in the correct order. TuneD does not do any sanity checks here, with the exception that it forces the cgroup to be in the location specified by the `cgroup_mount_point` option.

The syntax of the scheduler option starting with `group`, has been augmented to use `cgroup.cgroup_name` instead of the hexadecimal affinity. The matching processes are moved to the `cgroup cgroup_name`. You can also use cgroups not defined by the `cgroup` option as described above. For example, cgroups not managed by TuneD.

All cgroup names are sanitized by replacing all periods (.) with slashes (/). This prevents the plugin from writing outside the location specified by the `cgroup_mount_point` option.

**Example 3.13. Using cgroups v1 with the scheduler plug-in**

The following example creates 2 cgroups, `group1` and `group2`. It sets the cgroup `group1` affinity to CPU 2 and the cgroup `group2` to CPUs 0 and 2. Given a 4 CPU setup, the `isolated_cores=1` option moves all processes and threads to CPU cores 0, 2, and 3. Processes and threads specified by the `ps_blacklist` regular expression are not moved.

```
[scheduler]
cgroup_mount_point=/sys/fs/cgroup/cpuset
cgroup_mount_point_init=1
cgroup_groups_init=1
cgroup_for_isolated_cores=group
cgroup.group1=2
cgroup.group2=0,2

group.ksoftirqd=0:f:2:cgroup.group1:ksoftirqd.*
ps_blacklist=ksoftirqd.*;rcuc.*;rcub.*;ktimersoftd.*
isolated_cores=1
```

The `cgroup_ps_blacklist` option excludes processes belonging to the specified cgroups. The regular expression specified by this option is matched against cgroup hierarchies from `/proc/PID/cgroups`. Commas (,) separate cgroups v1 hierarchies from `/proc/PID/cgroups` before regular expression matching. The following is an example of content the regular expression is matched against:

```
10:hugetlb:/,9:perf_event:/,8:blkio/
```

Multiple regular expressions can be separated by semicolons (;). The semicolon represents a logical 'or' operator.

**Example 3.14. Excluding processes from the scheduler using cgroups**

In the following example, the scheduler plug-in moves all processes away from core 1, except for processes which belong to cgroup `/daemons`. The \b string is a regular expression metacharacter that matches a word boundary.
In the following example, the scheduler plugin excludes all processes which belong to a cgroup with a hierarchy-ID of 8 and controller-list blkio.

Recent kernels moved some sched_ and numa_balancing_ kernel run-time parameters from the /proc/sys/kernel directory managed by the sysctl utility, to debugfs, typically mounted under the /sys/kernel/debug directory. TuneD provides an abstraction mechanism for the following parameters via the scheduler plugin where, based on the kernel used, TuneD writes the specified value to the correct location:

- sched_min_granularity_ns
- sched_latency_ns
- sched_wakeup_granularity_ns
- sched_tunable_scaling
- sched_migration_cost_ns
- sched_nr_migrate
- numa_balancing_scan_delay_ms
- numa_balancing_scan_period_min_ms
- numa_balancing_scan_period_max_ms
- numa_balancing_scan_size_mb

Example 3.15. Set tasks' "cache hot" value for migration decisions.

On the old kernels, setting the following parameter meant that sysctl wrote a value of 500000 to the /proc/sys/kernel/sched_migration_cost_ns file:

```
[sysctl]
kernel.sched_migration_cost_ns=500000
```

This is, on more recent kernels, equivalent to setting the following parameter via the scheduler plugin:

```
[scheduler]
sched_migration_cost_ns=500000
```

Meaning TuneD writes a value of 500000 to the /sys/kernel/debug/sched/migration_cost_ns file.
3.10. VARIABLES IN TUNED PROFILES

Variables expand at run time when a TuneD profile is activated.

Using TuneD variables reduces the amount of necessary typing in TuneD profiles.

There are no predefined variables in TuneD profiles. You can define your own variables by creating the [variables] section in a profile and using the following syntax:

```
[variables]
variable_name=value
```

To expand the value of a variable in a profile, use the following syntax:

```
${variable_name}
```

**Example 3.16. Isolating CPU cores using variables**

In the following example, the `${isolated_cores}` variable expands to 1,2; hence the kernel boots with the `isolcpus=1,2` option:

```
[variables]
isolated_cores=1,2

[bootloader]
cmdline=isolcpus=${isolated_cores}
```

The variables can be specified in a separate file. For example, you can add the following lines to tuned.conf:

```
[variables]
include=/etc/tuned/my-variables.conf

[bootloader]
cmdline=isolcpus=${isolated_cores}
```

If you add the `isolated_cores=1,2` option to the `/etc/tuned/my-variables.conf` file, the kernel boots with the `isolcpus=1,2` option.

**Additional resources**

- tuned.conf(5) man page

3.11. BUILT-IN FUNCTIONS IN TUNED PROFILES

Built-in functions expand at run time when a TuneD profile is activated.

You can:

- Use various built-in functions together with TuneD variables
Create custom functions in Python and add them to **TuneD** in the form of plug-ins.

To call a function, use the following syntax:

```bash
${f:function_name:argument_1:argument_2}
```

To expand the directory path where the profile and the **tuned.conf** file are located, use the **PROFILE_DIR** function, which requires special syntax:

```bash
${i:PROFILE_DIR}
```

**Example 3.17. Isolating CPU cores using variables and built-in functions**

In the following example, the `${non_isolated_cores}` variable expands to `0,3-5`, and the **cpulist_invert** built-in function is called with the `0,3-5` argument:

```bash
[variables]
    non_isolated_cores=0,3-5

[bootloader]
    cmdline=isolcpus=${f:cpulist_invert:${non_isolated_cores}}
```

The **cpulist_invert** function inverts the list of CPUs. For a 6-CPU machine, the inversion is `1,2`, and the kernel boots with the **isolcpus=1,2** command-line option.

**Additional resources**

- **tuned.conf(5) man page**

**3.12. BUILT-IN FUNCTIONS AVAILABLE IN TUNED PROFILES**

The following built-in functions are available in all **TuneD** profiles:

**PROFILE_DIR**

*Returns the directory path where the profile and the **tuned.conf** file are located.*

**exec**

*Executes a process and returns its output.*

**assertion**

*Compared two arguments. If they do not match, the function logs text from the first argument and aborts profile loading.*

**assertion_non_equal**

*Compares two arguments. If they match, the function logs text from the first argument and aborts profile loading.*

**kb2s**

*Converts kilobytes to disk sectors.*

**s2kb**

*Converts disk sectors to kilobytes.*

**strip**
Creates a string from all passed arguments and deletes both leading and trailing white space.

**virt_check**
Checks whether **TuneD** is running inside a virtual machine (VM) or on bare metal:
- Inside a VM, the function returns the first argument.
- On bare metal, the function returns the second argument, even in case of an error.

**cpulist_invert**
Inverts a list of CPUs to make its complement. For example, on a system with 4 CPUs, numbered from 0 to 3, the inversion of the list 0,2,3 is 1.

**cpulist2hex**
Converts a CPU list to a hexadecimal CPU mask.

**cpulist2hex_invert**
Converts a CPU list to a hexadecimal CPU mask and inverts it.

**hex2cpulist**
Converts a hexadecimal CPU mask to a CPU list.

**cpulist_online**
Checks whether the CPUs from the list are online. Returns the list containing only online CPUs.

**cpulist_present**
Checks whether the CPUs from the list are present. Returns the list containing only present CPUs.

**cpulist_unpack**
Unpacks a CPU list in the form of 1-3,4 to 1,2,3,4.

**cpulist_pack**
Packs a CPU list in the form of 1,2,3,5 to 1-3,5.

### 3.13. CREATING NEW TUNED PROFILES

This procedure creates a new **TuneD** profile with custom performance rules.

**Prerequisites**
- The **TuneD** service is running. See [Installing and Enabling TuneD](#) for details.

**Procedure**

1. In the `/etc/tuned/` directory, create a new directory named the same as the profile that you want to create:

   ```bash
   # mkdir /etc/tuned/my-profile
   ```

2. In the new directory, create a file named `tuned.conf`. Add a **[main]** section and plug-in definitions in it, according to your requirements.
   For example, see the configuration of the **balanced** profile:

   ```ini
   [main]
   summary=General non-specialized TuneD profile
   ```
To activate the profile, use:

```
# tuned-adm profile my-profile
```

4. Verify that the Tuned profile is active and the system settings are applied:

```
$ tuned-adm active
Current active profile: my-profile

$ tuned-adm verify
Verification succeeded, current system settings match the preset profile.
See tuned log file ('/var/log/tuned/tuned.log') for details.
```

Additional resources

- `tuned.conf(5)` man page

### 3.14. MODIFYING EXISTING TUNED PROFILES

This procedure creates a modified child profile based on an existing Tuned profile.

**Prerequisites**

- The Tuned service is running. See Installing and Enabling Tuned for details.

**Procedure**

1. In the `/etc/tuned/` directory, create a new directory named the same as the profile that you want to create:

   ```
   # mkdir /etc/tuned/modified-profile
   ```

2. In the new directory, create a file named `tuned.conf`, and set the `[main]` section as follows:

   ```
   [main]
   include=parent-profile
   ```

   Replace `parent-profile` with the name of the profile you are modifying.
3. Include your profile modifications.

Example 3.18. Lowering swappiness in the throughput-performance profile

To use the settings from the throughput-performance profile and change the value of \texttt{vm.swappiness} to 5, instead of the default 10, use:

\begin{verbatim}
[main]
include=throughput-performance

[sysctl]
vm.swappiness=5
\end{verbatim}

4. To activate the profile, use:

\begin{verbatim}
# tuned-adm profile modified-profile
\end{verbatim}

5. Verify that the TuneD profile is active and the system settings are applied:

\begin{verbatim}
$ tuned-adm active
Current active profile: my-profile

$ tuned-adm verify
Verification succeeded, current system settings match the preset profile.
See tuned log file ('/var/log/tuned/tuned.log') for details.
\end{verbatim}

Additional resources

- \texttt{tuned.conf(5)} man page

3.15. SETTING THE DISK SCHEDULER USING TUNED

This procedure creates and enables a TuneD profile that sets a given disk scheduler for selected block devices. The setting persists across system reboots.

In the following commands and configuration, replace:

- \texttt{device} with the name of the block device, for example \texttt{sdf}
- \texttt{selected-scheduler} with the disk scheduler that you want to set for the device, for example \texttt{bfq}

Prerequisites

- The TuneD service is installed and enabled. For details, see Installing and enabling TuneD.

Procedure

1. Optional: Select an existing TuneD profile on which your profile will be based. For a list of available profiles, see TuneD profiles distributed with RHEL.
   To see which profile is currently active, use:
$ tuned-adm active

2. Create a new directory to hold your Tuned profile:

    # mkdir /etc/tuned/my-profile

3. Find the system unique identifier of the selected block device:

    $ udevadm info --query=property --name=/dev/device | grep -E '(WWN|SERIAL)'

    ID_WWN=0x5002538d00000000_
    ID_SERIAL=Generic-_SD_MMC_201205010309000000-0:0
    ID_SERIAL_SHORT=20120501030900000

    **NOTE**
    
    The command in this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the device system unique ID.

4. Create the `/etc/tuned/my-profile/tuned.conf` configuration file. In the file, set the following options:

   a. Optional: Include an existing profile:

      ```
      [main]
      include=existing-profile
      ```

   b. Set the selected disk scheduler for the device that matches the WWN identifier:

      ```
      [disk]
      devices_udev_regex=IDNAME=device system unique id
      elevator=selected-scheduler
      ```

      Here:

      - Replace `IDNAME` with the name of the identifier being used (for example, `ID_WWN`).
      - Replace `device system unique id` with the value of the chosen identifier (for example, `0x5002538d00000000`). To match multiple devices in the `devices_udev_regex` option, enclose the identifiers in parentheses and separate them with vertical bars:

        ```
        devices_udev_regex=(ID_WWN=0x5002538d00000000) |
          (ID_WWN=0x1234567800000000)
        ```

5. Enable your profile:

    ```
    # tuned-adm profile my-profile
    ```
Verification steps

1. Verify that the TuneD profile is active and applied:

   $ tuned-adm active

   Current active profile: my-profile

   $ tuned-adm verify

   Verification succeeded, current system settings match the preset profile. See TuneD log file ('/var/log/tuned/tuned.log') for details.

2. Read the contents of the /sys/block/device/queue/scheduler file:

   # cat /sys/block/device/queue/scheduler

   [mq-deadline] kyber bfq none

   In the file name, replace device with the block device name, for example sdc.

   The active scheduler is listed in square brackets ([ ]).

Additional resources

- Customizing TuneD profiles.
CHAPTER 4. REVIEWING A SYSTEM USING TUNA INTERFACE

Use the **tuna** tool to adjust scheduler tunables, tune thread priority, IRQ handlers, and isolate CPU cores and sockets. Tuna reduces the complexity of performing tuning tasks.

The **tuna** tool performs the following operations:

- Lists the CPUs on a system
- Lists the interrupt requests (IRQs) currently running on a system
- Changes policy and priority information about threads
- Displays the current policies and priorities of a system

4.1. INSTALLING TUNA TOOL

The **tuna** tool is designed to be used on a running system. This allows application-specific measurement tools to see and analyze system performance immediately after changes have been made.

This procedure describes how to install the **tuna** tool.

**Procedure**

- Install the **tuna** tool:
  
  ```
  # yum install tuna
  ```

**Verification steps**

- View the available **tuna** CLI options:
  
  ```
  # tuna -h
  ```

**Additional resources**

- **tuna(8)** man page

4.2. VIEWING THE SYSTEM STATUS USING TUNA TOOL

This procedure describes how to view the system status using the **tuna** command-line interface (CLI) tool.

**Prerequisites**

- The tuna tool is installed. For more information, see [Installing tuna tool](#).

**Procedure**

- To view the current policies and priorities:
  
  ```
  # tuna --show_threads
  ```
  
  thread
To view a specific thread corresponding to a PID or matching a command name:

```bash
# tuna --threads=pid_or_cmd_list --show_threads
```

The `pid_or_cmd_list` argument is a list of comma-separated PIDs or command-name patterns.

- To tune CPUs using the `tuna` CLI, see Tuning CPUs using tuna tool.
- To tune the IRQs using the `tuna` tool, see Tuning IRQs using tuna tool.
- To save the changed configuration:

```bash
# tuna --save=filename
```

This command saves only currently running kernel threads. Processes that are not running are not saved.

Additional resources

- `tuna(8)` man page

### 4.3. TUNING CPUS USING TUNA TOOL

The `tuna` tool commands can target individual CPUs.

Using the tuna tool, you can:

**Isolate CPUs**

All tasks running on the specified CPU move to the next available CPU. Isolating a CPU makes it unavailable by removing it from the affinity mask of all threads.

**Include CPUs**

Allows tasks to run on the specified CPU

**Restore CPUs**

Restores the specified CPU to its previous configuration.

This procedure describes how to tune CPUs using the `tuna` CLI.

**Prerequisites**

- The tuna tool is installed. For more information, see Installing tuna tool.

**Procedure**

- To specify the list of CPUs to be affected by a command:

```bash
# tuna --cpus=cpu_list [command]
```
The `cpu_list` argument is a list of comma-separated CPU numbers. For example, `--cpus=0,2` CPU lists can also be specified in a range, for example `--cpus="1-3"`, which would select CPUs 1, 2, and 3.

To add a specific CPU to the current `cpu_list`, for example, use `--cpus=+0`.

Replace `[command]` with, for example, `--isolate`.

- To isolate a CPU:

  ```
  # tuna --cpus=cpu_list --isolate
  ```

- To include a CPU:

  ```
  # tuna --cpus=cpu_list --include
  ```

- To use a system with four or more processors, display how to make all the ssh threads run on CPU 0 and 1, and all the http threads on CPU 2 and 3:

  ```
  # tuna --cpus=0,1 --threads=ssh* --move --cpus=2,3 --threads=http* --move
  ```

This command performs the following operations sequentially:

1. Selects CPUs 0 and 1.
2. Selects all threads that begin with `ssh`.
3. Moves the selected threads to the selected CPUs. Tuna sets the affinity mask of threads starting with `ssh` to the appropriate CPUs. The CPUs can be expressed numerically as 0 and 1, in hex mask as 0x3, or in binary as 11.
4. Resets the CPU list to 2 and 3.
5. Selects all threads that begin with `http`.
6. Moves the selected threads to the specified CPUs. Tuna sets the affinity mask of threads starting with `http` to the specified CPUs. The CPUs can be expressed numerically as 2 and 3, in hex mask as 0xC, or in binary as 1100.

**Verification steps**

- Display the current configuration and verify that the changes were performed as expected:

  ```
  # tuna --threads=gnome-screensaver* --show_threads --cpus=0 --move --show_threads --cpus=+0 --move --show_threads
  ```

  ```
  thread     ctxt_switches
  pid SCHED_ rtpri affinity voluntary nonvoluntary cmd
  3861   OTHER     0,1     33997           58 gnome-screensaver
  thread     ctxt_switches
  pid SCHED_ rtpri affinity voluntary nonvoluntary cmd
  3861   OTHER     0,1     33997           58 gnome-screensaver
  ```

Red Hat Enterprise Linux 8 Monitoring and managing system status and performance
This command performs the following operations sequentially:

1. Selects all threads that begin with the `gnome-sc` threads.
2. Displays the selected threads to enable the user to verify their affinity mask and RT priority.
3. Selects CPU 0.
4. Moves the `gnome-sc` threads to the specified CPU, CPU 0.
5. Shows the result of the move.
6. Resets the CPU list to CPU 1.
7. Moves the `gnome-sc` threads to the specified CPU, CPU 1.
8. Displays the result of the move.
9. Adds CPU 0 to the CPU list.
10. Moves the `gnome-sc` threads to the specified CPUs, CPUs 0 and 1.
11. Displays the result of the move.

Additional resources

- `/proc/cpupinfo` file
- `tuna(8)` man page

### 4.4. TUNINGIRQS USING TUNA TOOL

The `/proc/interrupts` file records the number of interrupts per IRQ, the type of interrupt, and the name of the device that is located at that IRQ.

This procedure describes how to tune the IRQs using the `tuna` tool.

**Prerequisites**

- The `tuna` tool is installed. For more information, see [Installing tuna tool](#).

**Procedure**

- To view the current IRQs and their affinity:

  ```
  # tuna --show_irds
  # users    affinity
  0 timer    0
  1 i8042    0
  7 parport0 0
  ```
To specify the list of IRQs to be affected by a command:

```
# tuna --irqs=irq_list [command]
```

The `irq_list` argument is a list of comma-separated IRQ numbers or user-name patterns. Replace `[command]` with, for example, `--spread`.

To move an interrupt to a specified CPU:

```
# tuna --irqs=128 --show_irqs
# users         affinity
 128 iwlwifi         0,1,2,3

# tuna --irqs=128 --cpus=3 --move
```

Replace `128` with the `irq_list` argument and `3` with the `cpu_list` argument.

The `cpu_list` argument is a list of comma-separated CPU numbers, for example, `--cpus=0,2`. For more information, see Tuning CPUs using tuna tool.

**Verification steps**

- Compare the state of the selected IRQs before and after moving any interrupt to a specified CPU:

```
# tuna --irqs=128 --show_irqs
# users         affinity
 128 iwlwifi         3
```

**Additional resources**

- `/proc/interrupts` file
- `tuna(8)` man page
CHAPTER 5. MONITORING PERFORMANCE USING RHEL SYSTEM ROLES

As a system administrator, you can use the metrics RHEL System Role with any Ansible Automation Platform control node to monitor the performance of a system.

5.1. PREPARING A CONTROL NODE AND MANAGED NODES TO USE RHEL SYSTEM ROLES

Before you can use individual RHEL System Roles to manage services and settings, you must prepare the control node and managed nodes.

5.1.1. Preparing a control node on RHEL 8

Before using RHEL System Roles, you must configure a control node. This system then configures the managed hosts from the inventory according to the playbooks.

Prerequisites

- RHEL 8.6 or later is installed. For more information about installing RHEL, see Performing a standard RHEL 8 installation.
- The system is registered to the Customer Portal.
- A Red Hat Enterprise Linux Server subscription is attached to the system.
- If available in your Customer Portal account, an Ansible Automation Platform subscription is attached to the system.

Procedure

1. Install the rhel-system-roles package:

   ```
   [root@control-node]# yum install rhel-system-roles
   ```

   This command installs the ansible-core package as a dependency.

   **NOTE**

   In RHEL 8.5 and earlier versions, Ansible packages were provided through Ansible Engine instead of Ansible Core, and with a different level of support. Do not use Ansible Engine because the packages might not be compatible with Ansible automation content in RHEL 8.6 and later. For more information, see Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories.

2. Create a user named ansible to manage and run playbooks:

   ```
   [root@control-node]# useradd ansible
   ```

3. Switch to the newly created ansible user:
Perform the rest of the procedure as this user.

4. Create an SSH public and private key:

```
[ansible@control-node]$ ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/home/ansible/.ssh/id_rsa):
Enter passphrase (empty for no passphrase): <password>
Enter same passphrase again: <password>
...
```

Use the suggested default location for the key file.

5. Optional: To prevent Ansible from prompting you for the SSH key password each time you establish a connection, configure an SSH agent.

6. Create the `~/.ansible.cfg` file with the following content:

```
[defaults]
inventory = /home/ansible/inventory
remote_user = ansible

[privilege_escalation]
become = True
become_method = sudo
become_user = root
become_ask_pass = True
```

**NOTE**

Settings in the `~/.ansible.cfg` file have a higher priority and override settings from the global `/etc/ansible/ansible.cfg` file.

With these settings, Ansible performs the following actions:

- Manages hosts in the specified inventory file.
- Uses the account set in the `remote_user` parameter when it establishes SSH connections to managed nodes.
- Uses the `sudo` utility to execute tasks on managed nodes as the `root` user.
- Prompts for the root password of the remote user every time you apply a playbook. This is recommended for security reasons.

7. Create an `~/inventory` file in INI or YAML format that lists the hostnames of managed hosts. You can also define groups of hosts in the inventory file. For example, the following is an inventory file in the INI format with three hosts and one host group named `US`:

```
managed-node-01.example.com

[US]
```
managed-node-02.example.com ansible_host=192.0.2.100
managed-node-03.example.com

Note that the control node must be able to resolve the hostnames. If the DNS server cannot resolve certain hostnames, add the `ansible_host` parameter next to the host entry to specify its IP address.

Next steps

- Prepare the managed nodes. For more information, see Preparing a managed node.

Additional resources

- Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories
- How to register and subscribe a system to the Red Hat Customer Portal using subscription-manager
- The `ssh-keygen(1)` man page
- Connecting to remote machines with SSH keys using ssh-agent
- Ansible configuration settings
- How to build your inventory
- Updates to using Ansible in RHEL 8.6 and 9.0

5.1.2. Preparing a managed node

Managed nodes are the systems listed in the inventory and which will be configured by the control node according to the playbook. You do not have to install Ansible on managed hosts.

Prerequisites

- You prepared the control node. For more information, see Preparing a control node on RHEL 8.
- You have SSH access from the control node.

**IMPORTANT**

Direct SSH access as the `root` user is a security risk. To reduce this risk, you will create a local user on this node and configure a `sudo` policy when preparing a managed node. Ansible on the control node can then use the local user account to log in to the managed node and run playbooks as different users, such as `root`.

Procedure

1. Create a user named `ansible`:

   ```sh
   [root@managed-node-01]# useradd ansible
   ```

   The control node later uses this user to establish an SSH connection to this host.
2. Set a password for the `ansible` user:

```
[root@managed-node-01]# passwd ansible
Changing password for user ansible.
New password: <password>
Retype new password: <password>
passwd: all authentication tokens updated successfully.
```

You must enter this password when Ansible uses `sudo` to perform tasks as the `root` user.

3. Install the `ansible` user’s SSH public key on the managed node:

   a. Log in to the control node as the `ansible` user, and copy the SSH public key to the managed node:

```
[ansible@control-node]$ ssh-copy-id managed-node-01.example.com
/usr/bin/ssh-copy-id: INFO: Source of key(s) to be installed:
"/home/ansible/.ssh/id_rsa.pub"
The authenticity of host 'managed-node-01.example.com (192.0.2.100)' can't be established.
ECDSA key fingerprint is SHA256:9bZ33GJNODK3zbNhvbokN/6Mq7hu3vpBXDrCxe7NAvo.
```

   b. When prompted, connect by entering `yes`:

```
Are you sure you want to continue connecting (yes/no/[fingerprint])? yes
```

```
/usr/bin/ssh-copy-id: INFO: attempting to log in with the new key(s), to filter out any that are already installed
/usr/bin/ssh-copy-id: INFO: 1 key(s) remain to be installed -- if you are prompted now it is to install the new keys
```

   c. When prompted, enter the password:

```
ansible@managed-node-01.example.com's password: <password>
```

```
Number of key(s) added: 1
```

```
Now try logging into the machine, with: "ssh '<managed-node-01.example.com>'" and check to make sure that only the key(s) you wanted were added.
```

   d. Verify the SSH connection by remotely executing a command on the control node:

```
[ansible@control-node]$ ssh <managed-node-01.example.com> whoami
ansible
```

4. Create a `sudo` configuration for the `ansible` user:

   a. Create and edit the `/etc/sudoers.d/ansible` file by using the `visudo` command:

```
[root@managed-node-01]# visudo /etc/sudoers.d/ansible
```

The benefit of using `visudo` over a normal editor is that this utility provides basic sanity checks and checks for parse errors before installing the file.
b. Configure a `sudoers` policy in the `/etc/sudoers.d/ansible` file that meets your requirements, for example:

- To grant permissions to the `ansible` user to run all commands as any user and group on this host after entering the `ansible` user’s password, use:

  ```
  ansible ALL=(ALL) ALL
  ```

- To grant permissions to the `ansible` user to run all commands as any user and group on this host without entering the `ansible` user’s password, use:

  ```
  ansible ALL=(ALL) NOPASSWD: ALL
  ```

Alternatively, configure a more fine-granular policy that matches your security requirements. For further details on `sudoers` policies, see the `sudoers(5)` man page.

**Verification**

1. Verify that you can execute commands from the control node on an all managed nodes:

   ```
   [ansible@control-node]$ ansible all -m ping
   BECOME password: <password>
   managed-node-01.example.com | SUCCESS => 
   "ansible_facts": 
   "discovered_interpreter_python": "/usr/bin/python3"
   },
   "changed": false,
   "ping": "pong"
   }
   ...
   ```

   The hard-coded all group dynamically contains all hosts listed in the inventory file.

2. Verify that privilege escalation works correctly by running the `whoami` utility on a managed host by using the Ansible `command` module:

   ```
   [ansible@control-node]$ ansible managed-node-01.example.com -m command -a whoami
   BECOME password: <password>
   managed-node-01.example.com | CHANGED | rc=0 >>
   root
   ```

   If the command returns root, you configured `sudo` on the managed nodes correctly.

**Additional resources**

- Preparing a control node on RHEL 8.
- The `sudoers(5)` man page

**5.2. INTRODUCTION TO THE METRICS SYSTEM ROLE**

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems. The `metrics` System Role configures
performance analysis services for the local system and, optionally, includes a list of remote systems to be monitored by the local system. The **metrics** System Role enables you to use **pcp** to monitor your systems performance without having to configure **pcp** separately, as the set-up and deployment of **pcp** is handled by the playbook.

**Table 5.1. metrics system role variables**

<table>
<thead>
<tr>
<th>Role variable</th>
<th>Description</th>
<th>Example usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics_monitored_hosts</td>
<td>List of remote hosts to be analyzed by the target host. These hosts will have metrics recorded on the target host, so ensure enough disk space exists below /var/log for each host.</td>
<td>metrics_monitored_hosts: [&quot;webserver.example.com&quot;, &quot;database.example.com&quot;]</td>
</tr>
<tr>
<td>metrics_retention_days</td>
<td>Configures the number of days for performance data retention before deletion.</td>
<td>metrics_retention_days: 14</td>
</tr>
<tr>
<td>metrics_graph_service</td>
<td>A boolean flag that enables the host to be set up with services for performance data visualization via pcp and grafana. Set to false by default.</td>
<td>metrics_graph_service: no</td>
</tr>
<tr>
<td>metrics_query_service</td>
<td>A boolean flag that enables the host to be set up with time series query services for querying recorded pcp metrics via redis. Set to false by default.</td>
<td>metrics_query_service: no</td>
</tr>
<tr>
<td>metrics_provider</td>
<td>Specifies which metrics collector to use to provide metrics. Currently, pcp is the only supported metrics provider.</td>
<td>metrics_provider: &quot;pcp&quot;</td>
</tr>
<tr>
<td>metrics_manage_firewall</td>
<td>Uses the firewall role to manage port access directly from the metrics role. Set to false by default.</td>
<td>metrics_manage_firewall: true</td>
</tr>
<tr>
<td>metrics_manage_selinux</td>
<td>Uses the selinux role to manage port access directly from the metrics role. Set to false by default.</td>
<td>metrics_manage_selinux: true</td>
</tr>
</tbody>
</table>

**NOTE**

For details about the parameters used in **metrics_connections** and additional information about the **metrics** System Role, see the `/usr/share/ansible/roles/rhel-system-roles.metrics/README.md` file.
5.3. USING THE METRICS SYSTEM ROLE TO MONITOR YOUR LOCAL SYSTEM WITH VISUALIZATION

This procedure describes how to use the metrics RHEL System Role to monitor your local system while simultaneously provisioning data visualization via Grafana.

Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the rhel-system-roles package installed on the machine you want to monitor.

Procedure

1. Configure localhost in the /etc/ansible/hosts Ansible inventory by adding the following content to the inventory:

   ```
   localhost ansible_connection=local
   ```

2. Create an Ansible playbook with the following content:

   ```yaml
   ---
   - name: Manage metrics
     hosts: localhost
     vars:
       metrics_graph_service: yes
       metrics_manage_firewall: true
       metrics_manage_selinux: true
     roles:
       - rhel-system-roles.metrics
   ```

3. Run the Ansible playbook:

   ```
   # ansible-playbook name_of_your_playbook.yml
   ```

   **NOTE**
   Because the metrics_graph_service boolean is set to value="yes", Grafana is automatically installed and provisioned with pcp added as a data source. Because metrics_manage_firewall and metrics_manage_selinux are both set to true, the metrics role uses the firewall and selinux system roles to manage the ports used by the metrics role.

4. To view visualization of the metrics being collected on your machine, access the grafana web interface as described in Accessing the Grafana web UI.

5.4. USING THE METRICS SYSTEM ROLE TO SET UP A FLEET OF INDIVIDUAL SYSTEMS TO MONITOR THEMSELVES

This procedure describes how to use the metrics System Role to set up a fleet of machines to monitor themselves.
Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.
- You have the SSH connection established.

Procedure

1. Add the name or IP address of the machines you want to monitor via the playbook to the `/etc/ansible/hosts` Ansible inventory file under an identifying group name enclosed in brackets:

```
[remotes]
webserver.example.com
database.example.com
```

2. Create an Ansible playbook with the following content:

```yaml
---
- hosts: remotes
  vars:
    metrics_retention_days: 0
    metrics_manage_firewall: true
    metrics_manage_selinux: true
  roles:
    - rhel-system-roles.metrics
```

   **NOTE**

   Because `metrics_manage_firewall` and `metrics_manage_selinux` are both set to `true`, the metrics role uses the `firewall` and `selinux` roles to manage the ports used by the `metrics` role.

3. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml -k
```

   Where the `-k` prompt for password to connect to remote system.

### 5.5. USING THE `METRICS` SYSTEM ROLE TO MONITOR A FLEET OF MACHINES CENTRALLY VIA YOUR LOCAL MACHINE

This procedure describes how to use the `metrics` System Role to set up your local machine to centrally monitor a fleet of machines while also provisioning visualization of the data via `grafana` and querying of the data via `redis`.

Prerequisites

- The Ansible Core package is installed on the control machine.
You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.

**Procedure**

1. Create an Ansible playbook with the following content:

```yaml
---
- hosts: localhost
  vars:
    metrics_graph_service: yes
    metrics_query_service: yes
    metrics_retention_days: 10
    metrics_monitored_hosts: ["database.example.com", "webserver.example.com"]
    metrics_manage_firewall: yes
    metrics_manage_selinux: yes
  roles:
    - rhel-system-roles.metrics
```

2. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml
```

**NOTE**

Because the `metrics_graph_service` and `metrics_query_service` booleans are set to `value="yes"`, **grafana** is automatically installed and provisioned with **pcp** added as a data source with the **pcp** data recording indexed into **redis**, allowing the **pcp** querying language to be used for complex querying of the data. Because `metrics_manage_firewall` and `metrics_manage_selinux` are both set to `true`, the **metrics** role uses the **firewall** and **selinux** roles to manage the ports used by the **metrics** role.

3. To view a graphical representation of the metrics being collected centrally by your machine and to query the data, access the **grafana** web interface as described in **Accessing the Grafana web UI**.

5.6. SETTING UP AUTHENTICATION WHILE MONITORING A SYSTEM USING THE METRICS SYSTEM ROLE

PCP supports the **scram-sha-256** authentication mechanism through the Simple Authentication Security Layer (SASL) framework. The **metrics** RHEL System Role automates the steps to setup authentication using the **scram-sha-256** authentication mechanism. This procedure describes how to setup authentication using the **metrics** RHEL System Role.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.

**Procedure**
1. Include the following variables in the Ansible playbook you want to setup authentication for:

```yaml
---
vars:
  metrics_username: your_username
  metrics_password: your_password
  metrics_manage_firewall: true
  metrics_manage_selinux: true
```

**NOTE**

Because `metrics_manage_firewall` and `metrics_manage_selinux` are both set to `true`, the `metrics` role uses the `firewall` and `selinux` roles to manage the ports used by the `metrics` role.

2. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml
```

**Verification steps**

- Verify the `sasl` configuration:

```
# pminfo -f -h "pcp://ip_adress?username=your_username" disk.dev.read
Password:
disk.dev.read
inst [0 or "sda"] value 19540
```

*ip_adress* should be replaced by the IP address of the host.

### 5.7. USING THE METRICS SYSTEM ROLE TO CONFIGURE AND ENABLE METRICS COLLECTION FOR SQL SERVER

This procedure describes how to use the `metrics` RHEL System Role to automate the configuration and enabling of metrics collection for Microsoft SQL Server via `pcp` on your local system.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to monitor.
- You have installed Microsoft SQL Server for Red Hat Enterprise Linux and established a ‘trusted’ connection to an SQL server. See [Install SQL Server and create a database on Red Hat](#).
- You have installed the Microsoft ODBC driver for SQL Server for Red Hat Enterprise Linux. See [Red Hat Enterprise Server and Oracle Linux](#).

**Procedure**

1. Configure **localhost** in the `/etc/ansible/hosts` Ansible inventory by adding the following content to the inventory:
2. Create an Ansible playbook that contains the following content:

```yaml
---
- hosts: localhost
  vars:
    metrics_from_mssql: true
    metrics_manage_firewall: true
    metrics_manage_selinux: true
  roles:
    - role: rhel-system-roles.metrics
```

**NOTE**

Because `metrics_manage_firewall` and `metrics_manage_selinux` are both set to `true`, the `metrics` role uses the `firewall` and `selinux` roles to manage the ports used by the `metrics` role.

3. Run the Ansible playbook:

```bash
# ansible-playbook name_of_your_playbook.yml
```

**Verification steps**

- Use the `pcp` command to verify that SQL Server PMDA agent (mssql) is loaded and running:

  ```bash
  # pcp
  platform: Linux rhel82-2.local 4.18.0-167.el8.x86_64 #1 SMP Sun Dec 15 01:24:23 UTC 2019 x86_64
  hardware: 2 cpus, 1 disk, 1 node, 2770MB RAM
  timezone: PDT+7
  services: pmcd pmproxy
    pmcd: Version 5.0.2-1, 12 agents, 4 clients
    pmda: root pmcd proc pmproxy xfs linux nfsclient mmv kvm mssql
    jbd2 dm
  pmlogger: primary logger: /var/log/pcp/pmlogger/rhel82-2.local/20200326.16.31
  pmie: primary engine: /var/log/pcp/pmie/rhel82-2.local/pmie.log
  ```

**Additional resources**

- For more information about using Performance Co-Pilot for Microsoft SQL Server, see this Red Hat Developers Blog post.
CHAPTER 6. SETTING UP PCP

Performance Co-Pilot (PCP) is a suite of tools, services, and libraries for monitoring, visualizing, storing, and analyzing system-level performance measurements.

6.1. OVERVIEW OF PCP

You can add performance metrics using Python, Perl, C++, and C interfaces. Analysis tools can use the Python, C++, C client APIs directly, and rich web applications can explore all available performance data using a JSON interface.

You can analyze data patterns by comparing live results with archived data.

Features of PCP:

- Light-weight distributed architecture, which is useful during the centralized analysis of complex systems.
- It allows the monitoring and management of real-time data.
- It allows logging and retrieval of historical data.

PCP has the following components:

- The Performance Metric Collector Daemon (pmcd) collects performance data from the installed Performance Metric Domain Agents (pmda). PMDAs can be individually loaded or unloaded on the system and are controlled by the PMCD on the same host.
- Various client tools, such as pminfo or pmstat, can retrieve, display, archive, and process this data on the same host or over the network.
- The pcp package provides the command-line tools and underlying functionality.
- The pcp-gui package provides the graphical application. Install the pcp-gui package by executing the yum install pcp-gui command. For more information, see Visually tracing PCP log archives with the PCP Charts application.

Additional resources

- pcp(1) man page
- /usr/share/doc/pcp-doc/ directory
- Tools distributed with PCP
- Index of Performance Co-Pilot (PCP) articles, solutions, tutorials, and white papers from on Red Hat Customer Portal
- Side-by-side comparison of PCP tools with legacy tools Red Hat Knowledgebase article
- PCP upstream documentation

6.2. INSTALLING AND ENABLING PCP

To begin using PCP, install all the required packages and enable the PCP monitoring services.
This procedure describes how to install PCP using the `pcp` package. If you want to automate the PCP installation, install it using the `pcp-zeroconf` package. For more information about installing PCP by using `pcp-zeroconf`, see Setting up PCP with `pcp-zeroconf`.

**Procedure**

1. Install the `pcp` package:
   ```bash
   # yum install pcp
   ```

2. Enable and start the `pmcd` service on the host machine:
   ```bash
   # systemctl enable pmcd
   # systemctl start pmcd
   ```

**Verification steps**

- Verify if the `pmcd` process is running on the host:
  ```bash
  # pcp
  ```

**Performance Co-Pilot configuration on workstation:**

- **platform**: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019 x86_64
- **hardware**: 12 cpus, 2 disks, 1 node, 36023MB RAM
- **timezone**: CEST-2
- **services**: pmcd
- **pmcd**: Version 4.3.0-1, 8 agents
- **pmda**: root pmcd proc xfs linux mmv kvm jbd2

**Additional resources**

- `pmcd(1)` man page
- Tools distributed with PCP

### 6.3. DEPLOYING A MINIMAL PCP SETUP

The minimal PCP setup collects performance statistics on Red Hat Enterprise Linux. The setup involves adding the minimum number of packages on a production system needed to gather data for further analysis.

You can analyze the resulting `tar.gz` file and the archive of the `pmlogger` output using various PCP tools and compare them with other sources of performance information.

**Prerequisites**

- PCP is installed. For more information, see Installing and enabling PCP.

**Procedure**
1. Update the **pmlogger** configuration:
   ```
   # pmlogconf -r /var/lib/pcp/config/pmlogger/config.default
   ```

2. Start the **pmcd** and **pmlogger** services:
   ```
   # systemctl start pmcd.service
   # systemctl start pmlogger.service
   ```

3. Execute the required operations to record the performance data.

4. Stop the **pmcd** and **pmlogger** services:
   ```
   # systemctl stop pmcd.service
   # systemctl stop pmlogger.service
   ```

5. Save the output and save it to a **tar.gz** file named based on the host name and the current date and time:
   ```
   # cd /var/log/pcp/pmlogger/
   # tar -czf $(hostname).$(date +%F-%Hh%M).pcp.tar.gz $(hostname)
   ```

   Extract this file and analyze the data using PCP tools.

- **System services distributed with PCP**

### 6.4. SYSTEM SERVICES DISTRIBUTED WITH PCP

The following table describes roles of various system services, which are distributed with PCP.

**Table 6.1. Roles of system services distributed with PCP**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pmcd</td>
<td>The Performance Metric Collector Daemon (PMCD).</td>
</tr>
<tr>
<td>pmie</td>
<td>The Performance Metrics Inference Engine.</td>
</tr>
<tr>
<td>pmlogger</td>
<td>The performance metrics logger.</td>
</tr>
<tr>
<td>pmproxy</td>
<td>The realtime and historical performance metrics proxy, time series query and REST API service.</td>
</tr>
</tbody>
</table>
### 6.5. TOOLS DISTRIBUTED WITH PCP

The following table describes usage of various tools, which are distributed with PCP.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>pcp</strong></td>
<td>Displays the current status of a Performance Co-Pilot installation.</td>
</tr>
<tr>
<td><strong>pcp-atop</strong></td>
<td>Shows the system-level occupation of the most critical hardware resources from the performance point of view: CPU, memory, disk, and network.</td>
</tr>
<tr>
<td><strong>pcp-atopsar</strong></td>
<td>Generates a system-level activity report over a variety of system resource utilization. The report is generated from a raw logfile previously recorded using pmlogger or the -w option of pcp-atop.</td>
</tr>
<tr>
<td><strong>pcp-dmcache</strong></td>
<td>Displays information about configured Device Mapper Cache targets, such as: device IOPs, cache and metadata device utilization, as well as hit and miss rates and ratios for both reads and writes for each cache device.</td>
</tr>
<tr>
<td><strong>pcp-dstat</strong></td>
<td>Displays metrics of one system at a time. To display metrics of multiple systems, use <code>--host</code> option.</td>
</tr>
<tr>
<td><strong>pcp-free</strong></td>
<td>Reports on free and used memory in a system.</td>
</tr>
<tr>
<td><strong>pcp-htop</strong></td>
<td>Displays all processes running on a system along with their command line arguments in a manner similar to the <code>top</code> command, but allows you to scroll vertically and horizontally as well as interact using a mouse. You can also view processes in a tree format and select and act on multiple processes at once.</td>
</tr>
<tr>
<td><strong>pcp-ipcs</strong></td>
<td>Displays information about the inter-process communication (IPC) facilities that the calling process has read access for.</td>
</tr>
<tr>
<td><strong>pcp-numastat</strong></td>
<td>Displays NUMA allocation statistics from the kernel memory allocator.</td>
</tr>
<tr>
<td><strong>pcp-pidstat</strong></td>
<td>Displays information about individual tasks or processes running on the system such as: CPU percentage, memory and stack usage, scheduling, and priority. Reports live data for the local host by default.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pcp-ss</td>
<td>Displays socket statistics collected by the pmdasockets Performance Metrics Domain Agent (PMDA).</td>
</tr>
<tr>
<td>pcp-uptime</td>
<td>Displays how long the system has been running, how many users are currently logged on, and the system load averages for the past 1, 5, and 15 minutes.</td>
</tr>
<tr>
<td>pcp-vmstat</td>
<td>Provides a high-level system performance overview every 5 seconds. Displays information about processes, memory, paging, block IO, traps, and CPU activity.</td>
</tr>
<tr>
<td>pmchart</td>
<td>Plots performance metrics values available through the facilities of the Performance Co-Pilot.</td>
</tr>
<tr>
<td>pmclient</td>
<td>Displays high-level system performance metrics by using the Performance Metrics Application Programming Interface (PMAPI).</td>
</tr>
<tr>
<td>pmconfig</td>
<td>Displays the values of configuration parameters.</td>
</tr>
<tr>
<td>pmdbg</td>
<td>Displays available Performance Co-Pilot debug control flags and their values.</td>
</tr>
<tr>
<td>pmdiff</td>
<td>Compares the average values for every metric in either one or two archives, in a given time window, for changes that are likely to be of interest when searching for performance regressions.</td>
</tr>
<tr>
<td>pmdumplog</td>
<td>Displays control, metadata, index, and state information from a Performance Co-Pilot archive file.</td>
</tr>
<tr>
<td>pmdumptext</td>
<td>Outputs the values of performance metrics collected live or from a Performance Co-Pilot archive.</td>
</tr>
<tr>
<td>pmerr</td>
<td>Displays available Performance Co-Pilot error codes and their corresponding error messages.</td>
</tr>
<tr>
<td>pmfind</td>
<td>Finds PCP services on the network.</td>
</tr>
<tr>
<td>pmie</td>
<td>An inference engine that periodically evaluates a set of arithmetic, logical, and rule expressions. The metrics are collected either from a live system, or from a Performance Co-Pilot archive file.</td>
</tr>
<tr>
<td>pmieconf</td>
<td>Displays or sets configurable pmie variables.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pmiectl</td>
<td>Manages non-primary instances of pmie.</td>
</tr>
<tr>
<td>pminfo</td>
<td>Displays information about performance metrics. The metrics are collected either from a live system, or from a Performance Co-Pilot archive file.</td>
</tr>
<tr>
<td>pmisostat</td>
<td>Reports I/O statistics for SCSI devices (by default) or device-mapper devices (with the -x dm option).</td>
</tr>
<tr>
<td>pmic</td>
<td>Interactively configures active pmlogger instances.</td>
</tr>
<tr>
<td>pmlogcheck</td>
<td>Identifies invalid data in a Performance Co-Pilot archive file.</td>
</tr>
<tr>
<td>pmlogconf</td>
<td>Creates and modifies a pmlogger configuration file.</td>
</tr>
<tr>
<td>pmlogctl</td>
<td>Manages non-primary instances of pmlogger.</td>
</tr>
<tr>
<td>pmloglabel</td>
<td>Verifies, modifies, or repairs the label of a Performance Co-Pilot archive file.</td>
</tr>
<tr>
<td>pmlogsummary</td>
<td>Calculates statistical information about performance metrics stored in a Performance Co-Pilot archive file.</td>
</tr>
<tr>
<td>pmprobe</td>
<td>Determines the availability of performance metrics.</td>
</tr>
<tr>
<td>pmrep</td>
<td>Reports on selected, easily customizable, performance metrics values.</td>
</tr>
<tr>
<td>pmsocks</td>
<td>Allows access to a Performance Co-Pilot hosts through a firewall.</td>
</tr>
<tr>
<td>pmstat</td>
<td>Periodically displays a brief summary of system performance.</td>
</tr>
<tr>
<td>pmstore</td>
<td>Modifies the values of performance metrics.</td>
</tr>
<tr>
<td>pmtrace</td>
<td>Provides a command line interface to the trace PMDA.</td>
</tr>
<tr>
<td>pmval</td>
<td>Displays the current value of a performance metric.</td>
</tr>
</tbody>
</table>

### 6.6. PCP DEPLOYMENT ARCHITECTURES

Performance Co-Pilot (PCP) supports multiple deployment architectures, based on the scale of the PCP deployment, and offers many options to accomplish advanced setups.
Available scaling deployment setup variants based on the recommended deployment set up by Red Hat, sizing factors, and configuration options include:

**NOTE**

Since the PCP version 5.3.0 is unavailable in Red Hat Enterprise Linux 8.4 and the prior minor versions of Red Hat Enterprise Linux 8, Red Hat recommends localhost and pmlogger farm architectures.

For more information about known memory leaks in pmproxy in PCP versions before 5.3.0, see [Memory leaks in pmproxy in PCP](#).

**Localhost**

Each service runs locally on the monitored machine. When you start a service without any configuration changes, this is the default deployment. Scaling beyond the individual node is not possible in this case.

By default, the deployment setup for Redis is standalone, localhost. However, Redis can optionally perform in a highly-available and highly scalable clustered fashion, where data is shared across multiple hosts. Another viable option is to deploy a Redis cluster in the cloud, or to utilize a managed Redis cluster from a cloud vendor.

**Decentralized**

The only difference between localhost and decentralized setup is the centralized Redis service. In this model, the host executes **pmlogger** service on each monitored host and retrieves metrics from a local **pmcd** instance. A local **pmproxy** service then exports the performance metrics to a central Redis instance.

![Figure 6.1. Decentralized logging](image)

**Centralized logging - pmlogger farm**

When the resource usage on the monitored hosts is constrained, another deployment option is a **pmlogger** farm, which is also known as centralized logging. In this setup, a single logger host executes multiple **pmlogger** processes, and each is configured to retrieve performance metrics from a
different remote \text{pmcd} host. The centralized logger host is also configured to execute the \text{pmproxy} service, which discovers the resulting PCP archives logs and loads the metric data into a Redis instance.

**Figure 6.2. Centralized logging - pmlogger farm**

![Centralized logging - pmlogger farm diagram]

**Federated - multiple pmlogger farms**

For large scale deployments, Red Hat recommends to deploy multiple \text{pmlogger} farms in a federated fashion. For example, one \text{pmlogger} farm per rack or data center. Each \text{pmlogger} farm loads the metrics into a central Redis instance.
NOTE

By default, the deployment setup for Redis is standalone, localhost. However, Redis can optionally perform in a highly-available and highly scalable clustered fashion, where data is shared across multiple hosts. Another viable option is to deploy a Redis cluster in the cloud, or to utilize a managed Redis cluster from a cloud vendor.

</tr>
<tr>
<td>Recommended deployment setup</td>
<td>Localhost, Decentralized, or Centralized logging</td>
<td>Decentralized, Centralized logging, or Federated</td>
<td>Decentralized or Federated</td>
</tr>
</tbody>
</table>

### 6.8. SIZING FACTORS

The following are the sizing factors required for scaling:

**Remote system size**

The number of CPUs, disks, network interfaces, and other hardware resources affects the amount of data collected by each `pmllogger` on the centralized logging host.

**Logged Metrics**

The number and types of logged metrics play an important role. In particular, the `per-process proc.*` metrics require a large amount of disk space, for example, with the standard `pcp-zeroconf` setup, 10s logging interval, 11 MB without proc metrics versus 155 MB with proc metrics - a factor of 10 times more. Additionally, the number of instances for each metric, for example the number of CPUs, block devices, and network interfaces also impacts the required storage capacity.

**Logging Interval**

The interval how often metrics are logged, affects the storage requirements. The expected daily PCP archive file sizes are written to the `pmllogger.log` file for each `pmllogger` instance. These values are uncompressed estimates. Since PCP archives compress very well, approximately 10:1, the actual long term disk space requirements can be determined for a particular site.

**pmllogrewrite**
After every PCP upgrade, the `pmlogrewrite` tool is executed and rewrites old archives if there were changes in the metric metadata from the previous version and the new version of PCP. This process duration scales linear with the number of archives stored.

Additional resources

- `pmlogrewrite(1)` and `pmlogger(1)` man pages

6.9. CONFIGURATION OPTIONS FOR PCP SCALING

The following are the configuration options, which are required for scaling:

sysctl and rlimit settings

When archive discovery is enabled, `pmproxy` requires four descriptors for every `pmlogger` that it is monitoring or log-tailing, along with the additional file descriptors for the service logs and `pmproxy` client sockets, if any. Each `pmlogger` process uses about 20 file descriptors for the remote `pmcd` socket, archive files, service logs, and others. In total, this can exceed the default 1024 soft limit on a system running around 200 `pmlogger` processes. The `pmproxy` service in `pcp-5.3.0` and later automatically increases the soft limit to the hard limit. On earlier versions of PCP, tuning is required if a high number of `pmlogger` processes are to be deployed, and this can be accomplished by increasing the soft or hard limits for `pmlogger`. For more information, see How to set limits (ulimit) for services run by systemd.

Local Archives

The `pmlogger` service stores metrics of local and remote `pmcds` in the `/var/log/pcp/pmlogger/` directory. To control the logging interval of the local system, update the `/etc/pcp/pmlogger/control.d/configfile` file and add `-t X` in the arguments, where `X` is the logging interval in seconds. To configure which metrics should be logged, execute `pmlogconf /var/lib/pcp/config/pmlogger/config.clienthostname`. This command deploys a configuration file with a default set of metrics, which can optionally be further customized. To specify retention settings, that is when to purge old PCP archives, update the `/etc/sysconfig/pmlogger_timers` file and specify `PMLOGGER_DAILY_PARAMS="-E -k X"`, where `X` is the amount of days to keep PCP archives.

Redis

The `pmproxy` service sends logged metrics from `pmlogger` to a Redis instance. The following are the available two options to specify the retention settings in the `/etc/pcp/pmproxy/pmproxy.conf` configuration file:

- `stream.expire` specifies the duration when stale metrics should be removed, that is metrics which were not updated in a specified amount of time in seconds.

- `stream.maxlen` specifies the maximum number of metric values for one metric per host. This setting should be the retention time divided by the logging interval, for example 20160 for 14 days of retention and 60s logging interval (60*60*24*14/60)

Additional resources

- `pmproxy(1)`, `pmlogger(1)`, and `sysctl(8)` man pages

6.10. EXAMPLE: ANALYZING THE CENTRALIZED LOGGING DEPLOYMENT
The following results were gathered on a centralized logging setup, also known as pmlogger farm deployment, with a default `pcp-zeroconf 5.3.0` installation, where each remote host is an identical container instance running `pmcd` on a server with 64 CPU cores, 376 GB RAM, and one disk attached.

The logging interval is 10s, proc metrics of remote nodes are not included, and the memory values refer to the Resident Set Size (RSS) value.

### Table 6.4. Detailed utilization statistics for 10s logging interval

<table>
<thead>
<tr>
<th>Number of Hosts</th>
<th>10</th>
<th>50</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCP Archives Storage per Day</td>
<td>91 MB</td>
<td>522 MB</td>
</tr>
<tr>
<td><strong>pmlogger</strong> Memory</td>
<td>160 MB</td>
<td>580 MB</td>
</tr>
<tr>
<td><strong>pmlogger</strong> Network per Day (In)</td>
<td>2 MB</td>
<td>9 MB</td>
</tr>
<tr>
<td><strong>pmproxy</strong> Memory</td>
<td>1.4 GB</td>
<td>6.3 GB</td>
</tr>
<tr>
<td>Redis Memory per Day</td>
<td>2.6 GB</td>
<td>12 GB</td>
</tr>
</tbody>
</table>

### Table 6.5. Used resources depending on monitored hosts for 60s logging interval

<table>
<thead>
<tr>
<th>Number of Hosts</th>
<th>10</th>
<th>50</th>
<th>100</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCP Archives Storage per Day</td>
<td>20 MB</td>
<td>120 MB</td>
<td>271 MB</td>
</tr>
<tr>
<td><strong>pmlogger</strong> Memory</td>
<td>104 MB</td>
<td>524 MB</td>
<td>1049 MB</td>
</tr>
<tr>
<td><strong>pmlogger</strong> Network per Day (In)</td>
<td>0.38 MB</td>
<td>1.75 MB</td>
<td>3.48 MB</td>
</tr>
<tr>
<td><strong>pmproxy</strong> Memory</td>
<td>2.67 GB</td>
<td>5.5 GB</td>
<td>9 GB</td>
</tr>
<tr>
<td>Redis Memory per Day</td>
<td>0.54 GB</td>
<td>2.65 GB</td>
<td>5.3 GB</td>
</tr>
</tbody>
</table>

**NOTE**

The **pmproxy** queues Redis requests and employs Redis pipelining to speed up Redis queries. This can result in high memory usage. For troubleshooting this issue, see [Troubleshooting high memory usage](#).  

### 6.11. EXAMPLE: ANALYZING THE FEDERATED SETUP DEPLOYMENT

The following results were observed on a federated setup, also known as multiple pmlogger farms, consisting of three centralized logging (pmlogger farm) setups, where each pmlogger farm was monitoring 100 remote hosts, that is 300 hosts in total.

This setup of the pmlogger farms is identical to the configuration mentioned in the
Example: Analyzing the centralized logging deployment for 60s logging interval, except that the Redis servers were operating in cluster mode.

Table 6.6. Used resources depending on federated hosts for 60s logging interval

<table>
<thead>
<tr>
<th>PCP Archives Storage per Day</th>
<th>pmlogger Memory</th>
<th>Network per Day (In/Out)</th>
<th>pmproxy Memory</th>
<th>Redis Memory per Day</th>
</tr>
</thead>
<tbody>
<tr>
<td>277 MB</td>
<td>1058 MB</td>
<td>15.6 MB / 12.3 MB</td>
<td>6-8 GB</td>
<td>5.5 GB</td>
</tr>
</tbody>
</table>

Here, all values are per host. The network bandwidth is higher due to the inter-node communication of the Redis cluster.

6.12. TROUBLESHOOTING HIGH MEMORY USAGE

The following scenarios can result in high memory usage:

- The pmproxy process is busy processing new PCP archives and does not have spare CPU cycles to process Redis requests and responses.
- The Redis node or cluster is overloaded and cannot process incoming requests on time.

The pmproxy service daemon uses Redis streams and supports the configuration parameters, which are PCP tuning parameters and affects Redis memory usage and key retention. The /etc/pcp/pmproxy/pmproxy.conf file lists the available configuration options for pmproxy and the associated APIs.

The following procedure describes how to troubleshoot high memory usage issue.

Prerequisites

1. Install the pcp-pmda-redis package:

   ```
   # yum install pcp-pmda-redis
   ```

2. Install the redis PMDA:

   ```
   # cd /var/lib/pcp/pmdas/redis && ./Install
   ```

Procedure

- To troubleshoot high memory usage, execute the following command and observe the inflight column:

  ```
  $ pmrep :pmproxy
       backlog  inflight  reqs/s  resp/s  wait req err  resp err  changed  throttled
          byte  count  count/s  count/s  count/s  count/s  count/s  count/s
  14:59:08  0       0       N/A      N/A      N/A      N/A      N/A      N/A
  14:59:09  0       0       2268.9  2268.9  28       0        0       2.0      4.0
  14:59:10  0       0       0.0     0.0     0        0        0       0.0      0.0
  14:59:11  0       0       0.0     0.0     0        0        0       0.0      0.0
  ```
This column shows how many Redis requests are in-flight, which means they are queued or sent, and no reply was received so far.

A high number indicates one of the following conditions:

- The `pmproxy` process is busy processing new PCP archives and does not have spare CPU cycles to process Redis requests and responses.

- The Redis node or cluster is overloaded and cannot process incoming requests on time.

- To troubleshoot the high memory usage issue, reduce the number of `pmlogger` processes for this farm, and add another pmlogger farm. Use the federated - multiple pmlogger farms setup. If the Redis node is using 100% CPU for an extended amount of time, move it to a host with better performance or use a clustered Redis setup instead.

- To view the `pmproxy.redis.*` metrics, use the following command:

```
$ pminfo -ftd pmproxy.redis
```

```
pmproxy.redis.responses.wait [wait time for responses]
   Data Type: 64-bit unsigned int  InDom: PM_INDOM_NULL 0xffffffff
   Semantics: counter  Units: microsec
   value 546028367374
pmproxy.redis.responses.error [number of error responses]
   Data Type: 64-bit unsigned int  InDom: PM_INDOM_NULL 0xffffffff
   Semantics: counter  Units: count
   value 1164
 [...]
```

To view how many Redis requests are inflight, see the `pmproxy.redis.requests.inflight.total` metric and `pmproxy.redis.requests.inflight.bytes` metric to view how many bytes are occupied by all current inflight Redis requests.

In general, the redis request queue would be zero but can build up based on the usage of large pmlogger farms, which limits scalability and can cause high latency for `pmproxy` clients.

- Use the `pminfo` command to view information about performance metrics. For example, to view the `redis.*` metrics, use the following command:

```
$ pminfo -ftd redis
```

```
redis.redis_build_id [Build ID]
   Data Type: string  InDom: 24.0 0x6000000
   Semantics: discrete  Units: count
   inst [0 or "localhost:6379"] value "87e335e57cffa755"
redis.total_commands_processed [Total number of commands processed by the server]
   Data Type: 64-bit unsigned int  InDom: 24.0 0x6000000
   Semantics: counter  Units: count
```
inst [0 or "localhost:6379"] value 595627069

redis.used_memory_peak [Peak memory consumed by Redis (in bytes)]
  Data Type: 32-bit unsigned int  InDom: 24.0 0x6000000
  Semantics: instant  Units: count
  inst [0 or "localhost:6379"] value 572234920

To view the peak memory usage, see the `redis.used_memory_peak` metric.

Additional resources

- `pmdaredis(1)`, `pmproxy(1)`, and `pminfo(1)` man pages
- PCP deployment architectures
CHAPTER 7. LOGGING PERFORMANCE DATA WITH PMLOGGER

With the PCP tool you can log the performance metric values and replay them later. This allows you to perform a retrospective performance analysis.

Using the pmlogger tool, you can:

- Create the archived logs of selected metrics on the system
- Specify which metrics are recorded on the system and how often

7.1. MODIFYING THE PMLOGGER CONFIGURATION FILE WITH PMLOGCONF

When the pmlogger service is running, PCP logs a default set of metrics on the host.

Use the pmlogconf utility to check the default configuration. If the pmlogger configuration file does not exist, pmlogconf creates it with a default metric values.

Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.

Procedure

1. Create or modify the pmlogger configuration file:

   # pmlogconf -r /var/lib/pcp/config/pmlogger/config.default

2. Follow pmlogconf prompts to enable or disable groups of related performance metrics and to control the logging interval for each enabled group.

Additional resources

- pmlogconf(1) and pmlogger(1) man pages
- Tools distributed with PCP
- System services distributed with PCP

7.2. EDITING THE PMLOGGER CONFIGURATION FILE MANUALLY

To create a tailored logging configuration with specific metrics and given intervals, edit the pmlogger configuration file manually. The default pmlogger configuration file is /var/lib/pcp/config/pmlogger/config.default. The configuration file specifies which metrics are logged by the primary logging instance.

In manual configuration, you can:

- Record metrics which are not listed in the automatic configuration.
- Choose custom logging frequencies.
• Add PMDA with the application metrics.

Prerequisites

• PCP is installed. For more information, see Installing and enabling PCP.

Procedure

• Open and edit the `/var/lib/pcp/config/pmlogger/config.default` file to add specific metrics:

```bash
# It is safe to make additions from here on ...  
#  
log mandatory on every 5 seconds {  
  xfs.write  
  xfs.write_bytes  
  xfs.read  
  xfs.read_bytes  
}

log mandatory on every 10 seconds {  
  xfs.allocs  
  xfs.block_map  
  xfs.transactions  
  xfs.log  
}

[access]  
  disallow * : all;  
  allow localhost : enquire;
```

Additional resources

• `pmlogger(1)` man page

• Tools distributed with PCP

• System services distributed with PCP

7.3. ENABLING THE PMLOGGER SERVICE

The `pmlogger` service must be started and enabled to log the metric values on the local machine.

This procedure describes how to enable the `pmlogger` service.

Prerequisites

• PCP is installed. For more information, see Installing and enabling PCP.

Procedure

• Start and enable the `pmlogger` service:
# systemctl start pmlogger
# systemctl enable pmlogger

Verification steps

- Verify if the `pmlogger` service is enabled:

  # pcp

  Performance Co-Pilot configuration on workstation:

  platform: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019 x86_64
  hardware: 12 cpus, 2 disks, 1 node, 36023MB RAM
  timezone: CEST-2
  services: pmcd
  pmda: root pmcd proc xfs linux mmv kvm jbd2
  pmlogger: primary logger: /var/log/pcp/pmlogger/workstation/20190827.15.54

Additional resources

- `pmlogger(1)` man page
- Tools distributed with PCP
- System services distributed with PCP
- `/var/lib/pcp/config/pmlogger/config.default` file

## 7.4. SETTING UP A CLIENT SYSTEM FOR METRICS COLLECTION

This procedure describes how to set up a client system so that a central server can collect metrics from clients running PCP.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

1. Install the `pcp-system-tools` package:

   # yum install pcp-system-tools

2. Configure an IP address for `pmcd`:

   # echo "-i 192.168.4.62" >>/etc/pcp/pmcd/pmcd.options

   Replace `192.168.4.62` with the IP address, the client should listen on.

   By default, `pmcd` is listening on the localhost.
3. Configure the firewall to add the public zone permanently:

   # firewall-cmd --permanent --zone=public --add-port=44321/tcp
   success

   # firewall-cmd --reload
   success

4. Set an SELinux boolean:

   # setsebool -P pcp_bind_all_unreserved_ports on

5. Enable the pmcd and pmlogger services:

   # systemctl enable pmcd pmlogger
   # systemctl restart pmcd pmlogger

Verification steps

- Verify if the pmcd is correctly listening on the configured IP address:

  # ss -tulp | grep 44321
  LISTEN 0 5 127.0.0.1:44321 0.0.0.0:* users:("pmcd",pid=151595,fd=6)
  LISTEN 0 5 192.168.4.62:44321 0.0.0.0:* users:("pmcd",pid=151595,fd=0)
  LISTEN 0 5 [:1]:44321 [:]:* users:("pmcd",pid=151595,fd=7)

Additional resources

- pmlogger(1), firewall-cmd(1), ss(8), and setsebool(8) man pages
- Tools distributed with PCP
- System services distributed with PCP
- /var/lib/pcp/config/pmlogger/config.default file

7.5. SETTING UP A CENTRAL SERVER TO COLLECT DATA

This procedure describes how to create a central server to collect metrics from clients running PCP.

Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.
- Client is configured for metrics collection. For more information, see Setting up a client system for metrics collection.

Procedure

1. Install the pcp-system-tools package:

   # yum install pcp-system-tools
2. Create the `/etc/pcp/pmlogger/control.d/remote` file with the following content:

```plaintext
# DO NOT REMOVE OR EDIT THE FOLLOWING LINE
$version=1.1
192.168.4.13 n n PCP_ARCHIVE_DIR/rhel7u4a -r -T24h10m -c config.rhel7u4a
192.168.4.14 n n PCP_ARCHIVE_DIR/rhel6u10a -r -T24h10m -c config.rhel6u10a
192.168.4.62 n n PCP_ARCHIVE_DIR/rhel8u1a -r -T24h10m -c config.rhel8u1a
```

Replace 192.168.4.13, 192.168.4.14 and 192.168.4.62 with the client IP addresses.

**NOTE**

In Red Hat Enterprise Linux 8.0, 8.1 and 8.2 use the following format for remote hosts in the control file: `PCP_LOG_DIR/pmlogger/host_name`.

3. Enable the `pmcd` and `pmlogger` services:

```plaintext
# systemctl enable pmcd pmlogger
# systemctl restart pmcd pmlogger
```

**Verification steps**

- Ensure that you can access the latest archive file from each directory:

```plaintext
# for i in /var/log/pcp/pmlogger/rhel*/.*.0; do pmdumplog -L $i; done
```

The archive files from the `/var/log/pcp/pmlogger/` directory can be used for further analysis and graphing.

**Additional resources**

- `pmlogger(1)` man page
- Tools distributed with PCP
- System services distributed with PCP
- `/var/lib/pcp/config/pmlogger/config.default` file
7.6. REPLAYING THE PCP LOG ARCHIVES WITH PMREP

After recording the metric data, you can replay the PCP log archives. To export the logs to text files and import them into spreadsheets, use PCP utilities such as `pcp2csv`, `pcp2xml`, `pmrep` or `pmlogsummary`.

Using the `pmrep` tool, you can:

- View the log files
- Parse the selected PCP log archive and export the values into an ASCII table
- Extract the entire archive log or only select metric values from the log by specifying individual metrics on the command line

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).
- The `pmlogger` service is enabled. For more information, see [Enabling the pmlogger service](#).
- Install the `pcp-system-tools` package:

  ```bash
  # yum install pcp-gui
  ```

Procedure

- Display the data on the metric:

  ```bash
  $ pmrep --start @3:00am --archive 20211128 --interval 5seconds --samples 10 --output csv
disk.dev.write
Time,"disk.dev.write-sda","disk.dev.write-sdb"
2021-11-28 03:00:00,,
2021-11-28 03:00:05,4.000,5.200
2021-11-28 03:00:10,1.600,7.600
2021-11-28 03:00:15,0.800,7.100
2021-11-28 03:00:20,16.600,8.400
2021-11-28 03:00:25,21.400,7.200
2021-11-28 03:00:30,21.200,6.800
2021-11-28 03:00:35,21.400,7.200
2021-11-28 03:00:40,12.400,33.800
2021-11-28 03:00:45,9.800,20.600
  ```

The mentioned example displays the data on the `disk.dev.write` metric collected in an archive at a 5 seconds interval in comma-separated-value format.

**NOTE**

Replace `20211128` in this example with a filename containing the `pmlogger` archive you want to display data for.

Additional resources

- `pmlogger(1)`, `pmrep(1)`, and `pmlogsummary(1)` man pages
- Tools distributed with PCP
- System services distributed with PCP
CHAPTER 8. MONITORING PERFORMANCE WITH PERFORMANCE CO-PILOT

Performance Co-Pilot (PCP) is a suite of tools, services, and libraries for monitoring, visualizing, storing, and analyzing system-level performance measurements.

As a system administrator, you can monitor the system’s performance using the PCP application in Red Hat Enterprise Linux 8.

8.1. MONITORING POSTFIX WITH PMDA-POSTFIX

This procedure describes how to monitor performance metrics of the postfix mail server with pmda-postfix. It helps to check how many emails are received per second.

Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.
- The pmlogger service is enabled. For more information, see Enabling the pmlogger service.

Procedure

1. Install the following packages:
   a. Install the pcp-system-tools:
      
      # yum install pcp-system-tools
   b. Install the pmda-postfix package to monitor postfix:
      
      # yum install pcp-pmda-postfix postfix
   c. Install the logging daemon:
      
      # yum install rsyslog
   d. Install the mail client for testing:
      
      # yum install mutt

2. Enable the postfix and rsyslog services:

   # systemctl enable postfix rsyslog
   # systemctl restart postfix rsyslog

3. Enable the SELinux boolean, so that pmda-postfix can access the required log files:

   # setsebool -P pcp_read_generic_logs=on

4. Install the PMDA:

   # cd /var/lib/pcp/pmdas/postfix/
# ./Install

Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Waiting for pmcd to terminate ...
Starting pmcd ...
Check postfix metrics have appeared ... 7 metrics and 58 values

Verification steps

- Verify the `pmda-postfix` operation:
  
  `echo testmail | mutt root`

- Verify the available metrics:
  
  `# pminfo postfix`

  `postfix.received`
  `postfix.sent`
  `postfix.queues.incoming`
  `postfix.queues.maildrop`
  `postfix.queues.hold`
  `postfix.queues.deferred`
  `postfix.queues.active`

Additional resources

- `rsyslogd(8), postfix(1), and setsebool(8) man pages`

- `Tools distributed with PCP`

- `System services distributed with PCP`

- `/var/lib/pcp/config/pmlogger/config.default file`

8.2. VISUALLY TRACING PCP LOG ARCHIVES WITH THE PCP CHARTS APPLICATION

After recording metric data, you can replay the PCP log archives as graphs. The metrics are sourced from one or more live hosts with alternative options to use metric data from PCP log archives as a source of historical data. To customize the PCP Charts application interface to display the data from the performance metrics, you can use line plot, bar graphs, or utilization graphs.

Using the PCP Charts application, you can:

- Replay the data in the PCP Charts application application and use graphs to visualize the retrospective data alongside live data of the system.

- Plot performance metric values into graphs.

- Display multiple charts simultaneously.
Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.
- Logged performance data with the pmlogger. For more information, see Logging performance data with pmlogger.
- Install the pcp-gui package:

  # yum install pcp-gui

Procedure

1. Launch the PCP Charts application from the command line:

   # pmchart

   **Figure 8.1. PCP Charts application**

   The pmtime server settings are located at the bottom. The start and pause button allows you to control:

   - The interval in which PCP polls the metric data
   - The date and time for the metrics of historical data

2. Click File and then New Chart to select metric from both the local machine and remote machines by specifying their host name or address. Advanced configuration options include the ability to manually set the axis values for the chart, and to manually choose the color of the plots.

3. Record the views created in the PCP Charts application:

   Following are the options to take images or record the views created in the PCP Charts application:

   - Click File and then Export to save an image of the current view.
Click **Record** and then **Start** to start a recording. Click **Record** and then **Stop** to stop the recording. After stopping the recording, the recorded metrics are archived to be viewed later.

4. Optional: In the **PCP Charts** application, the main configuration file, known as the **view**, allows the metadata associated with one or more charts to be saved. This metadata describes all chart aspects, including the metrics used and the chart columns. Save the custom **view** configuration by clicking **File** and then **Save View**, and load the **view** configuration later. The following example of the **PCP Charts** application view configuration file describes a stacking chart graph showing the total number of bytes read and written to the given XFS file system **loop1**:

```bash
#kmchart
version 1

chart title "Filesystem Throughput /loop1" style stacking antialiasing off
plot legend "Read rate" metric xfs.read_bytes instance "loop1"
plot legend "Write rate" metric xfs.write_bytes instance "loop1"
```

**Additional resources**

- pmchart(1) and pmtime(1) man pages
- Tools distributed with PCP

### 8.3. COLLECTING DATA FROM SQL SERVER USING PCP

With Red Hat Enterprise Linux 8.2 or later, the SQL Server agent is available in Performance Co-Pilot (PCP), which helps you to monitor and analyze database performance issues.

This procedure describes how to collect data for Microsoft SQL Server via **pcp** on your system.

**Prerequisites**

- You have installed Microsoft SQL Server for Red Hat Enterprise Linux and established a ‘trusted’ connection to an SQL server.
- You have installed the Microsoft ODBC driver for SQL Server for Red Hat Enterprise Linux.

**Procedure**

1. Install PCP:

   ```bash
   # yum install pcp-zeroconf
   ```

2. Install packages required for the **pyodbc** driver:

   ```bash
   # yum install gcc-c++ python3-devel unixODBC-devel
   # yum install python3-pyodbc
   ```

3. Install the **mssql** agent:

   a. Install the Microsoft SQL Server domain agent for PCP:
# yum install pcp-pmda-mssql

b. Edit the /etc/pcp/mssql/mssql.conf file to configure the SQL server account's username and password for the mssql agent. Ensure that the account you configure has access rights to performance data.

username: user_name
password: user_password

Replace user_name with the SQL Server account and user_password with the SQL Server user password for this account.

4. Install the agent:

```bash
# cd /var/lib/pcp/pmdas/mssql
# ./Install
Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Check mssql metrics have appeared ... 168 metrics and 598 values
```

Verification steps

- Using the pcp command, verify if the SQL Server PMDA (mssql) is loaded and running:

  ```bash
  $ pcp
  Performance Co-Pilot configuration on rhel.local:
  platform: Linux rhel.local 4.18.0-167.el8.x86_64 #1 SMP Sun Dec 15 01:24:23 UTC 2019 x86_64
  hardware: 2 cpus, 1 disk, 1 node, 2770MB RAM
  timezone: PDT+7
  services: pmcd pmproxy
  pmcd: Version 5.0.2-1, 12 agents, 4 clients
  pmda: root pmcd proc pmproxy xfs linux nfscient mmv kvm mssql jbd2 dm
  pmlogger: primary logger: /var/log/pcp/pmlogger/rhel.local/20200326.16.31
  pmie: primary engine: /var/log/pcp/pmie/rhel.local/pmie.log
  
  View the complete list of metrics that PCP can collect from the SQL Server:

  ```bash
  # pminfo mssql
  
  After viewing the list of metrics, you can report the rate of transactions. For example, to report on the overall transaction count per second, over a five second time window:

  ```bash
  # pmval -t 1 -T 5 mssql.databases.transactions
  
  View the graphical chart of these metrics on your system by using the pmchart command. For more information, see Visually tracing PCP log archives with the PCP Charts application.

  Additional resources

90
- pcp(1), pminfo(1), pmval(1), pmchart(1), and pmdamssql(1) man pages

- Performance Co-Pilot for Microsoft SQL Server with RHEL 8.2 Red Hat Developers Blog post
CHAPTER 9. PERFORMANCE ANALYSIS OF XFS WITH PCP

The XFS PMDA ships as part of the `pcp` package and is enabled by default during the installation. It is used to gather performance metric data of XFS file systems in Performance Co-Pilot (PCP).

You can use PCP to analyze XFS file system’s performance.

9.1. INSTALLING XFS PMDA MANUALLY

If the XFS PMDA is not listed in the `pcp` configuration output, install the PMDA agent manually.

This procedure describes how to manually install the PMDA agent.

Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.

Procedure

1. Navigate to the xfs directory:
   ```bash
   # cd /var/lib/pcp/pmdas/xfs/
   ```

2. Install the XFS PMDA manually:
   ```bash
   xfs]
   # ./Install
   ``
   You will need to choose an appropriate configuration for install of the “xfs” Performance Metrics Domain Agent (PMDA).
   
   - collector collect performance statistics on this system
   - monitor allow this system to monitor local and/or remote systems
   - both collector and monitor configuration for this system

   Please enter c(ollector) or m(onitor) or (both) [b]
   Updating the Performance Metrics Name Space (PMNS) ...
   Terminate PMDA if already installed ...
   Updating the PMCD control file, and notifying PMCD ...
   Waiting for pmcd to terminate ...
   Starting pmcd ...
   Check xfs metrics have appeared ... 149 metrics and 149 values

3. Select the intended PMDA role by entering `c` for collector, `m` for monitor, or `b` for both. The PMDA installation script prompts you to specify one of the following PMDA roles:

   - The `collector` role allows the collection of performance metrics on the current system
   - The `monitor` role allows the system to monitor local systems, remote systems, or both
     The default option is both `collector` and `monitor`, which allows the XFS PMDA to operate correctly in most scenarios.

Verification steps
- Verify that the **pmcd** process is running on the host and the XFS PMDA is listed as enabled in the configuration:

```bash
# pcp
Performance Co-Pilot configuration on workstation:
platform: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019
x86_64
hardware: 12 cpus, 2 disks, 1 node, 36023MB RAM
timezone: CEST-2
services: pmcd
pmcd: Version 4.3.0-1, 8 agents
pmda: root pmcd proc xfs linux mmv kvm jbd2
```

**Additional resources**

- **pmcd(1) man page**
- **Tools distributed with PCP**

### 9.2. EXAMINING XFS PERFORMANCE METRICS WITH PMINFO

PCP enables XFS PMDA to allow the reporting of certain XFS metrics per each of the mounted XFS file systems. This makes it easier to pinpoint specific mounted file system issues and evaluate performance.

The **pminfo** command provides per-device XFS metrics for each mounted XFS file system.

This procedure displays a list of all available metrics provided by the XFS PMDA.

**Prerequisites**

- PCP is installed. For more information, see [Installing and enabling PCP](#).

**Procedure**

- Display the list of all available metrics provided by the XFS PMDA:
  ```bash
  # pminfo xfs
  ```

- Display information for the individual metrics. The following examples examine specific XFS **read** and **write** metrics using the **pminfo** tool:
  - Display a short description of the **xfs.write_bytes** metric:
    ```bash
    # pminfo --oneline xfs.write_bytes
    xfs.write_bytes [number of bytes written in XFS file system write operations]
    ```
  - Display a long description of the **xfs.read_bytes** metric:
    ```bash
    # pminfo --helptext xfs.read_bytes
    xfs.read_bytes
    ```
Help:
This is the number of bytes read via read(2) system calls to files in XFS file systems. It can be used in conjunction with the read_calls count to calculate the average size of the read operations to file in XFS file systems.

- Obtain the current performance value of the `xfs.read_bytes` metric:

```
# pinfo --fetch xfs.read_bytes
xfs.read_bytes
  value 4891346238
```

- Obtain per-device XFS metrics with `pminfo`:

```
# pminfo --fetch --oneline xfs.perdev.read xfs.perdev.write
xfs.perdev.read [number of XFS file system read operations]
  inst [0 or "loop1"] value 0
  inst [0 or "loop2"] value 0

xfs.perdev.write [number of XFS file system write operations]
  inst [0 or "loop1"] value 86
  inst [0 or "loop2"] value 0
```

### Additional resources
- `pminfo(1)` man page
- PCP metric groups for XFS
- Per-device PCP metric groups for XFS

### 9.3. RESETTING XFS PERFORMANCE METRICS WITH PMSTORE

With PCP, you can modify the values of certain metrics, especially if the metric acts as a control variable, such as the `xfs.control.reset` metric. To modify a metric value, use the `pmstore` tool.

This procedure describes how to reset XFS metrics using the `pmstore` tool.

#### Prerequisites
- PCP is installed. For more information, see [Installing and enabling PCP](#).

#### Procedure

1. Display the value of a metric:

   ```bash
   $ pminfo -f xfs.write
   xfs.write
     value 325262
   ```

2. Reset all the XFS metrics:
# pmstore xfs.control.reset 1
xfs.control.reset old value=0 new value=1

Verification steps

- View the information after resetting the metric:

  $ pminfo --fetch xfs.write

  xfs.write
  value 0

Additional resources

- [pmstore(1)](pmstore.1) and [pminfo(1)](pminfo.1) man pages
- Tools distributed with PCP
- PCP metric groups for XFS

## 9.4. PCP METRIC GROUPS FOR XFS

The following table describes the available PCP metric groups for XFS.

<table>
<thead>
<tr>
<th>Metric Group</th>
<th>Metrics provided</th>
</tr>
</thead>
<tbody>
<tr>
<td>xfs.*</td>
<td>General XFS metrics including the read and write operation counts, read and write byte counts. Along with counters for the number of times inodes are flushed, clustered and number of failure to cluster.</td>
</tr>
<tr>
<td>xfs.allocs.* xfs.alloc_btree.*</td>
<td>Range of metrics regarding the allocation of objects in the file system, these include number of extent and block creations/frees. Allocation tree lookup and compares along with extend record creation and deletion from the btree.</td>
</tr>
<tr>
<td>xfs.block_map.* xfs.bmap_btree.*</td>
<td>Metrics include the number of block map read/write and block deletions, extent list operations for insertion, deletions and lookups. Also operations counters for compares, lookups, insertions and deletion operations from the blockmap.</td>
</tr>
<tr>
<td>xfs.dir_ops.*</td>
<td>Counters for directory operations on XFS file systems for creation, entry deletions, count of “getdent” operations.</td>
</tr>
<tr>
<td>Metric Group</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>xfs.transactions.*</td>
<td>Counters for the number of meta-data transactions, these include the count for the number of synchronous and asynchronous transactions along with the number of empty transactions.</td>
</tr>
<tr>
<td>xfs.inode_ops.*</td>
<td>Counters for the number of times that the operating system looked for an XFS inode in the inode cache with different outcomes. These count cache hits, cache misses, and so on.</td>
</tr>
<tr>
<td>xfs.log.*</td>
<td>Counters for the number of log buffer writes over XFS file systems includes the number of blocks written to disk. Metrics also for the number of log flushes and pinning.</td>
</tr>
<tr>
<td>xfs.log_tail.*</td>
<td></td>
</tr>
<tr>
<td>xfs.xstrat.*</td>
<td>Counts for the number of bytes of file data flushed out by the XFS flush daemon along with counters for number of buffers flushed to contiguous and non-contiguous space on disk.</td>
</tr>
<tr>
<td>xfs.attr.*</td>
<td>Counts for the number of attribute get, set, remove and list operations over all XFS file systems.</td>
</tr>
<tr>
<td>xfs.quota.*</td>
<td>Metrics for quota operation over XFS file systems, these include counters for number of quota reclaims, quota cache misses, cache hits and quota data reclaims.</td>
</tr>
<tr>
<td>xfs.buffer.*</td>
<td>Range of metrics regarding XFS buffer objects. Counters include the number of requested buffer calls, successful buffer locks, waited buffer locks, miss_locks, miss_retries and buffer hits when looking up pages.</td>
</tr>
<tr>
<td>xfs.btree.*</td>
<td>Metrics regarding the operations of the XFS btree.</td>

### 9.5. Per-Device PCP Metric Groups for XFS

The following table describes the available per-device PCP metric group for XFS.

Table 9.2. Per-device PCP metric groups for XFS

<table>
<thead>
<tr>
<th>Metric Group</th>
<th>Metrics provided</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>xfs.perdev.*</code></td>
<td>General XFS metrics including the read and write operation counts, read and write byte counts. Along with counters for the number of times inodes are flushed, clustered and number of failure to cluster.</td>
</tr>
<tr>
<td><code>xfs.perdev.allocs.*</code></td>
<td>Range of metrics regarding the allocation of objects in the file system, these include number of extent and block creations/frees. Allocation tree lookup and compares along with extend record creation and deletion from the btree.</td>
</tr>
<tr>
<td><code>xfs.perdev.alloc_btree.*</code></td>
<td>Range of metrics regarding the allocation of objects in the file system, these include number of extent and block creations/frees. Allocation tree lookup and compares along with extend record creation and deletion from the btree.</td>
</tr>
<tr>
<td><code>xfs.perdev.block_map.*</code></td>
<td>Metrics include the number of block map read/write and block deletions, extent list operations for insertion, deletions and lookups. Also operations counters for compares, lookups, insertions and deletion operations from the blockmap.</td>
</tr>
<tr>
<td><code>xfs.perdev.bmap_btree.*</code></td>
<td>Metrics include the number of block map read/write and block deletions, extent list operations for insertion, deletions and lookups. Also operations counters for compares, lookups, insertions and deletion operations from the blockmap.</td>
</tr>
<tr>
<td><code>xfs.perdev.dir_ops.*</code></td>
<td>Counters for directory operations of XFS file systems for creation, entry deletions, count of “getdent” operations.</td>
</tr>
<tr>
<td><code>xfs.perdev.transactions.*</code></td>
<td>Counters for the number of meta-data transactions, these include the count for the number of synchronous and asynchronous transactions along with the number of empty transactions.</td>
</tr>
<tr>
<td><code>xfs.perdev.inode_ops.*</code></td>
<td>Counters for the number of times that the operating system looked for an XFS inode in the inode cache with different outcomes. These count cache hits, cache misses, and so on.</td>
</tr>
<tr>
<td><code>xfs.perdev.log.*</code></td>
<td>Counters for the number of log buffer writes over XFS file systems includes the number of blocks written to disk. Metrics also for the number of log flushes and pinning.</td>
</tr>
<tr>
<td><code>xfs.perdev.log_tail.*</code></td>
<td>Counters for the number of log buffer writes over XFS file systems includes the number of blocks written to disk. Metrics also for the number of log flushes and pinning.</td>
</tr>
<tr>
<td><code>xfs.perdev.xstrat.*</code></td>
<td>Counts for the number of bytes of file data flushed out by the XFS flush deamon along with counters for number of buffers flushed to contiguous and non-contiguous space on disk.</td>
</tr>
<tr>
<td><code>xfs.perdev.attr.*</code></td>
<td>Counts for the number of attribute get, set, remove and list operations over all XFS file systems.</td>
</tr>
<tr>
<td><code>xfs.perdev.quota.*</code></td>
<td>Metrics for quota operation over XFS file systems, these include counters for number of quota reclaims, quota cache misses, cache hits and quota data reclaims.</td>

CHAPTER 10. SETTING UP GRAPHICAL REPRESENTATION OF PCP METRICS

Using a combination of `pcp`, `grafana`, `pcp redis`, `pcp bpftrace`, and `pcp vector` provides graphical representation of the live data or data collected by Performance Co-Pilot (PCP).

10.1. SETTING UP PCP WITH PCP-ZEROCONF

This procedure describes how to set up PCP on a system with the `pcp-zeroconf` package. Once the `pcp-zeroconf` package is installed, the system records the default set of metrics into archived files.

Procedure

- Install the `pcp-zeroconf` package:
  
  ```bash
  # yum install pcp-zeroconf
  ```

Verification steps

- Ensure that the `pmlogger` service is active, and starts archiving the metrics:
  
  ```bash
  # pcp | grep pmlogger
  pmlogger: primary logger: /var/log/pcp/pmlogger/localhost.localdomain/20200401.00.12
  ```

Additional resources

- `pmlogger` man page
- Monitoring performance with Performance Co-Pilot

10.2. SETTING UP A GRAFANA-SERVER

Grafana generates graphs that are accessible from a browser. The `grafana-server` is a back-end server for the Grafana dashboard. It listens, by default, on all interfaces, and provides web services accessed through the web browser. The `grafana-pcp` plugin interacts with the `pmproxy` protocol in the backend.

This procedure describes how to set up a `grafana-server`.

Prerequisites

- PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.

Procedure

1. Install the following packages:

   ```bash
   # yum install grafana grafana-pcp
   ```

2. Restart and enable the following service:

   ```bash
   # systemctl restart grafana-server
   # systemctl enable grafana-server
   ```
3. Open the server’s firewall for network traffic to the Grafana service.

```bash
# firewall-cmd --permanent --add-service=grafana
success

# firewall-cmd --reload
success
```

**Verification steps**

- Ensure that the `grafana-server` is listening and responding to requests:
  ```bash
  # ss -ntlp | grep 3000
  LISTEN 0 128 *:3000 *:* users:(("grafana-server",pid=19522,fd=7))
  ```

- Ensure that the `grafana-pcp` plugin is installed:
  ```bash
  # grafana-cli plugins ls | grep performancecopilot-pcp-app
  performancecopilot-pcp-app @ 3.1.0
  ```

**Additional resources**

- `pmproxy(1)` and `grafana-server` man pages

### 10.3. ACCESSING THE GRAFANA WEB UI

This procedure describes how to access the Grafana web interface.

Using the Grafana web interface, you can:

- add PCP Redis, PCP bpftrace, and PCP Vector data sources
- create dashboard
- view an overview of any useful metrics
- create alerts in PCP Redis

**Prerequisites**

1. PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.

2. The `grafana-server` is configured. For more information, see Setting up a grafana-server.

**Procedure**

1. On the client system, open a browser and access the `grafana-server` on port **3000**, using `http://192.0.2.0:3000` link.
   Replace `192.0.2.0` with your machine IP.

2. For the first login, enter **admin** in both the Email or username and Password field.
Grafana prompts to set a **New password** to create a secured account. If you want to set it later, click **Skip**.

3. From the menu, hover over the **Configuration** icon and then click **Plugins**.

4. In the **Plugins** tab, type performance co-pilot in the **Search by name or type** text box and then click **Performance Co-Pilot** (PCP) plugin.

5. In the **Plugins / Performance Co-Pilot** pane, click **Enable**.

6. Click Grafana **icon. The Grafana **Home** page is displayed.

![Figure 10.1. Home Dashboard](image)

**NOTE**

The top corner of the screen has a similar **icon, but it controls the general Dashboard settings.**

7. In the Grafana **Home** page, click **Add your first data source** to add PCP Redis, PCP bpftrace, and PCP Vector data sources. For more information about adding data source, see:

   - To add pcp redis data source, view default dashboard, create a panel, and an alert rule, see [Creating panels and alert in PCP Redis data source](#).

   - To add pcp bpftrace data source and view the default dashboard, see [Viewing the PCP bpftrace System Analysis dashboard](#).

   - To add pcp vector data source, view the default dashboard, and to view the vector checklist, see [Viewing the PCP Vector Checklist](#).

8. Optional: From the menu, hover over the **admin profile** **icon to change the Preferences** including **Edit Profile, Change Password**, or to **Sign out**.

**Additional resources**
Additional resources

- `grafana-cli` and `grafana-server` man pages

10.4. CONFIGURING PCP REDIS

Use the PCP Redis data source to:

- View data archives
- Query time series using pmseries language
- Analyze data across multiple hosts

Prerequisites

1. PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.
2. The `grafana-server` is configured. For more information, see Setting up a grafana-server.

Procedure

1. Install the `redis` package:
   ```bash
   # yum install redis
   ```
2. Start and enable the following services:
   ```bash
   # systemctl start pmproxy redis
   # systemctl enable pmproxy redis
   ```
3. Mail transfer agent, for example, `sendmail` or `postfix` is installed and configured.
4. Ensure that the `allow_loading_unsigned_plugins` parameter is set to PCP Redis database in the `grafana.ini` file:
   ```bash
   # vi /etc/grafana/grafana.ini
   allow_loading_unsigned_plugins = pcp-redis-datasource
   ```
5. Restart the `grafana-server`:
   ```bash
   # systemctl restart grafana-server
   ```

Verification steps

- Ensure that the `pmproxy` and `redis` are working:
  ```bash
  # pmseries disk.dev.read
  2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
  ```
  This command does not return any data if the `redis` package is not installed.

Additional resources
10.5. CREATING PANELS AND ALERT IN PCP REDIS DATA SOURCE

After adding the PCP Redis data source, you can view the dashboard with an overview of useful metrics, add a query to visualize the load graph, and create alerts that help you to view the system issues after they occur.

Prerequisites

1. The PCP Redis is configured. For more information, see Configuring PCP Redis.
2. The grafana-server is accessible. For more information, see Accessing the Grafana web UI.

Procedure

1. Log into the Grafana web UI.
2. In the Grafana Home page, click Add your first data source.
3. In the Add data source pane, type redis in the Filter by name or type text box and then click PCP Redis.
4. In the Data Sources / PCP Redis pane, perform the following:
   a. Add http://localhost:44322 in the URL field and then click Save & Test.
   b. Click Dashboards tab → Import → PCP Redis: Host Overview to see a dashboard with an overview of any useful metrics.

Figure 10.2. PCP Redis: Host Overview

5. Add a new panel:
   a. From the menu, hover over the icon to add a panel.

Create icon → Dashboard → Add new panel
b. In the **Query** tab, select the **PCP Redis** from the query list instead of the selected **default** option and in the text field of **A**, enter metric, for example, **kernel.all.load** to visualize the kernel load graph.

c. Optional: Add **Panel title** and **Description**, and update other options from the **Settings**.

d. Click **Save** to apply changes and save the dashboard. Add **Dashboard name**.

e. Click **Apply** to apply changes and go back to the dashboard.

**Figure 10.3. PCP Redis query panel**

6. Create an alert rule:

   a. In the **PCP Redis query panel** click **Alert** and then click **Create**

   b. Edit the **Name**, **Evaluate query**, and **For** fields from the **Rule**, and specify the **Conditions** for your alert.

c. Click **Save** to apply changes and save the dashboard. Click **Apply** to apply changes and go back to the dashboard.

**Figure 10.4. Creating alerts in the PCP Redis panel**
d. Optional: In the same panel, scroll down and click **Delete** icon to delete the created rule.

e. Optional: From the menu, click **Alerting** icon to view the created alert rules with different alert statuses, to edit the alert rule, or to pause the existing rule from the **Alert Rules** tab.

To add a notification channel for the created alert rule to receive an alert notification from Grafana, see *Adding notification channels for alerts*.

### 10.6. ADDING NOTIFICATION CHANNELS FOR ALERTS

By adding notification channels, you can receive an alert notification from Grafana whenever the alert rule conditions are met and the system needs further monitoring.

You can receive these alerts after selecting any one type from the supported list of notifiers, which includes **DingDing**, **Discord**, **Email**, **Google Hangouts Chat**, **HipChat**, **Kafka REST Proxy**, **LINE**, **Microsoft Teams**, **OpsGenie**, **PagerDuty**, **Prometheus Alertmanager**, **Pushover**, **Sensu**, **Slack**, **Telegram**, **Threema Gateway**, **VictorOps**, and **webhook**.

**Prerequisites**

1. The **grafana-server** is accessible. For more information, see Accessing the Grafana web UI.

2. An alert rule is created. For more information, see Creating panels and alert in PCP Redis data source.

3. Configure SMTP and add a valid sender’s email address in the **grafana/grafana.ini** file:

```bash
# vi /etc/grafana/grafana.ini

[smtp]
enabled = true
from_address = abc@gmail.com
```

Replace *abc@gmail.com* by a valid email address.

4. Restart **grafana-server**

```bash
# systemctl restart grafana-server.service
```

**Procedure**

1. From the menu, hover over the **Alerting** icon → click Notification channels → Add channel.

2. In the Add notification channel details pane, perform the following:

   a. Enter your name in the **Name** text box

   b. Select the communication **Type**, for example, Email and enter the email address. You can add multiple email addresses using the ; separator.

   c. Optional: Configure **Optional Email settings** and **Notification settings**.
3. Click **Save**.

4. Select a notification channel in the alert rule:
   
   a. From the menu, hover over the **Alerting** icon and then click **Alert rules**.

   b. From the **Alert Rules** tab, click the created alert rule.

   c. On the **Notifications** tab, select your notification channel name from the **Send to** option, and then add an alert message.

   d. Click **Apply**.

Additional resources

- Upstream Grafana documentation for alert notifications

10.7. SETTING UP AUTHENTICATION BETWEEN PCP COMPONENTS

You can setup authentication using the **scram-sha-256** authentication mechanism, which is supported by PCP through the Simple Authentication Security Layer (SASL) framework.

**NOTE**

From Red Hat Enterprise Linux 8.3, PCP supports the **scram-sha-256** authentication mechanism.

Procedure

1. Install the **sasl** framework for the **scram-sha-256** authentication mechanism:

   ```bash
   # yum install cyrus-sasl-scram cyrus-sasl-lib
   ```

2. Specify the supported authentication mechanism and the user database path in the **pmcd.conf** file:

   ```bash
   # vi /etc/sasl2/pmcd.conf
   mech_list: scram-sha-256
   sasldb_path: /etc/pcp/passwd.db
   ```

3. Create a new user:

   ```bash
   # useradd -r metrics
   ```

   Replace **metrics** by your user name.

4. Add the created user in the user database:

   ```bash
   # saslpasswd2 -a pmcd metrics
   ```

   Password:
Again (for verification):

To add the created user, you are required to enter the `metrics` account password.

5. Set the permissions of the user database:

   # chown root:pcp /etc/pcp/passwd.db
   # chmod 640 /etc/pcp/passwd.db

6. Restart the `pmcd` service:

   # systemctl restart pmcd

Verification steps

- Verify the `sasl` configuration:

   # pminfo -f -h "pcp://127.0.0.1?username=metrics" disk.dev.read
   Password:
   disk.dev.read
   inst [0 or "sda"] value 19540

Additional resources

- `saslauthd(8), pminfo(1), and sha256` man pages
- How can I setup authentication between PCP components, like PMDAs and pmcd in RHEL 8.2?

10.8. INSTALLING PCP BPFTRACE

Install the PCP `bpftrace` agent to introspect a system and to gather metrics from the kernel and user-space tracepoints.

The `bpftrace` agent uses bpftrace scripts to gather the metrics. The `bpftrace` scripts use the enhanced Berkeley Packet Filter (eBPF).

This procedure describes how to install a `pcp bpftrace`.

Prerequisites

1. PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.

2. The `grafana-server` is configured. For more information, see Setting up a grafana-server.

3. The `scram-sha-256` authentication mechanism is configured. For more information, see Setting up authentication between PCP components.

Procedure

1. Install the `pcp-pmda-bpftrace` package:

   # yum install pcp-pmda-bpftrace
2. Edit the `bpftrace.conf` file and add the user that you have created in the [setting-up-authentication-between-pcp-components]:

```bash
# vi /var/lib/pcp/pmdas/bpftrace/bpftrace.conf

[dynamic_scripts]
  enabled = true
  auth_enabled = true
  allowed_users = root, metrics
```

Replace `metrics` by your user name.

3. Install `bpftrace` PMDA:

```bash
# cd /var/lib/pcp/pmdas/bpftrace/
# ./Install

Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Check bpftrace metrics have appeared ... 7 metrics and 6 values
```

The `pmda-bpftrace` is now installed, and can only be used after authenticating your user. For more information, see Viewing the PCP bpftrace System Analysis dashboard.

Additional resources
- `pmdabpftrace(1)` and `bpftrace` man pages

10.9. VIEWING THE PCP BPFTRACE SYSTEM ANALYSIS DASHBOARD

Using the PCP bpftrace data source, you can access the live data from sources which are not available as normal data from the `pmlogger` or archives.

In the PCP bpftrace data source, you can view the dashboard with an overview of useful metrics.

Prerequisites

1. The PCP bpftrace is installed. For more information, see Installing PCP bpftrace.

2. The `grafana-server` is accessible. For more information, see Accessing the Grafana web UI.

Procedure

1. Log into the Grafana web UI.

2. In the Grafana Home page, click Add your first data source

3. In the Add data source pane, type bpftrace in the Filter by name or type text box and then click PCP bpftrace.

4. In the Data Sources / PCP bpftrace pane, perform the following:
b. Toggle the Basic Auth option and add the created user credentials in the User and Password field.

c. Click Save & Test.

Figure 10.5. Adding PCP bpftrace in the data source

d. Click Dashboards tab → Import → PCP bpftrace: System Analysis to see a dashboard with an overview of any useful metrics.

Figure 10.6. PCP bpftrace: System Analysis

10.10. INSTALLING PCP VECTOR

This procedure describes how to install a pcp vector.

Prerequisites

1. PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.

2. The grafana-server is configured. For more information, see Setting up a grafana-server.
Procedure

1. Install the `pcp-pmda-bcc` package:

   # yum install pcp-pmda-bcc

2. Install the `bcc` PMDA:

   # cd /var/lib/pcp/pmdas/bcc
   # ./install

   [Wed Apr  1 00:27:48] pmdabcc(22341) Info: Initializing, currently in 'notready' state.
   [Wed Apr  1 00:27:48] pmdabcc(22341) Info: Enabled modules:
   [Wed Apr  1 00:27:48] pmdabcc(22341) Info: ['biolatency', 'sysfork',
   [...] Updating the Performance Metrics Name Space (PMNS) ...
   Terminate PMDA if already installed ...
   Updating the PMCD control file, and notifying PMCD ...
   Check bcc metrics have appeared ... 1 warnings, 1 metrics and 0 values

Additional resources

- `pmdabcc(1)` man page

10.11. VIEWING THE PCP VECTOR CHECKLIST

The PCP Vector data source displays live metrics and uses the `pcp` metrics. It analyzes data for individual hosts.

After adding the PCP Vector data source, you can view the dashboard with an overview of useful metrics and view the related troubleshooting or reference links in the checklist.

Prerequisites

1. The PCP Vector is installed. For more information, see Installing PCP Vector.

2. The `grafana-server` is accessible. For more information, see Accessing the Grafana web UI.

Procedure

1. Log into the Grafana web UI.

2. In the Grafana Home page, click Add your first data source

3. In the Add data source pane, type vector in the Filter by name or type text box and then click PCP Vector.

4. In the Data Sources / PCP Vector pane, perform the following:
   a. Add `http://localhost:44322` in the URL field and then click Save & Test.
   b. Click Dashboards tab → Import → PCP Vector: Host Overview to see a dashboard with an overview of any useful metrics.
5. From the menu, hover over the Performance Co-Pilot plugin and then click PCP Vector Checklist. In the PCP checklist, click help or warning icon to view the related troubleshooting or reference links.

10.12. TROUBLESHOOTING GRAFANA ISSUES

It is sometimes necessary to troubleshoot Grafana issues, such as, Grafana does not display any data, the dashboard is black, or similar issues.

Procedure

- Verify that the pmlogger service is up and running by executing the following command:

  $ systemctl status pmlogger
• Verify if files were created or modified to the disk by executing the following command:

```bash
$ ls /var/log/pcp/pmlogger/$(hostname)/ -rlt
```

```bash
total 4024
-rw-r--r--. 1 pcp pcp   45996 Oct 13 2019 20191013.20.07.meta.xz
-rw-r--r--. 1 pcp pcp     412 Oct 13 2019 20191013.20.07.index
-rw-r--r--. 1 pcp pcp   32188 Oct 13 2019 20191013.20.30-00.meta.xz
```

• Verify that the `pmproxy` service is running by executing the following command:

```bash
$ systemctl status pmproxy
```

• Verify that `pmproxy` is running, time series support is enabled, and a connection to Redis is established by viewing the `/var/log/pcp/pmproxy/pmproxy.log` file and ensure that it contains the following text:

`pmproxy(1716) Info: Redis slots, command keys, schema version setup`

Here, `1716` is the PID of `pmproxy`, which will be different for every invocation of `pmproxy`.

• Verify if the Redis database contains any keys by executing the following command:

```bash
$ redis-cli dbsize
(integer) 34837
```

• Verify if any PCP metrics are in the Redis database and `pmproxy` is able to access them by executing the following commands:

```bash
$ pmseries disk.dev.read
2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
```

```bash
$ pmseries "disk.dev.read[count:10]"
2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
70e83e88d4e1857a3a31605c6d1333755f2dd17c
[Mon Jul 26 12:21:00.087401000 2021] 117758
70e83e88d4e1857a3a31605c6d1333755f2dd17c
70e83e88d4e1857a3a31605c6d1333755f2dd17c
[...]
```

```bash
$ redis-cli --scan --pattern ""$(pmseries 'disk.dev.read')"

pcp:metric.name:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:values:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:desc:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:labelvalue:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:instances:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:labelflags:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
```

• Verify if there are any errors in the Grafana logs by executing the following command:
$ journalctl -e -u grafana-server
-- Logs begin at Mon 2021-07-26 11:55:10 IST, end at Mon 2021-07-26 12:30:15 IST. --

CHAPTER 11. OPTIMIZING THE SYSTEM PERFORMANCE USING THE WEB CONSOLE

Learn how to set a performance profile in the RHEL web console to optimize the performance of the system for a selected task.

11.1. PERFORMANCE TUNING OPTIONS IN THE WEB CONSOLE

Red Hat Enterprise Linux 8 provides several performance profiles that optimize the system for the following tasks:

- Systems using the desktop
- Throughput performance
- Latency performance
- Network performance
- Low power consumption
- Virtual machines

The TuneD service optimizes system options to match the selected profile.

In the web console, you can set which performance profile your system uses.

Additional resources

- Getting started with TuneD

11.2. SETTING A PERFORMANCE PROFILE IN THE WEB CONSOLE

This procedure uses the web console to optimize the system performance for a selected task.

Prerequisites

- Make sure the web console is installed and accessible. For details, see Installing the web console.

Procedure

1. Log into the RHEL web console. For details, see Logging in to the web console.

2. Click Overview.

3. In the Performance Profile field, click the current performance profile.
4. In the **Change Performance Profile** dialog box, change the profile if necessary.

5. Click **Change Profile**.

**Verification steps**

- The **Overview** tab now shows the selected performance profile.

**11.3. MONITORING PERFORMANCE ON THE LOCAL SYSTEM USING THE WEB CONSOLE**

Red Hat Enterprise Linux web console uses the Utilization Saturation and Errors (USE) Method for troubleshooting. The new performance metrics page has a historical view of your data organized chronologically with the newest data at the top.

In the **Metrics and history** page, you can view events, errors, and graphical representation for resource utilization and saturation.

**Prerequisites**

- The web console is installed and accessible. For details, see [Installing the web console](#).

  - The **cockpit-pcp** package, which enables collecting the performance metrics, is installed:
    
    a. To install the package from the web console interface:
      
      i. Log in to the web console with administrative privileges. For details, see [Logging in to the web console](#).
      
      ii. In the **Overview** page, click **View metrics and history**.

      iii. Click the **Install cockpit-pcp** button.

      iv. In the **Install software** dialog window, click **Install**.

    b. To install the package from the command-line interface, use:
# yum install cockpit-pcp

- The Performance Co-Pilot (PCP) service is enabled:

  # systemctl enable --now pmlogger.service pmproxy.service

Procedure

1. Log into the RHEL 8 web console. In the Overview page click View metrics and history to view the Metrics and history page.

11.4. MONITORING PERFORMANCE ON SEVERAL SYSTEMS USING THE WEB CONSOLE AND GRAFANA

Grafana enables you to collect data from several systems at once and review a graphical representation of their collected Performance Co-Pilot (PCP) metrics. You can set up performance metrics monitoring and export for several systems in the web console interface.

Prerequisites

- The web console must be installed and accessible. For details, see link: Installing the web console.
• Install the **cockpit-pcp** package.

1. From the web console interface:
   a. Log in to the web console with administrative privileges. For details, see [Logging in to the web console](#).
   
   b. In the **Overview** page, click **View details and history**.
   
   c. Click the **Install cockpit-pcp** button.
   
   d. In the **Install software** dialog window, click **Install**.
   
   e. Log out and in again to see the metrics history.

2. To install the package from the command-line interface, use:

   ```bash
   # yum install cockpit-pcp
   ```

• Enable the PCP service:

   ```bash
   # systemctl enable --now pmlogger.service pmproxy.service
   ```

• Set up Grafana dashboard. For more information, see [Setting up a grafana-server](#).

• Install the **redis** package.

   ```bash
   # yum install redis
   ```

   Alternatively, you can install the package from the web console interface later in the procedure.

**Procedure**

1. In the **Overview** page, click **View metrics and history** in the **Usage** table.

2. Click the **Metrics settings** button.

3. Move the **Export to network** slider to active position.

   ![Metrics settings](image)

   **Metrics settings**

   Performance Co-Pilot collects and analyzes performance metrics from your system.  

   ![](image)

   **Collect metrics** (pmlogger.service)

   **Export to network** (pmproxy.service)

   ![Save Cancel](button)
If you do not have the `redis` package installed, the web console prompts you to install it.

4. To open the `pmproxy` service, select a zone from a drop-down list and click the **Add pmproxy**
   button.

5. Click **Save**.

**Verification**

1. Click **Networking**.

2. In the **Firewall** table, click the **Edit rules and zones** button.

3. Search for **pmproxy** in your selected zone.

**IMPORTANT**

Repeat this procedure on all the systems you want to watch.

**Additional resources**

- Setting up graphical representation of PCP metrics
CHAPTER 12. SETTING THE DISK SCHEDULER

The disk scheduler is responsible for ordering the I/O requests submitted to a storage device.

You can configure the scheduler in several different ways:

- Set the scheduler using TuneD, as described in Setting the disk scheduler using TuneD
- Set the scheduler using udev, as described in Setting the disk scheduler using udev rules
- Temporarily change the scheduler on a running system, as described in Temporarily setting a scheduler for a specific disk

NOTE

In Red Hat Enterprise Linux 8, block devices support only multi-queue scheduling. This enables the block layer performance to scale well with fast solid-state drives (SSDs) and multi-core systems.

The traditional, single-queue schedulers, which were available in Red Hat Enterprise Linux 7 and earlier versions, have been removed.

12.1. AVAILABLE DISK SCHEDULERS

The following multi-queue disk schedulers are supported in Red Hat Enterprise Linux 8:

none

Implements a first-in first-out (FIFO) scheduling algorithm. It merges requests at the generic block layer through a simple last-hit cache.

mq-deadline

Attempts to provide a guaranteed latency for requests from the point at which requests reach the scheduler.

The mq-deadline scheduler sorts queued I/O requests into a read or write batch and then schedules them for execution in increasing logical block addressing (LBA) order. By default, read batches take precedence over write batches, because applications are more likely to block on read I/O operations. After mq-deadline processes a batch, it checks how long write operations have been starved of processor time and schedules the next read or write batch as appropriate.

This scheduler is suitable for most use cases, but particularly those in which the write operations are mostly asynchronous.

bfq

Targets desktop systems and interactive tasks.

The bfq scheduler ensures that a single application is never using all of the bandwidth. In effect, the storage device is always as responsive as if it was idle. In its default configuration, bfq focuses on delivering the lowest latency rather than achieving the maximum throughput.

bfq is based on cfq code. It does not grant the disk to each process for a fixed time slice but assigns a budget measured in number of sectors to the process.

This scheduler is suitable while copying large files and the system does not become unresponsive in this case.
The scheduler tunes itself to achieve a latency goal by calculating the latencies of every I/O request submitted to the block I/O layer. You can configure the target latencies for read, in the case of cache-misses, and synchronous write requests. This scheduler is suitable for fast devices, for example NVMe, SSD, or other low latency devices.

### 12.2. DIFFERENT DISK SCHEDULERS FOR DIFFERENT USE CASES

Depending on the task that your system performs, the following disk schedulers are recommended as a baseline prior to any analysis and tuning tasks:

<table>
<thead>
<tr>
<th>Use case</th>
<th>Disk scheduler</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traditional HDD with a SCSI interface</td>
<td>Use <code>mq-deadline</code> or <code>bfq</code>.</td>
</tr>
<tr>
<td>High-performance SSD or a CPU-bound system with fast storage</td>
<td>Use <code>none</code>, especially when running enterprise applications. Alternatively, use <code>kyber</code>.</td>
</tr>
<tr>
<td>Desktop or interactive tasks</td>
<td>Use <code>bfq</code>.</td>
</tr>
<tr>
<td>Virtual guest</td>
<td>Use <code>mq-deadline</code>. With a host bus adapter (HBA) driver that is multi-queue capable, use <code>none</code>.</td>
</tr>
</tbody>
</table>

### 12.3. THE DEFAULT DISK SCHEDULER

Block devices use the default disk scheduler unless you specify another scheduler.

**NOTE**

For **non-volatile Memory Express (NVMe)** block devices specifically, the default scheduler is `none` and Red Hat recommends not changing this.

The kernel selects a default disk scheduler based on the type of device. The automatically selected scheduler is typically the optimal setting. If you require a different scheduler, Red Hat recommends to use `udev` rules or the `TuneD` application to configure it. Match the selected devices and switch the scheduler only for those devices.

### 12.4. DETERMINING THE ACTIVE DISK SCHEDULER

This procedure determines which disk scheduler is currently active on a given block device.

**Procedure**

- Read the content of the `/sys/block/device/queue/scheduler` file:

```
# cat /sys/block/device/queue/scheduler
[mq-deadline] kyber bfq none
```
In the file name, replace device with the block device name, for example sdc.

The active scheduler is listed in square brackets ([ ]).

12.5. SETTING THE DISK SCHEDULER USING TUNED

This procedure creates and enables a Tuned profile that sets a given disk scheduler for selected block devices. The setting persists across system reboots.

In the following commands and configuration, replace:

- device with the name of the block device, for example sdf
- selected-scheduler with the disk scheduler that you want to set for the device, for example bfq

Prerequisites

- The Tuned service is installed and enabled. For details, see Installing and enabling Tuned.

Procedure

1. Optional: Select an existing Tuned profile on which your profile will be based. For a list of available profiles, see Tuned profiles distributed with RHEL.

   To see which profile is currently active, use:

   ```
   $ tuned-adm active
   ```

2. Create a new directory to hold your Tuned profile:

   ```
   # mkdir /etc/tuned/my-profile
   ```

3. Find the system unique identifier of the selected block device:

   ```
   $ udevadm info --query=property --name=/dev/device | grep -E '(WWN|SERIAL)'
   ID_WWN=0x5002538d00000000_
   ID_SERIAL=Generic-_SD_MMC_20120501030900000-0:0
   ID_SERIAL_SHORT=20120501030900000
   ```

   **NOTE**

   The command in this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the device system unique ID.

4. Create the /etc/tuned/my-profile/tuned.conf configuration file. In the file, set the following options:

   a. Optional: Include an existing profile:
b. Set the selected disk scheduler for the device that matches the WWN identifier:

```
[disk]
devices_udev_regex=IDNAME=device system unique id
elevator=selected-scheduler
```

Here:
- Replace `IDNAME` with the name of the identifier being used (for example, `ID_WWN`).
- Replace `device system unique id` with the value of the chosen identifier (for example, `0x5002538d00000000`).

To match multiple devices in the `devices_udev_regex` option, enclose the identifiers in parentheses and separate them with vertical bars:

```
devices_udev_regex=(ID_WWN=0x5002538d00000000)|
(ID_WWN=0x1234567800000000)
```

5. Enable your profile:

```
# tuned-adm profile my-profile
```

**Verification steps**

1. Verify that the TuneD profile is active and applied:

```
$ tuned-adm active
Current active profile: my-profile

$ tuned-adm verify
Verification succeeded, current system settings match the preset profile. See TuneD log file (`/var/log/tuned/tuned.log`) for details.
```

2. Read the contents of the `/sys/block/device/queue/scheduler` file:

```
# cat /sys/block/device/queue/scheduler
[mq-deadline] kyber bfq none
```

In the file name, replace `device` with the block device name, for example `sdc`.

The active scheduler is listed in square brackets (`[]`).

**Additional resources**

- Customizing TuneD profiles.
12.6. SETTING THE DISK SCHEDULER USING UDEV RULES

This procedure sets a given disk scheduler for specific block devices using udev rules. The setting persists across system reboots.

In the following commands and configuration, replace:

- device with the name of the block device, for example sdf
- selected-scheduler with the disk scheduler that you want to set for the device, for example bfq

Procedure

1. Find the system unique identifier of the block device:

   ```bash
   $ udevadm info --name=/dev/device | grep -E '(WWN|SERIAL)'
   E: ID_WWN=0x5002538d00000000
   E: ID_SERIAL=Generic-_SD_MMC_20120501030900000-0:0
   E: ID_SERIAL_SHORT=20120501030900000
   ```

   **NOTE**

   The command in this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the device system unique ID.

2. Configure the udev rule. Create the /etc/udev/rules.d/99-scheduler.rules file with the following content:

   ```bash
   ACTION=="add|change", SUBSYSTEM=="block", ENV{IDNAME}=="device system unique id", ATTR{queue/scheduler}="selected-scheduler"
   ```

   Here:

   - Replace IDNAME with the name of the identifier being used (for example, ID_WWN).
   - Replace device system unique id with the value of the chosen identifier (for example, 0x5002538d00000000).

3. Reload udev rules:

   ```bash
   # udevadm control --reload-rules
   ```

4. Apply the scheduler configuration:

   ```bash
   # udevadm trigger --type=devices --action=change
   ```

Verification steps

- Verify the active scheduler:
12.7. TEMPORARILY SETTING A SCHEDULER FOR A SPECIFIC DISK

This procedure sets a given disk scheduler for specific block devices. The setting does not persist across system reboots.

Procedure

- Write the name of the selected scheduler to the `/sys/block/device/queue/scheduler` file:

```
# echo selected-scheduler > /sys/block/device/queue/scheduler
```

In the file name, replace `device` with the block device name, for example `sdc`.

Verification steps

- Verify that the scheduler is active on the device:

```
# cat /sys/block/device/queue/scheduler
```
CHAPTER 13. TUNING THE PERFORMANCE OF A SAMBA SERVER

Learn what settings can improve the performance of Samba in certain situations, and which settings can have a negative performance impact.

Parts of this section were adopted from the Performance Tuning documentation published in the Samba Wiki. License: CC BY 4.0. Authors and contributors: See the history tab on the Wiki page.

Prerequisites
- Samba is set up as a file or print server
  See Using Samba as a server.

13.1. SETTING THE SMB PROTOCOL VERSION

Each new SMB version adds features and improves the performance of the protocol. The recent Windows and Windows Server operating systems always support the latest protocol version. If Samba also uses the latest protocol version, Windows clients connecting to Samba benefit from the performance improvements. In Samba, the default value of the server max protocol is set to the latest supported stable SMB protocol version.

NOTE
To always have the latest stable SMB protocol version enabled, do not set the `server max protocol` parameter. If you set the parameter manually, you will need to modify the setting with each new version of the SMB protocol, to have the latest protocol version enabled.

The following procedure explains how to use the default value in the `server max protocol` parameter.

Procedure
1. Remove the `server max protocol` parameter from the `[global]` section in the `/etc/samba/smb.conf` file.
2. Reload the Samba configuration
   ```
   # smbcontrol all reload-config
   ```

13.2. TUNING SHARES WITH DIRECTORIES THAT CONTAIN A LARGE NUMBER OF FILES

Linux supports case-sensitive file names. For this reason, Samba needs to scan directories for uppercase and lowercase file names when searching or accessing a file. You can configure a share to create new files only in lowercase or uppercase, which improves the performance.

Prerequisites
- Samba is configured as a file server
Procedure

1. Rename all files on the share to lowercase.

   **NOTE**
   Using the settings in this procedure, files with names other than in lowercase will no longer be displayed.

2. Set the following parameters in the share’s section:

   ```
   case sensitive = true
   default case = lower
   preserve case = no
   short preserve case = no
   ```

   For details about the parameters, see their descriptions in the `smb.conf(5)` man page.

3. Verify the `/etc/samba/smb.conf` file:

   ```
   # testparm
   ```

4. Reload the Samba configuration:

   ```
   # smbcontrol all reload-config
   ```

After you applied these settings, the names of all newly created files on this share use lowercase. Because of these settings, Samba no longer needs to scan the directory for uppercase and lowercase, which improves the performance.

13.3. SETTINGS THAT CAN HAVE A NEGATIVE PERFORMANCE IMPACT

By default, the kernel in Red Hat Enterprise Linux is tuned for high network performance. For example, the kernel uses an auto-tuning mechanism for buffer sizes. Setting the `socket options` parameter in the `/etc/samba/smb.conf` file overrides these kernel settings. As a result, setting this parameter decreases the Samba network performance in most cases.

To use the optimized settings from the Kernel, remove the `socket options` parameter from the `[global]` section in the `/etc/samba/smb.conf`. 
CHAPTER 14. OPTIMIZING VIRTUAL MACHINE PERFORMANCE

Virtual machines (VMs) always experience some degree of performance deterioration in comparison to the host. The following sections explain the reasons for this deterioration and provide instructions on how to minimize the performance impact of virtualization in RHEL 8, so that your hardware infrastructure resources can be used as efficiently as possible.

14.1. WHAT INFLUENCES VIRTUAL MACHINE PERFORMANCE

VMs are run as user-space processes on the host. The hypervisor therefore needs to convert the host’s system resources so that the VMs can use them. As a consequence, a portion of the resources is consumed by the conversion, and the VM therefore cannot achieve the same performance efficiency as the host.

The impact of virtualization on system performance
More specific reasons for VM performance loss include:

- Virtual CPUs (vCPUs) are implemented as threads on the host, handled by the Linux scheduler.
- VMs do not automatically inherit optimization features, such as NUMA or huge pages, from the host kernel.
- Disk and network I/O settings of the host might have a significant performance impact on the VM.
- Network traffic typically travels to a VM through a software-based bridge.
- Depending on the host devices and their models, there might be significant overhead due to emulation of particular hardware.

The severity of the virtualization impact on the VM performance is influenced by a variety factors, which include:

- The number of concurrently running VMs.
- The amount of virtual devices used by each VM.
- The device types used by the VMs.

Reducing VM performance loss
RHEL 8 provides a number of features you can use to reduce the negative performance effects of virtualization. Notably:

- The TuneD service can automatically optimize the resource distribution and performance of your VMs.
- Block I/O tuning can improve the performances of the VM’s block devices, such as disks.
- NUMA tuning can increase vCPU performance.
- Virtual networking can be optimized in various ways.
IMPORTANT
Tuning VM performance can have adverse effects on other virtualization functions. For example, it can make migrating the modified VM more difficult.

14.2. OPTIMIZING VIRTUAL MACHINE PERFORMANCE USING TUNED

The **TuneD** utility is a tuning profile delivery mechanism that adapts RHEL for certain workload characteristics, such as requirements for CPU-intensive tasks or storage-network throughput responsiveness. It provides a number of tuning profiles that are pre-configured to enhance performance and reduce power consumption in a number of specific use cases. You can edit these profiles or create new profiles to create performance solutions tailored to your environment, including virtualized environments.

To optimize RHEL 8 for virtualization, use the following profiles:

- For RHEL 8 virtual machines, use the `virtual-guest` profile. It is based on the generally applicable `throughput-performance` profile, but also decreases the swappiness of virtual memory.

- For RHEL 8 virtualization hosts, use the `virtual-host` profile. This enables more aggressive writeback of dirty memory pages, which benefits the host performance.

**Prerequisites**

- The **TuneD** service is installed and enabled.

**Procedure**

To enable a specific **TuneD** profile:

1. List the available **TuneD** profiles.

   ```
   # tuned-adm list
   
   Available profiles:
   - balanced             - General non-specialized TuneD profile
   - desktop              - Optimize for the desktop use-case
   [...]                   
   - virtual-guest        - Optimize for running inside a virtual guest
   - virtual-host         - Optimize for running KVM guests
   Current active profile: balanced
   ```

2. Optional: Create a new **TuneD** profile or edit an existing **TuneD** profile. For more information, see **Customizing TuneD profiles**.

3. Activate a **TuneD** profile.

   ```
   # tuned-adm profile selected-profile
   
   - To optimize a virtualization host, use the `virtual-host` profile.
   
   # tuned-adm profile virtual-host
   
   - On a RHEL guest operating system, use the `virtual-guest` profile.
   ```
# tuned-adm profile virtual-guest

Additional resources

- Monitoring and managing system status and performance

## 14.3. CONFIGURING VIRTUAL MACHINE MEMORY

To improve the performance of a virtual machine (VM), you can assign additional host RAM to the VM. Similarly, you can decrease the amount of memory allocated to a VM so the host memory can be allocated to other VMs or tasks.

To perform these actions, you can use the web console or the command-line interface.

### 14.3.1. Adding and removing virtual machine memory using the web console

To improve the performance of a virtual machine (VM) or to free up the host resources it is using, you can use the web console to adjust amount of memory allocated to the VM.

**Prerequisites**

- The guest OS is running the memory balloon drivers. To verify this is the case:
  1. Ensure the VM’s configuration includes the `memballoon` device:

```
# virsh dumpxml testguest | grep memballoon
<memballoon model='virtio'>
</memballoon>
```

If this command displays any output and the model is not set to `none`, the `memballoon` device is present.

- Ensure the balloon drivers are running in the guest OS.
  - In Windows guests, the drivers are installed as a part of the `virtio-win` driver package. For instructions, see Installing paravirtualized KVM drivers for Windows virtual machines.
  - In Linux guests, the drivers are generally included by default and activate when the `memballoon` device is present.

- The web console VM plug-in is installed on your system.

**Procedure**

1. **Optional:** Obtain the information about the maximum memory and currently used memory for a VM. This will serve as a baseline for your changes, and also for verification.

```
# virsh dominfo testguest
Max memory: 2097152 KiB
Used memory: 2097152 KiB
```

2. In the Virtual Machines interface, click the VM whose information you want to see.
A new page opens with an Overview section with basic information about the selected VM and a Console section to access the VM’s graphical interface.

3. Click **edit** next to the **Memory** line in the Overview pane. The **Memory Adjustment** dialog appears.

4. Configure the virtual CPUs for the selected VM.
   
   - **Maximum allocation** - Sets the maximum amount of host memory that the VM can use for its processes. You can specify the maximum memory when creating the VM or increase it later. You can specify memory as multiples of MiB or GiB.
     Adjusting maximum memory allocation is only possible on a shut-off VM.
   
   - **Current allocation** - Sets the actual amount of memory allocated to the VM. This value can be less than the Maximum allocation but cannot exceed it. You can adjust the value to regulate the memory available to the VM for its processes. You can specify memory as multiples of MiB or GiB.
     If you do not specify this value, the default allocation is the **Maximum allocation** value.

5. Click **Save**. The memory allocation of the VM is adjusted.

**Additional resources**

- Adding and removing virtual machine memory using the command-line interface
- Optimizing virtual machine CPU performance

14.3.2. Adding and removing virtual machine memory using the command-line interface

To improve the performance of a virtual machine (VM) or to free up the host resources it is using, you can use the CLI to adjust amount of memory allocated to the VM.

**Prerequisites**

- The guest OS is running the memory balloon drivers. To verify this is the case:

  1. Ensure the VM’s configuration includes the **memballoon** device:

     ```
     # virsh dumpxml testguest | grep membaloone
     <memballoon model="virtio">
     </memballoon>
     ```
If this command displays any output and the model is not set to none, the *memballoon* device is present.

2. Ensure the balloon drivers are running in the guest OS.
   - In Windows guests, the drivers are installed as a part of the *virtio-win* driver package. For instructions, see Installing paravirtualized KVM drivers for Windows virtual machines.
   - In Linux guests, the drivers are generally included by default and activate when the *memballoon* device is present.

Procedure

1. **Optional:** Obtain the information about the maximum memory and currently used memory for a VM. This will serve as a baseline for your changes, and also for verification.
   
   ```
   # virsh dominfo testguest
   Max memory:     2097152 KiB
   Used memory:    2097152 KiB
   ```

2. Adjust the maximum memory allocated to a VM. Increasing this value improves the performance potential of the VM, and reducing the value lowers the performance footprint the VM has on your host. Note that this change can only be performed on a shut-off VM, so adjusting a running VM requires a reboot to take effect.
   For example, to change the maximum memory that the testguest VM can use to 4096 MiB:
   
   ```
   # virt-xml testguest --edit --memory memory=4096,currentMemory=4096
   Domain 'testguest' defined successfully.
   Changes will take effect after the domain is fully powered off.
   ```

   To increase the maximum memory of a running VM, you can attach a memory device to the VM. This is also referred to as *memory hot plug*. For details, see Attaching devices to virtual machines.

   **WARNING**
   Removing memory devices from a running VM (also referred as a memory hot unplug) is not supported, and highly discouraged by Red Hat.

3. **Optional:** You can also adjust the memory currently used by the VM, up to the maximum allocation. This regulates the memory load that the VM has on the host until the next reboot, without changing the maximum VM allocation.
   
   ```
   # virsh setmem testguest --current 2048
   ```

Verification

1. Confirm that the memory used by the VM has been updated:
2. **Optional:** If you adjusted the current VM memory, you can obtain the memory balloon statistics of the VM to evaluate how effectively it regulates its memory use.

```bash
# virsh dominfo testguest
Max memory: 4194304 KiB
Used memory: 2097152 KiB
```

```bash
# virsh domstats --balloon testguest
Domain: 'testguest'
balloon.current=365624
balloon.maximum=4194304
balloon.swap_in=0
balloon.swap_out=0
balloon.major_fault=306
balloon.minor_fault=156117
balloon.unused=3834448
balloon.available=4035008
balloon.usable=3746340
balloon.last-update=1587971682
balloon.disk_caches=75444
balloon.hugetlb_pgalloc=0
balloon.hugetlb_pgfail=0
balloon.rss=1005456
```

**Additional resources**

- Adding and removing virtual machine memory using the web console
- Optimizing virtual machine CPU performance

### 14.3.3. Additional resources

- Attaching devices to virtual machines.

### 14.4. OPTIMIZING VIRTUAL MACHINE I/O PERFORMANCE

The input and output (I/O) capabilities of a virtual machine (VM) can significantly limit the VM’s overall efficiency. To address this, you can optimize a VM’s I/O by configuring block I/O parameters.

#### 14.4.1. Tuning block I/O in virtual machines

When multiple block devices are being used by one or more VMs, it might be important to adjust the I/O priority of specific virtual devices by modifying their I/O weights.

Increasing the I/O weight of a device increases its priority for I/O bandwidth, and therefore provides it with more host resources. Similarly, reducing a device’s weight makes it consume less host resources.

**NOTE**

Each device’s weight value must be within the 100 to 1000 range. Alternatively, the value can be 0, which removes that device from per-device listings.

**Procedure**
To display and set a VM's block I/O parameters:

1. Display the current `<blkio>` parameters for a VM:

   ```
   # virsh dumpxml VM-name
   ```

   ```xml
   <domain>
   [...]
   <blkiotune>
   <weight>800</weight>
   <device>
   <path>/dev/sda</path>
   <weight>1000</weight>
   </device>
   <device>
   <path>/dev/sdb</path>
   <weight>500</weight>
   </device>
   </blkiotune>
   [...]
   </domain>
   ```

2. Edit the I/O weight of a specified device:

   ```
   # virsh blkiotune VM-name --device-weights device, I/O-weight
   ```

   For example, the following changes the weight of the `/dev/sda` device in the `liftrul` VM to 500.

   ```
   # virsh blkiotune liftrul --device-weights /dev/sda, 500
   ```

### 14.4.2. Disk I/O throttling in virtual machines

When several VMs are running simultaneously, they can interfere with system performance by using excessive disk I/O. Disk I/O throttling in KVM virtualization provides the ability to set a limit on disk I/O requests sent from the VMs to the host machine. This can prevent a VM from over-utilizing shared resources and impacting the performance of other VMs.

To enable disk I/O throttling, set a limit on disk I/O requests sent from each block device attached to VMs to the host machine.

**Procedure**

1. Use the `virsh domblklist` command to list the names of all the disk devices on a specified VM.

   ```
   # virsh domblklist rollin-coal
   Target  Source
   -----------------------------
   vda     /var/lib/libvirt/images/rollin-coal.qcow2
   sda     -
   sdb     /home/horridly-demanding-processes.iso
   ```

2. Find the host block device where the virtual disk that you want to throttle is mounted.

   For example, if you want to throttle the `sdb` virtual disk from the previous step, the following output shows that the disk is mounted on the `/dev/nvme0n1p3` partition.
3. Set I/O limits for the block device using the `virsh blkiotune` command.

```
# virsh blkiotune VM-name --parameter device,limit
```

The following example throttles the `sdb` disk on the `rollin-coal` VM to 1000 read and write I/O operations per second and to 50 MB per second read and write throughput.

```
# virsh blkiotune rollin-coal --device-read-iops-sec /dev/nvme0n1p3,1000 --device-write-iops-sec /dev/nvme0n1p3,1000 --device-write-bytes-sec /dev/nvme0n1p3,52428800 --device-read-bytes-sec /dev/nvme0n1p3,52428800
```

### Additional information
- Disk I/O throttling can be useful in various situations, for example when VMs belonging to different customers are running on the same host, or when quality of service guarantees are given for different VMs. Disk I/O throttling can also be used to simulate slower disks.
- I/O throttling can be applied independently to each block device attached to a VM and supports limits on throughput and I/O operations.
- Red Hat does not support using the `virsh blkdeviotune` command to configure I/O throttling in VMs. For more information about unsupported features when using RHEL 8 as a VM host, see [Unsupported features in RHEL 8 virtualization](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html-single/unsupported_features_in_rhel_8_virtualization).

### 14.4.3. Enabling multi-queue virtio-scsi

When using `virtio-scsi` storage devices in your virtual machines (VMs), the **multi-queue virtio-scsi** feature provides improved storage performance and scalability. It enables each virtual CPU (vCPU) to have a separate queue and interrupt to use without affecting other vCPUs.

#### Procedure
- To enable multi-queue virtio-scsi support for a specific VM, add the following to the VM's XML configuration, where $N$ is the total number of vCPU queues:

```
<controller type='scsi' index='0' model='virtio-scsi'>
  <driver queues='$N'/>
</controller>
```

### 14.5. OPTIMIZING VIRTUAL MACHINE CPU PERFORMANCE

Much like physical CPUs in host machines, vCPUs are critical to virtual machine (VM) performance. As a result, optimizing vCPUs can have a significant impact on the resource efficiency of your VMs. To optimize your vCPU:
1. Adjust how many host CPUs are assigned to the VM. You can do this using the CLI or the web console.

2. Ensure that the vCPU model is aligned with the CPU model of the host. For example, to set the testguest1 VM to use the CPU model of the host:

   ```
   # virt-xml testguest1 --edit --cpu host-model
   ```

3. Deactivate kernel same-page merging (KSM).

4. If your host machine uses Non-Uniform Memory Access (NUMA), you can also configure NUMA for its VMs. This maps the host’s CPU and memory processes onto the CPU and memory processes of the VM as closely as possible. In effect, NUMA tuning provides the vCPU with a more streamlined access to the system memory allocated to the VM, which can improve the vCPU processing effectiveness.
   For details, see Configuring NUMA in a virtual machine and Sample vCPU performance tuning scenario.

### 14.5.1. Adding and removing virtual CPUs using the command-line interface

To increase or optimize the CPU performance of a virtual machine (VM), you can add or remove virtual CPUs (vCPUs) assigned to the VM.

When performed on a running VM, this is also referred to as vCPU hot plugging and hot unplugging. However, note that vCPU hot unplug is not supported in RHEL 8, and Red Hat highly discourages its use.

#### Prerequisites

- **Optional:** View the current state of the vCPUs in the targeted VM. For example, to display the number of vCPUs on the testguest VM:

  ```
  # virsh vcpucount testguest
  maximum config 4
  maximum live 2
  current config 2
  current live 1
  ```

  This output indicates that testguest is currently using 1 vCPU, and 1 more vCPU can be hot plugged to it to increase the VM’s performance. However, after reboot, the number of vCPUs testguest uses will change to 2, and it will be possible to hot plug 2 more vCPUs.

#### Procedure

1. Adjust the maximum number of vCPUs that can be attached to a VM, which takes effect on the VM’s next boot.
   For example, to increase the maximum vCPU count for the testguest VM to 8:

   ```
   # virsh setvcpus testguest 8 --maximum --config
   ```

   Note that the maximum may be limited by the CPU topology, host hardware, the hypervisor, and other factors.

2. Adjust the current number of vCPUs attached to a VM, up to the maximum configured in the previous step. For example:
To increase the number of vCPUs attached to the running testguest VM to 4:

```
# virsh setvcpus testguest 4 --live
```

This increases the VM’s performance and host load footprint of testguest until the VM’s next boot.

To permanently decrease the number of vCPUs attached to the testguest VM to 1:

```
# virsh setvcpus testguest 1 --config
```

This decreases the VM’s performance and host load footprint of testguest after the VM’s next boot. However, if needed, additional vCPUs can be hot plugged to the VM to temporarily increase its performance.

**Verification**

- Confirm that the current state of vCPU for the VM reflects your changes.

```
# virsh vcpucount testguest
maximum config 8
maximum live 4
current config 1
current live 4
```

**Additional resources**

- [Managing virtual CPUs using the web console](#)

### 14.5.2. Managing virtual CPUs using the web console

Using the RHEL 8 web console, you can review and configure virtual CPUs used by virtual machines (VMs) to which the web console is connected.

**Prerequisites**

- The web console VM plug-in [is installed on your system](#).

**Procedure**

1. In the Virtual Machines interface, click the VM whose information you want to see. A new page opens with an Overview section with basic information about the selected VM and a Console section to access the VM’s graphical interface.

2. Click edit next to the number of vCPUs in the Overview pane. The vCPU details dialog appears.
1. Configure the virtual CPUs for the selected VM.
   - **vCPU Count** - The number of vCPUs currently in use.
     
     **NOTE**
     The vCPU count cannot be greater than the vCPU Maximum.
   
   - **vCPU Maximum** - The maximum number of virtual CPUs that can be configured for the VM. If this value is higher than the **vCPU Count**, additional vCPUs can be attached to the VM.
   
   - **Sockets** - The number of sockets to expose to the VM.
   
   - **Cores per socket** - The number of cores for each socket to expose to the VM.
   
   - **Threads per core** - The number of threads for each core to expose to the VM.
     Note that the **Sockets**, **Cores per socket**, and **Threads per core** options adjust the CPU topology of the VM. This may be beneficial for vCPU performance and may impact the functionality of certain software in the guest OS. If a different setting is not required by your deployment, keep the default values.

2. Click **Apply**.
   The virtual CPUs for the VM are configured.

   **NOTE**
   Changes to virtual CPU settings only take effect after the VM is restarted.

**Additional resources**

- *Adding and removing virtual CPUs using the command-line interface*

**14.5.3. Configuring NUMA in a virtual machine**

The following methods can be used to configure Non-Uniform Memory Access (NUMA) settings of a virtual machine (VM) on a RHEL 8 host.

**Prerequisites**
• The host is a NUMA-compatible machine. To detect whether this is the case, use the `virsh nodeinfo` command and see the **NUMA cell(s)** line:

```
# virsh nodeinfo
CPU model: x86_64
CPU(s): 48
CPU frequency: 1200 MHz
CPU socket(s): 1
Core(s) per socket: 12
Thread(s) per core: 2
NUMA cell(s): 2
Memory size: 67012964 KiB
```

If the value of the line is 2 or greater, the host is NUMA-compatible.

**Procedure**

For ease of use, you can set up a VM's NUMA configuration using automated utilities and services. However, manual NUMA setup is more likely to yield a significant performance improvement.

**Automatic methods**

• Set the VM's NUMA policy to **Preferred**. For example, to do so for the `testguest5` VM:

```
# virt-xml testguest5 --edit --vcpus placement=auto
# virt-xml testguest5 --edit --numatune mode=preferred
```

• Enable automatic NUMA balancing on the host:

```
# echo 1 > /proc/sys/kernel/numa_balancing
```

• Use the `numad` command to automatically align the VM CPU with memory resources.

```
# numad
```

**Manual methods**

1. Pin specific vCPU threads to a specific host CPU or range of CPUs. This is also possible on non-NUMA hosts and VMs, and is recommended as a safe method of vCPU performance improvement.

For example, the following commands pin vCPU threads 0 to 5 of the `testguest6` VM to host CPUs 1, 3, 5, 7, 9, and 11, respectively:

```
# virsh vcpupin testguest6 0 1
# virsh vcpupin testguest6 1 3
# virsh vcpupin testguest6 2 5
# virsh vcpupin testguest6 3 7
# virsh vcpupin testguest6 4 9
# virsh vcpupin testguest6 5 11
```

Afterwards, you can verify whether this was successful:

```
# virsh vcpupin testguest6
VCPUs  CPU Affinity
----------------------------------
```
2. After pinning vCPU threads, you can also pin QEMU process threads associated with a specified VM to a specific host CPU or range of CPUs. For example, the following commands pin the QEMU process thread of testguest6 to CPUs 13 and 15, and verify this was successful:

```
# virsh emulatorpin testguest6 13,15
# virsh emulatorpin testguest6
emulator: CPU Affinity
----------------------------------
*: 13,15
```

3. Finally, you can also specify which host NUMA nodes will be assigned specifically to a certain VM. This can improve the host memory usage by the VM’s vCPU. For example, the following commands set testguest6 to use host NUMA nodes 3 to 5, and verify this was successful:

```
# virsh numatune testguest6 --nodeset 3-5
# virsh numatune testguest6
```

**NOTE**

For best performance results, it is recommended to use all of the manual tuning methods listed above.

**Known issues**

- NUMA tuning currently cannot be performed on IBM Z hosts

**Additional resources**

- Sample vCPU performance tuning scenario
- View the current NUMA configuration of your system using the numastat utility

**14.5.4. Sample vCPU performance tuning scenario**

To obtain the best vCPU performance possible, Red Hat recommends using manual vcpupin, emulatorpin, and numatune settings together, for example like in the following scenario.

**Starting scenario**

- Your host has the following hardware specifics:
  - 2 NUMA nodes
  - 3 CPU cores on each node
  - 2 threads on each core
The output of `virsh nodeinfo` of such a machine would look similar to:

```bash
# virsh nodeinfo
CPU model:           x86_64
CPU(s):              12
CPU frequency:       3661 MHz
CPU socket(s):       2
Core(s) per socket:  3
Thread(s) per core:  2
NUMA cell(s):        2
Memory size:         31248692 KiB
```

- You intend to modify an existing VM to have 8 vCPUs, which means that it will not fit in a single NUMA node.
  Therefore, you should distribute 4 vCPUs on each NUMA node and make the vCPU topology resemble the host topology as closely as possible. This means that vCPUs that run as sibling threads of a given physical CPU should be pinned to host threads on the same core. For details, see the Solution below:

**Solution**

1. Obtain the information about the host topology:

```bash
# virsh capabilities
```

The output should include a section that looks similar to the following:

```xml
<topology>
  <cells num="2">
    <cell id="0">
      <memory unit="KiB">15624346</memory>
      <pages unit="KiB" size="4">3906086</pages>
      <pages unit="KiB" size="2048">0</pages>
      <pages unit="KiB" size="1048576">0</pages>
      <distances>
        <sibling id="0" value="10" />
        <sibling id="1" value="21" />
      </distances>
    </cell>
    <cell id="1">
      <memory unit="KiB">15624346</memory>
      <pages unit="KiB" size="4">3906086</pages>
      <pages unit="KiB" size="2048">0</pages>
      <pages unit="KiB" size="1048576">0</pages>
      <distances>
        <sibling id="0" value="21" />
        <sibling id="1" value="10" />
      </distances>
    </cell>
  </cells>
  <cpus num="6">
    <cpu id="0" socket_id="0" core_id="0" siblings="0,3" />
    <cpu id="1" socket_id="0" core_id="1" siblings="1,4" />
    <cpu id="2" socket_id="0" core_id="2" siblings="2,5" />
    <cpu id="3" socket_id="0" core_id="0" siblings="0,3" />
    <cpu id="4" socket_id="0" core_id="1" siblings="1,4" />
    <cpu id="5" socket_id="0" core_id="2" siblings="2,5" />
  </cpus>
</topology>
```
2. **Optional:** Test the performance of the VM using the applicable tools and utilities.

3. Set up and mount 1 GiB huge pages on the host:
   a. Add the following line to the host’s kernel command line:
      
      ```
      default_hugepagesz=1G hugepagesz=1G
      ```
   
   b. Create the `/etc/systemd/system/hugetlb-gigantic-pages.service` file with the following content:
      
      ```
      [Unit]
      Description=HugeTLB Gigantic Pages Reservation
      DefaultDependencies=no
      Before=dev-hugepages.mount
      ConditionPathExists=/sys/devices/system/node
      ConditionKernelCommandLine=hugepagesz=1G
      
      [Service]
      Type=oneshot
      RemainAfterExit=yes
      ExecStart=/etc/systemd/hugetlb-reserve-pages.sh
      
      [Install]
      WantedBy=sysinit.target
      ```
   
   c. Create the `/etc/systemd/hugetlb-reserve-pages.sh` file with the following content:
      
      ```
      #!/bin/sh
      
      nodes_path=/sys/devices/system/node/
      if [ ! -d $nodes_path ]; then
        echo "ERROR: $nodes_path does not exist"
        exit 1
      fi
      
      reserve_pages()
      {
        echo $1 > $nodes_path/hugepages/hugepages-1048576kB/nr_hugepages
      }
      ```
This reserves four 1GiB huge pages from `node1` and four 1GiB huge pages from `node2`.

d. Make the script created in the previous step executable:

```
# chmod +x /etc/systemd/hugetlb-reserve-pages.sh
```

e. Enable huge page reservation on boot:

```
# systemctl enable hugetlb-gigantic-pages
```

4. Use the `virsh edit` command to edit the XML configuration of the VM you wish to optimize, in this example `super-vm`:

```
# virsh edit super-vm
```

5. Adjust the XML configuration of the VM in the following way:

a. Set the VM to use 8 static vCPUs. Use the `<vcpu/>` element to do this.

b. Pin each of the vCPU threads to the corresponding host CPU threads that it mirrors in the topology. To do so, use the `<vcpupin/>` elements in the `<cputune/>` section.

Note that, as shown by the `virsh capabilities` utility above, host CPU threads are not ordered sequentially in their respective cores. In addition, the vCPU threads should be pinned to the highest available set of host cores on the same NUMA node. For a table illustration, see the Sample topology section below.

The XML configuration for steps a. and b. can look similar to:

```
<
cputune

  <vcpupin vcpu='0' cpuset='1'/>
  <vcpupin vcpu='1' cpuset='4'/>
  <vcpupin vcpu='2' cpuset='2'/>
  <vcpupin vcpu='3' cpuset='5'/>
  <vcpupin vcpu='4' cpuset='7'/>
  <vcpupin vcpu='5' cpuset='10'/>
  <vcpupin vcpu='6' cpuset='8'/>
  <vcpupin vcpu='7' cpuset='11'/>
  <emulatorpin cpuset='6,9'/>

</cputune>
```

c. Set the VM to use 1 GiB huge pages:

```
<
memoryBacking

  <hugepages>
    <page size='1' unit='GiB'/>
  </hugepages>

</memoryBacking>
```

d. Configure the VM’s NUMA nodes to use memory from the corresponding NUMA nodes on the host. To do so, use the `<memnode/>` elements in the `<numatune/>` section:
e. Ensure the CPU mode is set to host-passthrough, and that the CPU uses cache in passthrough mode:

```xml
<cpu mode="host-passthrough">
    <topology sockets="2" cores="2" threads="2"/>
    <cache mode="passthrough"/>
</cpu>
```

Verification

1. Confirm that the resulting XML configuration of the VM includes a section similar to the following:

```xml
[...]
    <memoryBacking>
        <hugepages>
            <page size='1' unit='GiB'/>
        </hugepages>
    </memoryBacking>
    <vcpu placement='static'>8</vcpu>
    <cputune>
        <vcpupin vcpu='0' cpuset='1'/>
        <vcpupin vcpu='1' cpuset='4'/>
        <vcpupin vcpu='2' cpuset='2'/>
        <vcpupin vcpu='3' cpuset='5'/>
        <vcpupin vcpu='4' cpuset='7'/>
        <vcpupin vcpu='5' cpuset='10'/>
        <vcpupin vcpu='6' cpuset='8'/>
        <vcpupin vcpu='7' cpuset='11'/>
        <emulatorpin cpuset='6,9'/>
    </cputune>
    <numatune>
        <memory mode="preferred" nodeset="1"/>
        <memnode cellid="0" mode="strict" nodeset="0"/>
        <memnode cellid="1" mode="strict" nodeset="1"/>
    </numatune>
    <cpu mode="host-passthrough">
        <topology sockets="2" cores="2" threads="2"/>
        <cache mode="passthrough"/>
    </cpu>
    <numa>
        <cell id="0" cpus="0-3" memory="2" unit='GiB'>
            <distances>
                <sibling id='0' value='10'/>
                <sibling id='1' value='21'/>
            </distances>
        </cell>
        <cell id="1" cpus="4-7" memory="2" unit='GiB'>
            <distances>
                <sibling id='0' value='21'/>
                <sibling id='1' value='10'/>
            </distances>
        </cell>
    </numa>
```
2. Optional: Test the performance of the VM using the applicable tools and utilities to evaluate the impact of the VM's optimization.

Sample topology

- The following tables illustrate the connections between the vCPUs and the host CPUs they should be pinned to:

Table 14.1. Host topology

<table>
<thead>
<tr>

<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this scenario, there are 2 NUMA nodes and 8 vCPUs. Therefore, 4 vCPU threads should be pinned to each node.
In addition, Red Hat recommends leaving at least a single CPU thread available on each node for host system operations.

Because in this example, each NUMA node houses 3 cores, each with 2 host CPU threads, the set for node 0 translates as follows:

```
<cpuset cpumask='1'>
<vcpu vcpu='0'/>
<vcpu vcpu='1'/>
<vcpu vcpu='2'/>
<vcpu vcpu='3'/>
```

14.5.5. Deactivating kernel same-page merging

Although kernel same-page merging (KSM) improves memory density, it increases CPU utilization, and might adversely affect overall performance depending on the workload. In such cases, you can improve the virtual machine (VM) performance by deactivating KSM.

Depending on your requirements, you can either deactivate KSM for a single session or persistently.

Procedure

- To deactivate KSM for a single session, use the `systemctl` utility to stop `ksm` and `ksmtuned` services.

  ```
  # systemctl stop ksm
  # systemctl stop ksmtuned
  ```

- To deactivate KSM persistently, use the `systemctl` utility to disable `ksm` and `ksmtuned` services.

  ```
  # systemctl disable ksm
  Removed /etc/systemd/system/multi-user.target.wants/ksm.service.
  # systemctl disable ksmtuned
  Removed /etc/systemd/system/multi-user.target.wants/ksmtuned.service.
  ```

**NOTE**

Memory pages shared between VMs before deactivating KSM will remain shared. To stop sharing, delete all the PageKSM pages in the system using the following command:

```
# echo 2 > /sys/kernel/mm/ksm/run
```

After anonymous pages replace the KSM pages, the `khugepaged` kernel service will rebuild transparent hugepages on the VM’s physical memory.

14.6. OPTIMIZING VIRTUAL MACHINE NETWORK PERFORMANCE

Due to the virtual nature of a VM’s network interface card (NIC), the VM loses a portion of its allocated host network bandwidth, which can reduce the overall workload efficiency of the VM. The following tips can minimize the negative impact of virtualization on the virtual NIC (vNIC) throughput.

**Procedure**
Use any of the following methods and observe if it has a beneficial effect on your VM network performance:

Enable the vhost_net module

On the host, ensure the vhost_net kernel feature is enabled:

```bash
# Ismod | grep vhost
vhost_net       32768  1
vhost           53248  1 vhost_net
tap             24576  1 vhost_net
tun             57344  6 vhost_net
```

If the output of this command is blank, enable the vhost_net kernel module:

```bash
# modprobe vhost_net
```

Set up multi-queue virtio-net

To set up the multi-queue virtio-net feature for a VM, use the virsh edit command to edit the XML configuration of the VM. In the XML, add the following to the <devices> section, and replace N with the number of vCPUs in the VM, up to 16:

```xml
<interface type='network'>
    <source network='default'/>
    <model type='virtio'/>
    <driver name='vhost' queues='N'/>
</interface>
```

If the VM is running, restart it for the changes to take effect.

Batching network packets

In Linux VM configurations with a long transmission path, batching packets before submitting them to the kernel may improve cache utilization. To set up packet batching, use the following command on the host, and replace tap0 with the name of the network interface that the VMs use:

```bash
# ethtool -C tap0 rx-frames 64
```

SR-IOV

If your host NIC supports SR-IOV, use SR-IOV device assignment for your vNICs. For more information, see Managing SR-IOV devices.

Additional resources

- Understanding virtual networking

14.7. VIRTUAL MACHINE PERFORMANCE MONITORING TOOLS

To identify what consumes the most VM resources and which aspect of VM performance needs optimization, performance diagnostic tools, both general and VM-specific, can be used.

Default OS performance monitoring tools
For standard performance evaluation, you can use the utilities provided by default by your host and guest operating systems:

- On your RHEL 8 host, as root, use the `top` utility or the `system monitor` application, and look for `qemu` and `virt` in the output. This shows how much host system resources your VMs are consuming.
  - If the monitoring tool displays that any of the `qemu` or `virt` processes consume a large portion of the host CPU or memory capacity, use the `perf` utility to investigate. For details, see below.
  - In addition, if a `vhost_net` thread process, named for example `vhost_net-1234`, is displayed as consuming an excessive amount of host CPU capacity, consider using virtual network optimization features, such as `multi-queue virtio-net`.

- On the guest operating system, use performance utilities and applications available on the system to evaluate which processes consume the most system resources.
  - On Linux systems, you can use the `top` utility.
  - On Windows systems, you can use the `Task Manager` application.

**perf kvm**

You can use the `perf` utility to collect and analyze virtualization-specific statistics about the performance of your RHEL 8 host. To do so:

1. On the host, install the `perf` package:
   ```bash
   # yum install perf
   ```

2. Use one of the `perf kvm stat` commands to display perf statistics for your virtualization host:
   - For real-time monitoring of your hypervisor, use the `perf kvm stat live` command.
   - To log the perf data of your hypervisor over a period of time, activate the logging using the `perf kvm stat record` command. After the command is canceled or interrupted, the data is saved in the `perf.data.guest` file, which can be analyzed using the `perf kvm stat report` command.

3. Analyze the `perf` output for types of VM-EXIT events and their distribution. For example, the `PAUSE_INSTRUCTION` events should be infrequent, but in the following output, the high occurrence of this event suggests that the host CPUs are not handling the running vCPUs well. In such a scenario, consider shutting down some of your active VMs, removing vCPUs from these VMs, or tuning the performance of the vCPUs.

   ```bash
   # perf kvm stat report
   ```

   Analyze events for all VMs, all VCPUs:

   ```none
   VM-EXIT   Samples  Samples%  Time%  Min Time  Max Time  Avg time
   EXTERNAL_INTERRUPT  365634  31.59%  18.04%  0.42us  58780.59us  204.08us ( +/- 0.99% )
   MSR_WRITE    293428  25.35%  0.13%  0.59us  17873.02us  1.80us ( +/- 4.63% )
   ```
PREEMPTION_TIMER     276162  23.86%  0.23%  0.51us  21396.03us  3.38us (+- 5.19%)
PAUSE_INSTRUCTION     189375  16.36%  11.75%  0.72us  29655.25us  256.77us (+- 0.70%)
HLT  20440     1.77%  69.83%  0.62us  79319.41us  14134.56us (+- 0.79%)
VMCALL      12426     1.07%  0.03%  1.02us   5416.25us   8.77us (+- 7.36%)
EXCEPTION_NMI         27     0.00%  0.00%  0.69us   1.34us   0.98us (+- 3.50%)
EPT_MISCONFIG          5     0.00%  0.00%  5.15us   10.85us   7.88us (+- 11.67%)

Total Samples:1157497, Total events handled time:413728274.66us.

Other event types that can signal problems in the output of `perf kvm stat` include:

- **INSN_EMULATION** - suggests suboptimal VM I/O configuration.

For more information about using `perf` to monitor virtualization performance, see the `perf-kvm` man page.

**numastat**

To see the current NUMA configuration of your system, you can use the `numastat` utility, which is provided by installing the `numactl` package.

The following shows a host with 4 running VMs, each obtaining memory from multiple NUMA nodes. This is not optimal for vCPU performance, and warrants adjusting:

```
# numastat -c qemu-kvm

Per-node process memory usage (in MBs)
PID          Node 0 Node 1 Node 2 Node 3 Node 4 Node 5 Node 6 Node 7 Total
---------------  ------ ------ ------ ------ ------ ------ ------ ------ -----
51722 (qemu-kvm)     68     16    357   6936      2      3    147    598  8128
51747 (qemu-kvm)    245     11      5     18   5172   2532      1     92  8076
53736 (qemu-kvm)   1393      3      1      2     12      0      0   8113  8118
53773 (qemu-kvm)   1393      3      1      2     12      0      0   8113  8118
---------------  ------ ------ ------ ------ ------ ------ ------ ------ -----
Total              1769    463   2024   7462  10037   2672    169  7837 32434

In contrast, the following shows memory being provided to each VM by a single node, which is significantly more efficient.

```

```
# numastat -c qemu-kvm

Per-node process memory usage (in MBs)
PID          Node 0 Node 1 Node 2 Node 3 Node 4 Node 5 Node 6 Node 7 Total
---------------  ------ ------ ------ ------ ------ ------ ------ ------ -----
51747 (qemu-kvm)      0      0      7      0  8072      0     1    0   8080
53736 (qemu-kvm)      0      0      7      0     0     0   8113     0   8120
53773 (qemu-kvm)      0      0      7      0     0     0   8110   8118
59065 (qemu-kvm)      0      0   8050     0     0     0     0     0   8051
---------------  ------ ------ ------ ------ ------ ------ ------ ------ -----
Total              0     0  8072    0  8072     0  8114  8110 32368

```

14.8. ADDITIONAL RESOURCES

- Optimizing Windows virtual machines
CHAPTER 15. IMPORTANCE OF POWER MANAGEMENT

Reducing the overall power consumption of computer systems helps to save cost. Effectively optimizing energy consumption of each system component includes studying different tasks that your system performs, and configuring each component to ensure that its performance is correct for that job. Lowering the power consumption of a specific component or of the system as a whole leads to lower heat and performance.

Proper power management results in:

- heat reduction for servers and computing centers
- reduced secondary costs, including cooling, space, cables, generators, and uninterruptible power supplies (UPS)
- extended battery life for laptops
- lower carbon dioxide output
- meeting government regulations or legal requirements regarding Green IT, for example, Energy Star
- meeting company guidelines for new systems

This section describes the information regarding power management of your Red Hat Enterprise Linux systems.

15.1. POWER MANAGEMENT BASICS

Effective power management is built on the following principles:

An idle CPU should only wake up when needed

Since Red Hat Enterprise Linux 6, the kernel runs tickless, which means the previous periodic timer interrupts have been replaced with on-demand interrupts. Therefore, idle CPUs are allowed to remain idle until a new task is queued for processing, and CPUs that have entered lower power states can remain in these states longer. However, benefits from this feature can be offset if your system has applications that create unnecessary timer events. Polling events, such as checks for volume changes or mouse movement, are examples of such events.

Red Hat Enterprise Linux includes tools using which you can identify and audit applications on the basis of their CPU usage. For more information see, Audit and analysis overview and Tools for auditing.

Unused hardware and devices should be disabled completely

This is true for devices that have moving parts, for example, hard disks. In addition to this, some applications may leave an unused but enabled device “open”; when this occurs, the kernel assumes that the device is in use, which can prevent the device from going into a power saving state.

Low activity should translate to low wattage

In many cases, however, this depends on modern hardware and correct BIOS configuration or UEFI on modern systems, including non-x86 architectures. Make sure that you are using the latest official firmware for your systems and that in the power management or device configuration sections of the BIOS the power management features are enabled. Some features to look for include:

- Collaborative Processor Performance Controls (CPPC) support for ARM64
PowerNV support for IBM Power Systems

- SpeedStep
- PowerNow!
- Cool’n’Quiet
- ACPI (C-state)
- Smart

If your hardware has support for these features and they are enabled in the BIOS, Red Hat Enterprise Linux uses them by default.

Different forms of CPU states and their effects

Modern CPUs together with Advanced Configuration and Power Interface (ACPI) provide different power states. The three different states are:

- Sleep (C-states)
- Frequency and voltage (P-states)
- Heat output (T-states or thermal states)

A CPU running on the lowest sleep state, consumes the least amount of watts, but it also takes considerably more time to wake it up from that state when needed. In very rare cases this can lead to the CPU having to wake up immediately every time it just went to sleep. This situation results in an effectively permanently busy CPU and loses some of the potential power saving if another state had been used.

A turned off machine uses the least amount of power

One of the best ways to save power is to turn off systems. For example, your company can develop a corporate culture focused on “green IT” awareness with a guideline to turn off machines during lunch break or when going home. You also might consolidate several physical servers into one bigger server and virtualize them using the virtualization technology, which is shipped with Red Hat Enterprise Linux.

15.2. AUDIT AND ANALYSIS OVERVIEW

The detailed manual audit, analysis, and tuning of a single system is usually the exception because the time and cost spent to do so typically outweighs the benefits gained from these last pieces of system tuning.

However, performing these tasks once for a large number of nearly identical systems where you can reuse the same settings for all systems can be very useful. For example, consider the deployment of thousands of desktop systems, or an HPC cluster where the machines are nearly identical. Another reason to do auditing and analysis is to provide a basis for comparison against which you can identify regressions or changes in system behavior in the future. The results of this analysis can be very helpful in cases where hardware, BIOS, or software updates happen regularly and you want to avoid any surprises with regard to power consumption. Generally, a thorough audit and analysis gives you a much better idea of what is really happening on a particular system.

Auditing and analyzing a system with regard to power consumption is relatively hard, even with the most modern systems available. Most systems do not provide the necessary means to measure power use via software. Exceptions exist though:
iLO management console of Hewlett Packard server systems has a power management module that you can access through the web.

IBM provides a similar solution in their BladeCenter power management module.

On some Dell systems, the IT Assistant offers power monitoring capabilities as well.

Other vendors are likely to offer similar capabilities for their server platforms, but as can be seen there is no single solution available that is supported by all vendors. Direct measurements of power consumption are often only necessary to maximize savings as far as possible.

15.3. TOOLS FOR AUDITING

Red Hat Enterprise Linux 8 offers tools using which you can perform system auditing and analysis. Most of them can be used as supplementary sources of information in case you want to verify what you have discovered already or in case you need more in-depth information about certain parts.

Many of these tools are used for performance tuning as well, which include:

**PowerTOP**

It identifies specific components of kernel and user-space applications that frequently wake up the CPU. Use the `powertop` command as root to start the PowerTop tool and `powertop --calibrate` to calibrate the power estimation engine. For more information about PowerTop, see [Managing power consumption with PowerTOP](#).

**Diskdevstat and netdevstat**

They are SystemTap tools that collect detailed information about the disk activity and network activity of all applications running on a system. Using the collected statistics by these tools, you can identify applications that waste power with many small I/O operations rather than fewer, larger operations. Using the `yum install tuned-utils-systemtap kernel-debuginfo` command as root, install the `diskdevstat` and `netdevstat` tool.

To view the detailed information about the disk and network activity, use:

```bash
# diskdevstat
```

```
PID  UID  DEV   WRITE_CNT WRITE_MIN WRITE_MAX WRITE_AVG READ_CNT READ_MIN READ_MAX READ_AVG COMMAND
3575 1000  dm-2   59 0.000 0.365 0.006 5 0.000 0.000 0.000 mozStorage #5
3575 1000  dm-2   7 0.000 0.000 0.000 0 0.000 0.000 0.000 localStorage DB
...
```

```bash
# netdevstat
```

```
PID  UID  DEV   XMIT_CNT XMIT_MIN XMIT_MAX XMIT_AVG RECV_CNT RECV_MIN RECV_MAX RECV_AVG COMMAND
3572 991  enp0s31f6 40 0.000 0.882 0.108 0 0.000 0.000 0.000 openvpn
3575 1000  enp0s31f6 27 0.000 1.363 0.160 0 0.000 0.000 0.000 Socket Thread
...
```
With these commands, you can specify three parameters: `update_interval`, `total_duration`, and `display_histogram`.

**TuneD**

It is a profile-based system tuning tool that uses the `udev` device manager to monitor connected devices, and enables both static and dynamic tuning of system settings. You can use the `tuned-adm recommend` command to determine which profile Red Hat recommends as the most suitable for a particular product. For more information about TuneD, see Getting started with TuneD and Customizing TuneD profiles. Using the `powertop2tuned` utility, you can create custom TuneD profiles from PowerTOP suggestions. For more information about the `powertop2tuned` utility, see Optimizing power consumption.

**Virtual memory statistics (vmstat)**

It is provided by the `procps-ng` package. Using this tool, you can view the detailed information about processes, memory, paging, block I/O, traps, and CPU activity.

To view this information, use:

```bash
$ vmstat
procs -----------memory---------- ---swap-- -----io---- -system-- ------cpu-----
r  b  swpd  free    buff   cache   si   so  bi   bo   in  cs  us  sy id  wa  st
1  0   0   5805576 380856 4852848   0    0  119  73  814  640  2   2 96   0   0
```

Using the `vmstat -a` command, you can display active and inactive memory. For more information about other `vmstat` options, see the `vmstat` man page.

**iostat**

It is provided by the `sysstat` package. This tool is similar to `vmstat`, but only for monitoring I/O on block devices. It also provides more verbose output and statistics.

To monitor the system I/O, use:

```bash
$ iostat
avg-cpu:  %user   %nice %system %iowait  %steal   %idle
          2.05    0.46    1.55    0.26    0.00   95.67

Device     tps     kB_read/s    kB_wrtn/s    kB_read    kB_wrtn
nvme0n1    53.54     899.48     616.99      3445229     2363196
dm-0       42.84     753.72     238.71      2886921      914296
dm-1        0.03       0.60       0.00         2292           0
dm-2       24.15     143.12     379.80       548193     1454712
```

**blktrace**

It provides detailed information about how time is spent in the I/O subsystem.

To view this information in human readable format, use:

```bash
# blktrace -d /dev/dm-0 -o - | blkparse -i -
```

Here, The first column, 253,0 is the device major and minor tuple. The second column, 1, gives information about the CPU, followed by columns for timestamps and PID of the process issuing the I/O process.
The sixth column, Q, shows the event type, the 7th column, W for write operation, the 8th column, 76423384, is the block number, and the + 8 is the number of requested blocks.

The last field, [kworker/u16:1], is the process name.

By default, the blktrace command runs forever until the process is explicitly killed. Use the -w option to specify the run-time duration.

turbostat

It is provided by the kernel-tools package. It reports on processor topology, frequency, idle power-state statistics, temperature, and power usage on x86-64 processors.

To view this summary, use:

```
# turbostat
```

By default, turbostat prints a summary of counter results for the entire screen, followed by counter results every 5 seconds. Specify a different period between counter results with the -i option, for example, execute turbostat -i 10 to print results every 10 seconds instead.

Turbostat is also useful for identifying servers that are inefficient in terms of power usage or idle time. It also helps to identify the rate of system management interrupts (SMIs) occurring on the system. It can also be used to verify the effects of power management tuning.

cpupower

It is a collection of tools to examine and tune power saving related features of processors. Use the cpupower command with the frequency-info, frequency-set, idle-info, idle-set, set, info, and monitor options to display and set processor related values.

For example, to view available cpufreq governors, use:

```
$ cpupower frequency-info --governors
analyzing CPU 0:
available cpufreq governors: performance powersave
```

For more information about cpupower, see Viewing CPU related information.

GNOME Power Manager

It is a daemon that is installed as part of the GNOME desktop environment. GNOME Power Manager notifies you of changes in your system’s power status; for example, a change from battery to AC power. It also reports battery status, and warns you when battery power is low.

Additional resources

- powertop(1), diskdevstat(8), netdevstat(8), tuned(8), vmstat(8), iostat(1), blktrace(8), blkparse(8), and turbostat(8) man pages
- cpupower(1), cpupower-set(1), cpupower-info(1), cpupower-idle(1), cpupower-frequency-set(1), cpupower-frequency-info(1), and cpupower-monitor(1) man pages
CHAPTER 16. MANAGING POWER CONSUMPTION WITH POWERTOP

As a system administrator, you can use the PowerTOP tool to analyze and manage power consumption.

16.1. THE PURPOSE OF POWERTOP

PowerTOP is a program that diagnoses issues related to power consumption and provides suggestions on how to extend battery lifetime.

The PowerTOP tool can provide an estimate of the total power usage of the system and also individual power usage for each process, device, kernel worker, timer, and interrupt handler. The tool can also identify specific components of kernel and user-space applications that frequently wake up the CPU.

Red Hat Enterprise Linux 8 uses version 2.x of PowerTOP.

16.2. USING POWERTOP

Prerequisites

- To be able to use PowerTOP, make sure that the powertop package has been installed on your system:

  # yum install powertop

16.2.1. Starting PowerTOP

Procedure

- To run PowerTOP, use the following command:

  # powertop

IMPORTANT

Laptops should run on battery power when running the powertop command.

16.2.2. Calibrating PowerTOP

Procedure

1. On a laptop, you can calibrate the power estimation engine by running the following command:

  # powertop --calibrate

2. Let the calibration finish without interacting with the machine during the process. Calibration takes time because the process performs various tests, cycles through brightness levels and switches devices on and off.
3. When the calibration process is completed, **PowerTOP** starts as normal. Let it run for approximately an hour to collect data. When enough data is collected, power estimation figures will be displayed in the first column of the output table.

[NOTE]

Note that `powertop --calibrate` can only be used on laptops.

### 16.2.3. Setting the measuring interval

By default, **PowerTOP** takes measurements in 20 seconds intervals.

If you want to change this measuring frequency, use the following procedure:

**Procedure**

- Run the `powertop` command with the `--time` option:

  ```bash
  # powertop --time=time in seconds
  ```

### 16.2.4. Additional resources

For more details on how to use **PowerTOP**, see the `powertop` man page.

### 16.3. POWERTOP STATISTICS

While it runs, **PowerTOP** gathers statistics from the system.

**PowerTOP**'s output provides multiple tabs:

- **Overview**
- **Idle stats**
- **Frequency stats**
- **Device stats**
- **Tunables**
- **WakeUp**

You can use the **Tab** and **Shift+Tab** keys to cycle through these tabs.

#### 16.3.1. The Overview tab

In the **Overview** tab, you can view a list of the components that either send wakeups to the CPU most frequently or consume the most power. The items within the **Overview** tab, including processes, interrupts, devices, and other resources, are sorted according to their utilization.

The adjacent columns within the **Overview** tab provide the following pieces of information:

**Usage**
Power estimation of how the resource is being used.

Events/s
Wakes per second. The number of wakes per second indicates how efficiently the services or the devices and drivers of the kernel are performing. Less wakes means that less power is consumed. Components are ordered by how much further their power usage can be optimized.

Category
Classification of the component; such as process, device, or timer.

Description
Description of the component.

If properly calibrated, a power consumption estimation for every listed item in the first column is shown as well.

Apart from this, the Overview tab includes the line with summary statistics such as:

- Total power consumption
- Remaining battery life (only if applicable)
- Summary of total wakes per second, GPU operations per second, and virtual file system operations per second

16.3.2. The Idle stats tab

The Idle stats tab shows usage of C-states for all processors and cores, while the Frequency stats tab shows usage of P-states including the Turbo mode, if applicable, for all processors and cores. The duration of C- or P-states is an indication of how well the CPU usage has been optimized. The longer the CPU stays in the higher C- or P-states (for example C4 is higher than C3), the better the CPU usage optimization is. Ideally, residency is 90% or more in the highest C- or P-state when the system is idle.

16.3.3. The Device stats tab

The Device stats tab provides similar information to the Overview tab but only for devices.

16.3.4. The Tunables tab

The Tunables tab contains PowerTOP’s suggestions for optimizing the system for lower power consumption.

Use the up and down keys to move through suggestions, and the enter key to toggle the suggestion on or off.

16.3.5. The WakeUp tab

The WakeUp tab displays the device wakeup settings available for users to change as and when required.

Use the up and down keys to move through the available settings, and the enter key to enable or disable a setting.
16.4. WHY POWERTOP DOES NOT DISPLAY FREQUENCY STATS VALUES IN SOME INSTANCES

While using the Intel P-State driver, PowerTOP only displays values in the Frequency Stats tab if the driver is in passive mode. But, even in this case, the values may be incomplete.

In total, there are three possible modes of the Intel P-State driver:

- Active mode with Hardware P-States (HWP)
- Active mode without HWP
- Passive mode

Switching to the ACPI CPUfreq driver results in complete information being displayed by PowerTOP. However, it is recommended to keep your system on the default settings.

To see what driver is loaded and in what mode, run:

```
# cat /sys/devices/system/cpu/cpu0/cpufreq/scaling_driver
```

- `intel_pstate` is returned if the Intel P-State driver is loaded and in active mode.
- `intel_cpufreq` is returned if the Intel P-State driver is loaded and in passive mode.
- `acpi-cpufreq` is returned if the ACPI CPUfreq driver is loaded.

While using the Intel P-State driver, add the following argument to the kernel boot command line to force the driver to run in passive mode:

```
intel_pstate=passive
```
To disable the Intel P-State driver and use, instead, the ACPI CPUfreq driver, add the following argument to the kernel boot command line:

`intel_pstate=disable`

### 16.5. GENERATING AN HTML OUTPUT

Apart from the powertop’s output in terminal, you can also generate an HTML report.

**Procedure**

- Run the `powertop` command with the `--html` option:
  ```
  # powertop --html=htmlfile.html
  ```
  Replace the `htmlfile.html` parameter with the required name for the output file.

### 16.6. OPTIMIZING POWER CONSUMPTION

To optimize power consumption, you can use either the powertop service or the powertop2tuned utility.

#### 16.6.1. Optimizing power consumption using the powertop service

You can use the `powertop` service to automatically enable all PowerTOP’s suggestions from the Tunables tab on the boot:

**Procedure**

- Enable the `powertop` service:
  ```
  # systemctl enable powertop
  ```

#### 16.6.2. The powertop2tuned utility

The `powertop2tuned` utility allows you to create custom TuneD profiles from PowerTOP suggestions.

By default, `powertop2tuned` creates profiles in the `/etc/tuned/` directory, and bases the custom profile on the currently selected TuneD profile. For safety reasons, all PowerTOP tunings are initially disabled in the new profile.

To enable the tunings, you can:

- Uncomment them in the `/etc/tuned/profile_name/tuned.conf` file.
- Use the `--enable` or `-e` option to generate a new profile that enables most of the tunings suggested by PowerTOP. Certain potentially problematic tunings, such as the USB autosuspend, are disabled by default and need to be uncommented manually.

#### 16.6.3. Optimizing power consumption using the powertop2tuned utility
Prerequisites

- The `powertop2tuned` utility is installed on the system:

  ```bash
  # yum install tuned-utils
  ```

Procedure

1. Create a custom profile:

  ```bash
  # powertop2tuned new_profile_name
  ```

2. Activate the new profile:

  ```bash
  # tuned-adm profile new_profile_name
  ```

Additional information

- For a complete list of options that `powertop2tuned` supports, use:

  ```bash
  $ powertop2tuned --help
  ```

16.6.4. Comparison of powertop.service and powertop2tuned

Optimizing power consumption with `powertop2tuned` is preferred over `powertop.service` for the following reasons:

- The `powertop2tuned` utility represents integration of PowerTOP into TuneD, which enables to benefit of advantages of both tools.

- The `powertop2tuned` utility allows for fine-grained control of enabled tuning.

- With `powertop2tuned`, potentially dangerous tuning are not automatically enabled.

- With `powertop2tuned`, rollback is possible without reboot.
CHAPTER 17. TUNING CPU FREQUENCY TO OPTIMIZE ENERGY CONSUMPTION

You can optimize the power consumption of your system by using the available **cpupower** commands to set CPU speed on a system according to your requirements after setting up the required CPUfreq governor.

17.1. SUPPORTED CPUPOWER TOOL COMMANDS

The **cpupower** tool is a collection of tools to examine and tune power saving related features of processors.

The **cpupower** tool supports the following commands:

- **idle-info**
  Displays the available idle states and other statistics for the CPU idle driver using the **cpupower idle-info** command. For more information, see [CPU Idle States](#).

- **idle-set**
  Enables or disables specific CPU idle state using the **cpupower idle-set** command as root. Use `-d` to disable and `-e` to enable a specific CPU idle state.

- **frequency-info**
  Displays the current **cpufreq** driver and available **cpufreq** governors using the **cpupower frequency-info** command. For more information, see [CPUfreq drivers](#), [Core CPUfreq Governors](#), and [Intel P-state CPUfreq governors](#).

- **frequency-set**
  Sets the **cpufreq** and governors using the **cpupower frequency-set** command as root. For more information, see [Setting up CPUfreq governor](#).

- **set**
  Sets processor power saving policies using the **cpupower set** command as root.
  Using the **--perf-bias** option, you can enable software on supported Intel processors to determine the balance between optimum performance and saving power. Assigned values range from 0 to 15, where 0 is optimum performance and 15 is optimum power efficiency. By default, the **--perf-bias** option applies to all cores. To apply it only to individual cores, add the **--cpu cpulist** option.

- **info**
  Displays processor power related and hardware configurations, which you have enabled using the **cpupower set** command. For example, if you assign the **--perf-bias** value as 5:

  ```bash
  # cpupower set --perf-bias 5
  # cpupower info
  analyzing CPU 0:
  perf-bias: 5
  ```

- **monitor**
  Displays the idle statistics and CPU demands using the **cpupower monitor** command.

  ```bash
  # cpupower monitor
  | Nehalem | Mperf | Idle_Stats
  | CPU| C3 | C6 | PC3 | PC6 | C0 | Cx | Freq | POLL | C1 | C1E | C3 | C6 | C7s | C8 | C9 | C10
  ```
Using the `-l` option, you can list all available monitors on your system and the `-m` option to display information related to specific monitors. For example, to monitor information related to the `Mperf` monitor, use the `cpupower monitor -m Mperf` command as root.

Additional resources

- `cpupower(1)`, `cpupower-idle-info(1)`, `cpupower-idle-set(1)`, `cpupower-frequency-set(1)`, `cpupower-frequency-info(1)`, `cpupower-set(1)`, `cpupower-info(1)`, and `cpupower-monitor(1)` man pages

### 17.2. CPU IDLE STATES

CPUs with the x86 architecture support various states, such as, few parts of the CPU are deactivated or using lower performance settings, known as C-states.

With this state, you can save power by partially deactivating CPUs that are not in use. There is no need to configure the C-state, unlike P-states that require a governor and potentially some set up to avoid undesirable power or performance issues. C-states are numbered from C0 upwards, with higher numbers representing decreased CPU functionality and greater power saving. C-states of a given number are broadly similar across processors, although the exact details of the specific feature sets of the state may vary between processor families. C-states 0–3 are defined as follows:

**C0**
In this state, the CPU is working and not idle at all.

**C1, Halt**
In this state, the processor is not executing any instructions but is typically not in a lower power state. The CPU can continue processing with practically no delay. All processors offering C-states need to support this state. Pentium 4 processors support an enhanced C1 state called C1E that actually is a state for lower power consumption.

**C2, Stop-Clock**
In this state, the clock is frozen for this processor but it keeps the complete state for its registers and caches, so after starting the clock again it can immediately start processing again. This is an optional state.

**C3, Sleep**
In this state, the processor goes to sleep and does not need to keep its cache up to date. Due to this reason, waking up from this state needs considerably more time than from the C2 state. This is an optional state.

You can view the available idle states and other statistics for the CPUIdle driver using the following command:

```
$ cpupower idle-info
CPUIdle governor: menu
analyzing CPU 0:

Number of idle states: 9
Available idle states: POLL C1 C1E C3 C6 C7s C8 C9 C10
[...]
```
Intel CPUs with the "Nehalem" microarchitecture features a C6 state, which can reduce the voltage supply of a CPU to zero, but typically reduces power consumption by between 80% and 90%. The kernel in Red Hat Enterprise Linux 8 includes optimizations for this new C-state.

**Additional resources**

- `cpupower(1)` and `cpupower-idle(1)` man pages

### 17.3. OVERVIEW OF CPUFREQ

One of the most effective ways to reduce power consumption and heat output on your system is CPUfreq, which is supported by x86 and ARM64 architectures in Red Hat Enterprise Linux 8. CPUfreq, also referred to as CPU speed scaling, is the infrastructure in the Linux kernel that enables it to scale the CPU frequency in order to save power.

CPU scaling can be done automatically depending on the system load, in response to Advanced Configuration and Power Interface (ACPI) events, or manually by user-space programs, and it allows the clock speed of the processor to be adjusted on the fly. This enables the system to run at a reduced clock speed to save power. The rules for shifting frequencies, whether to a faster or slower clock speed and when to shift frequencies, are defined by the CPUfreq governor.

You can view the `cpufreq` information using the `cpupower frequency-info` command as root.

#### 17.3.1. CPUfreq drivers

Using the `cpupower frequency-info --driver` command as root, you can view the current CPUfreq driver.

The following are the two available drivers for CPUfreq that can be used:

**ACPI CPUfreq**

Advanced Configuration and Power Interface (ACPI) CPUfreq driver is a kernel driver that controls the frequency of a particular CPU through ACPI, which ensures the communication between the kernel and the hardware.

**Intel P-state**

In Red Hat Enterprise Linux 8, Intel P-state driver is supported. The driver provides an interface for controlling the P-state selection on processors based on the Intel Xeon E series architecture or newer architectures.

Currently, Intel P-state is used by default for supported CPUs. You can switch to using ACPI CPUfreq by adding the `intel_pstate=disable` command to the kernel command line.

Intel P-state implements the `setpolicy()` callback. The driver decides what P-state to use based on the policy requested from the CPUfreq core. If the processor is capable of selecting its next P-state internally, the driver offloads this responsibility to the processor. If not, the driver implements algorithms to select the next P-state.

Intel P-state provides its own `sysfs` files to control the P-state selection. These files are located in the `/sys/devices/system/cpu/intel_pstate/` directory. Any changes made to the files are applicable to all CPUs.

This directory contains the following files that are used for setting P-state parameters:

- `/sys/devices/system/cpu/intel_pstate/max_perf_pct` limits the maximum P-state requested by the driver expressed in a
- `max_perf_pct` limits the maximum P-state requested by the driver expressed in a percentage of available performance. The available P-state performance can be reduced by the `no_turbo` setting.

- `min_perf_pct` limits the minimum P-state requested by the driver, expressed in a percentage of the maximum `no-turbo` performance level.

- `no_turbo` limits the driver to selecting P-state below the turbo frequency range.

- `turbo_pct` displays the percentage of the total performance supported by hardware that is in the turbo range. This number is independent of whether `turbo` has been disabled or not.

- `num_pstates` displays the number of P-states that are supported by hardware. This number is independent of whether turbo has been disabled or not.

Additional resources

- `cpupower-frequency-info(1)` man page

### 17.3.2. Core CPUfreq governors

A CPUfreq governor defines the power characteristics of the system CPU, which in turn affects the CPU performance. Each governor has its own unique behavior, purpose, and suitability in terms of workload. Using the `cpupower frequency-info --governor` command as root, you can view the available CPUfreq governors.

Red Hat Enterprise Linux 8 includes multiple core CPUfreq governors:

**cpufreq_performance**

It forces the CPU to use the highest possible clock frequency. This frequency is statically set and does not change. As such, this particular governor offers no power saving benefit. It is only suitable for hours of a heavy workload, and only during times wherein the CPU is rarely or never idle.

**cpufreq_powersave**

It forces the CPU to use the lowest possible clock frequency. This frequency is statically set and does not change. This governor offers maximum power savings, but at the cost of the lowest CPU performance. The term "powersave" can sometimes be deceiving though, since in principle a slow CPU on full load consumes more power than a fast CPU that is not loaded. As such, while it may be advisable to set the CPU to use the `powersave` governor during times of expected low activity, any unexpected high loads during that time can cause the system to actually consume more power. The Powersave governor is more of a speed limiter for the CPU than a power saver. It is most useful in systems and environments where overheating can be a problem.

**cpufreq_ondemand**

It is a dynamic governor, using which you can enable the CPU to achieve maximum clock frequency when the system load is high, and also minimum clock frequency when the system is idle. While this allows the system to adjust power consumption accordingly with respect to system load, it does so at the expense of latency between frequency switching. As such, latency can offset any performance or power saving benefits offered by the `ondemand` governor if the system switches between idle and heavy workloads too often. For most systems, the `ondemand` governor can provide the best compromise between heat emission, power consumption, performance, and manageability. When the system is only busy at specific times of the day, the `ondemand` governor automatically switches between maximum and minimum frequency depending on the load without any further intervention.

**cpufreq_userspace**
It allows user-space programs, or any process running as root, to set the frequency. Of all the governors, **userspace** is the most customizable and depending on how it is configured, it can offer the best balance between performance and consumption for your system.

**cpufreq_conservative**

Similar to the **ondemand** governor, the **conservative** governor also adjusts the clock frequency according to usage. However, the **conservative** governor switches between frequencies more gradually. This means that the **conservative** governor adjusts to a clock frequency that it considers best for the load, rather than simply choosing between maximum and minimum. While this can possibly provide significant savings in power consumption, it does so at an ever greater latency than the **ondemand** governor.

**NOTE**

You can enable a governor using **cron** jobs. This allows you to automatically set specific governors during specific times of the day. As such, you can specify a low-frequency governor during idle times, for example, after work hours, and return to a higher-frequency governor during hours of heavy workload.

For instructions on how to enable a specific governor, see [Setting up CPUfreq governor](#).

### 17.3.3. Intel P-state CPUfreq governors

By default, the Intel P-state driver operates in active mode with or without Hardware p-state (HWP) depending on whether the CPU supports HWP.

Using the `cpupower frequency-info --governor` command as root, you can view the available CPUfreq governors.

**NOTE**

The functionality of **performance** and **powersave** Intel P-state CPUfreq governors is different compared to core CPUfreq governors of the same names.

The Intel P-state driver can operate in the following three different modes:

**Active mode with hardware-managed P-states**

When active mode with HWP is used, the Intel P-state driver instructs the CPU to perform the P-state selection. The driver can provide frequency hints. However, the final selection depends on CPU internal logic. In active mode with HWP, the Intel P-state driver provides two P-state selection algorithms:

- **performance**: With the **performance** governor, the driver instructs internal CPU logic to be performance-oriented. The range of allowed P-states is restricted to the upper boundary of the range that the driver is allowed to use.

- **powersave**: With the **powersave** governor, the driver instructs internal CPU logic to be powersave-oriented.

**Active mode without hardware-managed P-states**

When active mode without HWP is used, the Intel P-state driver provides two P-state selection algorithms:
• **performance**: With the performance governor, the driver chooses the maximum P-state it is allowed to use.

• **powersave**: With the powersave governor, the driver chooses P-states proportional to the current CPU utilization. The behavior is similar to the ondemand CPUfreq core governor.

**Passive mode**
When the passive mode is used, the Intel P-state driver functions the same as the traditional CPUfreq scaling driver. All available generic CPUFreq core governors can be used.

### 17.3.4. Setting up CPUfreq governor

All CPUfreq drivers are built in as part of the kernel-tools package, and selected automatically. To set up CPUfreq, you need to select a governor.

**Prerequisites**

- To use cpupower, install the kernel-tools package:

  ```sh
  # yum install kernel-tools
  ```

**Procedure**

1. View which governors are available for use for a specific CPU:

   ```sh
   # cpupower frequency-info --governors
   analyzing CPU 0:
   available cpufreq governors: performance powersave
   ```

2. Enable one of the governors on all CPUs:

   ```sh
   # cpupower frequency-set --governor performance
   ```

   Replace the performance governor with the cpufreq governor name as per your requirement.

   To only enable a governor on specific cores, use -c with a range or comma-separated list of CPU numbers. For example, to enable the userspace governor for CPUs 1-3 and 5, use:

   ```sh
   # cpupower -c 1-3,5 frequency-set --governor cpufreq_userspace
   ```

**NOTE**

If the kernel-tools package is not installed, the CPUfreq settings can be viewed in the /sys/devices/system/cpu/cpu[0-9]/directory. Settings and values can be changed by writing to these tunables. For example, to set the minimum clock speed of cpu0 to 360 MHz, use:

```sh
# echo 360000 > /sys/devices/system/cpu/cpu0/cpufreq/scaling_min_freq
```

**Verification**

- Verify that the governor is enabled:
# cpupower frequency-info
analyzing CPU 0:
    driver: intel_pstate
    CPUs which run at the same hardware frequency: 0
    CPUs which need to have their frequency coordinated by software: 0
    maximum transition latency: Cannot determine or is not supported.
    hardware limits: 400 MHz - 4.20 GHz
    available cpufreq governors: performance powersave
    current policy: frequency should be within 400 MHz and 4.20 GHz.
    The governor "performance" may decide which speed to use within this range.
    current CPU frequency: Unable to call hardware
    current CPU frequency: 3.88 GHz (asserted by call to kernel)
    boost state support:
        Supported: yes
        Active: yes

The current policy displays the recently enabled cpufreq governor. In this case, it is performance.

Additional resources

- cpupower-frequency-info(1) and cpupower-frequency-set(1) man pages
CHAPTER 18. GETTING STARTED WITH PERF

As a system administrator, you can use the perf tool to collect and analyze performance data of your system.

18.1. INTRODUCTION TO PERF

The perf user-space tool interfaces with the kernel-based subsystem Performance Counters for Linux (PCL). perf is a powerful tool that uses the Performance Monitoring Unit (PMU) to measure, record, and monitor a variety of hardware and software events. perf also supports tracepoints, kprobes, and uprobes.

18.2. INSTALLING PERF

This procedure installs the perf user-space tool.

Procedure

- Install the perf tool:
  
  # yum install perf

18.3. COMMON PERF COMMANDS

perf stat

This command provides overall statistics for common performance events, including instructions executed and clock cycles consumed. Options allow for selection of events other than the default measurement events.

perf record

This command records performance data into a file, perf.data, which can be later analyzed using the perf report command.

perf report

This command reads and displays the performance data from the perf.data file created by perf record.

perf list

This command lists the events available on a particular machine. These events will vary based on performance monitoring hardware and software configuration of the system.

perf top

This command performs a similar function to the top utility. It generates and displays a performance counter profile in realtime.

perf trace

This command performs a similar function to the strace tool. It monitors the system calls used by a specified thread or process and all signals received by that application.

perf help

This command displays a complete list of perf commands.

Additional resources
- Add the **--help** option to a subcommand to open the man page.
CHAPTER 19. PROFILING CPU USAGE IN REAL TIME WITH PERF TOP

You can use the perf top command to measure CPU usage of different functions in real time.

Prerequisites
- You have the perf user space tool installed as described in Installing perf.

19.1. THE PURPOSE OF PERF TOP

The perf top command is used for real time system profiling and functions similarly to the top utility. However, where the top utility generally shows you how much CPU time a given process or thread is using, perf top shows you how much CPU time each specific function uses. In its default state, perf top tells you about functions being used across all CPUs in both the user-space and the kernel-space. To use perf top you need root access.

19.2. PROFILING CPU USAGE WITH PERF TOP

This procedure activates perf top and profiles CPU usage in real time.

Prerequisites
- You have the perf user space tool installed as described in Installing perf.
- You have root access

Procedure
- Start the perf top monitoring interface:

  # perf top

The monitoring interface looks similar to the following:

<table>
<thead>
<tr>
<th>Overhead</th>
<th>Shared Object</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.20%</td>
<td>[kernel]</td>
<td>[k] do_syscall_64</td>
</tr>
<tr>
<td>2.17%</td>
<td>[kernel]</td>
<td>[k] module_get_kallsym</td>
</tr>
<tr>
<td>1.49%</td>
<td>[kernel]</td>
<td>[k] copy_user_enhanced_fast_string</td>
</tr>
<tr>
<td>1.37%</td>
<td>libpthread-2.29.so</td>
<td>pthread_mutex_lock 1.31% [unknown] [.] 00000000000000000</td>
</tr>
<tr>
<td>1.07%</td>
<td>[kernel]</td>
<td>[k] psi_task_change</td>
</tr>
<tr>
<td>0.94%</td>
<td>[kernel]</td>
<td>[k] switch_mm_irqs_off</td>
</tr>
<tr>
<td>0.74%</td>
<td>[kernel]</td>
<td>[k] entry_SYSCALL_64</td>
</tr>
<tr>
<td>0.69%</td>
<td>[kernel]</td>
<td>[k] syscall_return_via_sysret</td>
</tr>
<tr>
<td>0.69%</td>
<td>libxul.so</td>
<td>[.] 0x000000000113f9b0</td>
</tr>
<tr>
<td>0.67%</td>
<td>[kernel]</td>
<td>[k] kallsyms_expand_symbol.constprop.0</td>
</tr>
<tr>
<td>0.65%</td>
<td>firefox</td>
<td>[.] moz_xmalloc</td>
</tr>
<tr>
<td>0.65%</td>
<td>libpthread-2.29.so</td>
<td>pthread_mutex_unlock_usercnt 0.60% firefox</td>
</tr>
<tr>
<td>0.60%</td>
<td>libxul.so</td>
<td>[.] 0x000000000241d1cd</td>
</tr>
<tr>
<td>0.60%</td>
<td>[kernel]</td>
<td>[k] do_sys_poll</td>
</tr>
</tbody>
</table>
In this example, the kernel function `do_syscall_64` is using the most CPU time.

Additional resources

- `perf-top(1)` man page

19.3. INTERPRETATION OF PERF TOP OUTPUT

The `perf top` monitoring interface displays the data in several columns:

The "Overhead" column
- Displays the percent of CPU a given function is using.

The "Shared Object" column
- Displays name of the program or library which is using the function.

The "Symbol" column
- Displays the function name or symbol. Functions executed in the kernel-space are identified by `[k]` and functions executed in the user-space are identified by `[.]`.

19.4. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES

For kernel functions, `perf` uses the information from the `/proc/kallsyms` file to map the samples to their respective function names or symbols. For functions executed in the user space, however, you might see raw function addresses because the binary is stripped.

The `debuginfo` package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information turned on (the `-g` option in GCC) to display the function names or symbols in such a situation.

**NOTE**

It is not necessary to re-run the `perf record` command after installing the `debuginfo` associated with an executable. Simply re-run the `perf report` command.

Additional Resources

- Enabling debugging with debugging information

19.5. ENABLING DEBUG AND SOURCE REPOSITORIES

A standard installation of Red Hat Enterprise Linux does not enable the debug and source repositories. These repositories contain information needed to debug the system components and measure their performance.

Procedure

- Enable the source and debug information package channels:
# subscription-manager repos --enable rhel-8-for-$(uname -i)-baseos-debug-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-baseos-source-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-appstream-debug-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-appstream-source-rpms

The `$(uname -i)` part is automatically replaced with a matching value for architecture of your system:

<table>
<thead>
<tr>
<th>Architecture name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>64-bit Intel and AMD</td>
<td>x86_64</td>
</tr>
<tr>
<td>64-bit ARM</td>
<td>aarch64</td>
</tr>
<tr>
<td>IBM POWER</td>
<td>ppc64le</td>
</tr>
<tr>
<td>64-bit IBM Z</td>
<td>s390x</td>
</tr>
</tbody>
</table>

19.6. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB

Debugging information is required to debug code. For code that is installed from a package, the GNU Debugger (GDB) automatically recognizes missing debug information, resolves the package name and provides concrete advice on how to get the package.

Prerequisites

- The application or library you want to debug must be installed on the system.
- GDB and the `debuginfo-install` tool must be installed on the system. For details, see Setting up to debug applications.
- Repositories providing `debuginfo` and `debugsource` packages must be configured and enabled on the system. For details, see Enabling debug and source repositories.

Procedure

1. Start GDB attached to the application or library you want to debug. GDB automatically recognizes missing debugging information and suggests a command to run.

   ```bash
   $ gdb -q /bin/ls
   Reading symbols from /bin/ls...Reading symbols from .gnu_debugdata for /usr/bin/ls...(no debugging symbols found)...done.
   (no debugging symbols found)...done.
   Missing separate debuginfos, use: dnf debuginfo-install coreutils-8.30-6.el8.x86_64
   (gdb)
   
   (gdb) q
   ```

2. Exit GDB: type `q` and confirm with `Enter`.
3. Run the command suggested by GDB to install the required **debuginfo** packages:

```
# dnf debuginfo-install coreutils-8.30-6.el8.x86_64
```

The **dnf** package management tool provides a summary of the changes, asks for confirmation and once you confirm, downloads and installs all the necessary files.

4. In case GDB is not able to suggest the **debuginfo** package, follow the procedure described in **Getting debuginfo packages for an application or library manually**.

**Additional resources**

- **How can I download or install debuginfo packages for RHEL systems?** — Red Hat Knowledgebase solution
CHAPTER 20. COUNTING EVENTS DURING PROCESS EXECUTION WITH PERF STAT

You can use the `perf stat` command to count hardware and software events during process execution.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

20.1. THE PURPOSE OF PERF STAT

The `perf stat` command executes a specified command, keeps a running count of hardware and software event occurrences during the commands execution, and generates statistics of these counts. If you do not specify any events, then `perf stat` counts a set of common hardware and software events.

20.2. COUNTING EVENTS WITH PERF STAT

You can use `perf stat` to count hardware and software event occurrences during command execution and generate statistics of these counts. By default, `perf stat` operates in per-thread mode.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

- Count the events.
  
  - Running the `perf stat` command without root access will only count events occurring in the user space:

```
$ perf stat ls
```

Example 20.1. Output of perf stat ran without root access

```
Desktop  Documents  Downloads  Music  Pictures  Public  Templates  Videos

Performance counter stats for 'ls':

    1.28 msec task-clock:u    #    0.165 CPUs utilized
    0  context-switches:u    #    0.000 M/sec
    0  cpu-migrations:u    #    0.000 K/sec
   104  page-faults:u    #    0.081 M/sec
1,054,302  cycles:u                #    0.823 GHz
1,136,989  instructions:u         #    1.08  insn per cycle
228,531  branches:u    #  178.447 M/sec
11,331  branch-misses:u    #    4.96% of all branches

0.007754312 seconds time elapsed

0.000000000 seconds user
0.007717000 seconds sys
```
As you can see in the previous example, when `perf stat` runs without root access the event names are followed by `.u`, indicating that these events were counted only in the user-space.

- To count both user-space and kernel-space events, you must have root access when running `perf stat`:

  ```
  # perf stat ls
  ```

**Example 20.2. Output of perf stat ran with root access**

```
Desktop  Documents  Downloads  Music  Pictures  Public  Templates  Videos

Performance counter stats for 'ls':

3.09 msec task-clock # 0.119 CPUs utilized
18 context-switches # 0.006 M/sec
3 cpu-migrations # 0.969 K/sec
108 page-faults # 0.035 M/sec
6,576,004 cycles # 2.125 GHz
5,694,223 instructions # 0.87 insn per cycle
1,092,372 branches # 352.960 M/sec
31,515 branch-misses # 2.89% of all branches

0.026020043 seconds time elapsed

0.000000000 seconds user
0.014061000 seconds sys
```

- By default, `perf stat` operates in per-thread mode. To change to CPU-wide event counting, pass the `-a` option to `perf stat`. To count CPU-wide events, you need root access:

  ```
  # perf stat -a ls
  ```

**Additional resources**

- `perf-stat(1)` man page

**20.3. INTERPRETATION OF PERF STAT OUTPUT**

`perf stat` executes a specified command and counts event occurrences during the command's execution and displays statistics of these counts in three columns:

1. The number of occurrences counted for a given event

2. The name of the event that was counted

3. When related metrics are available, a ratio or percentage is displayed after the hash sign (`#`) in the right-most column.

For example, when running in default mode, `perf stat` counts both cycles and instructions and, therefore, calculates and displays instructions per cycle in the right-most column. You can see similar behavior with regard to branch-misses as a percent of all branches since both events are
counted by default.

## 20.4. Attaching perf stat to a Running Process

You can attach `perf stat` to a running process. This will instruct `perf stat` to count event occurrences only in the specified processes during the execution of a command.

### Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

### Procedure

- Attach `perf stat` to a running process:

  ```
  $ perf stat -p ID1,ID2 sleep seconds
  ```

  The previous example counts events in the processes with the IDs of `ID1` and `ID2` for a time period of `seconds` seconds as dictated by using the `sleep` command.

### Additional resources

- `perf-stat(1)` man page
CHAPTER 21. RECORDING AND ANALYZING PERFORMANCE PROFILES WITH PERF

The `perf` tool allows you to record performance data and analyze it at a later time.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

21.1. THE PURPOSE OF PERF RECORD

The `perf record` command samples performance data and stores it in a file, `perf.data`, which can be read and visualized with other `perf` commands. `perf.data` is generated in the current directory and can be accessed at a later time, possibly on a different machine.

If you do not specify a command for `perf record` to record during, it will record until you manually stop the process by pressing `Ctrl+C`. You can attach `perf record` to specific processes by passing the `-p` option followed by one or more process IDs. You can run `perf record` without root access, however, doing so will only sample performance data in the user space. In the default mode, `perf record` uses CPU cycles as the sampling event and operates in per-thread mode with inherit mode enabled.

21.2. RECORDING A PERFORMANCE PROFILE WITHOUT ROOT ACCESS

You can use `perf record` without root access to sample and record performance data in the user-space only.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

- Sample and record the performance data:

  ```
  $ perf record command
  ```

  Replace `command` with the command you want to sample data during. If you do not specify a command, then `perf record` will sample data until you manually stop it by pressing `Ctrl+C`.

Additional resources

- `perf-record(1)` man page

21.3. RECORDING A PERFORMANCE PROFILE WITH ROOT ACCESS

You can use `perf record` with root access to sample and record performance data in both the user-space and the kernel-space simultaneously.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.
You have root access.

Procedure

- Sample and record the performance data:
  
  ```bash
  # perf record command
  ```

  Replace `command` with the command you want to sample data during. If you do not specify a command, then `perf record` will sample data until you manually stop it by pressing `Ctrl+C`.

Additional resources

- `perf-record(1)` man page

21.4. RECORDING A PERFORMANCE PROFILE IN PER-CPU MODE

You can use `perf record` in per-CPU mode to sample and record performance data in both and user-space and the kernel-space simultaneously across all threads on a monitored CPU. By default, per-CPU mode monitors all online CPUs.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

- Sample and record the performance data:
  
  ```bash
  # perf record -a command
  ```

  Replace `command` with the command you want to sample data during. If you do not specify a command, then `perf record` will sample data until you manually stop it by pressing `Ctrl+C`.

Additional resources

- `perf-record(1)` man page

21.5. CAPTURING CALL GRAPH DATA WITH PERF RECORD

You can configure the `perf record` tool so that it records which function is calling other functions in the performance profile. This helps to identify a bottleneck if several processes are calling the same function.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

- Sample and record performance data with the `--call-graph` option:
  
  ```bash
  $ perf record --call-graph method command
  ```
Replace `command` with the command you want to sample data during. If you do not specify a command, then `perf record` will sample data until you manually stop it by pressing `Ctrl+C`.

- Replace `method` with one of the following unwinding methods:

  - **fp**
    
    Uses the frame pointer method. Depending on compiler optimization, such as with binaries built with the GCC option `--fomit-frame-pointer`, this may not be able to unwind the stack.

  - **dwarf**
    
    Uses DWARF Call Frame Information to unwind the stack.

  - **lbr**
    
    Uses the last branch record hardware on Intel processors.

Additional resources

- `perf-record(1)` man page

### 21.6. ANALYZING PERF.DATA WITH PERF REPORT

You can use `perf report` to display and analyze a `perf.data` file.

**Prerequisites**

- You have the `perf` user space tool installed as described in [Installing perf](#).
- There is a `perf.data` file in the current directory.
- If the `perf.data` file was created with root access, you need to run `perf report` with root access too.

**Procedure**

- Display the contents of the `perf.data` file for further analysis:

```
# perf report
```

This command displays output similar to the following:

```
| Samples: 2K of event 'cycles', Event count (approx.): 235462960 |
|-------------------|-----------------|-----------------|-----------------|
| Overhead          | Command         | Shared Object   | Symbol          |
|                   |                 |                 |                 |
| 2.36%             | kswapd          | [kernel.kallsyms]     | [k] page_vma_mapped_walk |
| 2.13%             | sssd_kcm        | libc-2.28.so       | [] memset_avx2_erms 2.13% perf  |
|                   | [kernel.kallsyms] | [k] smp_call_function_single | 1.53% gnome-shell libc-2.28.so | [] stcmp_avx2 |
|                   |                 | libc-2.0.so.0.5600.4 | [] g_hash_table_lookup |
| 0.93%             | Xorg            | libc-2.28.so       | [] memmove_avx_unaligned_erms 0.89% gnome-shell libgobject-2.0.so.0.5600.4 | [] g_object_unref 0.87% kswapd0 [kernel.kallsyms] | [k] page_referenced_one 0.86% gnome-shell libc-2.28.so | [] memmove_avx_unaligned_erms 0.83% Xorg [kernel.kallsyms] | [k] alloc_vmap_area |
| 0.63%             | gnome-shell     | libglib-2.0.so.0.5600.4 | [] g_slice_alloc  |
| 0.53%             | gnome-shell     | libgirepository-1.0.so.1.0.0 | [] g_base_info_unref |
```
21.7. INTERPRETATION OF PERF REPORT OUTPUT

The table displayed by running the `perf report` command sorts the data into several columns:

The 'Overhead' column
   Indicates what percentage of overall samples were collected in that particular function.

The 'Command' column
   Tells you which process the samples were collected from.

The 'Shared Object' column
   Displays the name of the ELF image where the samples come from (the name [kernel.kallsyms] is used when the samples come from the kernel).

The 'Symbol' column
   Displays the function name or symbol.

In default mode, the functions are sorted in descending order with those with the highest overhead displayed first.

21.8. GENERATING A PERF.DATA FILE THAT IS READABLE ON A DIFFERENT DEVICE

You can use the `perf` tool to record performance data into a `perf.data` file to be analyzed on a different device.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.
- The kernel `debuginfo` package is installed. For more information, see Getting debuginfo packages for an application or library using GDB.

Procedure

1. Capture performance data you are interested in investigating further:

   ```bash
   # perf record -a --call-graph fp sleep seconds
   ```
This example would generate a perf.data over the entire system for a period of **seconds** seconds as dictated by the use of the `sleep` command. It would also capture call graph data using the frame pointer method.

2. Generate an archive file containing debug symbols of the recorded data:

   ```
   # perf archive
   ```

**Verification steps**

- Verify that the archive file has been generated in your current active directory:

  ```
  # ls perf.data*
  ```

  The output will display every file in your current directory that begins with `perf.data`. The archive file will be named either:

  ```
  perf.data.tar.gz
  ```
  or

  ```
  perf.data.tar.bz2
  ```

**Additional resources**

- Recording and analyzing performance profiles with perf
- Capturing call graph data with perf record

### 21.9. ANALYZING A PERF.DATA FILE THAT WAS CREATED ON A DIFFERENT DEVICE

You can use the `perf` tool to analyze a perf.data file that was generated on a different device.

**Prerequisites**

- You have the `perf` user space tool installed as described in Installing perf.
- A perf.data file and associated archive file generated on a different device are present on the current device being used.

**Procedure**

1. Copy both the perf.data file and the archive file into your current active directory.

2. Extract the archive file into `~/.debug`

   ```
   # mkdir -p ~/.debug
   # tar xf perf.data.tar.bz2 -C ~/.debug
   ```

**NOTE**

Red Hat Enterprise Linux 8 Monitoring and managing system status and performance
3. Open the `perf.data` file for further analysis:

```
# perf report
```

## 21.10. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES

For kernel functions, `perf` uses the information from the `/proc/kallsyms` file to map the samples to their respective function names or symbols. For functions executed in the user space, however, you might see raw function addresses because the binary is stripped.

The `debuginfo` package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information turned on (the `-g` option in GCC) to display the function names or symbols in such a situation.

### NOTE

It is not necessary to re-run the `perf record` command after installing the `debuginfo` associated with an executable. Simply re-run the `perf report` command.

### Additional Resources

- [Enabling debugging with debugging information](#)

## 21.11. ENABLING DEBUG AND SOURCE REPOSITORIES

A standard installation of Red Hat Enterprise Linux does not enable the debug and source repositories. These repositories contain information needed to debug the system components and measure their performance.

### Procedure

- Enable the source and debug information package channels:

  ```bash
  # subscription-manager repos --enable rhel-8-for-$({uname} -i)-baseos-debug-rpms
  # subscription-manager repos --enable rhel-8-for-$({uname} -i)-baseos-source-rpms
  # subscription-manager repos --enable rhel-8-for-$({uname} -i)-appstream-debug-rpms
  # subscription-manager repos --enable rhel-8-for-$({uname} -i)-appstream-source-rpms
  ```

The `$(uname -i)` part is automatically replaced with a matching value for architecture of your system:

<table>
<thead>
<tr>
<th>Architecture name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>64-bit Intel and AMD</td>
<td>x86_64</td>
</tr>
<tr>
<td>64-bit ARM</td>
<td>aarch64</td>
</tr>
</tbody>
</table>
21.12. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB

Debugging information is required to debug code. For code that is installed from a package, the GNU Debugger (GDB) automatically recognizes missing debug information, resolves the package name and provides concrete advice on how to get the package.

Prerequisites

- The application or library you want to debug must be installed on the system.
- GDB and the debuginfo-install tool must be installed on the system. For details, see Setting up to debug applications.
- Repositories providing debuginfo and debugsource packages must be configured and enabled on the system. For details, see Enabling debug and source repositories.

Procedure

1. Start GDB attached to the application or library you want to debug. GDB automatically recognizes missing debugging information and suggests a command to run.

```
$ gdb -q /bin/ls
Reading symbols from /bin/ls...Reading symbols from .gnu_debugdata for /usr/bin/ls...(no
debugging symbols found)...done.
(no debugging symbols found)...done.
Missing separate debuginfos, use: dnf debuginfo-install coreutils-8.30-6.el8.x86_64
(gdb)
```

2. Exit GDB: type q and confirm with Enter.

```
(gdb) q
```

3. Run the command suggested by GDB to install the required debuginfo packages:

```
# dnf debuginfo-install coreutils-8.30-6.el8.x86_64
```

The dnf package management tool provides a summary of the changes, asks for confirmation and once you confirm, downloads and installs all the necessary files.

4. In case GDB is not able to suggest the debuginfo package, follow the procedure described in Getting debuginfo packages for an application or library manually.

CHAPTER 22. INVESTIGATING BUSY CPUS WITH PERF

When investigating performance issues on a system, you can use the `perf` tool to identify and monitor the busiest CPUs in order to focus your efforts.

22.1. DISPLAYING WHICH CPU EVENTS WERE COUNTED ON WITH PERF STAT

You can use `perf stat` to display which CPU events were counted on by disabling CPU count aggregation. You must count events in system-wide mode by using the `-a` flag in order to use this functionality.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

- Count the events with CPU count aggregation disabled:

  ```
  # perf stat -a -A sleep seconds
  
  The previous example displays counts of a default set of common hardware and software events recorded over a time period of `seconds` seconds, as dictated by using the `sleep` command, over each individual CPU in ascending order, starting with `CPU0`. As such, it may be useful to specify an event such as `cycles`:
  
  ```
  # perf stat -a -A -e cycles sleep seconds
  ```

22.2. DISPLAYING WHICH CPU SAMPLES WERE TAKEN ON WITH PERF REPORT

The `perf record` command samples performance data and stores this data in a `perf.data` file which can be read with the `perf report` command. The `perf record` command always records which CPU samples were taken on. You can configure `perf report` to display this information.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

  - There is a `perf.data` file created with `perf record` in the current directory. If the `perf.data` file was created with root access, you need to run `perf report` with root access too.

Procedure

- Display the contents of the `perf.data` file for further analysis while sorting by CPU:

  ```
  # perf report --sort cpu
  
  You can sort by CPU and command to display more detailed information about where CPU time is being spent:
This example will list commands from all monitored CPUs by total overhead in descending order of overhead usage and identify the CPU the command was executed on.

Additional resources

- Recording and analyzing performance profiles with perf

22.3. DISPLAYING SPECIFIC CPUS DURING PROFILING WITH PERF TOP

You can configure `perf top` to display specific CPUs and their relative usage while profiling your system in real time.

**Prerequisites**

- You have the `perf` user space tool installed as described in Installing perf.

**Procedure**

- Start the `perf top` interface while sorting by CPU:

  ```
  # perf top --sort cpu
  ```

  This example will list CPUs and their respective overhead in descending order of overhead usage in real time.

  - You can sort by CPU and command for more detailed information of where CPU time is being spent:

    ```
    # perf top --sort cpu,comm
    ```

    This example will list commands by total overhead in descending order of overhead usage and identify the CPU the command was executed on in real time.

22.4. MONITORING SPECIFIC CPUS WITH PERF RECORD AND PERF REPORT

You can configure `perf record` to only sample specific CPUs of interest and analyze the generated `perf.data` file with `perf report` for further analysis.

**Prerequisites**

- You have the `perf` user space tool installed as described in Installing perf.

**Procedure**

1. Sample and record the performance data in the specific CPU’s, generating a `perf.data` file:

   - Using a comma separated list of CPUs:
# perf record -C 0,1 sleep seconds

The previous example samples and records data in CPUs 0 and 1 for a period of `seconds` seconds as dictated by the use of the `sleep` command.

- Using a range of CPUs:

  # perf record -C 0-2 sleep seconds

  The previous example samples and records data in all CPUs from CPU 0 to 2 for a period of `seconds` seconds as dictated by the use of the `sleep` command.

2. Display the contents of the `perf.data` file for further analysis:

  # perf report

  This example will display the contents of `perf.data`. If you are monitoring several CPUs and want to know which CPU data was sampled on, see Displaying which CPU samples were taken on with `perf report`. 
CHAPTER 23. MONITORING APPLICATION PERFORMANCE WITH PERF

You can use the **perf** tool to monitor and analyze application performance.

### 23.1. ATTACHING PERF RECORD TO A RUNNING PROCESS

You can attach **perf record** to a running process. This will instruct **perf record** to only sample and record performance data in the specified processes.

**Prerequisites**

- You have the **perf** user space tool installed as described in *Installing perf*.

**Procedure**

- Attach **perf record** to a running process:
  
  ```
  $ perf record -p ID1,ID2 sleep seconds
  ```

  The previous example samples and records performance data of the processes with the process ID's **ID1** and **ID2** for a time period of **seconds** seconds as dictated by using the **sleep** command. You can also configure **perf** to record events in specific threads:

  ```
  $ perf record -t ID1,ID2 sleep seconds
  ```

  **NOTE**

  When using the **-t** flag and stipulating thread ID’s, **perf** disables inheritance by default. You can enable inheritance by adding the **--inherit** option.

### 23.2. CAPTURING CALL GRAPH DATA WITH PERF RECORD

You can configure the **perf record** tool so that it records which function is calling other functions in the performance profile. This helps to identify a bottleneck if several processes are calling the same function.

**Prerequisites**

- You have the **perf** user space tool installed as described in *Installing perf*.

**Procedure**

- Sample and record performance data with the **--call-graph** option:
  
  ```
  $ perf record --call-graph method command
  ```

  - Replace **command** with the command you want to sample data during. If you do not specify a command, then **perf record** will sample data until you manually stop it by pressing **Ctrl+C**.

  - Replace **method** with one of the following unwinding methods:
1p

Uses the frame pointer method. Depending on compiler optimization, such as with binaries built with the GCC option --fomit-frame-pointer, this may not be able to unwind the stack.

dwarf

Uses DWARF Call Frame Information to unwind the stack.

lbr

Uses the last branch record hardware on Intel processors.

Additional resources

- perf-record(1) man page

23.3. ANALYZING PERF.DATA WITH PERF REPORT

You can use perf report to display and analyze a perf.data file.

Prerequisites

- You have the perf user space tool installed as described in Installing perf.
- There is a perf.data file in the current directory.
- If the perf.data file was created with root access, you need to run perf report with root access too.

Procedure

- Display the contents of the perf.data file for further analysis:

```
# perf report
```

This command displays output similar to the following:

<table>
<thead>
<tr>
<th>Overhead %</th>
<th>Command</th>
<th>Shared Object</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.36%</td>
<td>kswapd0 [kernel.kallsyms]</td>

Additional resources

- **perf-report(1)** man page
CHAPTER 24. CREATING UPROBES WITH PERF

24.1. CREATING UPROBES AT THE FUNCTION LEVEL WITH PERF

You can use the `perf` tool to create dynamic tracepoints at arbitrary points in a process or application. These tracepoints can then be used in conjunction with other `perf` tools such as `perf stat` and `perf record` to better understand the process or applications behavior.

**Prerequisites**

- You have the `perf` user space tool installed as described in Installing perf.

**Procedure**

1. Create the uprobe in the process or application you are interested in monitoring at a location of interest within the process or application:

   ```bash
   # perf probe -x /path/to/executable -a function
   Added new event:
   probe_executable:function (on function in /path/to/executable)
   
   You can now use it in all perf tools, such as:
   
   perf record -e probe_executable:function -aR sleep 1
   ``

**Additional resources**

- `perf-probe` man page
- Recording and analyzing performance profiles with perf
- Counting events during process execution with perf stat

24.2. CREATING UPROBES ON LINES WITHIN A FUNCTION WITH PERF

These tracepoints can then be used in conjunction with other `perf` tools such as `perf stat` and `perf record` to better understand the process or applications behavior.

**Prerequisites**

- You have the `perf` user space tool installed as described in Installing perf.
- You have gotten the debugging symbols for your executable:

  ```bash
  # objdump -t ./your_executable | head
  ``

**NOTE**

To do this, the `debuginfo` package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information, the `-g` option in GCC.
Procedure

1. View the function lines where you can place a uprobe:

   $ perf probe -x ./your_executable -L main

   Output of this command looks similar to:

   <main@/home/user/my_executable:0>
   0 int main(int argc, const char **argv)
   1 {
      int err;
      const char *cmd;
      char sbuf[STRERR_BUFSIZE];

      /* libsubcmd init */
      7 exec_cmd_init("perf", PREFIX, PERF_EXEC_PATH,
                      EXEC_PATH_ENVIRONMENT);
      8 pager_init(PERF_PAGER_ENVIRONMENT);

2. Create the uprobe for the desired function line:

   # perf probe -x ./my_executable main:8
   Added new event:
   probe_my_executable:main_L8 (on main:8 in /home/user/my_executable)

   You can now use it in all perf tools, such as:

   perf record -e probe_my_executable:main_L8 -aR sleep 1

24.3. PERF SCRIPT OUTPUT OF DATA RECORDED OVER UPROBES

A common method to analyze data collected using uprobes is using the perf script command to read a perf.data file and display a detailed trace of the recorded workload.

In the perf script example output:

- A uprobe is added to the function isprime() in a program called my_prog
- a is a function argument added to the uprobe. Alternatively, a could be an arbitrary variable visible in the code scope of where you add your uprobe:

   # perf script
   my_prog 1367 [007] 10802159.906593: probe_my_prog:isprime: (400551) a=2
   my_prog 1367 [007] 10802159.906623: probe_my_prog:isprime: (400551) a=3
   my_prog 1367 [007] 10802159.906625: probe_my_prog:isprime: (400551) a=4
   my_prog 1367 [007] 10802159.906627: probe_my_prog:isprime: (400551) a=5
   my_prog 1367 [007] 10802159.906629: probe_my_prog:isprime: (400551) a=6
   my_prog 1367 [007] 10802159.906631: probe_my_prog:isprime: (400551) a=7
   my_prog 1367 [007] 10802159.906633: probe_my_prog:isprime: (400551) a=13
   my_prog 1367 [007] 10802159.906635: probe_my_prog:isprime: (400551) a=17
   my_prog 1367 [007] 10802159.906637: probe_my_prog:isprime: (400551) a=19
CHAPTER 25. PROFILING MEMORY ACCESSES WITH PERF MEM

You can use the `perf mem` command to sample memory accesses on your system.

25.1. THE PURPOSE OF PERF MEM

The `mem` subcommand of the `perf` tool enables the sampling of memory accesses (loads and stores). The `perf mem` command provides information about memory latency, types of memory accesses, functions causing cache hits and misses, and, by recording the data symbol, the memory locations where these hits and misses occur.

25.2. SAMPLING MEMORY ACCESS WITH PERF MEM

This procedure describes how to use the `perf mem` command to sample memory accesses on your system. The command takes the same options as `perf record` and `perf report` as well as some options exclusive to the `mem` subcommand. The recorded data is stored in a `perf.data` file in the current directory for later analysis.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

1. Sample the memory accesses:

   ```
   # perf mem record -a sleep seconds
   ```

   This example samples memory accesses across all CPUs for a period of `seconds` seconds as dictated by the `sleep` command. You can replace the `sleep` command for any command during which you want to sample memory access data. By default, `perf mem` samples both memory loads and stores. You can select only one memory operation by using the `-t` option and specifying either "load" or "store" between `perf mem` and `record`. For loads, information over the memory hierarchy level, TLB memory accesses, bus snoops, and memory locks is captured.

2. Open the `perf.data` file for analysis:

   ```
   # perf mem report
   ```

   If you have used the example commands, the output is:

   ```
   Available samples
   35k cpu/mem-loads,ldlat=30/P
   54k cpu/mem-stores/P
   ```

   The `cpu/mem-loads,ldlat=30/P` line denotes data collected over memory loads and the `cpu/mem-stores/P` line denotes data collected over memory stores. Highlight the category of interest and press Enter to view the data:

   ```
   Samples: 35K of event 'cpu/mem-loads,ldlat=30/P', Event count (approx.): 4067062
   Overhead  Samples  Local Weight  Memory access  Symbol
   ```
<table>
<thead>
<tr>

Alternatively, you can sort your results to investigate different aspects of interest when displaying the data. For example, to sort data over memory loads by type of memory accesses occurring during the sampling period in descending order of overhead they account for:

# perf mem -t load report --sort=mem

For example, the output can be:

Samples: 35K of event 'cpu/mem-loads,ldlat=30/P', Event count (approx.): 40670

Additional resources

- perf-mem(1) man page.

25.3. INTERPRETATION OF PERF MEM REPORT OUTPUT

The table displayed by running the `perf mem report` command without any modifiers sorts the data into several columns:

The 'Overhead' column

Indicates percentage of overall samples collected in that particular function.

The 'Samples' column

Displays the number of samples accounted for by that row.

The 'Local Weight' column

Displays the access latency in processor core cycles.

The 'Memory Access' column

Displays the type of memory access that occurred.

The 'Symbol' column

Displays the function name or symbol.

The 'Shared Object' column

Displays the name of the ELF image where the samples come from (the name `kernel.kallsyms` is used when the samples come from the kernel).

The 'Data Symbol' column

Displays the address of the memory location that row was targeting.

IMPORTANT

Oftentimes, due to dynamic allocation of memory or stack memory being accessed, the 'Data Symbol' column will display a raw address.
The “Snoop” column
Displays bus transactions.

The 'TLB Access' column
Displays TLB memory accesses.

The 'Locked' column
Indicates if a function was or was not memory locked.

In default mode, the functions are sorted in descending order with those with the highest overhead displayed first.
CHAPTER 26. DETECTING FALSE SHARING

False sharing occurs when a processor core on a Symmetric Multi Processing (SMP) system modifies data items on the same cache line that is in use by other processors to access other data items that are not being shared between the processors.

This initial modification requires that the other processors using the cache line invalidate their copy and request an updated one despite the processors not needing, or even necessarily having access to, an updated version of the modified data item.

You can use the `perf c2c` command to detect false sharing.

26.1. THE PURPOSE OF PERF C2C

The `c2c` subcommand of the `perf` tool enables Shared Data Cache-to-Cache (C2C) analysis. You can use the `perf c2c` command to inspect cache-line contention to detect both true and false sharing.

Cache-line contention occurs when a processor core on a Symmetric Multi Processing (SMP) system modifies data items on the same cache line that is in use by other processors. All other processors using this cache-line must then invalidate their copy and request an updated one. This can lead to degraded performance.

The `perf c2c` command provides the following information:

- Cache lines where contention has been detected
- Processes reading and writing the data
- Instructions causing the contention
- The Non-Uniform Memory Access (NUMA) nodes involved in the contention

26.2. DETECTING CACHE-LINE CONTENTION WITH PERF C2C

Use the `perf c2c` command to detect cache-line contention in a system.

The `perf c2c` command supports the same options as `perf record` as well as some options exclusive to the `c2c` subcommand. The recorded data is stored in a `perf.data` file in the current directory for later analysis.

Prerequisites

- The `perf` user space tool is installed. For more information, see `installing perf`.

Procedure

- Use `perf c2c` to detect cache-line contention:

```
# perf c2c record -a sleep seconds
```

This example samples and records cache-line contention data across all CPU’s for a period of `seconds` as dictated by the `sleep` command. You can replace the `sleep` command with any command you want to collect cache-line contention data over.
26.3. VISUALIZING A PERF.DATA FILE RECORDED WITH PERF C2C RECORD

This procedure describes how to visualize the perf.data file, which is recorded using the perf c2c command.

Prerequisites

- The perf user space tool is installed. For more information, see Installing perf.
- A perf.data file recorded using the perf c2c command is available in the current directory. For more information, see Detecting cache-line contention with perf c2c.

Procedure

1. Open the perf.data file for further analysis:

```
# perf c2c report --stdio
```

This command visualizes the perf.data file into several graphs within the terminal:

### 26.4. INTERPRETATION OF PERF C2C REPORT OUTPUT

The visualization displayed by running the `perf c2c report --stdio` command sorts the data into several tables:

**Trace Events Information**

This table provides a high level summary of all the load and store samples, which are collected by the `perf c2c record` command.

**Global Shared Cache Line Event Information**

This table provides statistics over the shared cache lines.

**c2c Details**

This table provides information about what events were sampled and how the `perf c2c report` data is organized within the visualization.

**Shared Data Cache Line Table**

```plaintext

```
This table provides a one line summary for the hottest cache lines where false sharing is detected and is sorted in descending order by the amount of remote Hitm detected per cache line by default.

**Shared Cache Line Distribution Pareto**

This tables provides a variety of information about each cache line experiencing contention:

- The cache lines are numbered in the NUM column, starting at 0.
- The virtual address of each cache line is contained in the Data address Offset column and followed subsequently by the offset into the cache line where different accesses occurred.
- The Pid column contains the process ID.
- The Code Address column contains the instruction pointer code address.
- The columns under the cycles label show average load latencies.
- The cpu cnt column displays how many different CPUs samples came from (essentially, how many different CPUs were waiting for the data indexed at that given location).
- The Symbol column displays the function name or symbol.
- The Shared Object column displays the name of the ELF image where the samples come from (the name [kernel.kallsyms] is used when the samples come from the kernel).
- The Source:Line column displays the source file and line number.
- The Node{cpu list} column displays which specific CPUs samples came from for each node.

## 26.5. DETECTING FALSE SHARING WITH PERF C2C

This procedure describes how to detect false sharing using the `perf c2c` command.

**Prerequisites**

- The `perf` user space tool is installed. For more information, see [installing perf](#).
- A `perf.data` file recorded using the `perf c2c` command is available in the current directory. For more information, see [Detecting cache-line contention with perf c2c](#).

**Procedure**

1. Open the `perf.data` file for further analysis:

   ```bash
   # perf c2c report --stdio
   ``

   This opens the `perf.data` file in the terminal.

2. In the "Trace Event Information" table, locate the row containing the values for LLC Misses to Remote Cache (HITM):

   The percentage in the value column of the LLC Misses to Remote Cache (HITM) row represents the percentage of LLC misses that were occurring across NUMA nodes in modified cache-lines and is a key indicator false sharing has occurred.
Trace Event Information

Total records : 329219

<td>7</td>
<td></td>
</tr>
</tbody>
</table>
This table is sorted in descending order by the amount of remote Hitm detected per cache line. A high number in the Rmt column of the LLC Load Hitm section indicates false sharing and requires further inspection of the cache line on which it occurred to debug the false sharing activity.
CHAPTER 27. GETTING STARTED WITH FLAMEGRAPHS

As a system administrator, you can use **flamegraphs** to create visualizations of system performance data recorded with the **perf** tool. As a software developer, you can use **flamegraphs** to create visualizations of application performance data recorded with the **perf** tool.

Sampling stack traces is a common technique for profiling CPU performance with the **perf** tool. Unfortunately, the results of profiling stack traces with **perf** can be extremely verbose and labor-intensive to analyze. **flamegraphs** are visualizations created from data recorded with **perf** to make identifying hot code-paths faster and easier.

### 27.1. INSTALLING FLAMEGRAPHS

To begin using **flamegraphs**, install the required package.

**Procedure**

- Install the **flamegraphs** package:
  
  ```
  # yum install js-d3-flame-graph
  ```

### 27.2. CREATING FLAMEGRAPHS OVER THE ENTIRE SYSTEM

This procedure describes how to visualize performance data recorded over an entire system using **flamegraphs**.

**Prerequisites**

- **flamegraphs** are installed as described in **installing flamegraphs**.
- The **perf** tool is installed as described in **installing perf**.

**Procedure**

- Record the data and create the visualization:
  
  ```
  # perf script flamegraph -a -F 99 sleep 60
  ```

  This command samples and records performance data over the entire system for 60 seconds, as stipulated by use of the **sleep** command, and then constructs the visualization which will be stored in the current active directory as **flamegraph.html**. The command samples call-graph data by default and takes the same arguments as the **perf** tool, in this particular case:

  - **-a**
    Stipulates to record data over the entire system.
  
  - **-F**
    To set the sampling frequency per second.

**Verification steps**

- For analysis, view the generated visualization:
27.3. CREATING FLAMEGRAPHS OVER SPECIFIC PROCESSES

You can use flamegraphs to visualize performance data recorded over specific running processes.

Prerequisites

- flamegraphs are installed as described in installing flamegraphs.
- The perf tool is installed as described in installing perf.

Procedure

- Record the data and create the visualization:

  ```bash
  # perf script flamegraph -a -F 99 -p ID1,ID2 sleep 60
  ```

  This command samples and records performance data of the processes with the process ID's ID1 and ID2 for 60 seconds, as stipulated by use of the sleep command, and then constructs the visualization which will be stored in the current active directory as flamegraph.html. The command samples call-graph data by default and takes the same arguments as the perf tool, in this particular case:

  -a
  Stipulates to record data over the entire system.

  -F
  To set the sampling frequency per second.

  -p
  To stipulate specific process ID's to sample and record data over.

Verification steps

- For analysis, view the generated visualization:

  ```bash
  # xdg-open flamegraph.html
  ```

  This command opens the visualization in the default browser:
27.4. INTERPRETING FLAMEGRAPHS

Each box in the flamegraph represents a different function in the stack. The y-axis shows the depth of the stack with the topmost box in each stack being the function that was actually on-CPU and everything below it being ancestry. The x-axis displays the population of the sampled call-graph data.

The children of a stack in a given row are displayed based on the number of samples taken of each respective function in descending order along the x-axis; the x-axis does not represent the passing of time. The wider an individual box is, the more frequent it was on-CPU or part of an on-CPU ancestry at the time the data was being sampled.

Procedure

- To reveal the names of functions which may have not been displayed previously and further investigate the data click on a box within the flamegraph to zoom into the stack at that given location:

- To return to the default view of the flamegraph, click **Reset Zoom**.
IMPORTANT

Boxes representing user-space functions may be labeled as Unknown in flamegraphs because the binary of the function is stripped. The debuginfo package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information. Use the -g option in GCC, to display the function names or symbols in such a situation.

Additional resources

- Why perf displays some function names as raw functions addresses
- Enabling debugging with debugging information
CHAPTER 28. MONITORING PROCESSES FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS

You can create circular buffers that take event-specific snapshots of data with the `perf` tool in order to monitor performance bottlenecks in specific processes or parts of applications running on your system. In such cases, `perf` only writes data to a `perf.data` file for later analysis if a specified event is detected.

28.1. CIRCULAR BUFFERS AND EVENT-SPECIFIC SNAPSHOTS WITH PERF

When investigating performance issues in a process or application with `perf`, it may not be affordable or appropriate to record data for hours preceding a specific event of interest occurring. In such cases, you can use `perf record` to create custom circular buffers that take snapshots after specific events.

The `--overwrite` option makes `perf record` store all data in an overwritable circular buffer. When the buffer gets full, `perf record` automatically overwrites the oldest records which, therefore, never get written to a `perf.data` file.

Using the `--overwrite` and `--switch-output-event` options together configures a circular buffer that records and dumps data continuously until it detects the `--switch-output-event` trigger event. The trigger event signals to `perf record` that something of interest to the user has occurred and to write the data in the circular buffer to a `perf.data` file. This collects specific data you are interested in while simultaneously reducing the overhead of the running `perf` process by not writing data you do not want to a `perf.data` file.

28.2. COLLECTING SPECIFIC DATA TO MONITOR FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS

With the `perf` tool, you can create circular buffers that are triggered by events you specify in order to only collect data you are interested in. To create circular buffers that collect event-specific data, use the `--overwrite` and `--switch-output-event` options for `perf`.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.
- You have placed a uprobes in the process or application you are interested in monitoring at a location of interest within the process or application:

```
# perf probe -x /path/to/executable -a function
Added new event:
probe_executable:function (on function in /path/to/executable)
```

You can now use it in all perf tools, such as:

```
perf record -e probe_executable:function -aR sleep 1
```

Procedure

- Create the circular buffer with the uprobes as the trigger event:
This example initiates the executable and collects cpu cycles, specified after the `-e` option, until `perf` detects the uprobes, the trigger event specified after the `--switch-output-event` option. At that point, `perf` takes a snapshot of all the data in the circular buffer and stores it in a unique `perf.data` file identified by timestamp. This example produced a total of 2 snapshots, the last `perf.data` file was forced by pressing `Ctrl+c`.

```bash
# perf record --overwrite -e cycles --switch-output-event probe_executable:function
./executable
[ perf record: dump data: Woken up 1 times ]
[ perf record: Dump perf.data.2021021012231959 ]
[ perf record: dump data: Woken up 1 times ]
[ perf record: Dump perf.data.2021021012232008 ]
^C[ perf record: dump data: Woken up 1 times ]
[ perf record: Dump perf.data.2021021012232082 ]
[ perf record: Captured and wrote 5.621 MB perf.data.<timestamp> ]
```
CHAPTER 29. ADDING AND REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

By using the control pipe interface to enable and disable different tracepoints in a running perf collector, you can dynamically adjust what data you are collecting without having to stop or restart perf. This ensures you do not lose performance data that would have otherwise been recorded during the stopping or restarting process.

29.1. ADDING TRACEPOINTS TO A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

Add tracepoints to a running perf collector using the control pipe interface to adjust the data you are recording without having to stop perf and losing performance data.

Prerequisites

- You have the perf user space tool installed as described in Installing perf.

Procedure

1. Configure the control pipe interface:

   # mkfifo control ack perf.pipe

2. Run perf record with the control file setup and events you are interested in enabling:

   # perf record --control=fifo:control,ack -D -1 --no-buffering -e 'sched:*' -o - > perf.pipe

   In this example, declaring 'sched:*' after the -e option starts perf record with scheduler events.

3. In a second terminal, start the read side of the control pipe:

   # cat perf.pipe | perf --no-pager script -i -

   Starting the read side of the control pipe triggers the following message in the first terminal:

   Events disabled

4. In a third terminal, enable a tracepoint using the control file:

   # echo 'enable sched:sched_process_fork' > control

   This command triggers perf to scan the current event list in the control file for the declared event. If the event is present, the tracepoint is enabled and the following message appears in the first terminal:

   event sched:sched_process_fork enabled

   Once the tracepoint is enabled, the second terminal displays the output from perf detecting the tracepoint:
29.2. REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

Remove tracepoints from a running perf collector using the control pipe interface to reduce the scope of data you are collecting without having to stop perf and losing performance data.

Prerequisites

- You have the perf user space tool installed as described in Installing perf.
- You have added tracepoints to a running perf collector via the control pipe interface. For more information, see Adding tracepoints to a running perf collector without stopping or restarting perf.

Procedure

- Remove the tracepoint:

```
# echo 'disable sched:sched_process_fork' > control
```

**NOTE**

This example assumes you have previously loaded scheduler events into the control file and enabled the tracepoint sched:sched_process_fork.

This command triggers perf to scan the current event list in the control file for the declared event. If the event is present, the tracepoint is disabled and the following message appears in the terminal used to configure the control pipe:

```
event sched:sched_process_fork disabled
```
CHAPTER 30. PROFILING MEMORY ALLOCATION WITH NUMASTAT

With the numastat tool, you can display statistics over memory allocations in a system.

The numastat tool displays data for each NUMA node separately. You can use this information to investigate memory performance of your system or the effectiveness of different memory policies on your system.

30.1. DEFAULT NUMASTAT STATISTICS

By default, the numastat tool displays statistics over these categories of data for each NUMA node:

numa_hit
The number of pages that were successfully allocated to this node.

numa_miss
The number of pages that were allocated on this node because of low memory on the intended node. Each numa_miss event has a corresponding numa_foreign event on another node.

numa_foreign
The number of pages initially intended for this node that were allocated to another node instead. Each numa_foreign event has a corresponding numa_miss event on another node.

interleave_hit
The number of interleave policy pages successfully allocated to this node.

local_node
The number of pages successfully allocated on this node by a process on this node.

other_node
The number of pages allocated on this node by a process on another node.

NOTE
High numa_hit values and low numa_miss values (relative to each other) indicate optimal performance.

30.2. VIEWING MEMORY ALLOCATION WITH NUMASTAT

You can view the memory allocation of the system by using the numastat tool.

Prerequisites

- Install the numactl package:

  # yum install numactl

Procedure

- View the memory allocation of your system:

  $ numastat
  node0     node1
<table>
<thead>
<tr>
<th></th>
<th>First Value</th>
<th>Second Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>numa_hit</td>
<td>76557759</td>
<td>92126519</td>
</tr>
<tr>
<td>numa_miss</td>
<td>30772308</td>
<td>30827638</td>
</tr>
<tr>
<td>numa_foreign</td>
<td>30827638</td>
<td>30772308</td>
</tr>
<tr>
<td>interleave_hit</td>
<td>106507</td>
<td>103832</td>
</tr>
<tr>
<td>local_node</td>
<td>76502227</td>
<td>92086995</td>
</tr>
<tr>
<td>other_node</td>
<td>30827840</td>
<td>30867162</td>
</tr>
</tbody>
</table>

Additional resources

CHAPTER 31. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE CPU UTILIZATION

You can configure the operating system to optimize CPU utilization across their workloads.

31.1. TOOLS FOR MONITORING AND DIAGNOSING PROCESSOR ISSUES

The following are the tools available in Red Hat Enterprise Linux 8 to monitor and diagnose processor-related performance issues:

- **turbostat** tool prints counter results at specified intervals to help administrators identify unexpected behavior in servers, such as excessive power usage, failure to enter deep sleep states, or system management interrupts (SMIs) being created unnecessarily.

- **numactl** utility provides a number of options to manage processor and memory affinity. The **numactl** package includes the **libnuma** library which offers a simple programming interface to the NUMA policy supported by the kernel, and can be used for more fine-grained tuning than the **numactl** application.

- **numastat** tool displays per-NUMA node memory statistics for the operating system and its processes, and shows administrators whether the process memory is spread throughout a system or is centralized on specific nodes. This tool is provided by the **numactl** package.

- **numad** is an automatic NUMA affinity management daemon. It monitors NUMA topology and resource usage within a system in order to dynamically improve NUMA resource allocation and management.

- **/proc/interrupts** file displays the interrupt request (IRQ) number, the number of similar interrupt requests handled by each processor in the system, the type of interrupt sent, and a comma-separated list of devices that respond to the listed interrupt request.

- **pqos** utility is available in the **intel-cmt-cat** package. It monitors CPU cache and memory bandwidth on recent Intel processors. It monitors:
  - The instructions per cycle (IPC).
  - The count of last level cache MISSES.
  - The size in kilobytes that the program executing in a given CPU occupies in the LLC.
  - The bandwidth to local memory (MBL).
  - The bandwidth to remote memory (MBR).

- **x86_energy_perf_policy** tool allows administrators to define the relative importance of performance and energy efficiency. This information can then be used to influence processors that support this feature when they select options that trade off between performance and energy efficiency.

- **taskset** tool is provided by the **util-linux** package. It allows administrators to retrieve and set the processor affinity of a running process, or launch a process with a specified processor affinity.

Additional resources
31.2. TYPES OF SYSTEM TOPOLOGY

In modern computing, the idea of a CPU is a misleading one, as most modern systems have multiple processors. The topology of the system is the way these processors are connected to each other and to other system resources. This can affect system and application performance, and the tuning considerations for a system.

The following are the two primary types of topology used in modern computing:

Symmetric Multi-Processor (SMP) topology

SMP topology allows all processors to access memory in the same amount of time. However, because shared and equal memory access inherently forces serialized memory accesses from all the CPUs, SMP system scaling constraints are now generally viewed as unacceptable. For this reason, practically all modern server systems are NUMA machines.

Non-Uniform Memory Access (NUMA) topology

NUMA topology was developed more recently than SMP topology. In a NUMA system, multiple processors are physically grouped on a socket. Each socket has a dedicated area of memory and processors that have local access to that memory, these are referred to collectively as a node. Processors on the same node have high speed access to that node’s memory bank, and slower access to memory banks not on their node.

Therefore, there is a performance penalty when accessing non-local memory. Thus, performance sensitive applications on a system with NUMA topology should access memory that is on the same node as the processor executing the application, and should avoid accessing remote memory wherever possible.

Multi-threaded applications that are sensitive to performance may benefit from being configured to execute on a specific NUMA node rather than a specific processor. Whether this is suitable depends on your system and the requirements of your application. If multiple application threads access the same cached data, then configuring those threads to execute on the same processor may be suitable. However, if multiple threads that access and cache different data execute on the same processor, each thread may evict cached data accessed by a previous thread. This means that each thread ‘misses’ the cache and wastes execution time fetching data from memory and replacing it in the cache. Use the `perf` tool to check for an excessive number of cache misses.

31.2.1. Displaying system topologies

There are a number of commands that help understand the topology of a system. This procedure describes how to determine the system topology.

Procedure

- To display an overview of your system topology:

  ```bash
  $ numactl --hardware
  available: 4 nodes (0-3)
  node 0 cpus: 0 4 8 12 16 20 24 28 32 36
  node 0 size: 65415 MB
  node 0 free: 43971 MB
  [...]```
To gather the information about the CPU architecture, such as the number of CPUs, threads, cores, sockets, and NUMA nodes:

```
$ lscpu
Architecture:          x86_64
CPU op-mode(s):        32-bit, 64-bit
Byte Order:            Little Endian
CPU(s):                40
On-line CPU(s) list:   0-39
Thread(s) per core:    1
Core(s) per socket:    10
Socket(s):             4
NUMA node(s):          4
Vendor ID:             GenuineIntel
CPU family:            6
Model:                 47
Model name:            Intel(R) Xeon(R) CPU E7- 4870  @ 2.40GHz
Stepping:              2
CPU MHz:               2394.204
BogoMIPS:              4787.85
Virtualization:        VT-x

### 31.3. CONFIGURING KERNEL TICK TIME
By default, Red Hat Enterprise Linux 8 uses a tickless kernel, which does not interrupt idle CPUs in order to reduce power usage and allow new processors to take advantage of deep sleep states.

Red Hat Enterprise Linux 8 also offers a dynamic tickless option, which is useful for latency-sensitive workloads, such as high performance computing or realtime computing. By default, the dynamic tickless option is disabled. Red Hat recommends using the `cpu-partitioning TuneD` profile to enable the dynamic tickless option for cores specified as `isolated_cores`.

This procedure describes how to manually persistently enable dynamic tickless behavior.

**Procedure**

1. To enable dynamic tickless behavior in certain cores, specify those cores on the kernel command line with the `nohz_full` parameter. On a 16 core system, enable the `nohz_full=1-15` kernel option:

   ```bash
   # grubby --update-kernel=ALL --args="nohz_full=1-15"
   ```

   This enables dynamic tickless behavior on cores 1 through 15, moving all timekeeping to the only unspecified core (core 0).

2. When the system boots, manually move the `rcu` threads to the non-latency-sensitive core, in this case core 0:

   ```bash
   # for i in `pgrep rcu[^c]` ; do taskset -pc 0 $i ; done
   ```

3. Optional: Use the `isolcpus` parameter on the kernel command line to isolate certain cores from user-space tasks.

4. Optional: Set the CPU affinity for the kernel’s `write-back bdi-flush` threads to the housekeeping core:

   ```bash
   echo 1 > /sys/bus/workqueue/devices/writeback/cpumask
   ```

**Verification steps**

- Once the system is rebooted, verify if dynticks are enabled:

  ```bash
  # journalctl -xe | grep dynticks
  ```

- Verify that the dynamic tickless configuration is working correctly:

  ```bash
  # perf stat -C 1 -e irq_vectors:local_timer_entry taskset -c 1 sleep 3
  ```

  This command measures ticks on CPU 1 while telling CPU 1 to sleep for 3 seconds.

- The default kernel timer configuration shows around 3100 ticks on a regular CPU:

  ```bash
  # perf stat -C 0 -e irq_vectors:local_timer_entry taskset -c 0 sleep 3
  Performance counter stats for 'CPU(s) 0':
  ```
With the dynamic tickless kernel configured, you should see around 4 ticks instead:

```
# perf stat -C 1 -e irq_vectors:local_timer_entry taskset -c 1 sleep 3
```

Performance counter stats for 'CPU(s) 1':

```
  4    irq_vectors:local_timer_entry
3.001544078 seconds time elapsed
```

Additional resources

- **perf(1)** and **cpuset(7)** man pages

### 31.4. OVERVIEW OF AN INTERRUPT REQUEST

An interrupt request or IRQ is a signal for immediate attention sent from a piece of hardware to a processor. Each device in a system is assigned one or more IRQ numbers which allow it to send unique interrupts. When interrupts are enabled, a processor that receives an interrupt request immediately pauses execution of the current application thread in order to address the interrupt request.

Because interrupt halts normal operation, high interrupt rates can severely degrade system performance. It is possible to reduce the amount of time taken by interrupts by configuring interrupt affinity or by sending a number of lower priority interrupts in a batch (coalescing a number of interrupts).

Interrupt requests have an associated affinity property, **smp_affinity**, which defines the processors that handle the interrupt request. To improve application performance, assign interrupt affinity and process affinity to the same processor, or processors on the same core. This allows the specified interrupt and application threads to share cache lines.

On systems that support interrupt steering, modifying the **smp_affinity** property of an interrupt request sets up the hardware so that the decision to service an interrupt with a particular processor is made at the hardware level with no intervention from the kernel.

#### 31.4.1. Balancing interrupts manually

If your BIOS exports its NUMA topology, the **irqbalance** service can automatically serve interrupt requests on the node that is local to the hardware requesting service.

**Procedure**

1. Check which devices correspond to the interrupt requests that you want to configure.

2. Find the hardware specification for your platform. Check if the chipset on your system supports distributing interrupts.
a. If it does, you can configure interrupt delivery as described in the following steps. Additionally, check which algorithm your chipset uses to balance interrupts. Some BIOSes have options to configure interrupt delivery.

b. If it does not, your chipset always routes all interrupts to a single, static CPU. You cannot configure which CPU is used.

3. Check which Advanced Programmable Interrupt Controller (APIC) mode is in use on your system:

   ```
   $ journalctl --dmesg | grep APIC
   ```

   Here,

   - If your system uses a mode other than `flat`, you can see a line similar to **Setting APIC routing to physical flat**.
   
   - If you can see no such message, your system uses `flat` mode.

   If your system uses `x2apic` mode, you can disable it by adding the `nox2apic` option to the kernel command line in the **bootloader** configuration.

   Only non-physical flat mode (flat) supports distributing interrupts to multiple CPUs. This mode is available only for systems that have up to 8 CPUs.

4. Calculate the **smp_affinity mask**. For more information about how to calculate the **smp_affinity mask**, see **Setting the smp_affinity mask**.

Additional resources

- `journalctl(1)` and `taskset(1)` man pages

### 31.4.2. Setting the smp_affinity mask

The **smp_affinity** value is stored as a hexadecimal bit mask representing all processors in the system. Each bit configures a different CPU. The least significant bit is CPU 0.

The default value of the mask is `f`, which means that an interrupt request can be handled on any processor in the system. Setting this value to `1` means that only processor 0 can handle the interrupt.

**Procedure**

1. In binary, use the value 1 for CPUs that handle the interrupts. For example, to set CPU 0 and CPU 7 to handle interrupts, use `0000000010000001` as the binary code:

   **Table 31.1. Binary Bits for CPUs**

<table>
<thead>
<tr>
<th>CPU</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>
<th>1</th>

<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

2. Convert the binary code to hexadecimal:
   For example, to convert the binary code using Python:
On systems with more than 32 processors, you must delimit the **smp_affinity** values for discrete 32 bit groups. For example, if you want only the first 32 processors of a 64 processor system to service an interrupt request, use 0xffffffff,00000000.

3. The interrupt affinity value for a particular interrupt request is stored in the associated /proc/irq/irq_number/smp_affinity file. Set the **smp_affinity** mask in this file:

```
# echo mask > /proc/irq/irq_number/smp_affinity
```

CHAPTER 32. TUNING SCHEDULING POLICY

In Red Hat Enterprise Linux, the smallest unit of process execution is called a thread. The system scheduler determines which processor runs a thread, and for how long the thread runs. However, because the scheduler’s primary concern is to keep the system busy, it may not schedule threads optimally for application performance.

For example, say an application on a NUMA system is running on Node A when a processor on Node B becomes available. To keep the processor on Node B busy, the scheduler moves one of the application’s threads to Node B. However, the application thread still requires access to memory on Node A. But, this memory will take longer to access because the thread is now running on Node B and Node A memory is no longer local to the thread. Thus, it may take longer for the thread to finish running on Node B than it would have taken to wait for a processor on Node A to become available, and then to execute the thread on the original node with local memory access.

32.1. CATEGORIES OF SCHEDULING POLICIES

Performance sensitive applications often benefit from the designer or administrator determining where threads are run. The Linux scheduler implements a number of scheduling policies which determine where and for how long a thread runs.

The following are the two major categories of scheduling policies:

Normal policies

Normal threads are used for tasks of normal priority.

Realtime policies

Realtime policies are used for time-sensitive tasks that must complete without interruptions. Realtime threads are not subject to time slicing. This means the thread runs until they block, exit, voluntarily yield, or are preempted by a higher priority thread.

The lowest priority realtime thread is scheduled before any thread with a normal policy. For more information, see Static priority scheduling with SCHED_FIFO and Round robin priority scheduling with SCHED_RR.

Additional resources

- sched(7), sched_setaffinity(2), sched_getaffinity(2), sched_setscheduler(2), and sched_getscheduler(2) man pages

32.2. STATIC PRIORITY SCHEDULING WITH SCHED_FIFO

The SCHED_FIFO, also called static priority scheduling, is a realtime policy that defines a fixed priority for each thread. This policy allows administrators to improve event response time and reduce latency. It is recommended to not execute this policy for an extended period of time for time sensitive tasks.

When SCHED_FIFO is in use, the scheduler scans the list of all the SCHED_FIFO threads in order of priority and schedules the highest priority thread that is ready to run. The priority level of a SCHED_FIFO thread can be any integer from 1 to 99, where 99 is treated as the highest priority.

Red Hat recommends starting with a lower number and increasing priority only when you identify latency issues.
WARNING

Because realtime threads are not subject to time slicing, Red Hat does not recommend setting a priority as 99. This keeps your process at the same priority level as migration and watchdog threads; if your thread goes into a computational loop and these threads are blocked, they will not be able to run. Systems with a single processor will eventually hang in this situation.

Administrators can limit SCHED_FIFO bandwidth to prevent realtime application programmers from initiating realtime tasks that monopolize the processor.

The following are some of the parameters used in this policy:

```
/proc/sys/kernel/sched_rt_period_us
```

This parameter defines the time period, in microseconds, that is considered to be one hundred percent of the processor bandwidth. The default value is 1000000 µs, or 1 second.

```
/proc/sys/kernel/sched_rt_runtime_us
```

This parameter defines the time period, in microseconds, that is devoted to running real-time threads. The default value is 950000 µs, or 0.95 seconds.

### 32.3. ROUND ROBIN PRIORITY SCHEDULING WITH SCHED_RR

The SCHED_RR is a round-robin variant of the SCHED_FIFO. This policy is useful when multiple threads need to run at the same priority level.

Like SCHED_FIFO, SCHED_RR is a realtime policy that defines a fixed priority for each thread. The scheduler scans the list of all SCHED_RR threads in order of priority and schedules the highest priority thread that is ready to run. However, unlike SCHED_FIFO, threads that have the same priority are scheduled in a round-robin style within a certain time slice.

You can set the value of this time slice in milliseconds with the sched_rr_timeslice_ms kernel parameter in the /proc/sys/kernel/sched_rr_timeslice_ms file. The lowest value is 1 millisecond.

### 32.4. NORMAL SCHEDULING WITH SCHED_OTHER

The SCHED_OTHER is the default scheduling policy in Red Hat Enterprise Linux 8. This policy uses the Completely Fair Scheduler (CFS) to allow fair processor access to all threads scheduled with this policy. This policy is most useful when there are a large number of threads or when data throughput is a priority, as it allows more efficient scheduling of threads over time.

When this policy is in use, the scheduler creates a dynamic priority list based partly on the niceness value of each process thread. Administrators can change the niceness value of a process, but cannot change the scheduler’s dynamic priority list directly.

### 32.5. SETTING SCHEDULER POLICIES

Check and adjust scheduler policies and priorities by using the chrt command line tool. It can start new processes with the desired properties, or change the properties of a running process. It can also be used for setting the policy at runtime.
Procedure

1. View the process ID (PID) of the active processes:

   # ps

   Use the --pid or -p option with the ps command to view the details of the particular PID.

2. Check the scheduling policy, PID, and priority of a particular process:

   # chrt -p 468
   pid 468s current scheduling policy: SCHED_FIFO
   pid 468's current scheduling priority: 85

   # chrt -p 476
   pid 476's current scheduling policy: SCHED_OTHER
   pid 476's current scheduling priority: 0

   Here, 468 and 476 are PID of a process.

3. Set the scheduling policy of a process:
   a. For example, to set the process with PID 1000 to SCHED_FIFO, with a priority of 50:

      # chrt -f -p 50 1000

   b. For example, to set the process with PID 1000 to SCHED_OTHER, with a priority of 0:

      # chrt -o -p 0 1000

   c. For example, to set the process with PID 1000 to SCHED_RR, with a priority of 10:

      # chrt -r -p 10 1000

   d. To start a new application with a particular policy and priority, specify the name of the application:

      # chrt -f 36 /bin/my-app

Additional resources

- chrt(1) man page
- Policy Options for the chrt command
- Changing the priority of services during the boot process

32.6. POLICY OPTIONS FOR THE CHRT COMMAND

Using the chrt command, you can view and set the scheduling policy of a process.

The following table describes the appropriate policy options, which can be used to set the scheduling policy of a process.
### Table 32.1. Policy Options for the chrt Command

<table>
<thead>
<tr>
<th>Short option</th>
<th>Long option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f</td>
<td>--fifo</td>
<td>Set schedule to SCHED_FIFO</td>
</tr>
<tr>
<td>-o</td>
<td>--other</td>
<td>Set schedule to SCHED_OTHER</td>
</tr>
<tr>
<td>-r</td>
<td>--rr</td>
<td>Set schedule to SCHED_RR</td>
</tr>
</tbody>
</table>

### 32.7. CHANGING THE PRIORITY OF SERVICES DURING THE BOOT PROCESS

Using the `systemd` service, it is possible to set up real-time priorities for services launched during the boot process. The unit configuration directives are used to change the priority of a service during the boot process.

The boot process priority change is done by using the following directives in the service section:

- **CPUSchedulingPolicy=**
  
  Sets the CPU scheduling policy for executed processes. It is used to set `other`, `fifo`, and `rr` policies.

- **CPUSchedulingPriority=**
  
  Sets the CPU scheduling priority for executed processes. The available priority range depends on the selected CPU scheduling policy. For real-time scheduling policies, an integer between 1 (lowest priority) and 99 (highest priority) can be used.

The following procedure describes how to change the priority of a service, during the boot process, using the `mcelog` service.

#### Prerequisites

1. Install the TuneD package:
   
   ```bash
   # yum install tuned
   ```

2. Enable and start the TuneD service:
   
   ```bash
   # systemctl enable --now tuned
   ```

#### Procedure

1. View the scheduling priorities of running threads:
   
   ```bash
   # tuna --show_threads
   thread     ctxt_switches pid SCHED其它 affinity voluntary nonvoluntary cmd
   0xff 3181 292 systemd
   0xff 254 kthreadd
   2 0 rcu_gp
   0xff 2 0 rcu_par_gp
   ```
2. Create a supplementary `mcelog` service configuration directory file and insert the policy name and priority in this file:

```plaintext
# cat << EOF > /etc/systemd/system/mcelog.system.d/priority.conf

[SERVICE]
CPUSchedulingPolicy=fifo
CPUSchedulingPriority=20

EOF
```

3. Reload the `systemd` scripts configuration:

```plaintext
# systemctl daemon-reload
```

4. Restart the `mcelog` service:

```plaintext
# systemctl restart mcelog
```

Verification steps

- Display the `mcelog` priority set by `systemd` issue:

```plaintext
# tuna -t mcelog -P
thread ctxt_switches
  pid SCHED_rtpri affinity voluntary nonvoluntary cmd
826   FIFO   20  0,1,2,3  13          0  mcelog
```

Additional resources

- `systemd(1)` and `tuna(8)` man pages

### 32.8. PRIORITY MAP

Priorities are defined in groups, with some groups dedicated to certain kernel functions. For real-time scheduling policies, an integer between 1 (lowest priority) and 99 (highest priority) can be used.

The following table describes the priority range, which can be used while setting the scheduling policy of a process.

<table>
<thead>
<tr>
<th>Priority</th>
<th>Threads</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>

<td>Default hard-IRQ value</td>
<td></td>
</tr>
<tr>
<td>51 - 98</td>
<td>High priority threads</td>
<td>Use this range for threads that execute periodically and must have quick response times. Do not use this range for CPU-bound threads as you will starve interrupts.</td>
</tr>
<tr>
<td>99</td>
<td>Watchdogs and migration</td>
<td>System threads that must run at the highest priority.</td>
</tr>
</tbody>
</table>

### 32.9. TUNED CPU-PARTITIONING PROFILE

For tuning Red Hat Enterprise Linux 8 for latency-sensitive workloads, Red Hat recommends to use the `cpu-partitioning` TuneD profile.

Prior to Red Hat Enterprise Linux 8, the low-latency Red Hat documentation described the numerous low-level steps needed to achieve low-latency tuning. In Red Hat Enterprise Linux 8, you can perform low-latency tuning more efficiently by using the `cpu-partitioning` TuneD profile. This profile is easily customizable according to the requirements for individual low-latency applications.

The following figure is an example to demonstrate how to use the `cpu-partitioning` profile. This example uses the CPU and node layout.

**Figure 32.1. Figure cpu-partitioning**

You can configure the `cpu-partitioning` profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the following configuration options:
Isolated CPUs with load balancing

In the cpu-partitioning figure, the blocks numbered from 4 to 23, are the default isolated CPUs. The kernel scheduler’s process load balancing is enabled on these CPUs. It is designed for low-latency processes with multiple threads that need the kernel scheduler load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the `isolated_cores=cpu-list` option, which lists CPUs to isolate that will use the kernel scheduler load balancing.

The list of isolated CPUs is comma-separated or you can specify a range using a dash, such as `3-5`. This option is mandatory. Any CPU missing from this list is automatically considered a housekeeping CPU.

Isolated CPUs without load balancing

In the cpu-partitioning figure, the blocks numbered 2 and 3, are the isolated CPUs that do not provide any additional kernel scheduler process load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the `no_balance_cores=cpu-list` option, which lists CPUs to isolate that will not use the kernel scheduler load balancing.

Specifying the `no_balance_cores` option is optional, however any CPUs in this list must be a subset of the CPUs listed in the `isolated_cores` list.

Application threads using these CPUs need to be pinned individually to each CPU.

Housekeeping CPUs

Any CPU not isolated in the `cpu-partitioning-variables.conf` file is automatically considered a housekeeping CPU. On the housekeeping CPUs, all services, daemons, user processes, movable kernel threads, interrupt handlers, and kernel timers are permitted to execute.

Additional resources

- `tuned-profiles-cpu-partitioning(7)` man page

32.10. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING

This procedure describes how to tune a system for low-latency using the TuneD’s `cpu-partitioning` profile. It uses the example of a low-latency application that can use `cpu-partitioning` and the CPU layout as mentioned in the `cpu-partitioning` figure.

The application in this case uses:

- One dedicated reader thread that reads data from the network will be pinned to CPU 2.
- A large number of threads that process this network data will be pinned to CPUs 4-23.
- A dedicated writer thread that writes the processed data to the network will be pinned to CPU 3.

Prerequisites

- You have installed the `cpu-partitioning` TuneD profile by using the `yum install tuned-profiles-cpu-partitioning` command as root.
Procedure

1. Edit `/etc/tuned/cpu-partitioning-variables.conf` file and add the following information:

   ```
   # All isolated CPUs:
   isolated_cores=2-23
   # Isolated CPUs without the kernel’s scheduler load balancing:
   no_balance_cores=2,3
   ```

2. Set the `cpu-partitioning` TuneD profile:

   ```
   # tuned-adm profile cpu-partitioning
   ```

3. Reboot

   After rebooting, the system is tuned for low-latency, according to the isolation in the `cpu-partitioning` figure. The application can use `taskset` to pin the reader and writer threads to CPUs 2 and 3, and the remaining application threads on CPUs 4-23.

Additional resources

- `tuned-profiles-cpu-partitioning(7) man page`

### 32.11. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE

You can extend the TuneD profile to make additional tuning changes.

For example, the `cpu-partitioning` profile sets the CPUs to use `cstate=1`. In order to use the `cpu-partitioning` profile but to additionally change the CPU cstate from `cstate1` to `cstate0`, the following procedure describes a new TuneD profile named `my_profile`, which inherits the `cpu-partitioning` profile and then sets C state-0.

Procedure

1. Create the `/etc/tuned/my_profile` directory:

   ```
   # mkdir /etc/tuned/my_profile
   ```

2. Create a `tuned.conf` file in this directory, and add the following content:

   ```
   # vi /etc/tuned/my_profile/tuned.conf
   [main]
   summary=Customized tuning on top of cpu-partitioning
   include=cpu-partitioning
   [cpu]
   force_latency=cstate.id:0|1
   ```

3. Use the new profile:

   ```
   # tuned-adm profile my_profile
   ```
NOTE

In the shared example, a reboot is not required. However, if the changes in the `my_profile` profile require a reboot to take effect, then reboot your machine.

Additional resources

- `tuned-profiles-cpu-partitioning(7)` man page
CHAPTER 33. FACTORS AFFECTING I/O AND FILE SYSTEM PERFORMANCE

The appropriate settings for storage and file system performance are highly dependent on the storage purpose.

I/O and file system performance can be affected by any of the following factors:

- Data write or read patterns
- Sequential or random
- Buffered or Direct IO
- Data alignment with underlying geometry
- Block size
- File system size
- Journal size and location
- Recording access times
- Ensuring data reliability
- Pre-fetching data
- Pre-allocating disk space
- File fragmentation
- Resource contention

33.1. TOOLS FOR MONITORING AND DIAGNOSING I/O AND FILE SYSTEM ISSUES

The following tools are available in Red Hat Enterprise Linux 8 for monitoring system performance and diagnosing performance problems related to I/O, file systems, and their configuration:

- **vmstat** tool reports on processes, memory, paging, block I/O, interrupts, and CPU activity across the entire system. It can help administrators determine whether the I/O subsystem is responsible for any performance issues. If analysis with *vmstat* shows that the I/O subsystem is responsible for reduced performance, administrators can use the *iostat* tool to determine the responsible I/O device.

- **iostat** reports on I/O device load in your system. It is provided by the *sysstat* package.

- **blktrace** provides detailed information about how time is spent in the I/O subsystem. The companion utility *blkparse* reads the raw output from *blktrace* and produces a human readable summary of input and output operations recorded by *blktrace*.

- **btt** analyzes *blktrace* output and displays the amount of time that data spends in each area of the I/O stack, making it easier to spot bottlenecks in the I/O subsystem. This utility is provided as part of the *blktrace* package. Some of the important events tracked by the *blktrace* mechanism and analyzed by *btt* are:
Queuing of the I/O event (Q)

Dispatch of the I/O to the driver event (D)

Completion of I/O event (C)

- iowatcher can use the blktrace output to graph I/O over time. It focuses on the Logical Block Address (LBA) of disk I/O, throughput in megabytes per second, the number of seeks per second, and I/O operations per second. This can help to identify when you are hitting the operations-per-second limit of a device.

- BPF Compiler Collection (BCC) is a library, which facilitates the creation of the extended Berkeley Packet Filter (eBPF) programs. The eBPF programs are triggered on events, such as disk I/O, TCP connections, and process creations. The BCC tools are installed in the /usr/share/bcc/tools/ directory. The following bcc-tools helps to analyze performance:
  - biolatency summarizes the latency in block device I/O (disk I/O) in histogram. This allows the distribution to be studied, including two modes for device cache hits and for cache misses, and latency outliers.
  - biosnoop is a basic block I/O tracing tool for displaying each I/O event along with the issuing process ID, and the I/O latency. Using this tool, you can investigate disk I/O performance issues.
  - biotop is used for block i/o operations in the kernel.
  - filelife tool traces the stat() syscalls.
  - fileslower traces slow synchronous file reads and writes.
  - filetop displays file reads and writes by process.
  - ext4slower, nfsslower, and xfsslower are tools that show file system operations slower than a certain threshold, which defaults to 10ms. For more information, see the Analyzing system performance with BPF Compiler Collection.

- bpftace is a tracing language for eBPF used for analyzing performance issues. It also provides trace utilities like BCC for system observation, which is useful for investigating I/O performance issues.

- The following SystemTap scripts may be useful in diagnosing storage or file system performance problems:
  - disktop.stp: Checks the status of reading or writing disk every 5 seconds and outputs the top ten entries during that period.
  - iotime.stp: Prints the amount of time spent on read and write operations, and the number of bytes read and written.
  - traceio.stp: Prints the top ten executable based on cumulative I/O traffic observed, every second.
  - traceio2.stp: Prints the executable name and process identifier as reads and writes to the specified device occur.
  - Inodewatch.stp: Prints the executable name and process identifier each time a read or write occurs to the specified inode on the specified major or minor device.
- **inodewatch2.stp**: Prints the executable name, process identifier, and attributes each time the attributes are changed on the specified inode on the specified major or minor device.

**Additional resources**
- `vmstat(8), iostat(1), blktrace(8), blkparse(1), btt(1), bpftrace`, and `iowatcher(1)` man pages
- Analyzing system performance with BPF Compiler Collection

### 33.2. AVAILABLE TUNING OPTIONS FOR FORMATTING A FILE SYSTEM

Some file system configuration decisions cannot be changed after the device is formatted.

The following are the options available before formatting a storage device:

**Size**
Create an appropriately-sized file system for your workload. Smaller file systems require less time and memory for file system checks. However, if a file system is too small, its performance suffers from high fragmentation.

**Block size**
The block is the unit of work for the file system. The block size determines how much data can be stored in a single block, and therefore the smallest amount of data that is written or read at one time. The default block size is appropriate for most use cases. However, your file system performs better and stores data more efficiently if the block size or the size of multiple blocks is the same as or slightly larger than the amount of data that is typically read or written at one time. A small file still uses an entire block. Files can be spread across multiple blocks, but this can create additional runtime overhead.

Additionally, some file systems are limited to a certain number of blocks, which in turn limits the maximum size of the file system. Block size is specified as part of the file system options when formatting a device with the `mkfs` command. The parameter that specifies the block size varies with the file system.

**Geometry**
File system geometry is concerned with the distribution of data across a file system. If your system uses striped storage, like RAID, you can improve performance by aligning data and metadata with the underlying storage geometry when you format the device. Many devices export recommended geometry, which is then set automatically when the devices are formatted with a particular file system. If your device does not export these recommendations, or you want to change the recommended settings, you must specify geometry manually when you format the device with the `mkfs` command.

The parameters that specify file system geometry vary with the file system.

**External journals**
Journaling file systems document the changes that will be made during a write operation in a journal file prior to the operation being executed. This reduces the likelihood that a storage device will become corrupted in the event of a system crash or power failure, and speeds up the recovery process.
NOTE

Red Hat does not recommend using the external journals option.

Metadata-intensive workloads involve very frequent updates to the journal. A larger journal uses more memory, but reduces the frequency of write operations. Additionally, you can improve the seek time of a device with a metadata-intensive workload by placing its journal on dedicated storage that is as fast as, or faster than, the primary storage.

WARNING

Ensure that external journals are reliable. Losing an external journal device causes file system corruption. External journals must be created at format time, with journal devices being specified at mount time.

Additional resources

- `mkfs(8)` and `mount(8)` man pages
- Overview of available file systems

33.3. AVAILABLE TUNING OPTIONS FOR MOUNTING A FILE SYSTEM

The following are the options available to most file systems and can be specified as the device is mounted:

Access Time

Every time a file is read, its metadata is updated with the time at which access occurred (`atime`). This involves additional write I/O. The `relatime` is the default `atime` setting for most file systems. However, if updating this metadata is time consuming, and if accurate access time data is not required, you can mount the file system with the `noatime` mount option. This disables updates to metadata when a file is read. It also enables `nodiratime` behavior, which disables updates to metadata when a directory is read.

NOTE

Disabling `atime` updates by using the `noatime mount` option can break applications that rely on them, for example, backup programs.

Read-ahead

`Read-ahead` behavior speeds up file access by pre-fetching data that is likely to be needed soon and loading it into the page cache, where it can be retrieved more quickly than if it were on disk. The higher the read-ahead value, the further ahead the system pre-fetches data. Red Hat Enterprise Linux attempts to set an appropriate read-ahead value based on what it detects about your file system. However, accurate detection is not always possible. For example, if a storage array presents itself to the system as a single LUN, the system detects the single LUN, and does not set the appropriate read-ahead value for an array.
Workloads that involve heavy streaming of sequential I/O often benefit from high read-ahead values. The storage-related tuned profiles provided with Red Hat Enterprise Linux raise the read-ahead value, as does using LVM striping, but these adjustments are not always sufficient for all workloads.

Additional resources
- mount(8), xfs(5), and ext4(5) man pages

33.4. TYPES OF DISCARDING UNUSED BLOCKS

Regularly discarding blocks that are not in use by the file system is a recommended practice for both solid-state disks and thinly-provisioned storage.

The following are the two methods of discarding unused blocks:

**Batch discard**
This type of discard is part of the `fstrim` command. It discards all unused blocks in a file system that match criteria specified by the administrator. Red Hat Enterprise Linux 8 supports batch discard on XFS and ext4 formatted devices that support physical discard operations.

**Online discard**
This type of discard operation is configured at mount time with the discard option, and runs in real time without user intervention. However, it only discards blocks that are transitioning from used to free. Red Hat Enterprise Linux 8 supports online discard on XFS and ext4 formatted devices. Red Hat recommends batch discard, except where online discard is required to maintain performance, or where batch discard is not feasible for the system’s workload.

Pre-allocation marks disk space as being allocated to a file without writing any data into that space. This can be useful in limiting data fragmentation and poor read performance. Red Hat Enterprise Linux 8 supports pre-allocating space on XFS, ext4, and GFS2 file systems. Applications can also benefit from pre-allocating space by using the `fallocate(2)` glibc call.

Additional resources
- mount(8) and `fallocate(2)` man pages

33.5. SOLID-STATE DISKS TUNING CONSIDERATIONS

Solid-state disks (SSD) use NAND flash chips rather than rotating magnetic platters to store persistent data. SSD provides a constant access time for data across their full Logical Block Address range, and does not incur measurable seek costs like their rotating counterparts. They are more expensive per gigabyte of storage space and have a lesser storage density, but they also have lower latency and greater throughput than HDDs.

Performance generally degrades as the used blocks on an SSD approach the capacity of the disk. The degree of degradation varies by vendor, but all devices experience degradation in this circumstance. Enabling discard behavior can help to alleviate this degradation. For more information, see Types of discarding unused blocks.

The default I/O scheduler and virtual memory options are suitable for use with SSDs. Consider the following factors when configuring settings that can affect SSD performance:

I/O Scheduler
Any I/O scheduler is expected to perform well with most SSDs. However, as with any other storage type, Red Hat recommends benchmarking to determine the optimal configuration for a given workload. When using SSDs, Red Hat advises changing the I/O scheduler only for benchmarking particular workloads. For instructions on how to switch between I/O schedulers, see the `/usr/share/doc/kernel-version/Documentation/block/switching-sched.txt` file.

For single queue HBA, the default I/O scheduler is `deadline`. For multiple queue HBA, the default I/O scheduler is `none`. For information about how to set the I/O scheduler, see `Setting the disk scheduler`.

**Virtual Memory**

Like the I/O scheduler, virtual memory (VM) subsystem requires no special tuning. Given the fast nature of I/O on SSD, try turning down the `vm_dirty_background_ratio` and `vm_dirty_ratio` settings, as increased write-out activity does not usually have a negative impact on the latency of other operations on the disk. However, this tuning can generate more overall I/O, and is therefore not generally recommended without workload-specific testing.

**Swap**

An SSD can also be used as a swap device, and is likely to produce good page-out and page-in performance.

### 33.6. GENERIC BLOCK DEVICE TUNING PARAMETERS

The generic tuning parameters listed here are available in the `/sys/block/sdX/queue/` directory.

The following listed tuning parameters are separate from I/O scheduler tuning, and are applicable to all I/O schedulers:

**add_random**

Some I/O events contribute to the entropy pool for the `/dev/random`. This parameter can be set to 0 if the overhead of these contributions become measurable.

**iostats**

By default, `iostats` is enabled and the default value is 1. Setting `iostats` value to 0 disables the gathering of I/O statistics for the device, which removes a small amount of overhead with the I/O path. Setting `iostats` to 0 might slightly improve performance for very high performance devices, such as certain NVMe solid-state storage devices. It is recommended to leave `iostats` enabled unless otherwise specified for the given storage model by the vendor.

If you disable `iostats`, the I/O statistics for the device are no longer present within the `/proc/diskstats` file. The content of `/sys/diskstats` file is the source of I/O information for monitoring I/O tools, such as `sar` or `iostats`. Therefore, if you disable the `iostats` parameter for a device, the device is no longer present in the output of I/O monitoring tools.

**max_sectors_kb**

Specifies the maximum size of an I/O request in kilobytes. The default value is 512 KB. The minimum value for this parameter is determined by the logical block size of the storage device. The maximum value for this parameter is determined by the value of the `max_hw_sectors_kb`.

Red Hat recommends `max_sectors_kb` to always be a multiple of the optimal I/O size and the internal erase block size. Use a value of `logical_block_size` for either parameter if they are zero or not specified by the storage device.

**nomerges**

Most workloads benefit from request merging. However, disabling merges can be useful for debugging purposes. By default, the `nomerges` parameter is set to 0, which enables merging. To disable simple one-hit merging, set `nomerges` to 1. To disable all types of merging, set `nomerges`
to 2.

**nr_requests**

It is the maximum allowed number of the queued I/O. If the current I/O scheduler is **none**, this number can only be reduced; otherwise the number can be increased or reduced.

**optimal_io_size**

Some storage devices report an optimal I/O size through this parameter. If this value is reported, Red Hat recommends that applications issue I/O aligned to and in multiples of the optimal I/O size wherever possible.

**read_ahead_kb**

Defines the maximum number of kilobytes that the operating system may read ahead during a sequential read operation. As a result, the necessary information is already present within the kernel page cache for the next sequential read, which improves read I/O performance. Device mappers often benefit from a high read_ahead_kb value. 128 KB for each device to be mapped is a good starting point, but increasing the read_ahead_kb value up to request queue’s max_sectors_kb of the disk might improve performance in application environments where sequential reading of large files takes place.

**rotational**

Some solid-state disks do not correctly advertise their solid-state status, and are mounted as traditional rotational disks. Manually set the rotational value to 0 to disable unnecessary seek-reducing logic in the scheduler.

**rq_affinity**

The default value of the rq_affinity is 1. It completes the I/O operations on one CPU core, which is in the same CPU group of the issued CPU core. To perform completions only on the processor that issued the I/O request, set the rq_affinity to 2. To disable the mentioned two abilities, set it to 0.

**scheduler**

To set the scheduler or scheduler preference order for a particular storage device, edit the /sys/block/devname/queue/scheduler file, where devname is the name of the device you want to configure.
CHAPTER 34. TUNING THE NETWORK PERFORMANCE

Tuning the network settings is a complex process with many factors to consider. For example, this includes the CPU-to-memory architecture, the amount of CPU cores, and more. Red Hat Enterprise Linux uses default settings that are optimized for most scenarios. However, in certain cases, it can be necessary to tune network settings to increase the throughput or latency or to solve problems, such as packet drops.

34.1. TUNING NETWORK ADAPTER SETTINGS

In high-speed networks with 40 Gbps and faster, certain default values of network adapter-related kernel settings can be a cause of packet drops and performance degradation. Tuning these settings can prevent such problems.

34.1.1. Increasing the ring buffers to reduce a high packet drop rate

Receive ring buffers are shared between the device driver and network interface controller (NIC). The card assigns a transmit (TX) and receive (RX) ring buffer. As the name implies, the ring buffer is a circular buffer where an overflow overwrites existing data. There are two ways to move data from the NIC to the kernel, hardware interrupts and software interrupts, also called SoftIRQs.

The kernel uses the RX ring buffer to store incoming packets until they can be processed by the device driver. The device driver drains the RX ring, typically using SoftIRQs, which puts the incoming packets into a kernel data structure called an `sk_buff` or `skb` to begin its journey through the kernel and up to the application which owns the relevant socket.

The kernel uses the TX ring buffer to hold outgoing packets which are destined for the wire. These ring buffers reside at the bottom of the stack and are a crucial point at which packet drop can occur, which in turn will adversely affect network performance.

Increase the size of an Ethernet device’s ring buffers if the packet drop rate causes applications to report a loss of data, timeouts, or other issues.

Procedure

1. Display the packet drop statistics of the interface:

   ```bash
   # ethtool -S enp1s0
   ...
   rx_queue_0_drops: 97326
   rx_queue_1_drops: 63783
   ...
   ```

   Note that the output of the command depends on the network card and the driver.

   High values in `discard` or `drop` counters indicate that the available buffer fills up faster than the kernel can process the packets. Increasing the ring buffers can help to avoid such loss.

2. Display the maximum ring buffer sizes:

   ```bash
   # ethtool -g enp1s0
   Ring parameters for enp1s0:
   Pre-set maximums:
   RX: 4096
   RX Mini: 0
   ```
RX Jumbo: 16320
TX: 4096
Current hardware settings:
RX: 255
RX Mini: 0
RX Jumbo: 0
TX: 255

If the values in the **Pre-set maximums** section are higher than in the **Current hardware settings** section, you can change the settings in the next steps.

3. Identify the NetworkManager connection profile that uses the interface:

```
# nmcli connection show
NAME                UUID                                  TYPE      DEVICE
Example-Connection  a5eb6490-cc20-3668-81f8-0314a27f3f75  ethernet  enp1s0
```

4. Update the connection profile, and increase the ring buffers:

   - To increase the RX ring buffer, enter:
     ```
     # nmcli connection modify Example-Connection ethtool.ring-rx 4096
     ```
   - To increase the TX ring buffer, enter:
     ```
     # nmcli connection modify Example-Connection ethtool.ring-tx 4096
     ```

5. Reload the NetworkManager connection:

   ```
   # nmcli connection up Example-Connection
   ```

**IMPORTANT**

Depending on the driver your NIC uses, changing in the ring buffer can shortly interrupt the network connection.

- ifconfig and ip commands report packet drops
- Should I be concerned about a 0.05% packet drop rate?
- ethtool(8) man page

### 34.1.2. Tuning the network device backlog queue to avoid packet drops

When a network card receives packets and before the kernel protocol stack processes them, the kernel stores these packets in backlog queues. The kernel maintains a separate queue for each CPU core.

If the backlog queue for a core is full, the kernel drops all further incoming packets that the `netif_receive_skb()` kernel function assigns to this queue. If the server contains a 10 Gbps or faster network adapter or multiple 1 Gbps adapters, tune the backlog queue size to avoid this problem.
Prerequisites

- A 10 Gbps or faster or multiple 1 Gbps network adapters

Procedure

1. Determine whether tuning the backlog queue is needed, display the counters in the `/proc/net/softnet_stat` file:

   ```bash
   # awk '{for (i=1; i<=NF; i++) printf strtonum("0x" $i) (i==NF?"n":" ")}'
   /proc/net/softnet_stat | column -t
   221951548  0      0  0  0  0  0  0  0  0  0  0  0
   192058677  18862  0  0  0  0  0  0  0  0  0  0  1
   455324886  0      0  0  0  0  0  0  0  0  0  0  2
   ...
   ``

   This `awk` command converts the values in `/proc/net/softnet_stat` from hexadecimal to decimal format and displays them in table format. Each line represents a CPU core starting with core 0.

   The relevant columns are:
   - First column: The total number of received frames
   - Second column: The number of dropped frames because of a full backlog queue
   - Last column: The CPU core number

2. If the values in the second column of the `/proc/net/softnet_stat` file increment over time, increase the size of the backlog queue:

   a. Display the current backlog queue size:

      ```bash
      # sysctl net.core.netdev_max_backlog
      net.core.netdev_max_backlog = 1000
      ```

   b. Create the `/etc/sysctl.d/10-netdev_max_backlog.conf` file with the following content:

      ```bash
      net.core.netdev_max_backlog = 2000
      ```

      Set the `net.core.netdev_max_backlog` parameter to a double of the current value.

   c. Load the settings from the `/etc/sysctl.d/10-netdev_max_backlog.conf` file:

      ```bash
      # sysctl -p /etc/sysctl.d/10-netdev_max_backlog.conf
      ```

Verification

- Monitor the second column in the `/proc/net/softnet_stat` file:

  ```bash
  # awk '{for (i=1; i<=NF; i++) printf strtonum("0x" $i) (i==NF?"n":" ")}'
  /proc/net/softnet_stat | column -t
  ```

  If the values still increase, double the `net.core.netdev_max_backlog` value again. Repeat this process until the packet drop counters no longer increase.
34.1.3. Increasing the transmit queue length of a NIC to reduce the number of transmit errors

The kernel stores packets in a transmit queue before transmitting them. The default length (1000 packets) is typically sufficient for 10 Gbps and often also for 40 Gbps networks. However, in faster networks, or if you encounter an increasing number of transmit errors on an adapter, increase the queue length.

Procedure

1. Display the current transmit queue length:

```
# ip -s link show enp1s0
2: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
    mode DEFAULT group default qlen 1000
    ...'
```

In this example, the transmit queue length (qlen) of the enp1s0 interface is 1000.

2. Monitor the dropped packets counter of a network interface’s software transmit queue:

```
# tc -s qdisc show dev enp1s0
qdisc fq_codel 0: root refcnt 2 limit 1024p flows 1024 quantum 1514 target 5ms interval 100ms memory_limit 32Mb ecn drop_batch 64
Sent 16889923 bytes 426862765 pkt (dropped 191980, overlimits 0 requeues 2)
...'
```

3. If you encounter a high or increasing transmit error count, set a higher transmit queue length:

   a. Identify the NetworkManager connection profile that uses this interface:

```
# nmcli connection show
NAME                UUID                                  TYPE      DEVICE
Example-Connection  a5eb6490-cc20-3668-81f8-0314a27f3f75  ethernet enp1s0
```

   b. Create the /etc/NetworkManager/dispatcher.d/99-set-tx-queue-length-up NetworkManager dispatcher script with the following content:

```
#!/bin/bash
# Set TX queue length on enp1s0 to 2000
if [ "$1" == "enp1s0" ] && [ "$2" == "up" ]; then
    ip link set dev enp1s0 txqueuelen 2000
fi
```

   c. Set the executable bit on the /etc/NetworkManager/dispatcher.d/99-set-tx-queue-length-up file:

```
# chmod +x /etc/NetworkManager/dispatcher.d/99-set-tx-queue-length-up
```

   d. Reload the NetworkManager connection:

```
# nmcli connection up Example-Connection
```
Verification

1. Display the transmit queue length:

   ![Command Example]

   ```
   # ip -s link show enp1s0
   2: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
   mode DEFAULT group default qlen 2000
   ...
   ```

2. Monitor the dropped packets counter:

   ![Command Example]

   ```
   # tc -s qdisc show dev enp1s0
   ```

   If the dropped counter still increases, double the transmit queue length again. Repeat this process until the counter no longer increases.

### 34.2. TUNING IRQ BALANCING

On multi-core hosts, you can increase the performance by ensuring that Red Hat Enterprise Linux balances interrupt queues (IRQs) to distribute the interrupts across CPU cores.

#### 34.2.1. Interrupts and interrupt handlers

When a network interface controller (NIC) receives incoming data, it copies the data into kernel buffers by using Direct Memory Access (DMA). The NIC then notifies the kernel about this data by triggering a hard interrupt. These interrupts are processed by interrupt handlers which do minimal work, as they have already interrupted another task and the handlers cannot interrupt themselves. Hard interrupts can be costly in terms of CPU usage, especially if they use kernel locks.

The hard interrupt handler then leaves the majority of packet reception to a software interrupt request (SoftIRQ) process. The kernel can schedule these processes more fairly.

#### Example 34.1. Displaying hardware interrupts

The kernel stores the interrupt counters in the `/proc/interrupts` file. To display the counters for a specific NIC, such as `enp1s0`, enter:

```
# egrep "CPU|enp1s0" /proc/interrupts
```

<table>
<thead>
<tr>
<th>CPU</th>
<th>CPU1</th>
<th>CPU2</th>
<th>CPU3</th>
<th>CPU4</th>
<th>CPU5</th>
</tr>
</thead>
<tbody>
<tr>
<td>105:</td>
<td>141606</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>106:</td>
<td>0</td>
<td>141091</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>107:</td>
<td>2</td>
<td>163785</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>108:</td>
<td>3</td>
<td>0</td>
<td>194370</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>109:</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Each queue has an interrupt vector in the first column assigned to it. The kernel initializes these vectors when the system boots or when a user loads the NIC driver module. Each receive (RX) and transmit (TX) queue is assigned a unique vector that informs the interrupt handler which NIC or queue the interrupt is coming from. The columns represent the number of incoming interrupts for every CPU core.

#### 34.2.2. Software interrupt requests
Software interrupt requests (SoftIRQs) clear the receive ring buffers of network adapters. The kernel schedules SoftIRQ routines to run at a time when other tasks will not be interrupted. On Red Hat Enterprise Linux, processes named `ksoftirqd/cpu-number` run these routines and call driver-specific code functions.

To monitor the SoftIRQ counters for each CPU core, enter:

```
# watch -n1 'egrep "CPU|NET_RX|NET_TX" /proc/softirqs'
```

<table>
<thead>
<tr>
<th></th>
<th>CPU0</th>
<th>CPU1</th>
<th>CPU2</th>
<th>CPU3</th>
<th>CPU4</th>
<th>CPU5</th>
<th>CPU6</th>
<th>CPU7</th>
</tr>
</thead>
<tbody>
<tr>
<td>NET_TX</td>
<td>49672</td>
<td>52610</td>
<td>28175</td>
<td>97288</td>
<td>12633</td>
<td>19843</td>
<td>18746</td>
<td>220689</td>
</tr>
<tr>
<td>NET_RX</td>
<td>96</td>
<td>1615</td>
<td>789</td>
<td>46</td>
<td>31</td>
<td>1735</td>
<td>1315</td>
<td>470798</td>
</tr>
</tbody>
</table>

The command dynamically updates the output. Press `Ctrl+C` to interrupt the output.

### 34.2.3. NAPI Polling

New API (NAPI) is an extension to the device driver packet processing framework to improve the efficiency of incoming network packets. Hard interrupts are expensive because they usually cause a context switch from the kernel space to the user space and back again, and cannot interrupt themselves. Even with interrupt coalescence, the interrupt handler monopolizes a CPU core completely. With NAPI, the driver can use a polling mode instead of being hard-interrupted by the kernel for every packet that is received.

Under normal operation, the kernel issues an initial hard interrupt, followed by a soft interrupt request (SoftIRQ) handler that polls the network card using NAPI routines. To prevent SoftIRQs from monopolizing a CPU core, the polling routine has a budget that determines the CPU time the SoftIRQ can consume. On completion of the SoftIRQ poll routine, the kernel exits the routine and schedules it to run again at a later time to repeat the process of receiving packets from the network card.

### 34.2.4. The irqbalance service

On systems both with and without Non-Uniform Memory Access (NUMA) architecture, the `irqbalance` service balances interrupts effectively across CPU cores, based on system conditions. The `irqbalance` service runs in the background and monitors the CPU load every 10 seconds. The service moves interrupts to other CPU cores when a CPU’s load is too high. As a result, the system performs well and handles load more efficiently.

If `irqbalance` is not running, usually the CPU core 0 handles most of the interrupts. Even at moderate load, this CPU core can become busy trying to handle the workload of all the hardware in the system. As a consequence, interrupts or interrupt-based work can be missed or delayed. This can result in low network and storage performance, packet loss, and potentially other issues.

**IMPORTANT**

Disabling `irqbalance` can negatively impact the network throughput.

On systems with only a single CPU core, the `irqbalance` service provides no benefit and exits on its own.

By default, the `irqbalance` service is enabled and running on Red Hat Enterprise Linux. To re-enable the service if you disabled it, enter:

```
# systemctl enable --now irqbalance
```
Additional resources

- **Do we need irqbalance?** [solution](#)
- **How should I configure network interface IRQ channels?** [solution](#)

### 34.2.5. Increasing the time SoftIRQs can run on the CPU

If SoftIRQs do not run long enough, the rate of incoming data could exceed the kernel’s capability to drain the buffer fast enough. As a result, the network interface controller (NIC) buffers overflow and packets are lost.

If `softirqd` processes could not retrieve all packets from interfaces in one NAPI polling cycle, it is an indicator that the SoftIRQs do not have enough CPU time. This could be the case on hosts with fast NICs, such as 10 Gbps and faster. If you increase the values of the `net.core.netdev_budget` and `net.core.netdev_budget_usecs` kernel parameters, you can control the time and number of packets `softirqd` can process in a polling cycle.

**Procedure**

1. To determine whether tuning the `net.core.netdev_budget` parameter is needed, display the counters in the `/proc/net/softnet_stat` file:

   ```bash
   # awk '{for (i=1; i<=NF; i++) printf strtonum("0x" $i) (i==NF?"n": "")}'
   /proc/net/softnet_stat | column -t
   221951548  0  0  0  0  0  0  0  0  0  0  0
   192058677  0  20380  0  0  0  0  0  0  0  0  1
   455324886  0  0  0  0  0  0  0  0  0  0  2
   ...
   ``

   This `awk` command converts the values in `/proc/net/softnet_stat` from hexadecimal to decimal format and displays them in the table format. Each line represents a CPU core starting with core 0.

   The relevant columns are:

   - **First column**: The total number of received frames.
   - **Third column**: The number times `softirqd` processes that could not retrieve all packets from interfaces in one NAPI polling cycle.
   - **Last column**: The CPU core number.

2. If the counters in the third column of the `/proc/net/softnet_stat` file increment over time, tune the system:

   a. Display the current values of the `net.core.netdev_budget_usecs` and `net.core.netdev_budget` parameters:

   ```bash
   # sysctl net.core.netdev_budget_usecs net.core.netdev_budget
   net.core.netdev_budget_usecs = 2000
   net.core.netdev_budget = 300
   ```

   With these settings, `softirqd` processes have up to 2000 microseconds to process up to 300 messages from the NIC in one polling cycle. Polling ends based on which condition is met first.
b. Create the `/etc/sysctl.d/10-netdev_budget.conf` file with the following content:

```bash
net.core.netdev_budget = 600
net.core.netdev_budget_usecs = 4000
```

Set the parameters to a double of their current values.

c. Load the settings from the `/etc/sysctl.d/10-netdev_budget.conf` file:

```bash
# sysctl -p /etc/sysctl.d/10-netdev_budget.conf
```

Verification

- Monitor the third column in the `/proc/net/softnet_stat` file:

```bash
# awk '{for (i=1; i<=NF; i++) printf strtonum("0x" $i) (i==NF?"\n":"")}'
/proc/net/softnet_stat | column -t
```

If the values still increase, set `net.core.netdev_budget_usecs` and `net.core.netdev_budget` to higher values. Repeat this process until the counters no longer increase.

## 34.3. IMPROVING THE NETWORK LATENCY

CPU power management features can cause unwanted delays in time-sensitive application processing. You can disable some or all of these power management features to improve the network latency.

For example, if the latency is higher when the server is idle than under heavy load, CPU power management settings could influence the latency.

**IMPORTANT**

Disabling CPU power management features can cause a higher power consumption and heat loss.

### 34.3.1. How the CPU power states influence the network latency

The consumption state (C-states) of CPUs optimize and reduce the power consumption of computers. The C-states are numbered, starting at C0. In C0, the processor is fully powered and executing. In C1, the processor is fully powered but not executing. The higher the number of the C-state, the more components the CPU turns off.

Whenever a CPU core is idle, the built-in power saving logic steps in and attempts to move the core from the current C-state to a higher one by turning off various processor components. If the CPU core must process data, Red Hat Enterprise Linux (RHEL) sends an interrupt to the processor to wake up the core and set its C-state back to C0.

Moving out of deep C-states back to C0 takes time due to turning power back on to various components of the processor. On multi-core systems, it can also happen that many of the cores are simultaneously idle and, therefore, in deeper C-states. If RHEL tries to wake them up at the same time, the kernel can generate a large number of Inter-Processor Interrupts (IPIs) while all cores return from deep C-states. Due to locking that is required while processing interrupts, the system can then stall for some time while handling all the interrupts. This can result in large delays in the application response to events.
Example 34.2. Displaying times in C-state per core

The Idle Stats page in the PowerTOP application displays how much time the CPU cores spend in each C-state:

<table>
<thead>
<tr>
<th>Pkg(HW)</th>
<th>Core(HW)</th>
<th>CPU(OS) 0</th>
<th>CPU(OS) 4</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>C0 active</td>
<td>2.5%</td>
</tr>
<tr>
<td></td>
<td>POLL</td>
<td>0.0%</td>
<td>0.0 ms</td>
</tr>
<tr>
<td>C2</td>
<td></td>
<td>C1</td>
<td>0.1%</td>
</tr>
<tr>
<td>C3</td>
<td></td>
<td>C3 (cc3)</td>
<td>0.1%</td>
</tr>
<tr>
<td>C6</td>
<td></td>
<td>C6 (cc6)</td>
<td>8.3%</td>
</tr>
<tr>
<td>C7</td>
<td></td>
<td>C7 (cc7)</td>
<td>76.6%</td>
</tr>
<tr>
<td>C8</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>C9</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>C10</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Additional resources

- Managing power consumption with PowerTOP

34.3.2. C-state settings in the EFI firmware

In most systems with an EFI firmware, you can enable and disable the individual consumption states (C-states). However, on Red Hat Enterprise Linux (RHEL), the idle driver determines whether the kernel uses the settings from the firmware:

- **intell_idle**: This is the default driver on hosts with an Intel CPU and ignores the C-state settings from the EFI firmware.

- **acpi_idle**: RHEL uses this driver on hosts with CPUs from vendors other than Intel and if **intell_idle** is disabled. By default, the **acpi_idle** driver uses the C-state settings from the EFI firmware.

Additional resources

- `/usr/share/doc/kernel-doc-<version>/Documentation/admin-guide/pm/cpuidle.rst` provided by the `kernel-doc` package

34.3.3. Disabling C-states by using a custom TuneD profile

The TuneD service uses the Power Management Quality of Service (PMQOS) interface of the kernel to set consumption states (C-states) locking. The kernel idle driver can communicate with this interface to dynamically limit the C-states. This prevents that administrators must hard code a maximum C-state value by using kernel command line parameters.

Prerequisites

- The `tuned` package is installed.
The tuned service is enabled and running.

Procedure

1. Display the active profile:

```bash
# tuned-adm active
Current active profile: network-latency
```

2. Create a directory for the custom TuneD profile:

```bash
# mkdir /etc/tuned/network-latency-custom/
```

3. Create the `/etc/tuned/network-latency-custom/tuned.conf` file with the following content:

```bash
[main]
include=network-latency

[cpu]
force_latency=cstate.id:1|2
```

This custom profile inherits all settings from the network-latency profile. The `force_latency` TuneD parameter specifies the latency in microseconds (µs). If the C-state latency is higher than the specified value, the idle driver in Red Hat Enterprise Linux prevents the CPU from moving to a higher C-state. With `force_latency=cstate.id:1|2`, TuneD first checks if the `/sys/devices/system/cpu/cpu_<number>_/cpuidle/state_<cstate.id>_` directory exists. In this case, TuneD reads the latency value from the latency file in this directory. If the directory does not exist, TuneD uses 2 microseconds as a fallback value.

4. Activate the network-latency-custom profile:

```bash
# tuned-adm profile network-latency-custom
```

Additional resources

- Getting started with TuneD
- Customizing TuneD profiles

34.3.4. Disabling C-states by using a kernel command line option

The `processor.max_cstate` and `intel_idle.max_cstat` kernel command line parameters configure the maximum consumption states (C-state) CPU cores can use. For example, setting the parameters to 1 ensures that the CPU will never request a C-state below C1.

Use this method to test whether the latency of applications on a host are being affected by C-states. To not hard code a specific state, consider using a more dynamic solution. See Disabling C-states by using a custom TuneD profile.

Prerequisites

- The tuned service is not running or configured to not update C-state settings.
Procedure

1. Display the idle driver the system uses:

   ```
   # cat /sys/devices/system/cpu/cpuidle/current_driver
   intel_idle
   ```

2. If the host uses the `intel_idle` driver, set the `intel_idle.max_cstate` kernel parameter to define the highest C-state that CPU cores should be able to use:

   ```
   # grubby --update-kernel=ALL --args="intel_idle.max_cstate=0"
   ```

   Setting `intel_idle.max_cstate=0` disables the `intel_idle` driver. Consequently, the kernel uses the `acpi_idle` driver that uses the C-state values set in the EFI firmware. For this reason, also set `processor.max_cstate` to override these C-state settings.

3. On every host, independent from the CPU vendor, set the highest C-state that CPU cores should be able to use:

   ```
   # grubby --update-kernel=ALL --args="processor.max_cstate=0"
   ```

   IMPORTANT

   If you set `processor.max_cstate=0` in addition to `intel_idle.max_cstate=0`, the `acpi_idle` driver overrides the value of `processor.max_cstate` and sets it to 1. As a result, with `processor.max_cstate=0 intel_idle.max_cstate=0`, the highest C-state the kernel will use is C1, not C0.

4. Restart the host for the changes to take effect:

   ```
   # reboot
   ```

Verification

1. Display the maximum C-state:

   ```
   # cat /sys/module/processor/parameters/max_cstate
   1
   ```

2. If the host uses the `intel_idle` driver, display the maximum C-state:

   ```
   # cat /sys/module/intel_idle/parameters/max_cstate
   0
   ```

Additional resources

- What are CPU “C-states” and how to disable them if needed?

- `/usr/share/doc/kernel-doc-<version>/Documentation/admin-guide/pm/cpuidle.rst` provided by the `kernel-doc` package
34.4. IMPROVING THE THROUGHPUT OF LARGE AMOUNTS OF CONTIGUOUS DATA STREAMS

According to the IEEE 802.3 standard, a default Ethernet frame without Virtual Local Area Network (VLAN) tag has a maximum size of 1518 bytes. Each of these frames includes an 18 bytes header, leaving 1500 bytes for payload. Consequently, for every 1500 bytes of data the server transmits over the network, 18 bytes (1.2%) Ethernet frame header are overhead and transmitted as well. Headers from layer 3 and 4 protocols increase the overhead per packet further.

Consider employing jumbo frames to save overhead if hosts on your network often send numerous contiguous data streams, such as backup servers or file servers hosting numerous huge files. Jumbo frames are non-standardized frames that have a larger Maximum Transmission Unit (MTU) than the standard Ethernet payload size of 1500 bytes. For example, if you configure jumbo frames with the maximum allowed MTU of 9000 bytes payload, the overhead of each frame reduces to 0.2%.

Depending on the network and services, it can be beneficial to enable jumbo frames only in specific parts of a network, such as the storage backend of a cluster. This avoids packet fragmentation.

34.4.1. Considerations before configuring jumbo frames

Depending on your hardware, applications, and services in your network, jumbo frames can have different impacts. Decide carefully whether enabling jumbo frames provides a benefit in your scenario.

Prerequisites

All network devices on the transmission path must support jumbo frames and use the same Maximum Transmission Unit (MTU) size. In the opposite case, you can face the following problems:

- Dropped packets.
- Higher latency due to fragmented packets.
- Increased risk of packet loss caused by fragmentation. For example, if a router fragments a single 9000-bytes frame into six 1500-bytes frames, and any of those 1500-byte frames are lost, the whole frame is lost because it cannot be reassembled.

In the following diagram, all hosts in the three subnets must use the same MTU if a host from network A sends a packet to a host in network C:

Benefits of jumbo frames
Higher throughput: Each frame contains more user data while the protocol overhead is fixed.

- Lower CPU utilization: Jumbo frames cause fewer interrupts and, therefore, save CPU cycles.

**Drawbacks of jumbo frames**

- Higher latency: Larger frames delay packets that follow.
- Increased memory buffer usage: Larger frames can fill buffer queue memory more quickly.

### 34.4.2. Configuring the MTU in an existing NetworkManager connection profile

If your network requires a different Maximum Transmission Unit (MTU) than the default, you can configure this setting in the corresponding NetworkManager connection profile.

Jumbo frames are network packets with a payload of between 1500 and 9000 bytes. All devices in the same broadcast domain have to support those frames.

**Prerequisites**

- All devices in the broadcast domain use the same MTU.
- You know the MTU of the network.
- You already configured a connection profile for the network with the divergent MTU.

**Procedure**

1. Optional: Display the current MTU:

   ```
   # ip link show
   ...
   3: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
   mode DEFAULT group default qlen 1000
   link/ether 52:54:00:74:79:56 brd ff:ff:ff:ff:ff:ff
   ...
   ```

2. Optional: Display the NetworkManager connection profiles:

   ```
   # nmcli connection show
   NAME UUID TYPE DEVICE
   Example f2f33f29-bb5c-3a07-9069-be72eaec3ecf ethernet enp1s0
   ...
   ```

3. Set the MTU in the profile that manages the connection to the network with the divergent MTU:

   ```
   # nmcli connection modify Example mtu 9000
   ```

4. Reactivate the connection:

   ```
   # nmcli connection up Example
   ```

**Verification**
1. Display the MTU setting:

```
# ip link show
...
3: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 9000 qdisc fq_codel state UP
mode DEFAULT group default qlen 1000
 link/ether 52:54:00:74:79:56 brd ff:ff:ff:ff:ff:ff
...
```

2. Verify that no host on the transmission paths fragments the packets:

- On the receiver side, display the IP reassembly statistics of the kernel:

```
# nstat -az IpReasm*

#kernel
IpReasmTimeout 0 0.0
IpReasmReqds 0 0.0
IpReasmOKs 0 0.0
IpReasmFails 0 0.0
```

If the counters return 0, packets were not reassembled.

- On the sender side, transmit an ICMP request with the prohibit-fragmentation-bit:

```
# ping -c1 -Mdo -s 8972 destination_host
```

If the command succeeds, the packet was not fragmented.

Calculate the value for the `-s` packet size option as follows: MTU size - 8 bytes ICMP header - 20 bytes IPv4 header = packet size

### 34.5. TUNING TCP CONNECTIONS FOR HIGH THROUGHPUT

Tune TCP-related settings on Red Hat Enterprise Linux to increase the throughput, reduce the latency, or prevent problems, such as packet loss.

#### 34.5.1. Testing the TCP throughput using iperf3

The `iperf3` utility provides a server and client mode to perform network throughput tests between two hosts.

**NOTE**

The throughput of applications depends on many factors, such as the buffer sizes that the application uses. Therefore, the results measured with testing utilities, such as `iperf3`, can be significantly different from those of applications on a server under production workload.

**Prerequisites**

- The `iperf3` package is installed on both the client and server.
- No other services on either host cause network traffic that substantially affects the test result.
• For 40 Gbps and faster connections, the network card supports Accelerated Receive Flow Steering (ARFS) and the feature is enabled on the interface.

Procedure

1. Optional: Display the maximum network speed of the network interface controller (NIC) on both the server and client:

   # ethtool enp1s0 | grep "Speed"
   Speed: 100000Mb/s

2. On the server:
   a. Temporarily open the default `iperf3` TCP port 5201 in the `firewalld` service:

   # firewall-cmd --add-port=5201/tcp
   # firewall-cmd --reload

   b. Start `iperf3` in server mode:

   # iperf3 --server

   The service now is waiting for incoming client connections.

3. On the client:
   a. Start measuring the throughput:

   # iperf3 --time 60 --zerocopy --client 192.0.2.1

   • `--time <seconds>` Defines the time in seconds when the client stops the transmission. Set this parameter to a value that you expect to work and increase it in later measurements. If the server sends packets at a faster rate than the devices on the transmit path or the client can process, packets can be dropped.

   • `--zerocopy`: Enables a zero copy method instead of using the `write()` system call. You require this option only if you want to simulate a zero-copy-capable application or to reach 40 Gbps and more on a single stream.

   • `--client <server>`: Enables the client mode and sets the IP address or name of the server that runs the `iperf3` server.

4. Wait until `iperf3` completes the test. Both the server and the client display statistics every second and a summary at the end. For example, the following is a summary displayed on a client:

   [ ID ] Interval Transfer  Bitrate   Retr
   [  5 ] 0.00-60.00  sec  101 GBytes 14.4 Gbits/sec 0 sender
   [  5 ] 0.00-60.04  sec  101 GBytes 14.4 Gbits/sec receiver

   In this example, the average bitrate was 14.4 Gbps.

5. On the server:
   a. Press `Ctrl+C` to stop the `iperf3` server.
b. Close the TCP port 5201 in **firewalld**:

```
# firewall-cmd --remove-port=5201/tcp
# firewall-cmd --reload
```

**Additional resources**

- [iperf3(1) man page](#)

### 34.5.2. The system-wide TCP socket buffer settings

Socket buffers temporarily store data that the kernel has received or should send:

- The read socket buffer holds packets that the kernel has received but which the application has not read yet.
- The write socket buffer holds packets that an application has written to the buffer but which the kernel has not passed to the IP stack and network driver yet.

If a TCP packet is too large and exceeds the buffer size or packets are sent or received at a too fast rate, the kernel drops any new incoming TCP packet until the data is removed from the buffer. In this case, increasing the socket buffers can prevent packet loss.

Both the `net.ipv4.tcp_rmem` (read) and `net.ipv4.tcp_wmem` (write) socket buffer kernel settings contain three values:

```
net.ipv4.tcp_rmem = 4096  131072  6291456
net.ipv4.tcp_wmem = 4096  16384  4194304
```

The displayed values are in bytes and Red Hat Enterprise Linux uses them in the following way:

- The first value is the minimum buffer size. New sockets cannot have a smaller size.
- The second value is the default buffer size. If an application sets no buffer size, this is the default value.
- The third value is the maximum size of automatically tuned buffers. Using the `setsockopt()` function with the `SO_SNDBUF` socket option in an application disables this maximum buffer size.

Note that the `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` parameters set the socket sizes for both the IPv4 and IPv6 protocols.

### 34.5.3. Increasing the system-wide TCP socket buffers

The system-wide TCP socket buffers temporarily store data that the kernel has received or should send. Both `net.ipv4.tcp_rmem` (read) and `net.ipv4.tcp_wmem` (write) socket buffer kernel settings each contain three settings: A minimum, default, and maximum value.
IMPORTANT

Setting too large buffer sizes wastes memory. Each socket can be set to the size that the application requests, and the kernel doubles this value. For example, if an application requests a 256 KiB socket buffer size and opens 1 million sockets, the system can use up to 512 GB RAM (512 KiB x 1 million) only for the potential socket buffer space.

Additionally, a too large value for the maximum buffer size can increase the latency.

Prerequisites

- You encountered a significant rate of dropped TCP packets.

Procedure

1. Determine the latency of the connection. For example, ping from the client to server to measure the average Round Trip Time (RTT):

   ```
   # ping -c 10 server.example.com
   ...
   --- server.example.com ping statistics ---
   10 packets transmitted, 10 received, 0% packet loss, time 9014ms
   rtt min/avg/max/mdev = 117.208/117.056/119.333/0.616 ms
   ```

   In this example, the latency is 117 ms.

2. Use the following formula to calculate the Bandwidth Delay Product (BDP) for the traffic you want to tune:

   \[
   \text{connection speed in bytes} \times \text{latency in ms} = \text{BDP in bytes}
   \]

   For example, to calculate the BDP for a 10 Gbps connection that has a 117 ms latency:

   \[
   (10 \times 1000 \times 1000 \times 1000 / 8) \times 117 = 10683760 \text{ bytes}
   \]

3. Create the `/etc/sysctl.d/10-tcp-socket-buffers.conf` file and either set the maximum read or write buffer size, or both, based on your requirements:

   ```
   net.ipv4.tcp_rmem = 4096 262144 21367520
   net.ipv4.tcp_wmem = 4096 24576 21367520
   ```

   Specify the values in bytes. Use the following rule of thumb when you try to identify optimized values for your environment:

   - Default buffer size (second value): Increase this value only slightly or set it to 524288 (512 KiB) at most. A too high default buffer size can cause buffer collapsing and, consequently, latency spikes.
   - Maximum buffer size (third value): A value double to triple of the BDP is often sufficient.

4. Load the settings from the `/etc/sysctl.d/10-tcp-socket-buffers.conf` file:

   ```
   # sysctl -p /etc/sysctl.d/10-tcp-socket-buffers.conf
   ```
5. Configure your applications to use a larger socket buffer size. The third value in the `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` parameters defines the maximum buffer size that the `setsockopt()` function in an application can request.
   For further details, see the documentation of the programming language of your application. If you are not the developer of the application, contact the developer.

6. If you have changed the second value in the `net.ipv4.tcp_rmem` or `net.ipv4.tcp_wmem` parameter, restart the applications to use the new TCP buffer sizes.
   If you have changed only the third value, you do not need to restart the application because auto-tuning applies these settings dynamically.

**Verification**

1. Optional: Test the TCP throughput using iperf3.

2. Monitor the packet drop statistics using the same method that you used when you encountered the packet drops.
   If packet drops still occur but at a lower rate, increase the buffer sizes further.

**Additional resources**

- `tcp(7)` man page
- `socket(7)` man page

### 34.5.4. TCP Window Scaling

The TCP Window Scaling feature, which is enabled by default in Red Hat Enterprise Linux, is an extension of the TCP protocol that significantly improves the throughput.

For example, on a 1 Gbps connection with 1.5 ms Round Trip Time (RTT):

- With TCP Window Scaling enabled, approximately 630 Mbps are realistic.
- With TCP Window Scaling disabled, the throughput goes down to 380 Mbps.

One of the features TCP provides is flow control. With flow control, a sender can send as much data as the receiver can receive, but no more. To achieve this, the receiver advertises a window value, which is the amount of data a sender can send.

TCP originally supported window sizes up to 64 KiB, but at high Bandwidth Delay Products (BDP), this value becomes a restriction because the sender cannot send more than 64 KiB at a time. High-speed connections can transfer much more than 64 KiB of data at a given time. For example, a 10 Gbps link with 1 ms of latency between systems can have more than 1 MiB of data in transit at a given time. It would be inefficient if a host sends only 64 KiB, then pauses until the other host receives that 64 KiB.

To remove this bottleneck, the TCP Window Scaling extension allows the TCP window value to be arithmetically shifted left to increase the window size beyond 64 KiB. For example, the largest window value of 65535 shifted 7 places to the left, resulting in a window size of almost 8 MiB. This enables transferring much more data at a given time.

TCP Window Scaling is negotiated during the three-way TCP handshake that opens every TCP connection. Both sender and receiver must support TCP Window Scaling for the feature to work. If either or both participants do not advertise window scaling ability in their handshake, the connection...
reverts to using the original 16-bit TCP window size.

By default, TCP Window Scaling is enabled in Red Hat Enterprise Linux:

```
# sysctl net.ipv4.tcp_window_scaling
net.ipv4.tcp_window_scaling = 1
```

If TCP Window Scaling is disabled (0) on your server, revert the setting in the same way as you set it.

- Configuring kernel parameters at runtime

### 34.5.5. How TCP SACK reduces the packet drop rate

The TCP Selective Acknowledgment (TCP SACK) feature, which is enabled by default in Red Hat Enterprise Linux (RHEL), is an enhancement of the TCP protocol and increases the efficiency of TCP connections.

In TCP transmissions, the receiver sends an ACK packet to the sender for every packet it receives. For example, a client sends the TCP packets 1-10 to the server but the packets number 5 and 6 get lost. Without TCP SACK, the server drops packets 7-10, and the client must retransmit all packets from the point of loss, which is inefficient. With TCP SACK enabled on both hosts, the client must re-transmit only the lost packets 5 and 6.

**IMPORTANT**

Disabling TCP SACK decreases the performance and causes a higher packet drop rate on the receiver side in a TCP connection.

By default, TCP SACK is enabled in RHEL. To verify:

```
# sysctl net.ipv4.tcp_sack
1
```

If TCP SACK is disabled (0) on your server, revert the setting in the same way as you set it.

- Configuring kernel parameters at runtime

### 34.6. TUNING UDP CONNECTIONS

Before you start tuning Red Hat Enterprise Linux to improve the throughput of UDP traffic, it is important to have the realistic expectations. UDP is a simple protocol. Compared to TCP, UDP does not contain features, such as flow control, congestion control, and data reliability. This makes it difficult to
reach reliable communication over UDP with a throughput rate that is close to the maximum speed of the network interface controller (NIC).

### 34.6.1. Detecting packet drops

There are multiple levels in the network stack in which the kernel can drop packets. Red Hat Enterprise Linux provides different utilities to display statistics of these levels. Use them to identify potential problems.

Note that you can ignore a very small rate of dropped packets. However, if you encounter a significant rate, consider tuning measures.

**NOTE**

The kernel drops network packets if the networking stack cannot handle the incoming traffic.

**Procedure**

1. Identify if the network interface controller (NIC) drops packets:
   
   a. Display the NIC and driver-specific statistics:

   ```
   # ethtool -S enp1s0
   NIC statistics:
     ...
     rx_queue_0 Drops: 17657
     ...
   
   The naming of the statistics and if they are available depend on the NIC and the driver.
   
   b. Display the interface statistics:

   ```
   # ip -s link show enp1s0
   2: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state
   UP mode DEFAULT group default qlen 1000
   link/ether 52:54:00:74:79:56 brd ff:ff:ff:ff:ff:ff
   RX: bytes packets errors dropped missed mcast
   84697611107 56866820 0 10904 0 0
   TX: bytes packets errors dropped carrier collisions
   5540028184 372234 0 0 0 0
   
   RX represents the statistics of received packets and TX of transmitted packets.
   
2. Identify UDP protocol-specific packet drops due to too small socket buffers or slow application processing:

   ```
   # nstat -az UdpSndbufErrors UdpRcvbufErrors
   #kernel
   UdpSndbufErrors 4 0.0
   UdpRcvbufErrors 45716659 0.0
   
   The second column in the output lists the counters.
Additional resources

- RHEL network interface dropping packets  solution
- Should I be concerned about a 0.05% packet drop rate?  solution

34.6.2. Testing the UDP throughput using iperf3

The iperf3 utility provides a server and client mode to perform network throughput tests between two hosts.

NOTE

The throughput of applications depend on many factors, such as the buffer sizes that the application uses. Therefore, the results measured with testing utilities, such as iperf3, can significantly be different from those of applications on a server under production workload.

Prerequisites

- The iperf3 package is installed on both the client and server.
- No other services on both hosts cause network traffic that substantially affects the test result.
- Optional: You increased the maximum UDP socket sizes on both the server and the client. For details, see Increasing the system-wide UDP socket buffers.

Procedure

1. Optional: Display the maximum network speed of the network interface controller (NIC) on both the server and client:

   ```
   # ethtool enp1s0 | grep "Speed"
   Speed: 10000Mb/s
   ```

2. On the server:

   a. Display the maximum UDP socket read buffer size, and note the value:

   ```
   # sysctl net.core.rmem_max
   net.core.rmem_max = 16777216
   ```

   The displayed value is in bytes.

   b. Temporarily open the default iperf3 port 5201 in the firewalld service:

   ```
   # firewall-cmd --add-port=5201/tcp --add-port=5201/udp
   # firewall-cmd --reload
   ```

   Note that, iperf3 opens only a TCP socket on the server. If a clients wants to use UDP, it first connects to this TCP port, and then the server opens a UDP socket on the same port number for performing the UDP traffic throughput test. For this reason, you must open port 5201 for both the TCP and UDP protocol in the local firewall.

   c. Start iperf3 in server mode:
# iperf3 --server

The service now waits for incoming client connections.

3. On the client:
   a. Display the Maximum Transmission Unit (MTU) of the interface that the client will use for the connection to the server, and note the value:

   ```bash
   # ip link show enp1s0
   2: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state
   UP mode DEFAULT group default qlen 1000
   ...
   ```
   
   b. Display the maximum UDP socket write buffer size, and note the value:

   ```bash
   # sysctl net.core.wmem_max
   net.core.wmem_max = 16777216
   ```
   
   The displayed value is in bytes.

   c. Start measuring the throughput:

   ```bash
   # iperf3 --udp --time 60 --window 16777216 --length 1472 --bitrate 2G --client 192.0.2.1
   ```
   
   - **--udp**: Use the UDP protocol for the test.
   - **--time <seconds>**: Defines the time in seconds when the client stops the transmission.
   - **--window <size>**: Sets the UDP socket buffer size. Ideally, the sizes are the same on both the client and server. In case that they are different, set this parameter to the value that is smaller: `net.core.wmem_max` on the client or `net.core.rmem_max` on the server.
   - **--length <size>**: Sets the length of the buffer to read and write. Set this option to the largest unfragmented payload. Calculate the ideal value as follows: MTU - IP header (20 bytes for IPv4 and 40 bytes for IPv6) - 8 bytes UDP header.
   - **--bitrate <rate>**: Limits the bit rate to the specified value in bits per second. You can specify units, such as `2G` for 2 Gbps. Set this parameter to a value that you expect to work and increase it in later measurements. If the server sends packets at a faster rate than the devices on the transmit path or the client can process them, packets can be dropped.
   - **--client <server>**: Enables the client mode and sets the IP address or name of the server that runs the `iperf3` server.

4. Wait until `iperf3` completes the test. Both the server and the client display statistics every second and a summary at the end. For example, the following is a summary displayed on a client:

   ```plaintext
   [ ID] Interval     Transfer     Bitrate       Jitter      Lost/Total Datagrams
   [ 5] 0.00-60.00 sec 14.0 GBytes   2.00 Gbits/sec 0.000 ms 0/10190216 (0%) sender
   [ 5] 0.00-60.04 sec 14.0 GBytes   2.00 Gbits/sec 0.002 ms 0/10190216 (0%) receiver
   ```
In this example, the average bit rate was 2 Gbps, and no packets were lost.

5. On the server:
   a. Press `Ctrl+C` to stop the `iperf3` server.
   b. Close port 5201 in `firewalld`:

   ```
   # firewall-cmd --remove-port=5201/tcp --remove-port=5201/udp
   # firewall-cmd --reload
   ```

Additional resources

- `iperf3(1)` man page

### 34.6.3. Impact of the MTU size on UDP traffic throughput

If your application uses a large UDP message size, using jumbo frames can improve the throughput. According to the IEEE 802.3 standard, a default Ethernet frame without Virtual Local Area Network (VLAN) tag has a maximum size of 1518 bytes. Each of these frames includes an 18 bytes header, leaving 1500 bytes for payload. Consequently, for every 1500 bytes of data the server transmits over the network, 18 bytes (1.2%) are overhead.

Jumbo frames are non-standardized frames that have a larger Maximum Transmission Unit (MTU) than the standard Ethernet payload size of 1500 bytes. For example, if you configure jumbo Frames with the maximum allowed MTU of 9000 bytes payload, the overhead of each frame reduces to 0.2%.

**IMPORTANT**

All network devices on the transmission path and the involved broadcast domains must support jumbo frames and use the same MTU. Packet fragmentation and reassembly due to inconsistent MTU settings on the transmission path reduces the network throughput.

Different connection types have certain MTU limitations:

- Ethernet: the MTU is limited to 9000 bytes.
- IP over InfiniBand (IPoIB) in datagram mode: The MTU is limited to 4 bytes less than the InfiniBand MTU.
- In-memory networking commonly supports larger MTUs. For details, see the respective documentation.

### 34.6.4. Impact of the CPU speed on UDP traffic throughput

In bulk transfers, the UDP protocol is much less efficient than TCP, mainly due to the missing packet aggregation in UDP. By default, the Generic Receive Offload (GRO) and Transmit Segmentation Offload (TSO) features are not enabled. Consequently, the CPU frequency can limit the UDP throughput for bulk transfer on high speed links.

For example, on a tuned host with a high Maximum Transmission Unit (MTU) and large socket buffers, a 3 GHz CPU can process the traffic of a 10 GBit NIC that sends or receives UDP traffic at full speed. However, you can expect about 1-2 Gbps speed loss for every 100 MHz CPU speed under 3 GHz when you transmit UDP traffic. Also, if a CPU speed of 3 GHz can closely achieve 10 Gbps, the same CPU restricts UDP traffic on a 40 GBit NIC to roughly 20-25 Gbps.
34.6.5. Increasing the system-wide UDP socket buffers

Socket buffers temporarily store data that the kernel has received or should send:

- The read socket buffer holds packets that the kernel has received but which the application has not read yet.
- The write socket buffer holds packets that an application has written to the buffer but which the kernel has not passed to the IP stack and network driver yet.

If a UDP packet is too large and exceeds the buffer size or packets are sent or received at a too fast rate, the kernel drops any new incoming UDP packet until the data is removed from the buffer. In this case, increasing the socket buffers can prevent packet loss.

**IMPORTANT**

Setting too large buffer sizes wastes memory. Each socket can be set to the size that the application requests, and the kernel doubles this value. For example, if an application requests a 256 KiB socket buffer size and opens 1 million sockets, the system requires 512 GB RAM (512 KiB x 1 million) only for the potential socket buffer space.

Prerequisites

- You encountered a significant rate of dropped UDP packets.

Procedure

1. Create the `/etc/sysctl.d/10-udp-socket-buffers.conf` file and either set the maximum read or write buffer size, or both, based on your requirements:

   ```
   net.core.rmem_max = 16777216
   net.core.wmem_max = 16777216
   ```

   Specify the values in bytes. The values in this example set the maximum size of buffers to 16 MiB. The default values of both parameters are **212992** bytes (208 KiB).

2. Load the settings from the `/etc/sysctl.d/10-udp-socket-buffers.conf` file:

   ```
   # sysctl -p /etc/sysctl.d/10-udp-socket-buffers.conf
   ```

3. Configure your applications to use the larger socket buffer sizes.

   The `net.core.rmem_max` and `net.core.wmem_max` parameters define the maximum buffer size that the `setsockopt()` function in an application can request. Note that, if you configure your application to not use the `setsockopt()` function, the kernel uses the values from the `rmem_default` and `wmem_default` parameters.

   For further details, see the documentation of the programming language of your application. If you are not the developer of the application, contact the developer.

4. Restart the applications to use the new UDP buffer sizes.

Verification

- Monitor the packet drop statistics using the same method as you used when you encountered the packet drops.
If packet drops still occur but at a lower rate, increase the buffer sizes further.

Additional resources

- What are the implications of changing socket buffer sizes? solution
- udp(7) man page
- socket(7) man page

34.7. IDENTIFYING APPLICATION READ SOCKET BUFFER BOTTLENECKS

If TCP applications do not clear the read socket buffers frequently enough, performance can suffer and packets can be lost. Red Hat Enterprise Linux provides different utilities to identify such problems.

34.7.1. Identifying receive buffer collapsing and pruning

When the data in the receive queue exceeds the receive buffer size, the TCP stack tries to free some space by removing unnecessary metadata from the socket buffer. This step is known as collapsing.

If collapsing fails to free sufficient space for additional traffic, the kernel prunes new data that arrives. This means that the kernel removes the data from the memory and the packet is lost.

To avoid collapsing and pruning operations, monitor whether TCP buffer collapsing and pruning happens on your server and, in this case, tune the TCP buffers.

Procedure

1. Use the nstat utility to query the TcpExtTCPRcvCollapsed and TcpExtRcvPruned counters:

```bash
# nstat -az TcpExtTCPRcvCollapsed TcpExtRcvPruned
#kernel
TcpExtRcvPruned   0   0.0
TcpExtTCPRcvCollapsed  612859  0.0
```

2. Wait some time and re-run the nstat command:

```bash
# nstat -az TcpExtTCPRcvCollapsed TcpExtRcvPruned
#kernel
TcpExtRcvPruned   0   0.0
TcpExtTCPRcvCollapsed  620358  0.0
```

3. If the values of the counters have increased compared to the first run, tuning is required:

   - If the application uses the setsockopt(SO_RCVBUF) call, consider removing it. With this call, the application only uses the receive buffer size specified in the call and turns off the socket’s ability to auto-tune its size.

   - If the application does not use the setsockopt(SO_RCVBUF) call, tune the default and maximum values of the TCP read socket buffer.

4. Display the receive backlog queue (Recv-Q):
5. Run the `ss -nt` command multiple times with a few seconds waiting time between each run. If the output lists only one case of a high value in the `Recv-Q` column, the application was between two receive operations. However, if the values in `Recv-Q` stays constant while `lastrcv` continually grows, or `Recv-Q` continually increases over time, one of the following problems can be the cause:

- The application does not check its socket buffers often enough. Contact the application vendor for details about how you can solve this problem.

- The application does not get enough CPU time. To further debug this problem:
  
  i. Display on which CPU cores the application runs:

```plaintext
# ps -eo pid,tid,psr,pcpu,stat,wchan:20,comm
   PID   TID  PSR %CPU STAT WCHAN                COMMAND
...  44594  44594  5  0.0 Ss  do_select            httpd
  44595  44595  3  0.0 S   skb_wait_for_more_pa httpd
  44596  44596  5  0.0 Sl   pipe_read            httpd
  44597  44597  5  0.0 Sl   pipe_read            httpd
  44602  44602  5  0.0 Sl   pipe_read            httpd
...```

  The `PSR` column displays the CPU cores the process is currently assigned to.

  ii. Identify other processes running on the same cores and consider assigning them to other cores.

Additional resources

- Increasing the system-wide TCP socket buffers

### 34.8. TUNING APPLICATIONS WITH A LARGE NUMBER OF INCOMING REQUESTS

If you run an application that handles a large number of incoming requests, such as web servers, it can be necessary to tune Red Hat Enterprise Linux to optimize the performance.

#### 34.8.1. Tuning the TCP listen backlog to process a high number of TCP connection attempts

When an application opens a TCP socket in `LISTEN` state, the kernel limits the number of accepted client connections this socket can handle. If clients try to establish more connections than the application can process, the new connections get lost or the kernel sends SYN cookies to the client.
If the system is under normal workload and too many connections from legitimate clients cause the kernel to send SYN cookies, tune Red Hat Enterprise Linux (RHEL) to avoid them.

Prerequisites

- RHEL logs possible SYN flooding on port `<ip_address>`:<port_number> error messages in the Systemd journal.
- The high number of connection attempts are from valid sources and not caused by an attack.

Procedure

1. To verify whether tuning is required, display the statistics for the affected port:

   ```
   # ss -ntl '( sport = :443 )'
   State  Recv-Q  Send-Q  Local Address:Port  Peer Address:Port  Process
   LISTEN  650  500  192.0.2.1:443  0.0.0.0:*  
   ```

   If the current number of connections in the backlog (Recv-Q) is larger than the socket backlog (Send-Q), the listen backlog is still not large enough and tuning is required.

2. Optional: Display the current TCP listen backlog limit:

   ```
   # sysctl net.core.somaxconn
   net.core.somaxconn = 4096
   ```

3. Create the `/etc/sysctl.d/10-socket-backlog-limit.conf` file, and set a larger listen backlog limit:

   ```
   net.core.somaxconn = 8192
   ```

   Note that applications can request a larger listen backlog than specified in the `net.core.somaxconn` kernel parameter but the kernel limits the application to the number you set in this parameter.

4. Load the setting from the `/etc/sysctl.d/10-socket-backlog-limit.conf` file:

   ```
   # sysctl -p /etc/sysctl.d/10-socket-backlog-limit.conf
   ```

5. Reconfigure the application to use the new listen backlog limit:

   - If the application provides a config option for the limit, update it. For example, the Apache HTTP Server provides the `ListenBacklog` configuration option to set the listen backlog limit for this service.
   - If you cannot configure the limit, recompile the application.

6. Restart the application.

Verification

1. Monitor the Systemd journal for further occurrences of possible SYN flooding on port `<port_number>` error messages.

2. Monitor the current number of connections in the backlog and compare it with the socket backlog:
If the current number of connections in the backlog (*Recv-Q*) is larger than the socket backlog (*Send-Q*), the listen backlog is not large enough and further tuning is required.

Additional resources

- kernel: Possible SYN flooding on port #. Sending cookies  solution
- Listening TCP server ignores SYN or ACK for new connection handshake  solution
- listen(2) man page

### 34.9. AVOIDING LISTEN QUEUE LOCK CONTENTION

Queue lock contention can cause packet drops and higher CPU usage and, consequently, a higher latency. You can avoid queue lock contention on the receive (RX) and transmit (TX) queue by tuning your application and using transmit packet steering.

#### 34.9.1. Avoiding RX queue lock contention: The SO_REUSEPORT and SO_REUSEPORT_BPF socket options

On a multi-core system, you can improve the performance of multi-threaded network server applications if the application opens the port by using the `SO_REUSEPORT` or `SO_REUSEPORT_BPF` socket option. If the application does not use one of these socket options, all threads are forced to share a single socket to receive the incoming traffic. Using a single socket causes:

- Significant contention on the receive buffer, which can cause packet drops and higher CPU usage.
- A significant increase of CPU usage
- Possibly packet drops

With the `SO_REUSEPORT` or `SO_REUSEPORT_BPF` socket option, multiple sockets on one host can bind to the same port:
Red Hat Enterprise Linux provides a code example of how to use the `SO_REUSEPORT` socket options in the kernel sources. To access the code example:

1. Enable the `rhel-8-for-x86_64-baseos-debug-rpms` repository:
   ```bash
   # subscription-manager repos --enable rhel-8-for-x86_64-baseos-debug-rpms
   ```

2. Install the `kernel-debuginfo-common-x86_64` package:
   ```bash
   # yum install kernel-debuginfo-common-x86_64
   ```

3. The code example is now available in the `/usr/src/debug/kernel-<version>/linux-<version>/tools/testing/selftests/net/reuseport_bpf_cpu.c` file.

Additional resources

- `socket(7)` man page
- `/usr/src/debug/kernel-<version>/linux-<version>/tools/testing/selftests/net/reuseport_bpf_cpu.c`

### 34.9.2. Avoiding TX queue lock contention: Transmit packet steering

In hosts with a network interface controller (NIC) that supports multiple queues, transmit packet steering (XPS) distributes the processing of outgoing network packets among several queues. This enables multiple CPUs to process the outgoing network traffic and to avoid transmit queue lock contention and, consequently, packet drops.

Certain drivers, such as `ixgbe`, `i40e`, and `mlx5` automatically configure XPS. To identify if the driver supports this capability, consult the documentation of your NIC driver. Consult your NIC driver’s documentation to identify if the driver supports this capability. If the driver does not support XPS autotuning, you can manually assign CPU cores to the transmit queues.

**NOTE**

Red Hat Enterprise Linux does not provide an option to permanently assign transmit queues to CPU cores. Use the commands in a script and run it when the system boots.
The NIC supports multiple queues.

The `numactl` package is installed.

**Procedure**

1. Display the count of available queues:

   ```bash
   # ethtool -l enp1s0
   Channel parameters for enp1s0:
   Pre-set maximums:
   RX: 0
   TX: 0
   Other: 0
   Combined: 4
   Current hardware settings:
   RX: 0
   TX: 0
   Other: 0
   Combined: 1
   ```

   The **Pre-set maximums** section shows the total number of queues and **Current hardware settings** the number of queues that are currently assigned to the receive, transmit, other, or combined queues.

2. Optional: If you require queues on specific channels, assign them accordingly. For example, to assign the 4 queues to the **Combined** channel, enter:

   ```bash
   # ethtool -L enp1s0 combined 4
   ```

3. Display to which Non-Uniform Memory Access (NUMA) node the NIC is assigned:

   ```bash
   # cat /sys/class/net/enp1s0/device/numa_node
   0
   ```

   If the file is not found or the command returns `-1`, the host is not a NUMA system.

4. If the host is a NUMA system, display which CPUs are assigned to which NUMA node:

   ```bash
   # lscpu | grep NUMA
   NUMA node(s):       2
   NUMA node0 CPU(s):  0-3
   NUMA node1 CPU(s):  4-7
   ```

5. In the example above, the NIC has 4 queues and the NIC is assigned to NUMA node 0. This node uses the CPU cores 0-3. Consequently, map each transmit queue to one of the CPU cores from 0-3:

   ```bash
   # echo 1 > /sys/class/net/enp1s0/queues/tx-0/xps_cpus
   # echo 2 > /sys/class/net/enp1s0/queues/tx-1/xps_cpus
   # echo 4 > /sys/class/net/enp1s0/queues/tx-2/xps_cpus
   # echo 8 > /sys/class/net/enp1s0/queues/tx-3/xps_cpus
   ```

   If the number of CPU cores and transmit (TX) queues is the same, use a 1 to 1 mapping to avoid
any kind of contention on the TX queue. Otherwise, if you map multiple CPUs on the same TX queue, transmit operations on different CPUs will cause TX queue lock contention and negatively impacts the transmit throughput.

Note that you must pass the bitmap, containing the CPU’s core numbers, to the queues. Use the following command to calculate the bitmap:

```
# printf %x $((1 << <core_number> ))
```

Verification

1. Identify the process IDs (PIDs) of services that send traffic:

```
# pidof <process_name>
12345 98765
```

2. Pin the PIDs to cores that use XPS:

```
# numactl -C 0-3 12345 98765
```

3. Monitor the `requeues` counter while the process send traffic:

```
# tc -s qdisc
qdisc fq_codel 0: dev enp10s0u1 root refcnt 2 limit 10240p flows 1024 quantum 1514 target 5ms interval 100ms memory_limit 32Mb ecn drop__batch 64
Sent 125728849 bytes 1067587 pkt (dropped 0, overlimits 0 requeues 30)
backlog 0b 0p requeues 30
...
```

If the `requeues` counter no longer increases at a significant rate, TX queue lock contention no longer happens.

Additional resources

- `/usr/share/doc/kernel-doc-<version>/Documentation/networking/scaling.rst`

34.9.3. Disabling the Generic Receive Offload feature on servers with high UDP traffic

Applications that use high-speed UDP bulk transfer should enable and use UDP Generic Receive Offload (GRO) on the UDP socket. However, you can disable GRO to increase the throughput if the following conditions apply:

- The application does not support GRO and the feature cannot be added.
- TCP throughput is not relevant.
Prerequisites

- The host mainly processes UDP traffic.
- The application does not use GRO.
- The host does not use UDP tunnel protocols, such as VXLAN.
- The host does not run virtual machines (VMs) or containers.

Procedure

1. Optional: Display the NetworkManager connection profiles:

   ```
   # nmcli connection show
   NAME     UUID                                  TYPE      DEVICE
   example  f2f33f29-bb5c-3a07-9069-be72eaec3ecf ethernet enp1s0
   ```

2. Disable GRO support in the connection profile:

   ```
   # nmcli connection modify example ethtool.feature-gro off
   ```

3. Reactivate the connection profile:

   ```
   # nmcli connection up example
   ```

Verification

1. Verify that GRO is disabled:

   ```
   # ethtool -k enp1s0 | grep generic-receive-offload
   generic-receive-offload: off
   ```

2. Monitor the throughput on the server. Re-enable GRO in the NetworkManager profile if the setting has negative side effects to other applications on the host.

Additional resources

- Improve UDP performance in RHEL 8.5

34.10. TUNING THE DEVICE DRIVER AND NIC

In RHEL, kernel modules provide drivers for network interface controllers (NICs). These modules
support parameters to tune and optimize the device driver and the NIC. For example, if the driver supports delaying the generation of receive interrupts, you can reduce the value of the corresponding parameter to avoid running out of receive descriptors.

**NOTE**

Not all modules support custom parameters, and the features depend on the hardware, as well as the driver and firmware version.

### 34.10.1. Configuring custom NIC driver parameters

Many kernel modules support setting parameters to tune the driver and the network interface controller (NIC). You can customize the settings according to the hardware and the driver.

**IMPORTANT**

If you set parameters on a kernel module, RHEL applies these settings to all devices that use this driver.

**Prerequisites**

- A NIC is installed in the host.
- The kernel module that provides the driver for the NIC supports the required tuning feature.
- You are logged in locally or using a network interface that is different from the one that uses the driver for which you want to change the parameters.

**Procedure**

1. Identify the driver:

   ```bash
   # ethtool -i enp0s31f6
   driver: e1000e
   version: ...
   firmware-version: ...
   ...
   
   Note that certain features can require a specific driver and firmware version.
   ```

2. Display the available parameters of the kernel module:

   ```bash
   # modinfo -p e1000e
   ...
   SmartPowerDownEnable: Enable PHY smart power down (array of int)
   parm:RxIntDelay: Receive Interrupt Delay (array of int)
   
   For further details on the parameters, see the kernel module’s documentation. For modules in RHEL, see the documentation in the `/usr/share/doc/kernel-doc-<version>/Documentation/networking/device_drivers/` directory that is provided by the `kernel-doc` package.
   ```

3. Create the `/etc/modprobe.d/nic-parameters.conf` file and specify the parameters for the module:

   -
options `<module_name> <parameter1>=<value> <parameter2>=<value>

For example, to enable the port power saving mechanism and set the generation of receive interrupts to 4 units, enter:

```
options e1000e SmartPowerDownEnable=1 RxIntDelay=4
```

4. Unload the module:

```
# modprobe -r e1000e
```

5. Load the module:

```
# modprobe e1000e
```

6. Reactivate the network connections:

```
# nmcli connection up `<profile_name>`
```

**Verification**

1. Display the kernel messages:

```
# dmesg
...[35309.225765] e1000e 0000:00:1f.6: Transmit Interrupt Delay set to 16
[35309.225769] e1000e 0000:00:1f.6: PHY Smart Power Down Enabled
...`

Note that not all modules log parameter settings to the kernel ring buffer.

2. Certain kernel modules create files for each module parameter in the `/sys/module/<driver>/parameters/` directory. Each of these files contain the current value of this parameter. You can display these files to verify a setting:

```
# cat /sys/module/<driver_name>/parameters/<parameter_name>
```

### 34.11. CONFIGURING NETWORK ADAPTER OFFLOAD SETTINGS

To reduce CPU load, certain network adapters use offloading features which move the network processing load to the network interface controller (NIC). For example, with Encapsulating Security Payload (ESP) offload, the NIC performs ESP operations to accelerate IPsec connections and reduce
By default, most offloading features in Red Hat Enterprise Linux are enabled. Only disable them in the following cases:

- Temporarily disable offload features for troubleshooting purposes.
- Permanently disable offload features when a specific feature negatively impacts your host.

If a performance-related offload feature is not enabled by default in a network driver, you can enable it manually.

### 34.11.1. Temporarily setting an offload feature

If you expect that an offload feature causes problems or reduces the performance of your host, you can attempt to narrow down the cause by temporarily enabling or disabling it, depending on its current state.

If you temporarily enable or disable an offload feature, it returns to its previous value on the next reboot.

#### Prerequisites

- The network card supports offload features.

#### Procedure

1. Display the interface’s available offload features and their current state:

   ```bash
   # ethtool -k enp1s0
   ...
   esp-hw-offload: on
   ntuple-filters: off
   rx-vlan-filter: off [fixed]
   ...
   
   The output depends on the capabilities of the hardware and its driver. Note that you cannot change the state of features that are flagged with `[fixed]`.
   
2. Temporarily disable an offload feature:

   ```bash
   # ethtool -K <interface> <feature> [on/off]
   
   - For example, to temporarily disable IPsec Encapsulating Security Payload (ESP) offload on the `enp10s0u1` interface, enter:
     ```bash
     # ethtool -K enp10s0u1 esp-hw-offload off
     ```
   
   - For example, to temporarily enable accelerated Receive Flow Steering (aRFS) filtering on the `enp10s0u1` interface, enter:
     ```bash
     # ethtool -K enp10s0u1 ntuple-filters on
     ```
   
#### Verification

1. Display the states of the offload features:
2. Test whether the problem you encountered before changing the offload feature still exists.

- If the problem no longer exists after changing a specific offload feature:
  
  i. Contact Red Hat Support and report the problem.
  
  ii. Consider permanently setting the offload feature until a fix is available.

- If the problem still exists after disabling a specific offload feature:
  
  i. Reset the setting to its previous state by using the `ethtool -K <interface> <feature> [on|off]` command.
  
  ii. Enable or disable a different offload feature to narrow down the problem.

Additional resources

- `ethtool(8)` man page

### 34.11.2. Permanently setting an offload feature

If you have identified a specific offload feature that limits the performance on your host, you can permanently enable or disable it, depending on its current state.

If you permanently enable or disable an offload feature, NetworkManager ensures that the feature still has this state after a reboot.

**Prerequisites**

- You identified a specific offload feature to limit the performance on your host.

**Procedure**

1. Identify the connection profile that uses the network interface on which you want to change the state of the offload feature:

```
# nmcli connection show
NAME     UUID                                  TYPE      DEVICE
Example   a5eb6490-cc20-3668-81f8-0314a27f3f75 ethernet enp1ss0
...
```

2. Permanently change the state of the offload feature:

```
# nmcli connection modify <connection_name> <feature> [on|off]
```

- For example, to permanently disable IPsec Encapsulating Security Payload (ESP) offload in the `Example` connection profile, enter:

```
# nmcli connection modify Example ethtool.feature-esp-hw-offload off
```
For example, to permanently enable accelerated Receive Flow Steering (aRFS) filtering in the Example connection profile, enter:

```
# nmcli connection modify Example ethtool.feature-ntuple on
```

3. Reactivate the connection profile:

```
# nmcli connection up Example
```

Verification

- Display the output states of the offload features:

```
# ethtool -k enp1s0
...
esp-hw-offload: off
ntuple-filters: on
...
```

Additional resources

- nm-settings-nmcli(5) man page

## 34.12. TUNING INTERRUPT COALESCENCE SETTINGS

Interrupt coalescence is a mechanism for reducing the number of interrupts generated by a network card. Generally, fewer interrupts can enhance the latency and overall performance of your network.

Tuning the interrupt coalescence settings involves adjusting the parameters that control:

- The number of packets that are combined into a single interrupt.
- The delay before generating an interrupt.

**IMPORTANT**

The optimal coalescence settings depend on the specific network conditions and hardware in use. Therefore, it might take several attempts to find the settings that work best for your environment and needs.

### 34.12.1. Optimizing RHEL for latency or throughput-sensitive services

The goal of coalesce tuning is to minimize the number of interrupts required for a given workload. In high-throughput situations, the goal is to have as few interrupts as possible while maintaining a high data rate. In low-latency situations, more interrupts can be used to handle traffic quickly.

You can adjust the settings on your network card to increase or decrease the number of packets that are combined into a single interrupt. As a result, you can achieve improved throughput or latency for your traffic.

**Procedure**
1. Identify the network interface that is experiencing the bottleneck:

```
# ethtool -S enp1s0
NIC statistics:
  rx_packets: 1234
  tx_packets: 5678
  rx_bytes: 12345678
  tx_bytes: 87654321
  rx_errors: 0
  tx_errors: 0
  rx_missed: 0
  tx_dropped: 0
  coalesced_pks: 0
  coalesced_events: 0
  coalesced_aborts: 0
```

Identify the packet counters containing "drop", "discard", or "error" in their name. These particular statistics measure the actual packet loss at the network interface card (NIC) packet buffer, which can be caused by NIC coalescence.

2. Monitor values of packet counters you identified in the previous step. Compare them to the expected values for your network to determine whether any particular interface experiences a bottleneck. Some common signs of a network bottleneck include, but are not limited to:

- Many errors on a network interface
- High packet loss
- Heavy usage of the network interface

```
NOTE
Other important factors are for example CPU usage, memory usage, and disk I/O when identifying a network bottleneck.
```

3. View the current coalescence settings:

```
# ethtool enp1s0
Settings for enp1s0:
  Supported ports: [ TP ]
  Supported link modes:   10baseT/Half 10baseT/Full
                          100baseT/Half 100baseT/Full
                          1000baseT/Full
  Supported pause frame use: No
  Supports auto-negotiation: Yes
  Advertised link modes:  10baseT/Half 10baseT/Full
                          100baseT/Half 100baseT/Full
                          1000baseT/Full
  Advertised pause frame use: No
  Advertised auto-negotiation: Yes
  Speed: 1000Mb/s
  Duplex: Full
  Port: Twisted Pair
  PHYAD: 0
```
Transceiver: internal
Auto-negotiation: on
MDI-X: Unknown
Supports Wake-on: g
Wake-on: g
Current message level: 0x00000033 (51)

In this output, monitor the Speed and Duplex fields. These fields display information about the network interface operation and whether it is running at its expected values.

4. Check the current interrupt coalescence settings:

```
# ethtool -c enp1s0
Coalesce parameters for enp1s0:
  Adaptive RX: off
  Adaptive TX: off
  RX usecs: 100
  RX frames: 8
  RX usecs irq: 100
  RX frames irq: 8
  TX usecs: 100
  TX frames: 8
  TX usecs irq: 100
  TX frames irq: 8
```

- The usecs values refer to the number of microseconds that the receiver or transmitter waits before generating an interrupt.
- The frames values refer to the number of frames that the receiver or transmitter waits before generating an interrupt.
- The irq values are used to configure the interrupt moderation when the network interface is already handling an interrupt.

**NOTE**

Not all network interface cards support reporting and changing all values from the example output.

- The Adaptive RX/TX value represents the adaptive interrupt coalescence mechanism, which adjusts the interrupt coalescence settings dynamically. Based on the packet conditions, the NIC driver auto-calculates coalesce values when Adaptive RX/TX are enabled (the algorithm differs for every NIC driver).

5. Modify the coalescence settings as needed. For example:

- While `ethtool.coalesce-adaptive-rx` is disabled, configure `ethtool.coalesce-rx-usecs` to set the delay before generating an interrupt to 100 microseconds for the RX packets:

  ```
  # nmcli connection modify enp1s0 ethtool.coalesce-rx-usecs 100
  ```

- Enable `ethtool.coalesce-adaptive-rx` while `ethtool.coalesce-rx-usecs` is set to its default value:
Red Hat recommends that modifying the Adaptive-RX setting as follows:

- Users concerned with low latency (sub-50us) should not enable Adaptive-RX.
- Users concerned with throughput can probably enable Adaptive-RX with no harm. If they do not want to use the adaptive interrupt coalescence mechanism, they can try setting large values like 100us, or 250us to `ethtool.coalesce-rx-usecs`.
- Users unsure about their needs should not modify this setting until an issue occurs.

6. Re-activate the connection:

```
# nmcli connection up enp1s0
```

**Verification steps**

- Monitor the network performance and check for dropped packets:

```
# ethtool -S enp1s0
```

NIC statistics:

```
rx_packets: 1234
tx_packets: 5678
rx_bytes: 12345678
tx_bytes: 87654321
rx_errors: 0
tx_errors: 0
rx_missed: 0
tx_dropped: 0
coalesced_pkts: 12
coalesced_events: 34
coalesced_aborts: 56
...
```

The value of the `rx_errors`, `rx_dropped`, `tx_errors`, and `tx_dropped` fields should be 0 or close to it (up to few hundreds, depending on the network traffic and system resources). A high value in these fields indicates a network problem. Your counters can have different names. Closely monitor packet counters containing "drop", "discard", or "error" in their name.

The value of the `rx_packets`, `tx_packets`, `rx_bytes`, and `tx_bytes` should increase over time. If the values do not increase, there might be a network problem. The packet counters can have different names, depending on your NIC driver.

**IMPORTANT**

The `ethtool` command output can vary depending on the NIC and driver in use.

Users with focus on extremely low latency can use application-level metrics or the kernel packet time-stamping API for their monitoring purposes.

**Additional resources**

- Initial investigation for any performance issue
34.13. BENEFITS OF TCP TIMESTAMPS

TCP Timestamps are optional information in the TCP header and an extension of the TCP protocol. By default, TCP Timestamps are enabled in Red Hat Enterprise Linux, and the kernel uses TCP Timestamps to better estimate the round trip time (RTT) in TCP connections. This results in more accurate TCP window and buffer calculations.

Additionally, TCP Timestamps provide an alternative method to determine the age and order of a segment, and protect against wrapped sequence numbers. TCP packet headers record the sequence number in a 32-bit field. On a 10 Gbps connection, the value of this field can wrap after 1.7 seconds. Without TCP Timestamps, the receiver could not determine whether a segment with a wrapped sequence number is a new segment or an old duplicate. With TCP Timestamps, however, the receiver can make the correct choice to receive or discard the segment. Therefore, enabling TCP Timestamps on systems with fast network interfaces is essential.

The `net.ipv4.tcp_timestamps` kernel parameter can have one of the following values:

- **0**: TCP Timestamps are disabled.
- **1**: TCP Timestamps are enabled (default).
- **2**: TCP Timestamps are enabled but without random offsets.

**IMPORTANT**

Without random offsets for each connection, it is possible to approximately determine the host’s uptime and fingerprint and use this information in attacks.

By default, TCP Timestamps are enabled in Red Hat Enterprise Linux and use random offsets for each connection instead of only storing the current time:

```bash
# sysctl net.ipv4.tcp_timestamps
net.ipv4.tcp_timestamps = 1
```

If the `net.ipv4.tcp_timestamps` parameter has a different value than the default (1), revert the setting in the same way as you set it.

Additional resources

34.14. FLOW CONTROL FOR ETHERNET NETWORKS

On an Ethernet link, continuous data transmission between a network interface and a switch port can lead to full buffer capacity. Full buffer capacity results in network congestion. In this case, when the sender transmits data at a higher rate than the processing capacity of the receiver, packet loss can occur due to the lower data processing capacity of a network interface on the other end of the link which is a switch port.
The flow control mechanism manages data transmission across the Ethernet link where each sender and receiver has different sending and receiving capacities. To avoid packet loss, the Ethernet flow control mechanism temporarily suspends the packet transmission to manage a higher transmission rate from a switch port. Note that routers do not forward pause frames beyond a switch port.

When receive (RX) buffers become full, a receiver sends pause frames to the transmitter. The transmitter then stops data transmission for a short sub-second time frame, while continuing to buffer incoming data during this pause period. This duration provides enough time for the receiver to empty its interface buffers and prevent buffer overflow.

**NOTE**

Either end of the Ethernet link can send pause frames to another end. If the receive buffers of a network interface are full, the network interface will send pause frames to the switch port. Similarly, when the receive buffers of a switch port are full, the switch port sends pause frames to the network interface.

By default, most of the network drivers in Red Hat Enterprise Linux have pause frame support enabled. To display the current settings of a network interface, enter:

```
# ethtool --show-pause enp1s0
Pause parameters for enp1s0:
...  
RX: on
TX: on
...  
```

Verify with your switch vendor to confirm if your switch supports pause frames.

**Additional resources**

- [ethtool(8) man page](man)

CHAPTER 35. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE MEMORY ACCESS

You can configure the operating system to optimize memory access across workloads with the tools that are included in RHEL.

35.1. TOOLS FOR MONITORING AND DIAGNOSING SYSTEM MEMORY ISSUES

The following tools are available in Red Hat Enterprise Linux 8 for monitoring system performance and diagnosing performance problems related to system memory:

- **vmstat** tool, provided by the `procps-ng` package, displays reports of a system’s processes, memory, paging, block I/O, traps, disks, and CPU activity. It provides an instantaneous report of the average of these events since the machine was last turned on, or since the previous report.

- **valgrind** framework provides instrumentation to user-space binaries. Install this tool, using the `yum install valgrind` command. It includes a number of tools, that you can use to profile and analyze program performance, such as:
  
  - **memcheck** option is the default `valgrind` tool. It detects and reports on a number of memory errors that can be difficult to detect and diagnose, such as:
    - Memory access that should not occur
    - Undefined or uninitialized value use
    - Incorrectly freed heap memory
    - Pointer overlap
    - Memory leaks

  **NOTE**
  Memcheck can only report these errors, it cannot prevent them from occurring. However, `memcheck` logs an error message immediately before the error occurs.

  - **cachegrind** option simulates application interaction with a system’s cache hierarchy and branch predictor. It gathers statistics for the duration of application’s execution and outputs a summary to the console.

  - **massif** option measures the heap space used by a specified application. It measures both useful space and any additional space allocated for bookkeeping and alignment purposes.

Additional resources

- `vmstat(8)` and `valgrind(1)` man pages
- `/usr/share/doc/valgrind-version/valgrind_manual.pdf` file

35.2. OVERVIEW OF A SYSTEM’S MEMORY
The Linux Kernel is designed to maximize the utilization of a system’s memory resources (RAM). Due to these design characteristics, and depending on the memory requirements of the workload, part of the system’s memory is in use within the kernel on behalf of the workload, while a small part of the memory is free. This free memory is reserved for special system allocations, and for other low or high priority system services.

The rest of the system’s memory is dedicated to the workload itself, and divided into the following two categories:

**File memory**

Pages added in this category represent parts of files in permanent storage. These pages, from the page cache, can be mapped or unmapped in an application’s address spaces. You can use applications to map files into their address space using the `mmap` system calls, or to operate on files via the buffered I/O read or write system calls. Buffered I/O system calls, as well as applications that map pages directly, can re-utilize unmapped pages. As a result, these pages are stored in the cache by the kernel, especially when the system is not running any memory intensive tasks, to avoid re-issuing costly I/O operations over the same set of pages.

**Anonymous memory**

Pages in this category are in use by a dynamically allocated process, or are not related to files in permanent storage. This set of pages back up the in-memory control structures of each task, such as the application stack and heap areas.

Figure 35.1. Memory usage patterns

### 35.3. VIRTUAL MEMORY PARAMETERS

The virtual memory parameters are listed in the `/proc/sys/vm` directory.

The following are the available virtual memory parameters:

**vm.dirty_ratio**

Is a percentage value. When this percentage of the total system memory is modified, the system begins writing the modifications to the disk with the `pdflush` operation. The default value is 20 percent.

**vm.dirty_background_ratio**

A percentage value. When this percentage of total system memory is modified, the system begins writing the modifications to the disk in the background. The default value is 10 percent.

**vm.overcommit_memory**

Red Hat Enterprise Linux 8 Monitoring and managing system status and performance
Defines the conditions that determine whether a large memory request is accepted or denied. The default value is 0.

By default, the kernel performs checks if a virtual memory allocation request fits into the present amount of memory (total + swap) and rejects only large requests. Otherwise virtual memory allocations are granted, and this means they allow memory overcommitment.

Setting the overcommit_memory parameter’s value:

- When this parameter is set to 1, the kernel performs no memory overcommit handling. This increases the possibility of memory overload, but improves performance for memory-intensive tasks.

- When this parameter is set to 2, the kernel denies requests for memory equal to or larger than the sum of the total available swap space and the percentage of physical RAM specified in the overcommit_ratio. This reduces the risk of overcommitting memory, but is recommended only for systems with swap areas larger than their physical memory.

vm.overcommit_ratio

Specifies the percentage of physical RAM considered when overcommit_memory is set to 2. The default value is 50.

vm.max_map_count

Defines the maximum number of memory map areas that a process can use. The default value is 65530. Increase this value if your application needs more memory map areas.

vm.min_free_kbytes

Sets the size of the reserved free pages pool. It is also responsible for setting the min_page, low_page, and high_page thresholds that govern the behavior of the Linux kernel’s page reclaim algorithms. It also specifies the minimum number of kilobytes to keep free across the system. This calculates a specific value for each low memory zone, each of which is assigned a number of reserved free pages in proportion to their size.

Setting the vm.min_free_kbytes parameter’s value:

- Increasing the parameter value effectively reduces the application working set usable memory. Therefore, you might want to use it for only kernel-driven workloads, where driver buffers need to be allocated in atomic contexts.

- Decreasing the parameter value might render the kernel unable to service system requests, if memory becomes heavily contended in the system.

**WARNING**

Extreme values can be detrimental to the system’s performance. Setting the vm.min_free_kbytes to an extremely low value prevents the system from reclaiming memory effectively, which can result in system crashes and failure to service interrupts or other kernel services. However, setting vm.min_free_kbytes too high considerably increases system reclaim activity, causing allocation latency due to a false direct reclaim state. This might cause the system to enter an out-of-memory state immediately.
The `vm.min_free_kbytes` parameter also sets a page reclaim watermark, called `min_pages`. This watermark is used as a factor when determining the two other memory watermarks, `low_pages` and `high_pages`, that govern page reclaim algorithms.

`/proc/PID/oom_adj`

In the event that a system runs out of memory, and the `panic_on_oom` parameter is set to 0, the `oom_killer` function kills processes, starting with the process that has the highest `oom_score`, until the system recovers.

The `oom_adj` parameter determines the `oom_score` of a process. This parameter is set per process identifier. A value of -17 disables the `oom_killer` for that process. Other valid values range from -16 to 15.

**NOTE**

Processes created by an adjusted process inherit the `oom_score` of that process.

`vm.swappiness`

The swappiness value, ranging from 0 to 200, controls the degree to which the system favors reclaiming memory from the anonymous memory pool, or the page cache memory pool.

Setting the `swappiness` parameter’s value:

- Higher values favor file-mapped driven workloads while swapping out the less actively accessed processes’ anonymous mapped memory of RAM. This is useful for file-servers or streaming applications that depend on data, from files in the storage, to reside on memory to reduce I/O latency for the service requests.

- Low values favor anonymous-mapped driven workloads while reclaiming the page cache (file mapped memory). This setting is useful for applications that do not depend heavily on the file system information, and heavily utilize dynamically allocated and private memory, such as mathematical and number crunching applications, and few hardware virtualization supervisors like QEMU.

The default value of the `vm.swappiness` parameter is 60.
WARNING

- Setting the `vm.swappiness` to 0 aggressively avoids swapping anonymous memory out to a disk, this increases the risk of processes being killed by the `oom_killer` function when under memory or I/O intensive workloads.

- If you are using `cgroupsV1`, the per-cgroup swappiness value exclusive to `cgroupsV1` will result in the system-wide swappiness configured by the `vm.swappiness` parameter having little-to-no effect on the swap behavior of the system. This issue might lead to unexpected and inconsistent swap behavior. In such cases, consider using the `vm.force_cgroup_v2_swappiness` parameter.

For more information, see the Premature swapping with swappiness=0 while there is still plenty of pagecache to be reclaimed KCS solution.

`force_cgroup_v2_swappiness`

This control is used to deprecate the per-cgroup swappiness value available only in `cgroupsV1`. Most of all system and user processes are run within a cgroup. Cgroup swappiness values default to 60. This can lead to effects where systems swappiness value has little effect on the swap behavior of their system. If a user does not care about the per-cgroup swappiness feature they can configure their system with `force_cgroup_v2_swappiness=1` to have more consistent swappiness behavior across their whole system.

Additional resources

- `sysctl(8)` man page
- `Setting memory-related kernel parameters`

35.4. FILE SYSTEM PARAMETERS

The file system parameters are listed in the `/proc/sys/fs` directory. The following are the available file system parameters:

`aio-max-nr`

Defines the maximum allowed number of events in all active asynchronous input/output contexts. The default value is `65536`, and modifying this value does not pre-allocate or resize any kernel data structures.

`file-max`

Determines the maximum number of file handles for the entire system. The default value on Red Hat Enterprise Linux 8 is either `8192` or one tenth of the free memory pages available at the time the kernel starts, whichever is higher.

Raising this value can resolve errors caused by a lack of available file handles.
35.5. KERNEL PARAMETERS

The default values for the kernel parameters are located in the `/proc/sys/kernel/` directory. These are set default values provided by the kernel or values specified by a user via `sysctl`.

The following are the available kernel parameters used to set up limits for the `msg*` and `shm*` System V IPC (`sysvipc`) system calls:

**msgmax**
- Defines the maximum allowed size in bytes of any single message in a message queue. This value must not exceed the size of the queue (`msgmnb`). Use the `sysctl msgmax` command to determine the current `msgmax` value on your system.

**msgmnb**
- Defines the maximum size in bytes of a single message queue. Use the `sysctl msgmnb` command to determine the current `msgmnb` value on your system.

**msgmni**
- Defines the maximum number of message queue identifiers, and therefore the maximum number of queues. Use the `sysctl msgmni` command to determine the current `msgmni` value on your system.

**shmall**
- Defines the total amount of shared memory pages that can be used on the system at one time. For example, a page is 4096 bytes on the AMD64 and Intel 64 architecture. Use the `sysctl shmall` command to determine the current `shmall` value on your system.

**shmmax**
- Defines the maximum size in bytes of a single shared memory segment allowed by the kernel. Shared memory segments up to 1Gb are now supported in the kernel. Use the `sysctl shmmax` command to determine the current `shmmax` value on your system.

**shmmni**
- Defines the system-wide maximum number of shared memory segments. The default value is 4096 on all systems.

35.6. SETTING MEMORY-RELATED KERNEL PARAMETERS

Setting a parameter temporarily is useful for determining the effect the parameter has on a system. You can later set the parameter persistently when you are sure that the parameter value has the desired effect.

This procedure describes how to set a memory-related kernel parameter temporarily and persistently.

**Procedure**
- To temporarily set the memory-related kernel parameters, edit the respective files in the `/proc` file system or the `sysctl` tool.

  For example, to temporarily set the `vm.overcommit_memory` parameter to 1:

```
Red Hat Enterprise Linux 8 Monitoring and managing system status and performance
286
```
# echo 1 > /proc/sys/vm/overcommit_memory
# sysctl -w vm.overcommit_memory=1

- To persistently set the memory-related kernel parameter, edit the /etc/sysctl.conf file and reload the settings.
  For example, to persistently set the `vm.overcommit_memory` parameter to 1:
  
  - Add the following content in the /etc/sysctl.conf file:
    ```
    vm.overcommit_memory=1
    ```
  - Reload the `sysctl` settings from the /etc/sysctl.conf file:
    ```
    # sysctl -p
    ```

**Additional resources**

- `sysctl(8)` man page
- `proc(5)` man page
CHAPTER 36. CONFIGURING HUGE PAGES

Physical memory is managed in fixed-size chunks called pages. On the x86_64 architecture, supported by Red Hat Enterprise Linux 8, the default size of a memory page is 4 KB. This default page size has proved to be suitable for general-purpose operating systems, such as Red Hat Enterprise Linux, which supports many different kinds of workloads.

However, specific applications can benefit from using larger page sizes in certain cases. For example, an application that works with a large and relatively fixed data set of hundreds of megabytes or even dozens of gigabytes can have performance issues when using 4 KB pages. Such data sets can require a huge amount of 4 KB pages, which can lead to overhead in the operating system and the CPU.

This section provides information about huge pages available in RHEL 8 and how you can configure them.

36.1. AVAILABLE HUGE PAGE FEATURES

With Red Hat Enterprise Linux 8, you can use huge pages for applications that work with big data sets, and improve the performance of such applications.

The following are the huge page methods, which are supported in RHEL 8:

**HugeTLB pages**

HugeTLB pages are also called static huge pages. There are two ways of reserving HugeTLB pages:

- **At boot time:** It increases the possibility of success because the memory has not yet been significantly fragmented. However, on NUMA machines, the number of pages is automatically split among the NUMA nodes.

For more information about parameters that influence HugeTLB page behavior at boot time, see [Parameters for reserving HugeTLB pages at boot time](#) and how to use these parameters to configure HugeTLB pages at boot time, see [Configuring HugeTLB at boot time](#).

- **At run time:** It allows you to reserve the huge pages per NUMA node. If the run-time reservation is done as early as possible in the boot process, the probability of memory fragmentation is lower.

For more information about parameters that influence HugeTLB page behavior at run time, see [Parameters for reserving HugeTLB pages at run time](#) and how to use these parameters to configure HugeTLB pages at run time, see [Configuring HugeTLB at run time](#).

**Transparent HugePages (THP)**

With THP, the kernel automatically assigns huge pages to processes, and therefore there is no need to manually reserve the static huge pages. The following are the two modes of operation in THP:

- **system-wide:** Here, the kernel tries to assign huge pages to a process whenever it is possible to allocate the huge pages and the process is using a large contiguous virtual memory area.

- **per-process:** Here, the kernel only assigns huge pages to the memory areas of individual processes which you can specify using the `madvise()` system call.

**NOTE**

The THP feature only supports 2 MB pages.
For more information about parameters that influence HugeTLB page behavior at boot time, see Enabling transparent hugepages and Disabling transparent hugepages.

### 36.2. PARAMETERS FOR RESERVING HUGETLB PAGES AT BOOT TIME

Use the following parameters to influence HugeTLB page behavior at boot time.

For more information on how to use these parameters to configure HugeTLB pages at boot time, see Configuring HugeTLB at boot time.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>hugepages</td>
<td>Defines the number of persistent huge pages configured in the kernel at boot time. In a NUMA system, huge pages, that have this parameter defined, are divided equally between nodes. You can assign huge pages to specific nodes at runtime by changing the value of the nodes in the /sys/devices/system/node/node_id/hugepages/hugepages-size/nr_hugepages file.</td>
<td>The default value is 0. To update this value at boot, change the value of this parameter in the /proc/sys/vm/nr_hugepages file.</td>
</tr>
<tr>
<td>hugepagesz</td>
<td>Defines the size of persistent huge pages configured in the kernel at boot time.</td>
<td>Valid values are 2 MB and 1 GB. The default value is 2 MB.</td>
</tr>
<tr>
<td>default_hugepagesz</td>
<td>Defines the default size of persistent huge pages configured in the kernel at boot time.</td>
<td>Valid values are 2 MB and 1 GB. The default value is 2 MB.</td>
</tr>
</tbody>
</table>

### 36.3. CONFIGURING HUGETLB AT BOOT TIME

The page size, which the HugeTLB subsystem supports, depends on the architecture. The x86_64 architecture supports 2 MB huge pages and 1 GB gigantic pages.

This procedure describes how to reserve a 1 GB page at boot time.

**Procedure**

1. To create a HugeTLB pool for 1 GB pages, enable the default_hugepagesz=1G and hugepagesz=1G kernel options:

   ```
   # grubby --update-kernel=ALL --args="default_hugepagesz=1G hugepagesz=1G"
   ```
2. Create a new file called `hugetlb-gigantic-pages.service` in the `/usr/lib/systemd/system/` directory and add the following content:

```
[Unit]
Description=HugeTLB Gigantic Pages Reservation
DefaultDependencies=no
Before=dev-hugepages.mount
ConditionPathExists=/sys/devices/system/node
ConditionKernelCommandLine=hugepagesz=1G

[Service]
Type=oneshot
RemainAfterExit=yes
ExecStart=/usr/lib/systemd/hugetlb-reserve-pages.sh

[Install]
WantedBy=sysinit.target
```

3. Create a new file called `hugetlb-reserve-pages.sh` in the `/usr/lib/systemd/` directory and add the following content:

```bash
#!/bin/sh

nodes_path=/sys/devices/system/node/
if [ ! -d $nodes_path ]; then
echo "ERROR: $nodes_path does not exist"
exit 1
fi

reserve_pages()
{
  echo $1 > $nodes_path/$2/hugepages/hugepages-1048576kB/nr_hugepages
}

reserve_pages number_of_pages node
```

For example, to reserve two 1 GB pages on node0 and one 1GB page on node1, replace the `number_of_pages` with 2 for node0 and 1 for node1:

```bash
reserve_pages 2 node0
reserve_pages 1 node1
```

4. Create an executable script:

```bash
# chmod +x /usr/lib/systemd/hugetlb-reserve-pages.sh
```

5. Enable early boot reservation:

```bash
# systemctl enable hugetlb-gigantic-pages
```
NOTE

- You can try reserving more 1 GB pages at runtime by writing to `nr_hugepages` at any time. However, to prevent failures due to memory fragmentation, reserve 1 GB pages early during the boot process.

- Reserving static huge pages can effectively reduce the amount of memory available to the system, and prevents it from properly utilizing its full memory capacity. Although a properly sized pool of reserved huge pages can be beneficial to applications that utilize it, an oversized or unused pool of reserved huge pages will eventually be detrimental to overall system performance. When setting a reserved huge page pool, ensure that the system can properly utilize its full memory capacity.

Additional resources

- `systemd.service(5)` man page

- `/usr/share/doc/kernel-doc-kernel_version/Documentation/vm/hugetlbpage.txt` file

### 36.4. PARAMETERS FOR RESERVING HUGETLB PAGES AT RUN TIME

Use the following parameters to influence HugeTLB page behavior at run time.

For more information about how to use these parameters to configure HugeTLB pages at run time, see Configuring HugeTLB at run time.

Table 36.2. Parameters used to configure HugeTLB pages at run time

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>File name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nr_hugepages</code></td>
<td>Defines the number of huge pages of a specified size assigned to a specified NUMA node.</td>
<td><code>/sys/devices/system/node/node_id/hugepages/hugepages-size/nr_hugepages</code></td>
</tr>
<tr>
<td><code>nr_overcommit_hugepages</code></td>
<td>Defines the maximum number of additional huge pages that can be created and used by the system through overcommitting memory. Writing any non-zero value into this file indicates that the system obtains that number of huge pages from the kernel's normal page pool if the persistent huge page pool is exhausted. As these surplus huge pages become unused, they are then freed and returned to the kernel's normal page pool.</td>
<td><code>/proc/sys/vm/nr_overcommit_hugepages</code></td>
</tr>
</tbody>
</table>

### 36.5. CONFIGURING HUGETLB AT RUN TIME

This procedure describes how to add 20 2048 kB huge pages to `node2`. 
To reserve pages based on your requirements, replace:

- 20 with the number of huge pages you wish to reserve,
- 2048kB with the size of the huge pages,
- node2 with the node on which you wish to reserve the pages.

**Procedure**

1. Display the memory statistics:

   ```bash
   # numastat -cm | egrep 'Node|Huge'
   Node 0 Node 1 Node 2 Node 3  Total add
   AnonHugePages         0      2      0      8     10
   HugePages_Total       0      0      0      0      0
   HugePages_Free        0      0      0      0      0
   HugePages_Surp        0      0      0      0      0
   ```

2. Add the number of huge pages of a specified size to the node:

   ```bash
   # echo 20 > /sys/devices/system/node/node2/hugepages/hugepages-2048kB/nr_hugepages
   ```

**Verification steps**

- Ensure that the number of huge pages are added:

  ```bash
  # numastat -cm | egrep 'Node|Huge'
  Node 0 Node 1 Node 2 Node 3  Total
  AnonHugePages         0      2      0      8     10
  HugePages_Total       0      0     40      0     40
  HugePages_Free        0      0     40      0     40
  HugePages_Surp        0      0      0      0      0
  ```

**Additional resources**

- `numastat(8)` man page

### 36.6. ENABLING TRANSPARENT HUGEPAGES

THP is enabled by default in Red Hat Enterprise Linux 8. However, you can enable or disable THP.

This procedure describes how to enable THP.

**Procedure**

1. Check the current status of THP:

   ```bash
   # cat /sys/kernel/mm/transparent_hugepage/enabled
   ```

2. Enable THP:

   ```bash
   # echo always > /sys/kernel/mm/transparent_hugepage/enabled
   ```
3. To prevent applications from allocating more memory resources than necessary, disable the system-wide transparent huge pages and only enable them for the applications that explicitly request it through the `madvise`:

```
# echo madvise > /sys/kernel/mm/transparent_hugepage/enabled
```

**NOTE**

Sometimes, providing low latency to short-lived allocations has higher priority than immediately achieving the best performance with long-lived allocations. In such cases, you can disable direct compaction while leaving THP enabled.

Direct compaction is a synchronous memory compaction during the huge page allocation. Disabling direct compaction provides no guarantee of saving memory, but can decrease the risk of higher latencies during frequent page faults. Note that if the workload benefits significantly from THP, the performance decreases. Disable direct compaction:

```
# echo madvise > /sys/kernel/mm/transparent_hugepage/defrag
```

Additional resources

- `madvise(2)` man page
- Disabling transparent hugepages.

### 36.7. DISABLING TRANSPARENT HUGEPAGES

THP is enabled by default in Red Hat Enterprise Linux 8. However, you can enable or disable THP. This procedure describes how to disable THP.

**Procedure**

1. Check the current status of THP:

```
# cat /sys/kernel/mm/transparent_hugepage/enabled
```

2. Disable THP:

```
# echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

### 36.8. IMPACT OF PAGE SIZE ON TRANSLATION LOOKASIDE BUFFER SIZE

Reading address mappings from the page table is time-consuming and resource-expensive, so CPUs are built with a cache for recently-used addresses, called the Translation Lookaside Buffer (TLB). However, the default TLB can only cache a certain number of address mappings.

If a requested address mapping is not in the TLB, called a TLB miss, the system still needs to read the page table to determine the physical to virtual address mapping. Because of the relationship between application memory requirements and the size of pages used to cache address mappings, applications
with large memory requirements are more likely to suffer performance degradation from TLB misses than applications with minimal memory requirements. It is therefore important to avoid TLB misses wherever possible.

Both HugeTLB and Transparent Huge Page features allow applications to use pages larger than 4 KB. This allows addresses stored in the TLB to reference more memory, which reduces TLB misses and improves application performance.
CHAPTER 37. GETTING STARTED WITH SYSTEMTAP

As a system administrator, you can use SystemTap to identify underlying causes of a bug or performance problem on a running Linux system.

As an application developer, you can use SystemTap to monitor in fine detail how your application behaves within the Linux system.

37.1. THE PURPOSE OF SYSTEMTAP

SystemTap is a tracing and probing tool that you can use to study and monitor the activities of your operating system (particularly, the kernel) in fine detail. SystemTap provides information similar to the output of tools such as `netstat`, `ps`, `top`, and `iostat`. However, SystemTap provides more filtering and analysis options for collected information. In SystemTap scripts, you specify the information that SystemTap gathers.

SystemTap aims to supplement the existing suite of Linux monitoring tools by providing users with the infrastructure to track kernel activity and combining this capability with two attributes:

**Flexibility**

the SystemTap framework enables you to develop simple scripts for investigating and monitoring a wide variety of kernel functions, system calls, and other events that occur in kernel space. With this, SystemTap is not so much a tool as it is a system that allows you to develop your own kernel-specific forensic and monitoring tools.

**Ease-of-Use**

SystemTap enables you to monitor kernel activity without having to recompile the kernel or reboot the system.

37.2. INSTALLING SYSTEMTAP

To begin using SystemTap, install the required packages. To use SystemTap on more than one kernel where a system has multiple kernels installed, install the corresponding required kernel packages for each kernel version.

**Prerequisites**

- You have enabled debug repositories as described in Enabling debug and source repositories.

**Procedure**

1. Install the required SystemTap packages:

   ```
   # yum install systemtap
   ```

2. Install the required kernel packages:

   a. Using `stap-prep`:

   ```
   # stap-prep
   ```

   b. If `stap-prep` does not work, install the required kernel packages manually:
# yum install kernel-debuginfo-$\{(uname -r)\} kernel-debuginfo-common-$\{(uname -i)\}-$\{(uname -r)\} kernel-devel-$\{(uname -r)\}$

$\{(uname -i)\}$ is automatically replaced with the hardware platform of your system and $\{(uname -r)\}$ is automatically replaced with the version of your running kernel.

### Verification steps

- If the kernel to be probed with SystemTap is currently in use, test if your installation was successful:

  ```
  # stap -v -e 'probe kernel.function("vfs_read") {printf("read performed\n"); exit()}'
  ```

  A successful SystemTap deployment results in an output similar to the following:

  ```
  Pass 1: parsed user script and 45 library script(s) in 340usr/0sys/358real ms.
  Pass 2: analyzed script: 1 probe(s), 1 function(s), 0 embed(s), 0 global(s) in 290usr/260sys/568real ms.
  Pass 3: translated to C into "/tmp/stapiArgLX/stap_e5886fa50499994e6a87aacc repertoire_399.c" in 490usr/430sys/938real ms.
  Pass 4: compiled C into "stap_e5886fa50499994e6a87aacc repertoire_399.ko" in 3310usr/430sys/3714real ms.
  Pass 5: starting run. 1
  read performed 2
  Pass 5: run completed in 10usr/40sys/73real ms. 3
  ```

  The last three lines of output (beginning with Pass 5) indicate that:

  1. SystemTap successfully created the instrumentation to probe the kernel and ran the instrumentation.
  2. SystemTap detected the specified event (in this case, A VFS read).
  3. SystemTap executed a valid handler (printed text and then closed it with no errors).

### 37.3. PRIVILEGES TO RUN SYSTEMTAP

Running SystemTap scripts requires elevated system privileges but, in some instances, non-privileged users might need to run SystemTap instrumentation on their machine.

To allow users to run SystemTap without root access, add users to both of these user groups:

**stapdev**

Members of this group can use **stap** to run SystemTap scripts, or **staprun** to run SystemTap instrumentation modules.

Running **stap** involves compiling SystemTap scripts into kernel modules and loading them into the kernel. This requires elevated privileges to the system, which are granted to **stapdev** members. Unfortunately, such privileges also grant effective root access to **stapdev** members. As such, only grant **stapdev** group membership to users who can be trusted with root access.

**stapusr**

Members of this group can only use **staprun** to run SystemTap instrumentation modules. In addition, Red Hat Enterprise Linux 8 Monitoring and managing system status and performance

296
Members of this group can only use `staprun` to run SystemTap instrumentation modules. In addition, they can only run those modules from the `/lib/modules/kernel_version/systemtap` directory. This directory must be owned only by the root user, and must only be writable by the root user.

### 37.4. RUNNING SYSTEMTAP SCRIPTS

You can run SystemTap scripts from standard input or from a file.

Sample scripts that are distributed with the installation of SystemTap can be found in the `/usr/share/systemtap/examples` directory.

#### Prerequisites

1. SystemTap and the associated required kernel packages are installed as described in [Installing SystemTap](#).

2. To run SystemTap scripts as a normal user, add the user to the SystemTap groups:

   ```bash
   # usermod --append --groups stapdev,stapusr user-name
   ```

#### Procedure

- Run the SystemTap script:
  - From standard input:
    ```bash
    # echo "probe timer.s(1) {exit()}" | stap -
    ```
    This command instructs `stap` to run the script passed by `echo` to standard input. To add `stap` options, insert them before the `-` character. For example, to make the results from this command more verbose, the command is:
    ```bash
    # echo "probe timer.s(1) {exit()}" | stap -v -
    ```
  - From a file:
    ```bash
    # stap file_name
    ```
CHAPTER 38. CROSS-INSTRUMENTATION OF SYSTEMTAP

Cross-instrumentation of SystemTap is creating SystemTap instrumentation modules from a SystemTap script on one system to be used on another system that does not have SystemTap fully deployed.

38.1. SYSTEMTAP CROSS-INSTRUMENTATION

When you run a SystemTap script, a kernel module is built out of that script. SystemTap then loads the module into the kernel.

Normally, SystemTap scripts can run only on systems where SystemTap is deployed. To run SystemTap on ten systems, SystemTap needs to be deployed on all those systems. In some cases, this might be neither feasible nor desired. For example, corporate policy might prohibit you from installing packages that provide compilers or debug information about specific machines, which will prevent the deployment of SystemTap.

To work around this, use cross-instrumentation. Cross-instrumentation is the process of generating SystemTap instrumentation modules from a SystemTap script on one system to be used on another system. This process offers the following benefits:

- The kernel information packages for various machines can be installed on a single host machine.

  IMPORTANT

  Kernel packaging bugs may prevent the installation. In such cases, the kernel-debuginfo and kernel-devel packages for the host system and target system must match. If a bug occurs, report the bug at https://bugzilla.redhat.com/.

- Each target machine needs only one package to be installed to use the generated SystemTap instrumentation module: systemtap-runtime.

  IMPORTANT

  The host system must be the same architecture and running the same distribution of Linux as the target system in order for the built instrumentation module to work.
38.2. INITIALIZING CROSS-INSTRUMENTATION OF SYSTEMTAP

Initialize cross-instrumentation of SystemTap to build SystemTap instrumentation modules from a SystemTap script on one system and use them on another system that does not have SystemTap fully deployed.

Prerequisites

- SystemTap is installed on the host system as described in Installing Systemtap.

- The systemtap-runtime package is installed on each target system:

```bash
# yum install systemtap-runtime
```

- Both the host system and target system are the same architecture.

- Both the host system and target system are running the same major version of Red Hat Enterprise Linux (such as Red Hat Enterprise Linux 8), they can be running different minor versions (such as 8.1 and 8.2).

**IMPORTANT**

Kernel packaging bugs may prevent multiple kernel-debuginfo and kernel-devel packages from being installed on one system. In such cases, the minor version for the host system and target system must match. If a bug occurs, report it at https://bugzilla.redhat.com/.

Procedure

1. Determine the kernel running on each target system:

   ```bash
   $ uname -r
   ``

   Repeat this step for each target system.

2. On the host system, install the target kernel and related packages for each target system by the method described in Installing Systemtap.
3. Build an instrumentation module on the host system, copy this module to and run this module on the target system either:

a. Using remote implementation:

   ```bash
   # stap --remote target_system script
   ```

   This command remotely implements the specified script on the target system. You must ensure an SSH connection can be made to the target system from the host system for this to be successful.

b. Manually:

   i. Build the instrumentation module on the host system:

   ```bash
   # stap -r kernel_version script -m module_name -p 4
   ```

   Here, `kernel_version` refers to the version of the target kernel determined in step 1, `script` refers to the script to be converted into an instrumentation module, and `module_name` is the desired name of the instrumentation module. The `-p 4` option tells SystemTap to not load and run the compiled module.

   ii. Once the instrumentation module is compiled, copy it to the target system and load it using the following command:

   ```bash
   # staprun module_name.ko
   ```
You can use helpful example SystemTap scripts available in the 
/usr/share/systemtap/testsuite/systemtap.examples/ directory, upon installing the systemtap-
testsuite package, to monitor and investigate the network activity of your system.

39.1. PROFILING NETWORK ACTIVITY WITH SYSTEMTAP

You can use the nettop.stp example SystemTap script to profile network activity. The script tracks
which processes are generating network traffic on the system, and provides the following information
about each process:

**PID**
The ID of the listed process.

**UID**
User ID. A user ID of 0 refers to the root user.

**DEV**
Which ethernet device the process used to send or receive data (for example, eth0, eth1).

**XMIT_PK**
The number of packets transmitted by the process.

**RECV_PK**
The number of packets received by the process.

**XMIT_KB**
The amount of data sent by the process, in kilobytes.

**RECV_KB**
The amount of data received by the service, in kilobytes.

**Prerequisites**
- You have installed SystemTap as described in [Installing SystemTap](#).

**Procedure**
- Run the nettop.stp script:

  ```
  # stap --example nettop.stp
  ```

  The nettop.stp script provides network profile sampling every 5 seconds.

  **Output of the nettop.stp script looks similar to the following:**

  ```
  [...]  PID  UID  DEV   XMIT_PK  RECV_PK  XMIT_KB  RECV_KB  COMMAND
  0     0     eth0   0        5        0        0        swapper
  11178 0     eth0   2        0        0        0        synergyc
  2886  4     eth0   79       0        5        0        cups-polld
  11362 0     eth0   0        61       0        5        firefox
  ```
### 39.2. TRACING FUNCTIONS CALLED IN NETWORK SOCKET CODE WITH SYSTEMTAP

You can use the `socket-trace.stp` example SystemTap script to trace functions called from the kernel’s net/socket.c file. This helps you identify, in finer detail, how each process interacts with the network at the kernel level.

#### Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

#### Procedure

- Run the `socket-trace.stp` script:

  ```bash
  # stap --example socket-trace.stp
  ```

A 3-second excerpt of the output of the `socket-trace.stp` script looks similar to the following:

```plaintext
[...
0 Xorg(3611): -> sock_poll
3 Xorg(3611): <-> sock_poll
0 Xorg(3611): -> sock_poll
3 Xorg(3611): <-> sock_poll
0 gnome-terminal(11106): -> sock_poll
5 gnome-terminal(11106): <-> sock_poll
0 scim-bridge(3883): -> sock_poll
3 scim-bridge(3883): <-> sock_poll
0 scim-bridge(3883): -> sys_socketcall
4 scim-bridge(3883): -> sys_recv
8 scim-bridge(3883): <-> sys_recvfrom
12 scim-bridge(3883): <-> sock_from_file
16 scim-bridge(3883): <-> sock_from_file
20 scim-bridge(3883): <-> sock_recvmsg
24 scim-bridge(3883): <-> sock_recvmsg
28 scim-bridge(3883): <-> sys_recvfrom
31 scim-bridge(3883): <-> sys_recv
35 scim-bridge(3883): <-> sys_socketcall
[...]
```
39.3. MONITORING NETWORK PACKET DROPS WITH SYSTEMTAP

The network stack in Linux can discard packets for various reasons. Some Linux kernels include a tracepoint, `kernel.trace("kfree_skb")`, which tracks where packets are discarded.

The `dropwatch.stp` SystemTap script uses `kernel.trace("kfree_skb")` to trace packet discards; the script summarizes what locations discard packets in every 5-second interval.

**Prerequisites**

- You have installed SystemTap as described in [Installing SystemTap](#).

**Procedure**

- Run the `dropwatch.stp` script:

```bash
# stap --example dropwatch.stp
```

Running the `dropwatch.stp` script for 15 seconds results in output similar to the following:

```
Monitoring for dropped packets
51 packets dropped at location 0xffffffff8024cd0f
2 packets dropped at location 0xffffffff8044b472
51 packets dropped at location 0xffffffff8024cd0f
1 packets dropped at location 0xffffffff8044b472
97 packets dropped at location 0xffffffff8024cd0f
1 packets dropped at location 0xffffffff8044b472
Stopping dropped packet monitor
```

**NOTE**

To make the location of packet drops more meaningful, see the `/boot/System.map-$(uname -r)` file. This file lists the starting addresses for each function, enabling you to map the addresses in the output of the `dropwatch.stp` script to a specific function name. Given the following snippet of the `/boot/System.map-$(uname -r)` file, the address `0xffffffff8024cd0f` maps to the function `unix_stream_recvmsg` and the address `0xffffffff8044b472` maps to the function `arp_rcv`:

```
[...]
ffffffff8024c5cd T unlock_new_inode
ffffffff8024c5da t unix_stream_sendmsg
ffffffff8024c920 t unix_stream_recvmsg
ffffffff8024cea1 t udp_v4_lookup_longway
[...]
ffffffff8044adcc t arp_process
ffffffff8044b360 t arp_rcv
ffffffff8044b487 t parp_redo
ffffffff8044b48c t arp_solicit
[...]
```
CHAPTER 40. PROFILING KERNEL ACTIVITY WITH SYSTEMTAP

You can profile the kernel activity by monitoring function calls with the following scripts.

40.1. COUNTING FUNCTION CALLS WITH SYSTEMTAP

You can use the `functioncallcount.stp` SystemTap script to count specific kernel function calls. You can also use this script to target multiple kernel functions.

**Prerequisites**

- You have installed SystemTap as described in [Installing Systemtap](#).

**Procedure**

- **Run the `functioncallcount.stp` script:**

  ```bash
  # stap --example functioncallcount.stp 'argument'
  ```

  This script takes the targeted kernel function as an argument. You can use the argument wildcards to target multiple kernel functions up to a certain extent.

  The output of the script, in alphabetical order, contains the names of the functions called and how many times it was called during the sample time.

  Consider the following example:

  ```bash
  # stap -w -v --example functioncallcount.stp "*@mm*.c" -c /bin/true
  ```

  where:

  - **-w**: Suppresses warnings.
  - **-v**: Makes the output of starting kernel visible.
  - **-c command**: Tells SystemTap to count function calls during the execution of a command, in this example being `/bin/true`.

  The output should look similar to the following:

  ```
  [...]__vma_link 97__vma_link_file 66__vma_link_list 97__vma_link_rb 97__xchg 103add_page_to_active_list 102add_page_to_inactive_list 19add_to_page_cache 19add_to_page_cache_lru 7all_vm_events 6alloc_pages_node 4630alloc_slabmgmt 67
  ```
40.2. TRACING FUNCTION CALLS WITH SYSTEEMTAP

You can use the para-callgraph.stp SystemTap script to trace function calls and function returns.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the para-callgraph.stp script.

  # stap --example para-callgraph.stp 'argument1' 'argument2'

The script para-callgraph.stp takes two command-line arguments:

1. The name of the function(s) whose entry/exit you’d like to trace.
2. An optional trigger function, which enables or disables tracing on a per-thread basis. Tracing in each thread will continue as long as the trigger function has not exited yet.

Consider the following example:

  # stap -wv --example para-callgraph.stp 'kernel.function("@fs/proc.c")' 'kernel.function("vfs_read")' -c "cat /proc/sys/vm/* || true"

where:

- -w : Suppresses warnings.
- -v : Makes the output of starting kernel visible.
- -c command : Tells SystemTap to count function calls during the execution of a command, in this example being /bin/true.

The output should look similar to the following:

[...]
40.3. DETERMINING TIME SPENT IN KERNEL AND USER SPACE WITH SYSTEMTAP

You can use the thread-times.stp SystemTap script to determine the amount of time any given thread is spending in either the kernel or user-space.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the thread-times.stp script:

  ```bash
  # stap --example thread-times.stp
  ```

This script will display the top 20 processes taking up CPU time during a 5-second period, along with the total number of CPU ticks made during the sample. The output of this script also notes the percentage of CPU time each process used, as well as whether that time was spent in kernel space or user space.

<table>
<thead>
<tr>
<th>tid</th>
<th>%user</th>
<th>%kernel (of 20002 ticks)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.00%</td>
<td>87.88%</td>
</tr>
<tr>

</tbody>
</table>
40.4. MONITORING POLLING APPLICATIONS WITH SYSEMSTAP

You can use `timeout.stp` SystemTap script to identify and monitor which applications are polling. Doing so allows you to track unnecessary or excessive polling, which helps you pinpoint areas for improvement in terms of CPU usage and power savings.

Prerequisites

- You have installed SystemTap as described in `Installing Systemtap`.

Procedure

- Run the `timeout.stp` script:

  ```
  # stap --example timeout.stp
  ```

  This script will track how many times each application uses the following system calls over time:
  - `poll`
  - `select`
  - `epoll`
  - `itimer`
  - `futex`
  - `nanosleep`
  - `signal`

In this example output you can see which process used which system call and how many times.

<table>
<thead>
<tr>
<th>uid</th>
<th>poll</th>
<th>select</th>
<th>epoll</th>
<th>itimer</th>
<th>futex</th>
<th>nanosleep</th>
<th>signal</th>
<th>process</th>
</tr>

</tbody>
</table>
40.5. TRACKING MOST FREQUENTLY USED SYSTEM CALLS WITH SYSTEMTAP

You can use the `topsys.stp` SystemTap script to list the top 20 system calls used by the system per 5-second interval. It also lists how many times each system call was used during that period.

**Prerequisites**

- You have installed SystemTap as described in [Installing Systemtap](#).

**Procedure**

- Run the `topsys.stp` script:

  ```bash
  # stap --example topsys.stp
  ```

  Consider the following example:

  ```bash
  # stap -v --example topsys.stp
  ```

  where `-v` makes the output of starting kernel visible.

  The output should look similar to the following:

<table>
<thead>
<tr>
<th>SYSCALL</th>
<th>COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>gettimeofday</td>
<td>1857</td>
</tr>
<tr>
<td>read</td>
<td>1821</td>
</tr>
<tr>
<td>ioctl</td>
<td>1568</td>
</tr>
<tr>
<td>poll</td>
<td>1033</td>
</tr>
<tr>
<td>close</td>
<td>638</td>
</tr>
<tr>

<tr>
<td>setitimer</td>
<td>106</td>
</tr>
<tr>
<td>stat</td>
<td>90</td>
</tr>
<tr>
<td>time</td>
<td>81</td>
</tr>
<tr>
<td>sigreturn</td>
<td>72</td>
</tr>
<tr>
<td>fstat</td>
<td>66</td>
</tr>
</tbody>
</table>

40.6. TRACKING SYSTEM CALL VOLUME PER PROCESS WITH SYSTEMTAP

You can use the `syscalls_by_proc.stp` SystemTap script to see which processes are performing the highest volume of system calls. It displays 20 processes performing the most of system calls.
Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the `syscalls_by_proc.stp` script:

  ```bash
  # stap --example syscalls_by_proc.stp
  ```

  Output of the `syscalls_by_proc.stp` script looks similar to the following:

  Collecting data... Type Ctrl-C to exit and display results
  #SysCalls Process Name
  1577 multiload-apple
  692 synergyc
  408 pcsd
  376 mixer_applet2
  299 gnome-terminal
  293 Xorg
  206 scim-panel-gtk
  95 gnome-power-man
  90 arts'd
  85 dhcdbus
  84 scim-bridge
  78 gnome-screensav
  66 scim-launcher
  ```
CHAPTER 41. MONITORING DISK AND I/O ACTIVITY WITH SYSTEMTAP

You can monitor disk and I/O activity with the following scripts.

41.1. SUMMARIZING DISK READ/WRITE TRAFFIC WITH SYSTEMTAP

You can use the `disktop.stp` SystemTap script to identify which processes are performing the heaviest disk reads and writes to the system.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the `disktop.stp` script:

  ```
  # stap --example disktop.stp
  ```

  The script displays the top ten processes responsible for the heaviest reads or writes to a disk.

  The output includes the following data per listed process:

<table>
<thead>
<tr>
<th>UID</th>
<th>PID</th>
<th>PPID</th>
<th>CMD</th>
<th>DEVICE</th>
<th>T</th>
<th>BYTES</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>26319</td>
<td>26294</td>
<td>firefox</td>
<td>sda5</td>
<td>W</td>
<td>90229</td>
</tr>
<tr>
<td>0</td>
<td>2758</td>
<td>2757</td>
<td>pam_timestamp_c</td>
<td>sda5</td>
<td>R</td>
<td>8064</td>
</tr>
<tr>
<td>0</td>
<td>2885</td>
<td>1</td>
<td>cupsd</td>
<td>sda5</td>
<td>W</td>
<td>1678</td>
</tr>
</tbody>
</table>

  Output of the `disktop.stp` script looks similar to the following:

  ```
  ...[output]...
  Mon Sep 29 03:38:28 2008 , Average:  19Kb/sec, Read: 7Kb, Write: 89Kb
  UID    PID    PPID  CMD          DEVICE  T BYTES
  0 26319 26294 firefox   sda5 W 90229
  0 2758 2757 pam_timestamp_c sda5 R 8064
  0 2885 1 cupsd   sda5 W 1678
  ```
41.2. TRACKING I/O TIME FOR EACH FILE READ OR WRITE WITH SYSTEMTAP

You can use the iotime.stp SystemTap script to monitor the amount of time it takes for each process to read from or write to any file. This helps you to determine what files are slow to load on a system.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the iotime.stp script:

  ```bash
  # stap --example iotime.stp
  ```

  The script tracks each time a system call opens, closes, reads from, and writes to a file. For each file any system call accesses, it counts the number of microseconds it takes for any reads or writes to finish and tracks the amount of data, in bytes, read from or written to the file.

  The output contains:

  - A timestamp, in microseconds
  - Process ID and process name
  - An access or iotime flag
  - The file accessed

  If a process was able to read or write any data, a pair of access and iotime lines should appear together. The access line refers to the time that a given process started accessing a file. The end of the access line will show the amount of data read or written. The iotime line will show the amount of time, in microseconds, that the process took in order to perform the read or write.

Output of the iotime.stp script looks similar to the following:

```plaintext
[...]
825946 3364 (NetworkManager) access /sys/class/net/eth0/carrier read: 8190 write: 0

[...]
```

41.3. TRACKING CUMULATIVE I/O WITH SYSTEMTAP
You can use the `traceio.stp` SystemTap script to track the cumulative amount of I/O to the system.

**Prerequisites**

- You have installed SystemTap as described in [Installing Systemtap](#).

**Procedure**

- Run the `traceio.stp` script:

  ```
  # stap --example traceio.stp
  ```

  The script prints the top ten executables generating I/O traffic over time. It also tracks the cumulative amount of I/O reads and writes done by those executables. This information is tracked and printed out in 1-second intervals, and in descending order.

  Output of the `traceio.stp` script looks similar to the following:

  ```
  Xorg r: 583401 KiB w: 0 KiB
  floaters r: 96 KiB w: 7130 KiB
  multiload-apple r: 538 KiB w: 537 KiB
  sshd r: 71 KiB w: 72 KiB
  pam_timestamp_c r: 138 KiB w: 0 KiB
  staprun r: 51 KiB w: 51 KiB
  snmpd r: 46 KiB w: 0 KiB
  pcsd r: 28 KiB w: 0 KiB
  irqbalance r: 27 KiB w: 4 KiB
  cupsd r: 4 KiB w: 18 KiB
  Xorg r: 588140 KiB w: 0 KiB
  floaters r: 97 KiB w: 7143 KiB
  multiload-apple r: 543 KiB w: 542 KiB
  sshd r: 72 KiB w: 72 KiB
  pam_timestamp_c r: 138 KiB w: 0 KiB
  staprun r: 51 KiB w: 51 KiB
  snmpd r: 46 KiB w: 0 KiB
  pcsd r: 28 KiB w: 0 KiB
  irqbalance r: 27 KiB w: 4 KiB
  cupsd r: 4 KiB w: 18 KiB
  ```

**41.4. MONITORING I/O ACTIVITY ON A SPECIFIC DEVICE WITH SYSTEMTAP**

You can use the `traceio2.stp` SystemTap script to monitor I/O activity on a specific device.

**Prerequisites**

- You have installed SystemTap as described in [Installing Systemtap](#).

**Procedure**

- Run the `traceio2.stp` script.
This script takes the whole device number as an argument. To find this number you can use:

```
# stat -c "0x%D" directory
```

Where `directory` is located on the device you want to monitor.

The output contains following:

- The name and ID of any process performing a read or write
- The function it is performing (`vfs_read` or `vfs_write`)
- The kernel device number

Consider following output of `# stap traceio2.stp 0x805`

```
[...]
synergyc(3722) vfs_read 0x800005
synergyc(3722) vfs_read 0x800005
cupsd(2889) vfs_write 0x800005
cupsd(2889) vfs_write 0x800005
cupsd(2889) vfs_write 0x800005
[...]
```

### 41.5. Monitoring Reads and Writes to a File with SystemTap

You can use the `inodewatch.stp` SystemTap script to monitor reads from and writes to a file in real time.

**Prerequisites**

- You have installed SystemTap as described in [Installing Systemtap](#).

**Procedure**

- Run the `inodewatch.stp` script.

```
# stap --example inodewatch.stp 'argument1' 'argument2' 'argument3'
```

The script `inodewatch.stp` takes three command-line arguments:

1. The file’s major device number.
2. The file’s minor device number.
3. The file’s inode number.

You can get these numbers using:

```
# stat -c '%D %i' filename
```
Where `filename` is an absolute path.

Consider following example:

```bash
# stat -c '%D %i' /etc/crontab
```

The output should look like:

```
805 1078319
```

where:

- **805** is the base-16 (hexadecimal) device number. The last two digits are the minor device number, and the remaining digits are the major number.
- **1078319** is the inode number.

To start monitoring `/etc/crontab`, run:

```bash
# stap inodewatch.stp 0x8 0x05 1078319
```

In the first two arguments you must use 0x prefixes for base-16 numbers.

The output contains following:

- The name and ID of any process performing a read or write
- The function it is performing (`vfs_read` or `vfs_write`)
- The kernel device number

The output of this example should look like:

```
cat(16437) vfs_read 0x800005/1078319
cat(16437) vfs_read 0x800005/1078319
```
CHAPTER 42. ANALYZING SYSTEM PERFORMANCE WITH BPF COMPILER COLLECTION

As a system administrator, you can use the BPF Compiler Collection (BCC) library to create tools for analyzing the performance of your Linux operating system and gathering information, which could be difficult to obtain through other interfaces.

42.1. INSTALLING THE BCC-TOOLS PACKAGE

Install the bcc-tools package, which also installs the BPF Compiler Collection (BCC) library as a dependency.

Procedure

1. Install bcc-tools.
   
   ```
   # yum install bcc-tools
   ```

   The BCC tools are installed in the `/usr/share/bcc/tools/` directory.

2. Optionally, inspect the tools:
   
   ```
   # ll /usr/share/bcc/tools/
   ...
   -rwxr-xr-x. 1 root root  4198 Dec 14 17:53 dcsnoop
   -rwxr-xr-x. 1 root root  3931 Dec 14 17:53 dcstat
   -rwxr-xr-x. 1 root root 20040 Dec 14 17:53 deadlock_detector
   -rw-r--r--. 1 root root  7105 Dec 14 17:53 deadlock_detector.c
   drwxr-xr-x. 3 root root  8192 Mar 11 10:28 doc
   -rwxr-xr-x. 1 root root  7588 Dec 14 17:53 execsnoop
   -rwxr-xr-x. 1 root root  6373 Dec 14 17:53 ext4dist
   -rwxr-xr-x. 1 root root 10401 Dec 14 17:53 ext4slower
   ...
   ```

   The doc directory in the listing above contains documentation for each tool.

42.2. USING SELECTED BCC-TOOLS FOR PERFORMANCE ANALYSES

Use certain pre-created programs from the BPF Compiler Collection (BCC) library to efficiently and securely analyze the system performance on the per-event basis. The set of pre-created programs in the BCC library can serve as examples for creation of additional programs.

Prerequisites

- Installed bcc-tools package
- Root permissions

Using execsnoop to examine the system processes

1. Run the execsnoop program in one terminal:
   
   ```
   # /usr/share/bcc/tools/execsnoop
   ```
2. In another terminal run, for example:

```bash
$ ls /usr/share/bcc/tools/doc/
```

The above creates a short-lived process of the `ls` command.

3. The terminal running `execsnoop` shows the output similar to the following:

```
PCOMM  PID   PPID   RET   ARGS
     ls  8382   8287     0 /usr/bin/ls --color=auto /usr/share/bcc/tools/doc/
```

The `execsnoop` program prints a line of output for each new process, which consumes system resources. It even detects processes of programs that run very shortly, such as `ls`, and most monitoring tools would not register them.

The `execsnoop` output displays the following fields:

- **PCOMM** - The parent process name. (`ls`)
- **PID** - The process ID. (`8382`)
- **PPID** - The parent process ID. (`8287`)
- **RET** - The return value of the `exec()` system call (`0`), which loads program code into new processes.
- **ARGS** - The location of the started program with arguments.

To see more details, examples, and options for `execsnoop`, refer to the `/usr/share/bcc/tools/doc/execsnoop_example.txt` file.

For more information about `exec()`, see `exec(3)` manual pages.

**Using opensnoop to track what files a command opens**

1. Run the `opensnoop` program in one terminal:

```bash
# /usr/share/bcc/tools/opensnoop -n uname
```

The above prints output for files, which are opened only by the process of the `uname` command.

2. In another terminal, enter:

```bash
$ uname
```

The command above opens certain files, which are captured in the next step.

3. The terminal running `opensnoop` shows the output similar to the following:

```
PID  COMM   FD  ERR  PATH
 8596  uname  3  0  /etc/ld.so.cache
 8596  uname  3  0  /lib64/libc.so.6
 8596  uname  3  0  /usr/lib/locale/locale-archive
```

Red Hat Enterprise Linux 8 Monitoring and managing system status and performance

316
The `opensnoop` program watches the `open()` system call across the whole system, and prints a line of output for each file that `uname` tried to open along the way.

The `opensnoop` output displays the following fields:

- **PID** - The process ID. (8596)
- **COMM** - The process name. (`uname`)
- **FD** - The file descriptor - a value that `open()` returns to refer to the open file. (3)
- **ERR** - Any errors.
- **PATH** - The location of files that `open()` tried to open.

If a command tries to read a non-existent file, then the FD column returns -1 and the ERR column prints a value corresponding to the relevant error. As a result, `opensnoop` can help you identify an application that does not behave properly.

To see more details, examples, and options for `opensnoop`, refer to the `/usr/share/bcc/tools/doc/opensnoop_example.txt` file.

For more information about `open()`, see `open(2)` manual pages.

**Using biotop to examine the I/O operations on the disk**

1. Run the `biotop` program in one terminal:

   ```
   # /usr/share/bcc/tools/biotop 30
   ```

   The command enables you to monitor the top processes, which perform I/O operations on the disk. The argument ensures that the command will produce a 30 second summary.

   **NOTE**

   When no argument provided, the output screen by default refreshes every 1 second.

2. In another terminal enter, for example:

   ```
   # dd if=/dev/vda of=/dev/zero
   ```

   The command above reads the content from the local hard disk device and writes the output to the `/dev/zero` file. This step generates certain I/O traffic to illustrate `biotop`.

3. The terminal running `biotop` shows the output similar to the following:

   ```
   PID   COMM      D MAJ MIN DISK I/O Kbytes AVGms
   9568   dd       R 252 0   vda   16294 14440636.0  3.69
   48     kswapd0  W 252 0   vda   1763 120696.0    1.65
   7571   gnome-shell R 252 0   vda   834 83612.0     0.33
   1891   gnome-shell R 252 0   vda  1379 19792.0     0.15
   7515   Xorg      R 252 0   vda   280  9940.0     0.28
   7579   lvmpipe-1 R 252 0   vda  228  6928.0     0.19
   9515   gnome-control-c R 252 0   vda   62  6444.0     0.43
   8112   gnome-terminal- R 252 0   vda   67  2572.0     1.54
   ```
The `biotop` output displays the following fields:

- **PID** - The process ID. (9568)
- **COMM** - The process name. (dd)
- **DISK** - The disk performing the read operations. (vda)
- **I/O** - The number of read operations performed. (16294)
- **Kbytes** - The amount of Kbytes reached by the read operations. (14,440,636)
- **AVGms** - The average I/O time of read operations. (3.69)

To see more details, examples, and options for `biotop`, refer to the `/usr/share/bcc/tools/doc/biotop_example.txt` file.

For more information about `dd`, see `dd(1)` manual pages.

**Using xfsslower to expose unexpectedly slow file system operations**

1. Run the `xfsslower` program in one terminal:

   ```
   # /usr/share/bcc/tools/xfsslower 1
   ```

   The command above measures the time the XFS file system spends in performing read, write, open or sync (`fsync`) operations. The 1 argument ensures that the program shows only the operations that are slower than 1 ms.

   **NOTE**

   When no arguments provided, `xfsslower` by default displays operations slower than 10 ms.

2. In another terminal enter, for example, the following:

   ```
   $ vim text
   ```

   The command above creates a text file in the `vim` editor to initiate certain interaction with the XFS file system.

3. The terminal running `xfsslower` shows something similar upon saving the file from the previous step:

   ```
   TIME COMM PID T BYTES OFF_KB LAT(ms) FILENAME
   ```
Each line above represents an operation in the file system, which took more time than a certain threshold. `xfsslower` is good at exposing possible file system problems, which can take form of unexpectedly slow operations.

The `xfsslower` output displays the following fields:

- **COMM** - The process name. (b'bash')
- **T** - The operation type. (R)
  - Read
  - Write
  - Sync
- **OFF_KB** - The file offset in KB. (0)
- **FILENAME** - The file being read, written, or synced.

To see more details, examples, and options for `xfsslower`, refer to the `/usr/share/bcc/tools/doc/xfsslower_example.txt` file.

For more information about `fsync`, see `fsync(2)` manual pages.
