Red Hat Enterprise Linux 8

Using authselect on a Red Hat Enterprise Linux host

Understanding, selecting, modifying, and creating authselect profiles
Understanding, selecting, modifying, and creating authselect profiles
Abstract

This documentation collection provides instructions on how to use authselect on a Red Hat Enterprise Linux 8 host.

PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Please let us know how we could make it better. To do so:

- For simple comments on specific passages:
  1. Make sure you are viewing the documentation in the *Multi-page HTML* format. In addition, ensure you see the Feedback button in the upper right corner of the document.
  2. Use your mouse cursor to highlight the part of text that you want to comment on.
  3. Click the Add Feedback pop-up that appears below the highlighted text.
  4. Follow the displayed instructions.

- For submitting more complex feedback, create a Bugzilla ticket:
  1. Go to the Bugzilla website.
  2. As the Component, use Documentation.
  3. Fill in the Description field with your suggestion for improvement. Include a link to the relevant part(s) of documentation.
  4. Click Submit Bug.
CHAPTER 1. CONFIGURING USER AUTHENTICATION USING AUTHSELECT

1.1. WHAT IS AUTHSELECT USED FOR

Authselect is a utility that simplifies the configuration of user authentication on a Red Hat Enterprise Linux host. Authselect offers two ready-made profiles that can be universally used with all modern identity management systems:

- the sssd profile
- the winbind profile

For legacy compatibility reasons, the nis profile is also available.

Red Hat recommends using authselect in semi-centralized identity management environments, for example if your company utilizes the LDAP, winbind or nis databases to authenticate users to use services in your domain.

**WARNING**

Do not use authselect if your host is part of Red Hat Enterprise Linux Identity Management or Active Directory. The ipa-client-install command, called when joining your host to a Red Hat Identity Management domain, takes full care of configuring authentication on your host. Similarly the realm join command, called when joining your host to an Active Directory domain, takes full care of configuring authentication on your host.

The authconfig utility, used in previous Red Hat Enterprise Linux versions, created and modified many different configuration files, making troubleshooting a difficult task. Authselect makes testing and troubleshooting easy because it only modifies files in these directories:

- /etc/nsswitch.conf
- /etc/pam.d/* files
- /etc/dconf/db/distro.d/* files

The Name Service Switch (NSS) configuration file, /etc/nsswitch.conf, is used by the GNU C Library and certain other applications to determine the sources from which to obtain name-service information in a range of categories, and in what order. Each category of information is identified by a database name.

Linux-PAM (Pluggable Authentication Modules) is a system of modules that handle the authentication tasks of applications (services) on the system. The nature of the authentication is dynamically configurable: the system administrator can choose how individual service-providing applications will authenticate users. This dynamic configuration is set by the contents of the configuration files in the /etc/pam.d/ directory, which list the PAMs that will do the authentication tasks required by this service, and the appropriate behavior of the PAM-API in the event that individual PAMs fail.
Once an authselect profile is selected for a given host, the profile will be applied to every user logging into the host.

1.2. CHOOSING AN AUTHSELECT PROFILE

As a system administrator, you can select a profile for the authselect utility for a specific host. The profile will be applied to every user logging into the host.

Procedure

1. Select the authselect profile that is appropriate for your authentication provider. For example, for logging into the network of a company that uses LDAP, choose sssd. Run the command as root:

   ```
   # authselect select sssd
   ```

2. Optionally, review the contents of the /etc/nsswitch.conf file:

   ```
   passwd:     sss files
   group:      sss files
   netgroup:   sss files
   automount:  sss files
   services:   sss files
   ...
   ```

   The content of the /etc/nsswitch.conf file shows that selecting the sssd profile means that the system first uses sssd if information concerning one of the first five items is requested. Only if the requested information is not found in the sssd cache and on the server providing authentication, or if sssd is not running, the system looks at the local files, that is /etc/*.

   For example, if information is requested about a user id, the user id is first searched in the sssd cache. If it is not found there, the /etc/passwd file is consulted. Analogically, if a user’s group affiliation is requested, it is first searched in the sssd cache and only if not found there, the /etc/group file is consulted.

   In practice, the local files database does not normally get consulted at all. The only exception is the case of the root user, which is never handled by sssd but by files.

3. Optionally, review the contents of the /etc/pam.d/system-auth file:

   ```
   # Generated by authselect on Tue Sep 11 22:59:06 2018
   # Do not modify this file manually.

   auth        required        pam_env.so
   auth        required        pam_faildelay.so delay=2000000
   auth        [default=1 ignore=ignore success=ok]    pam_succeed_if.so uid >= 1000 quiet
   auth        [default=1 ignore=ignore success=ok]    pam_localuser.so
   auth        sufficient      pam_unix.so nullok try_first_pass
   auth        requisite       pam_succeed_if.so uid >= 1000 quiet_success
   auth        sufficient      pam_sss.so forward_pass
   auth        required        pam_deny.so
   account    required        pam_unix.so
   account    sufficient      pam_localuser.so
   ...
   ```
Among other things, the `/etc/pam.d/system-auth` file contains information about:

- user password lockout condition
- the possibility to authenticate with a smart card
- the possibility to authenticate with fingerprints

You can modify the default profile settings by adding the following options to the
authselect select sssd or authselect select winbind command, for example:

- `with-faillock`
- `with-smartcard`
- `with-fingerprint`

To see the full list of available options, see Section 1.5, “Converting your scripts from authconfig to authselect” or the authselect-migration(7) man page.

**NOTE**

Make sure that the configuration files that are relevant for your profile are configured properly before finishing the authselect select procedure. For example, if the sssd daemon is not configured correctly and active, running authselect select results in only local users being able to authenticate, using pam_unix.

If adjusting a ready-made profile by adding one of the authselect select command-line options described above is not enough for your use case, you can:

- modify a ready-made profile by changing the `/etc/authselect/user-nsswitch.conf` file. For details, see Section 1.3, “Modifying a ready-made authselect profile”.
- create your own custom profile. For details, see Section 1.4, “Creating and deploying your own authselect profile”.

## 1.3. MODIFYING A READY-MADE AUTHSELECT PROFILE

As a system administrator, you can modify one of the default profiles, the sssd, winbind, or the nis profile, to suit your needs. You can modify any of the items in the `/etc/authselect/user-nsswitch.conf` file with the exception of:

- passwd
- group
- netgroup
- automount
- services

Running authselect select profile_name afterwards will result in permissible changes to the profile being transferred from `/etc/authselect/user-nsswitch.conf` to the `/etc/nsswitch.conf` file but unacceptable changes being overwritten by the default profile configuration.
IMPORTANT
Do not modify the /etc/nsswitch.conf file directly.

Procedure

1. Select an authselect profile, for example:

```
# authselect select sssd
```

2. Edit the /etc/authselect/user-nsswitch.conf file.

3. Apply the changes from the /etc/authselect/user-nsswitch.conf file:

```
# authselect apply-changes
```

4. Optionally, review the /etc/nsswitch.conf file to verify that the changes from /etc/authselect/user-nsswitch.conf have been propagated there.

1.4. CREATING AND DEPLOYING YOUR OWN AUTHSELECT PROFILE

As a system administrator, you can create and deploy a custom profile by customizing one of the default profiles, the sssd, winbind, or the nis profile. This is particularly useful if Section 1.3, “Modifying a ready-made authselect profile” is not enough for your needs. When you deploy a custom profile, the profile is applied to every user logging into the given host.

Procedure

1. Create your custom profile by using the authselect create-profile command. For example, to create a custom profile called user-profile based on the ready-made sssd profile but one in which you can configure the items in the /etc/nsswitch.conf file yourself:

```
# authselect create-profile user-profile -b sssd --symlink-meta --symlink-pam
```

New profile was created at /etc/authselect/custom/user-profile

Including the --symlink-pam option in the command means that PAM templates will be symbolic links to the origin profile files instead of their copy; including the --symlink-meta option means that meta files, such as README and REQUIREMENTS will be symbolic links to the origin profile files instead of their copy. This ensures that all future updates to the PAM templates and meta files in the original profile will be reflected in your custom profile, too.

The command has created a copy of the /etc/nsswitch.conf file in the /etc/authselect/custom/user-profile/ directory.

2. Configure the /etc/authselect/custom/user-profile/nsswitch.conf file.

3. Select the custom profile by running the authselect select command, and adding custom/name_of_the_profile as a parameter. For example, to select the user-profile profile:

```
# authselect select custom/user-profile
```

Selecting the user-profile profile for your machine means that if the sssd profile is subsequently updated by Red Hat, you will benefit from all the updates with the exception of updates made to the /etc/nsswitch.conf file.
Example
The following procedure shows how to create a profile based on the sssd profile which only consults the local static table lookup for hostnames in the /etc/hosts file, not in the dns or myhostname databases.

1. Edit the /etc/nsswitch.conf file by editing the following line:
   ```ini
   [hosts]
   files
   ```

2. Create a custom profile based on sssd that excludes changes to /etc/nsswitch.conf:
   ```bash
   # authselect create-profile user-profile -b sssd --symlink-meta --symlink-pam
   ```

3. Select the profile:
   ```bash
   # authselect select custom/user-profile
   ```

4. Optionally, check that selecting the custom profile has
   - created the /etc/pam.d/system-auth file according to the chosen sssd profile
   - left the configuration in the /etc/nsswitch.conf unchanged:
     ```ini
     [hosts]
     files
     ```

   NOTE
   Running authselect select sssd would, in contrast, result in
   ```ini
   [hosts]
   files dns myhostname
   ```

1.5. CONVERTING YOUR SCRIPTS FROM AUTHCONFIG TO AUTHSELECT

If you use ipa-client-install or realm join to join a domain, you can safely remove any authconfig call in your scripts. If this is not possible, replace each authconfig call with its equivalent authselect call. In doing that, select the correct profile and the appropriate options. In addition, edit the necessary configuration files:

- /etc/krb5.conf
- /etc/sssd/sssd.conf (for the sssd profile) or /etc/samba/smb.conf (for the winbind profile)

Table 1.1, “Relation of authconfig options to authselect profiles” and Table 1.2, “Authselect profile option equivalents of authconfig options” show the authselect equivalents of authconfig options.

Table 1.1. Relation of authconfig options to authselect profiles

<table>
<thead>
<tr>
<th>Authconfig options</th>
<th>Authselect profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>--enableldap --enableldapauth</td>
<td>sssd</td>
</tr>
</tbody>
</table>
Table 1.2. Authselect profile option equivalents of authconfig options

<table>
<thead>
<tr>
<th>Authconfig option</th>
<th>Authselect profile feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>--enablesmartcard</td>
<td>with-smartcard</td>
</tr>
<tr>
<td>--enablefingerprint</td>
<td>with-fingerprint</td>
</tr>
<tr>
<td>--enableecryptfs</td>
<td>with-ecryptfs</td>
</tr>
<tr>
<td>--enablemkhomedir</td>
<td>with-mkhomedir</td>
</tr>
<tr>
<td>--enablefaillock</td>
<td>with-faillock</td>
</tr>
<tr>
<td>--enablepamaccess</td>
<td>with-pamaccess</td>
</tr>
<tr>
<td>--enablewinbindkrb5</td>
<td>with-krb5</td>
</tr>
</tbody>
</table>

Table 1.3, “Examples of authselect commands equivalents to authconfig commands” shows example transformations of Kickstart calls to authconfig into Kickstart calls to authselect.

Table 1.3. Examples of authselect commands equivalents to authconfig commands

<table>
<thead>
<tr>
<th>authconfig command</th>
<th>authselect equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>authconfig --enablesldap --enableldapauth --enablefaillock --updateall</td>
<td>authselect select sssd with-faillock</td>
</tr>
<tr>
<td>authconfig --enablessssd --enablesssdauth --enablesmartcard --smartcardmodule=sssd --updateall</td>
<td>authselect select sssd with-smartcard</td>
</tr>
<tr>
<td>authconfig --enableecryptfs --enablepamaccess --updateall</td>
<td>authselect select sssd with-ecryptfs with-pamaccess</td>
</tr>
<tr>
<td>authconfig --enablewinbind --enablewinbindauth --winbindjoin=Administrator --updateall</td>
<td>realm join -U Administrator --client-software=winbind WINBINDDOMAIN</td>
</tr>
</tbody>
</table>
CHAPTER 2. CONFIGURING SMART CARDS USING
AUTHSELECT

This chapter describes how to configure your smart card to achieve one of the following aims:

- Enable both password and smart card authentication
- Disable password and enable smart card authentication
- Enable lock on removal

Prerequisites

- Authselect installed
  The authselect tool configures user authentication on Linux hosts and you can use it to
  configure smart card authentication parameters. For details about authselect, see Explaining
  authselect.

- Smart Card or USB device supported by RHEL 8
  For details, see Smart Card support in RHEL8.

2.1. CERTIFICATES ELIGIBLE FOR SMART CARDS

Before you can configure a smart card with authselect, you must import a certificate into your card. You
 can use the following tools to generate the certificate:

- Active Directory (AD)
- Identity Management (IdM)
  For details about how to create IdM certificates, see Requesting a new user certificate and
  exporting it to the client.
- Red Hat Certificate System (RHCS)
  For details, see Managing Smart Cards with the Enterprise Security Client.
- Local Certification Authority. You can use a certificate generated by the Local Certification
  Authority if the user is not part of a domain or for testing purposes.
  For details about how to create and import local certificates into a smart card, Configuring and
  importing local certificates to a smart card.

2.2. ENABLING USER PASSWORD AUTHENTICATION TO CONFIGURE
SMART CARD AUTHENTICATION

This section describes how to enable both smart card and password authentication on your system.

Prerequisites

- The Smart card contains your certificate and private key.
- The card is inserted into the reader and connected to the computer.
- The authselect tool is installed on your system.
Procedure

- Enter the following command to allow smart card and password authentication:

  ```shell
  # authselect select sssd with-smartcard --force
  ```

  At this point, smart card authentication is enabled, however, password authentication will work if you forget your smart card at home.

2.3. CONFIGURING AUTHSELECT TO ENFORCE SMART CARD AUTHENTICATION

The `authselect` tool enables you to configure smart card authentication on your system and to disable the default password authentication. The `authselect` command must include the following options:

- `with-smartcard` — enabling smart card authentication
- `with-smartcard-required` — enabling exclusive smart card authentication (authentication with a password is disabled)

Prerequisites

- Smart card contains your certificate and private key.
- The card is inserted into the reader and connected to the computer.
- The `authselect` tool is installed on your local system.

Procedure

- Enter the following command to enforce smart card authentication:

  ```shell
  # authselect select sssd with-smartcard with-smartcard-required --force
  ```

  At this point, you can only log in with a smart card. Password authentication will not be working any more.

2.4. CONFIGURING SMART CARD AUTHENTICATION WITH LOCK ON REMOVAL

The `authselect` service enables you to configure your smart card authentication to lock your screen instantly after removing the smart card from the reader. The `authselect` command must include the following variables:

- `with-smartcard` — enabling smart card authentication
- `with-smartcard-required` — enabling exclusive smart card authentication (authentication with a password is disabled)
- `with-smartcard-lock-on-removal` — enforcing log out after the smart card removal

Prerequisites
• Smart card contains your certificate and private key.
• The card is inserted into the reader and connected to the computer.
• The authselect tool is installed on your local system.

Procedure

• Enter the following command to enable smart card authentication, disable password authentication, and enforce lock on removal:

```
# authselect select sssd with-smartcard with-smartcard-required with-smartcard-lock-on-removal --force
```

Now, when you remove the card, the screen locks. You must re-insert your smart card to unlock it.
CHAPTER 3. CONFIGURING AND IMPORTING LOCAL CERTIFICATES TO A SMART CARD

This chapter describes a scenario where:

- The host is not connected to a domain.
- You want to authenticate with a smart card on this host.
- You want to configure SSH access using smart card authentication.
- You want to configure the smart card with **authselect**.

Use the following configuration to accomplish this scenario:

- Obtain a user certificate for the user who wants to authenticate with a smart card. The certificate should be generated by a trustworthy Certification Authority used in the domain. If you cannot get the certificate, you can generate a user certificate signed by a local certificate authority for testing purposes.
- Store the certificate and private key in a smart card.
- Configure the smart card authentication for SSH access.

**IMPORTANT**

If a host can be part of the domain, add the host to the domain and use certificates generated by Active Directory or Identity Management Certification Authority.

For details about how to create IdM certificates for a smart card, see [Configuring Identity Management for smart card authentication](#).

**Prerequisites**

- **Authselect installed**
  
  The authselect tool configures user authentication on Linux hosts and you can use it to configure smart card authentication parameters. For details about authselect, see [Explaining authselect](#).

- **Smart Card or USB device supported by RHEL 8**
  
  For details, see [Smart Card support in RHEL 8](#).

### 3.1. CREATING LOCAL CERTIFICATES

This section describes how to perform these tasks:

- Generate the OpenSSL certificate authority
- Create a certificate signing request
WARNING

The following steps are intended for testing purpose only. Certificates generated by a local self-signed Certificate Authority are not as secure as using AD, IdM, or RHCS Certification Authority. You should use a certificate generated by your enterprise Certification Authority even if the host is not part of the domain.

Procedure

1. Create a directory where you can generate the certificate, for example:

```bash
# mkdir /tmp/ca
# cd /tmp/ca
```

2. Set up the certificate (copy this text to your command line in the `ca` directory):

```bash
cat > ca.cnf <<EOF
[ ca ]
default_ca = CA_default

[ CA_default ]
dir = .
database = $dir/index.txt
new_certs_dir = $dir/newcerts
certificate = $dir/rootCA.crt
serial = $dir/serial
private_key = $dir/rootCA.key
RANDFILE = $dir/rand

default_days = 365
default_crl_days = 30
default_md = sha256

policy = policy_any
email_in_dn = no

name_opt = ca_default
cert_opt = ca_default
copy_extensions = copy

[ usr_cert ]
authorityKeyIdentifier = keyid, issuer

[ v3_ca ]
subjectKeyIdentifier = hash
authorityKeyIdentifier = keyid:always,issuer:always
basicConstraints = CA:true
keyUsage = critical, digitalSignature, cRLSign, keyCertSign

[ policy_any ]
EOF
```

Red Hat Enterprise Linux 8 Using authselect on a Red Hat Enterprise Linux host
3. Create the following directories:

```bash
# mkdir certs crl newcerts
```

4. Create the following files:

```bash
# touch index.txt crlnumber index.txt.attr
```

5. Write the number 01 in the serial file:

```bash
# echo 01 > serial
```

   This command writes a number 01 in the serial file. It is a serial number of the certificate. With each new certificate released by this CA the number increases by one.

6. Create an OpenSSL root CA key:

```bash
# openssl genrsa -out rootCA.key 2048
```

7. Create a self-signed root Certification Authority certificate:

```bash
# openssl req -batch -config ca.cnf \
-x509 -new -nodes -key rootCA.key -sha256 -days 10000 \
-set_serial 0 -extensions v3_ca -out rootCA.crt
```

8. Create the key for your username:

```bash
# openssl genrsa -out example.user.key 2048
```

   This key is generated in the local system which is not secure, therefore, remove the key from the system when the key is stored in the card.

   You can create a key directly in the smart card as well. For doing this, follow instructions created by the manufacturer of your smart card.

9. Create the certificate signing request configuration file (copy this text to your command line in the ca directory):

```bash
cat > req.cnf <<EOF
```
[ req ]
distinguished_name = req_distinguished_name
prompt = no

[ req_distinguished_name ]
O = Example
OU = Example Test
CN = testuser

[ req_exts ]
basicConstraints = CA:FALSE
nsCertType = client, email
nsComment = "testuser"
subjectKeyIdentifier = hash
keyUsage = critical, nonRepudiation, digitalSignature, keyEncipherment
extendedKeyUsage = clientAuth, emailProtection, msSmartcardLogin
subjectAltName = otherName:msUPN;UTF8:testuser@EXAMPLE.COM,
                 email:testuser@example.com
EOF

10. Create a certificate signing request for your example.user certificate:

    # openssl req -new -nodes -key example.user.key \
    -reqexts req_exts -config req.cnf -out testuser.csr

11. Configure the new certificate. Expiration period is set to 1 year:

    # openssl ca -config ca.cnf -batch -notext \
    -keyfile rootCA.key -in example.user.csr -days 365 \
    -extensions usr_cert -out example.user.crt

At this point, the certification authority and certificates are successfully generated and prepared for import into a smart card.

3.2. COPYING CERTIFICATES TO THE SSSD DIRECTORY

Gnome Desktop Manager (GDM) requires SSSD. If you use GDM, you need to copy the PEM certificate to the /etc/sssd/pki directory.

Prerequisites

- The local CA authority and certificates have been generated

Procedure

1. Ensure that you have SSSD installed on the system.

    # rpm -q sssd
    sssd-2.0.0.43.el8_0.3.x86_64

2. Create a /etc/sssd/pki directory:
3. Copy the rootCA.crt as a PEM file in the /etc/sssd/pki/ directory:

```bash
# cp /tmp/ca/rootCA.crt /etc/sssd/pki/sssd_auth_ca_db.pem
```

Now you have successfully generated the certificate authority and certificates, and you have saved them in the /etc/sssd/pki directory.

**NOTE**

If you want to share the Certificate Authority certificates with another application, you can change a location in sssd.conf:

- SSSD PAM responder: `pam_cert_db_path` in the `[pam]` section
- SSSD ssh responder: `ca_db` in the `[ssh]` section

For details, see `man mage for sssd.conf`.

Red Hat recommends to keep the default path and use a dedicated Certificate Authority certificate file for SSSD to make sure that only Certificate Authorities trusted for authentication are listed here.

### 3.3. INSTALLING GNUTLS-UTILS

To configure your smart card, you need a tool that can generate certificates and store them in the smart card.

You must:

- Install the `gnutls-utils` program which helps you to manage certificates.
- Start the `pcscd` service which communicates with the smart card reader.

#### Procedure

1. Install the `gnutls-utils` package which allows you to manage smart card settings for reading and writing from the smart card:

   ```bash
   # dnf -y install opensc gnutls-utils
   ```

2. Start the `pcscd` service.

   ```bash
   # systemctl start pcscd
   ```

Verify that the `pcscd` service is up and running.

### 3.4. STORING A CERTIFICATE ON THE SMART CARD

This section describes smart card configuration with `gnutls-utils` which helps you to configure:
- Erasing your smart card
- Setting a new PIN and PUK
- Creating a new slot in the smart card
- Storing the certificate and private key in the slot
- Locking the smart card settings (some smart cards need this type of finalization)

**Prerequisites**

- The **gnutls-utils** package is installed. For details, see [Installing gnutls-utils](#).
- The card is inserted in the reader and connected to the computer.

**Procedure**

1. Erase your smart card and authenticate yourself with PIN:

   ```bash
   # spawn pkcs15-init --erase-card --use-default-transport-keys
   Using reader with a card: Smart Card name
   PIN [Security Officer PIN] required.
   Please enter PIN [Security Officer PIN]:
   
   The card has been erased.
   
   # pkcs15-init --create-pkcs15 --use-default-transport-keys
   --pin redhat --puk redhat --so-pin redhat --so-puk redhat
   Using reader with a card: SCM Microsystems Inc. SCR 3320 [CCID Interface]
   (53311657131456) 00 00
   
   The **pkcs15-init** creates a new slot in the smart card and marks it with a label and an authentication ID.
   
2. Set your PIN and PUK — both twice for verification:

3. Add a label that is the name of the slot and the authentication ID:

4. Store the private key in the new slot of the smart card:

5. Store the certificate in the new slot of the smart card:
6. Optionally finalize the card settings with locking the settings:

```
# pkcs15-init -F
```

**IMPORTANT**

Some smart cards require this step.

At this stage, your smart card includes the certificate and private key in the newly created slot. PIN and PUK has been successfully created.

### 3.5. CONFIGURING SSH ACCESS USING SMART CARD AUTHENTICATION

SSH connections require authentication. You can use a password or a certificate. This section describes:

- the configuration necessary for enabling authentication using a certificate stored on a smart card
- the lock on removal configuration using the `authselect` tool

The lock on removal configuration enforces log out after the smart card removal.

For details about configuring smart cards with `authselect`, see [Configuring smart cards using authselect](#).

**Prerequisites**

- The smart card contains your certificate and private key.
- The card is inserted in the reader and connected to the computer.
- SSSD is installed and configured.
- Your username matches the Common Name (CN) or User ID (UID) in the certificate’s SUBJECT.
- The `pcsccd` service is running on your local machine. For details, see [Installing gnutls-utils](#).

**Procedure**

1. Create a new directory for SSH keys in the home directory of the user who uses smart card authentication:

```
# mkdir /home/example.user/.ssh
```
1. Run the `ssh-keygen` command to read the existing public key for the private key stored in the smart card. The command also appends the key to the `authorized_keys` file. It enables the SSH access authenticated by smart card.

```
# ssh-keygen -D /usr/lib64/pkcs11/opensc-pkcs11.so >>
~example.user/.ssh/authorized_keys
```

2. SSH requires access right configuration for the `.ssh` directory and the `authorized_keys` file. To set or change the access rights, enter:

```
# chown -R example.user:example.user ~example.user/.ssh/
# chmod 700 ~example.user/.ssh/
# chmod 600 ~example.user/.ssh/authorized_keys
```

3. Optionally, display the keys:

```
# cat ~example.user/.ssh/authorized_keys
```

The terminal displays the keys.

4. Verify that the smart card authentication is enabled in the `/etc/sssd/sssd.conf` file:

In the `[pam]` section, enable the pam certificate authentication module: `pam_cert_auth = True`

If the `sssd.conf` file has not been created yet, you can create the minimal functional configuration by copying the following script to the command line:

```
# cat > /etc/sssd/sssd.conf <<EOF
[sssd]
  services = nss, pam
  domains = shadowutils

[nss]

[pam]
pam_cert_auth = True

[domain/shadowutils]
id_provider = files
EOF
```

5. To use the SSH keys, configure the authentication with the `authselect` command:

```
# authselect select sssd with-smartcard with-smartcard-lock-on-removal --force
```

Now, you can verify the SSH access with the following command:

```
# ssh -l /usr/lib64/opensc-pkcs11.so -l example.user localhost hostname
```

If the configuration is successful, you are prompted to enter the smart card PIN.

The configuration works now locally. For smart card authentication working on remote servers, you must copy the public key and distribute it to `authorized_keys` files located on all servers on which you want to use SSH.
CHAPTER 4. REPORTING ON USER ACCESS ON HOSTS USING SSSD

The Security System Services Daemon (SSSD) tracks which users can or cannot access clients. This chapter describes creating access control reports and displaying user data using the sssctl tool.

Prerequisites

- SSSD packages are installed in your network environment.

4.1. THE SSSCTL COMMAND

sssctl is a command-line tool using Security System Services Daemon (SSSD) to gather information about:

- domain state
- client user authentication
- user access on clients of a particular domain
- information about cached content

With the sssctl tool, you can:

- manage the SSSD cache
- manage logs
- check configuration files

NOTE

The sssctl tool replaces sss_cache and sss_debuglevel tools.

Additional resources

- For details about sssctl, enter:

  # sssctl --help

4.2. GENERATING ACCESS CONTROL REPORTS USING SSSCTL

You can list the access control rules applied to the machine on which you are running the report because SSSD controls which users can log in to the client.

NOTE

The access report is not accurate because the tool does not track users locked out by the Key Distribution Center (KDC).
You must be logged in with administrator privileges

The `ssscctl` is available on RHEL 7 and RHEL 8 systems

**Procedure**

- To generate a report for the `idm.example.com` domain, enter:

  ```bash
  [root@client1 ~]# sssctl access-report idm.example.com
  1 rule cached
  Rule name: example.user
  Member users: example.user
  Member services: sshd
  ```

### 4.3. Displaying User Authorization Details Using SSSCctl

The `ssscctl user-checks` command helps debug problems in applications that use the System Security Services Daemon (SSSD) for user lookup, authentication, and authorization.

The `ssscctl user-checks [USER_NAME]` command displays user data available through Name Service Switch (NSS) and the InfoPipe responder for the D-Bus interface. The displayed data shows whether the user is authorized to log in using the `system-auth` Pluggable Authentication Module (PAM) service.

The command has two options:

- `-a` for a PAM action
- `-s` for a PAM service

If you do not define `-a` and `-s` options, the `ssscctl` tool uses default options: `-a acct -s system-auth`.

**Prerequisites**

- You must be logged in with administrator privileges
- The `ssscctl` tool is available on RHEL 7 and RHEL 8 systems

**Procedure**

- To display user data for a particular user, enter:

  ```bash
  [root@client1 ~]# sssctl user-checks -a acct -s sshd example.user
  user: example.user
  action: acct
  service: sshd
  ....
  ```

**Additional resources**

- For details on `ssscctl user-checks`, use the following command:

  ```bash
  sssctl user-checks --help
  ```
CHAPTER 5. QUERYING DOMAIN INFORMATION USING SSSD

Security System Services Daemon (SSSD) can list domains in Identity Management (IdM), including Active Directory domains in the cross-forest trust. You can also verify the status of each of the listed domains:

- Listing domains using the sssctl command
- Verifying the domain status using the sssctl command

5.1. LISTING DOMAINS USING SSSCTL

The `sssctl domain-list` command helps debug problems with the domain topology.

**NOTE**

The status might not be available immediately. If the domain is not visible, repeat the command.

**Prerequisites**

- You must be logged in with administrator privileges
- The `sssctl` is available on RHEL 7 and RHEL 8 systems

**Procedure**

1. To display help for the sssctl command, enter:

   ```
   [root@client1 ~]# sssctl --help
   ....
   ```

2. To display a list of available domains, enter:

   ```
   [root@client1 ~]# sssctl domain-list
   implicit_files
   idm.example.com
   ad.example.com
   sub1.ad.example.com
   ```

   The list includes domains in the cross-forest trust between Active Directory and Identity Management.

5.2. VERIFYING THE DOMAIN STATUS USING SSSCTL

The `sssctl domain-status` command helps debug problems with the domain topology.

**NOTE**

The status might not be available immediately. If the domain is not visible, repeat the command.

**Prerequisites**
You must be logged in with administrator privileges

The **sssctl** is available on RHEL 7 and RHEL 8 systems

**Procedure**

1. To display help for the sssctl command, enter:

   ```
   [root@client1 ~]# sssctl --help
   ```

2. To display user data for a particular domain, enter:

   ```
   [root@client1 ~]# sssctl domain-status idm.example.com
   Online status: Online
   Active servers:
   IPA: master.idm.example.com
   Discovered IPA servers:
   - master.idm.example.com
   ```

   The domain **idm.example.com** is online and visible from the client where you applied the command.

   If the domain is not available, the result is:

   ```
   [root@client1 ~]# sssctl domain-status ad.example.com
   Unable to get online status
   ```
