Building, running, and managing Linux containers on Red Hat Enterprise Linux 9
Abstract

This document describes how to work with Linux containers on Red Hat Enterprise Linux 9 systems using command-line tools such as podman, buildah, skopeo, runc and crun.
# Table of Contents

- **RHEL BETA RELEASE** .................................................. 5
- **MAKING OPEN SOURCE MORE INCLUSIVE** .......................... 6
- **PROVIDING FEEDBACK ON RED HAT DOCUMENTATION** .......... 7

## CHAPTER 1. STARTING WITH CONTAINERS ........................................ 8
  - 1.1. CHARACTERISTICS OF PODMAN, BUILDAH, AND SKOPEO .......... 8
  - 1.2. OVERVIEW OF PODMAN COMMANDS .................................. 9
  - 1.3. RUNNING CONTAINERS WITHOUT DOCKER .......................... 11

8.5. BUILDING UBI-BASED IMAGES ................................................................ 69
8.6. USING APPLICATION STREAM RUNTIME IMAGES ...................................... 70
8.7. GETTING UBI CONTAINER IMAGE SOURCE CODE ...................................... 70

CHAPTER 9. RUNNING SKOPEO, BUILDAH, AND PODMAN IN A CONTAINER ........ 73
9.1. RUNNING SKOPEO IN A CONTAINER ............................................................ 73
9.2. RUNNING SKOPEO IN A CONTAINER USING CREDENTIALS ...................... 74
9.3. RUNNING SKOPEO IN A CONTAINER USING AUTHFILES ............................ 75
9.4. COPYING CONTAINER IMAGES TO OR FROM THE HOST ........................... 76
9.5. RUNNING BUILDAH IN A CONTAINER ......................................................... 77
9.6. PRIVILEGED AND UNPRIVILEGED PODMAN CONTAINERS ...................... 78
9.7. RUNNING PODMAN WITH EXTENDED PRIVILEGES .................................... 78
9.8. RUNNING PODMAN WITH LESS PRIVILEGES ........................................... 79
9.9. BUILDING A CONTAINER INSIDE A PODMAN CONTAINER ....................... 80

CHAPTER 10. RUNNING SPECIAL CONTAINER IMAGES .......................................... 82
10.1. OPENING PRIVILEGES TO THE HOST ...................................................... 82
10.2. CONTAINER IMAGES WITH RUNLABELS .................................................. 82
10.3. RUNNING RSYSLOG WITH RUNLABELS .................................................... 82

CHAPTER 11. PORTING CONTAINERS TO OPENSHIFT USING PODMAN .............. 85
11.1. GENERATING A KUBERNETES YAML FILE USING PODMAN 85
11.2. GENERATING A KUBERNETES YAML FILE IN OPENSHIFT ENVIRONMENT 86
11.3. STARTING CONTAINERS AND PODS WITH PODMAN 87
11.4. STARTING CONTAINERS AND PODS IN OPENSHIFT ENVIRONMENT 88

CHAPTER 12. PORTING CONTAINERS TO SYSTEMD USING PODMAN ......................... 89
12.1. ENABLING SYSTEMD SERVICES 89
12.2. GENERATING A SYSTEMD UNIT FILE USING PODMAN 90
12.3. AUTO-GENERATING A SYSTEMD UNIT FILE USING PODMAN 91
12.4. AUTO-STARTING CONTAINERS USING SYSTEMD 93
12.5. AUTO-STARTING PODS USING SYSTEMD 94
12.6. AUTO-UPDATING CONTAINERS USING PODMAN 97
12.7. AUTO-UPDATING CONTAINERS USING SYSTEMD 99

CHAPTER 13. BUILDING CONTAINER IMAGES WITH BUILDAH ............................... 101
13.1. THE BUILDAH TOOL 101
13.2. INSTALLING BUILDAH 101
13.3. GETTING IMAGES WITH BUILDAH 102
13.4. RUNNING COMMANDS INSIDE OF THE CONTAINER 102
13.5. BUILDING AN IMAGE FROM A CONTAINERFILE WITH BUILDAH 103
13.6. INSPECTING CONTAINERS AND IMAGES WITH BUILDAH 104
13.7. MODIFYING A CONTAINER USING BUILDAH MOUNT 105
13.8. MODIFYING A CONTAINER USING BUILDAH COPY AND BUILDAH CONFIG 106
13.9. CREATING IMAGES FROM SCRATCH WITH BUILDAH 108
13.10. PUSHING CONTAINERS TO A PRIVATE REGISTRY 109
13.11. PUSHING CONTAINERS TO THE DOCKER HUB 110
13.12. REMOVING IMAGES WITH BUILDAH 111
13.13. REMOVING CONTAINERS WITH BUILDAH 112

CHAPTER 14. MONITORING CONTAINERS ......................................................... 113
14.1. PERFORMING A HEALTHCHECK ON A CONTAINER 113
14.2. DISPLAYING PODMAN SYSTEM INFORMATION 114
14.3. PODMAN EVENT TYPES 117
14.4. MONITORING PODMAN EVENTS 119

CHAPTER 15. USING THE CONTAINER-TOOLS API ............................................ 121
15.1. ENABLING THE PODMAN API USING SYSTEMD IN ROOT MODE 121
15.2. ENABLING THE PODMAN API USING SYSTEMD IN ROOTLESS MODE 122
15.3. RUNNING THE PODMAN API MANUALLY 122
RHEL BETA RELEASE

Red Hat provides Red Hat Enterprise Linux Beta access to all subscribed Red Hat accounts. The purpose of Beta access is to:

- Provide an opportunity to customers to test major features and capabilities prior to the general availability release and provide feedback or report issues.

- Provide Beta product documentation as a preview. Beta product documentation is under development and is subject to substantial change.

Note that Red Hat does not support the usage of RHEL Beta releases in production use cases. For more information, see What does Beta mean in Red Hat Enterprise Linux and can I upgrade a RHEL Beta installation to a General Availability (GA) release?.

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Please let us know how we could make it better. To do so:

- For simple comments on specific passages:
  1. Make sure you are viewing the documentation in the *Multi-page HTML* format. In addition, ensure you see the Feedback button in the upper right corner of the document.
  2. Use your mouse cursor to highlight the part of text that you want to comment on.
  3. Click the Add Feedback pop-up that appears below the highlighted text.
  4. Follow the displayed instructions.

- For submitting more complex feedback, create a Bugzilla ticket:
  1. Go to the Bugzilla website.
  2. As the Component, use Documentation.
  3. Fill in the Description field with your suggestion for improvement. Include a link to the relevant part(s) of documentation.
  4. Click Submit Bug.
CHAPTER 1. STARTING WITH CONTAINERS

Linux containers have emerged as a key open source application packaging and delivery technology, combining lightweight application isolation with the flexibility of image-based deployment methods. RHEL implements Linux containers using core technologies such as:

- Control groups (cgroups) for resource management
- Namespaces for process isolation
- SELinux for security
- Secure multi-tenancy

These technologies reduce the potential for security exploits and provide you with an environment for producing and running enterprise-quality containers.

Red Hat OpenShift provides powerful command-line and Web UI tools for building, managing, and running containers in units referred to as pods. Red Hat allows you to build and manage individual containers and container images outside of OpenShift. This guide describes the tools provided to perform those tasks that run directly on RHEL systems.

Unlike other container tools implementations, the tools described here do not center around the monolithic Docker container engine and `docker` command. Instead, Red Hat provides a set of command-line tools that can operate without a container engine. These include:

- **podman** - for directly managing pods and container images (`run`, `stop`, `start`, `ps`, `attach`, `exec`, and so on)
- **buildah** - for building, pushing, and signing container images
- **skopeo** - for copying, inspecting, deleting, and signing images
- **runc** - for providing container run and build features to podman and buildah
- **crun** - an optional runtime that can be configured and gives greater flexibility, control, and security for rootless containers

Because these tools are compatible with the Open Container Initiative (OCI), they can be used to manage the same Linux containers that are produced and managed by Docker and other OCI-compatible container engines. However, they are especially suited to run directly on Red Hat Enterprise Linux, in single-node use cases.

For a multi-node container platform, see OpenShift and Using the CRI-O Container Engine for details.

1.1. CHARACTERISTICS OF PODMAN, BUILDAH, AND SKOPEO

The Podman, Skopeo, and Buildah tools were developed to replace Docker command features. Each tool in this scenario is more lightweight and focused on a subset of features.

The main advantages of Podman, Skopeo and Buildah tools include:

- Running in rootless mode - rootless containers are much more secure, as they run without any added privileges
No daemon required - these tools have much lower resource requirements at idle, because if you are not running containers, Podman is not running. Docker, on the other hand, have a daemon always running.

Native systemd integration - Podman allows you to create systemd unit files and run containers as system services.

The characteristics of Podman, Skopeo, and Buildah include:

- Podman, Buildah, and the CRI-O container engine all use the same back-end store directory, /var/lib/containers, instead of using the Docker storage location /var/lib/docker, by default.

- Although Podman, Buildah, and CRI-O share the same storage directory, they cannot interact with each other’s containers. Those tools can share images.

- To interact programmatically with Podman, you can use the Podman v2.0 RESTful API, it works in both a rootful and a rootless environment. For more information, see chapter Using the container tools API.

Additional resources

- Say "Hello" to Buildah, Podman, and Skopeo
- Podman and Buildah for Docker users
- Buildah - a tool for building OCI container images
- Podman - a tool for running and managing containers
- Skopeo - a tool for copying and inspecting container images

1.2. OVERVIEW OF PODMAN COMMANDS

Table 1.1 shows a list of commands you can use with the podman command. Use podman -h to see a list of all Podman commands.

<table>
<thead>
<tr>
<th>podman command</th>
<th>Description</th>
<th>podman command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attach</td>
<td>Attach to a running container</td>
<td>commit</td>
<td>Create new image from changed container</td>
</tr>
<tr>
<td>build</td>
<td>Build an image using Containerfile instructions</td>
<td>create</td>
<td>Create, but do not start, a container</td>
</tr>
<tr>
<td>diff</td>
<td>Inspect changes on container’s filesystems</td>
<td>exec</td>
<td>Run a process in a running container</td>
</tr>
<tr>
<td>export</td>
<td>Export container’s filesystem contents as a tar archive</td>
<td>help, h</td>
<td>Shows a list of commands or help for one command</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>

<td>Display percentage of CPU, memory, network I/O, block I/O and PIDs for one or more containers</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### 1.3. RUNNING CONTAINERS WITHOUT DOCKER

Red Hat removed the Docker container engine and the docker command from RHEL 8.

If you still want to use Docker in RHEL, you can get Docker from different upstream projects, but it is unsupported in RHEL 8.

- You can install the `podman-docker` package, every time you run a `docker` command, it actually runs a `podman` command.

- Podman also supports the Docker Socket API, so the `podman-docker` package also sets up a link between `/var/run/docker.sock` and `/var/run/podman/podman.sock`. As a result, you can continue to run your Docker API commands with `docker-py` and `docker-compose` tools without requiring the Docker daemon. Podman will service the requests.

- The `podman` command, like the `docker` command, can build container images from a `Containerfile` or `Dockerfile`. The available commands that are usable inside a `Containerfile` and a `Dockerfile` are equivalent.

- Options to the `docker` command that are not supported by `podman` include network, node, plugin (`podman` does not support plugins), rename (use `rm` and create to rename containers with `podman`), secret, service, stack, and swarm (`podman` does not support Docker Swarm). The container and image options are used to run subcommands that are used directly in `podman`.

Additional resources
- [Podman Basics Cheat Sheet](#)

### 1.4. CHOOSING A RHEL ARCHITECTURE FOR CONTAINERS

Red Hat provides container images and container-related software for the following computer architectures:

- AMD64 and Intel 64 (base and layered images; no support for 32-bit architectures)
- PowerPC 8 and 9 64-bit (base image and most layered images)
64-bit IBM Z (base image and most layered images)

ARM 64-bit (base image only)

Although not all Red Hat images were supported across all architectures at first, nearly all are now available on all listed architectures.

Additional resources

- Universal Base Images (UBI): Images, repositories, and packages

1.5. GETTING CONTAINER TOOLS

This procedure shows how you can install the container-tools module which contains the Podman, Buildah, Skopeo, and runc tools.

Procedure

1. Install RHEL.

2. Register RHEL: Enter your user name and password. The user name and password are the same as your login credentials for Red Hat Customer Portal:

   ```shell
   # subscription-manager register
   Registering to: subscription.rhsm.redhat.com:443/subscription
   Username: ********
   Password: **********
   ```

3. Subscribe to RHEL.

   - To auto-subscribe to RHEL:
     ```shell
     # subscription-manager attach --auto
     ```
   - To subscribe to RHEL by Pool ID:
     ```shell
     # subscription-manager attach --pool PoolID
     ```

4. Install the container-tools module:

   ```shell
   # dnf module install -y container-tools
   ```

5. Optional. Install the podman-docker package:

   ```shell
   # dnf install -y podman-docker
   ```

   The podman-docker package replaces the Docker command-line interface and docker-api with the matching Podman commands instead.

1.6. SETTING UP ROOTLESS CONTAINERS

Running the container tools such as Podman, Skopeo, or Buildah as a user with superuser privileges (root user) is the best way to ensure that your containers have full access to any feature available on
your system. However, with the feature called "Rootless Containers" generally available as of RHEL 8.1, you can work with containers as a regular user.

Although container engines, such as Docker, let you run Docker commands as a regular (non-root) user, the Docker daemon that carries out those requests runs as root. As a result, regular users can make requests through their containers that can harm the system. By setting up rootless container users, system administrators prevent potentially damaging container activities from regular users, while still allowing those users to safely run most container features under their own accounts.

This procedure describes how to set up your system to use Podman, Skopeo, and Buildah tools to work with containers as a non-root user (rootless). It also describes some of the limitations you will encounter, because regular user accounts do not have full access to all operating system features that their containers might need to run.

**Prerequisites**

- You need to become a root user to set up your RHEL system to allow non-root user accounts to use container tools.

**Procedure**

1. Install RHEL.

2. Install the podman package:

   ```
   # dnf install podman -y
   ```

3. Create a new user account:

   ```
   # useradd -c "Joe Jones" joe
   # passwd joe
   ```

   - The user is automatically configured to be able to use rootless Podman.
   - The `useradd` command automatically sets the range of accessible user and group IDs automatically in the `/etc/subuid` and `/etc/subgid` files.

4. Connect to the user:

   ```
   $ ssh joe@server.example.com
   ```

   **NOTE**

   Do not use `su` or `su -` commands because these commands do not set the correct environment variables.

1. Pull the `registry.access.redhat.com/ubi8/ubi` container image:

   ```
   $ podman pull registry.access.redhat.com/ubi8/ubi
   ```

2. Run the container named `myubi` and display the OS version:

   ```
   $ podman run --rm --name=myubi registry.access.redhat.com/ubi8/ubi cat \
   ```
Additional resources

- Rootless containers with Podman: The basics

1.7. UPGRADING TO ROOTLESS CONTAINERS

This section shows how to upgrade to rootless containers from RHEL 7. You must configure user and group IDs manually.

Here are some things to consider when upgrading to rootless containers from RHEL 7:

- If you set up multiple rootless container users, use unique ranges for each user.
- Use 65536 UIDs and GIDs for maximum compatibility with existing container images, but the number can be reduced.
- Never use UIDs or GIDs under 1000 or reuse UIDs or GIDs from existing user accounts (which, by default, start at 1000).

Prerequisites

- The user account has been created.

Procedure

- Run the `usermod` command to assign UIDs and GIDs to a user:

  ```bash
  # usermod --add-subuids 200000-201000 --add-subgids 200000-201000 username
  
  # usermod --add-subuid command manually adds a range of accessible user IDs to the user’s account.
  
  # usermod --add-subgids command manually adds a range of accessible user GIDs and group IDs to the user’s account.
  
Verification steps

- Check that the UIDs and GIDs are set properly:

  ```bash
  # grep username /etc/subuid /etc/subgid
  
  #/etc/subuid:username:200000:1001
  
  #/etc/subgid:username:200000:1001
  
```

1.8. SPECIAL CONSIDERATIONS FOR ROOTLESS CONTAINERS

There are several considerations when running containers as a non-root user:

- The path to the host container storage is different for root users (`/var/lib/containers/storage`) and non-root users (`$HOME/local/share/containers/storage`).
• Users running rootless containers are given special permission to run as a range of user and group IDs on the host system. However, they have no root privileges to the operating system on the host.

• If you need to configure your rootless container environment, create configuration files in your home directory ($HOME/.config/containers). Configuration files include storage.conf (for configuring storage) and containers.conf (for a variety of container settings). You could also create a registries.conf file to identify container registries that are available when you use Podman to pull, search, or run images.

• There are some system features you cannot change without root privileges. For example, you cannot change the system clock by setting a SYS_TIME capability inside a container and running the network time service (ntpd). You have to run that container as root, bypassing your rootless container environment and using the root user’s environment. For example:

  $ sudo podman run -d --cap-add SYS_TIME ntpd

Note that this example allows ntpd to adjust time for the entire system, and not just within the container.

• A rootless container cannot access a port numbered less than 1024. Inside the rootless container namespace it can, for example, start a service that exposes port 80 from an httpd service from the container, but it is not accessible outside of the namespace:

  $ podman run -d httpd

However, a container would need root privileges, using the root user’s container environment, to expose that port to the host system:

  $ sudo podman run -d -p 80:80 httpd

• The administrator of a workstation can allow users to expose services on ports numbered lower than 1024, but they should understand the security implications. A regular user could, for example, run a web server on the official port 80 and make external users believe that it was configured by the administrator. This is acceptable on a workstation for testing, but might not be a good idea on a network-accessible development server, and definitely should not be done on production servers. To allow users to bind to ports down to port 80 run the following command:

  # echo 80 > /proc/sys/net/ipv4/ip_unprivileged_port_start

• Shortcomings of Rootless Podman

1.9. ADDITIONAL RESOURCES

• A Practical Introduction to Container Terminology
CHAPTER 2. TYPES OF CONTAINER IMAGES

The container image is a binary that includes all of the requirements for running a single container, and metadata describing its needs and capabilities.

There are two types of container images:

- Red Hat Enterprise Linux Base Images (RHEL base images)
- Red Hat Universal Base Images (UBI images)

Both types of container images are built from portions of Red Hat Enterprise Linux. By using these containers, users can benefit from great reliability, security, performance and life cycles.

The main difference between the two types of container images is that the UBI images allow you to share container images with others. You can build a containerized application using UBI, push it to your choice of registry server, easily share it with others, and even deploy it on non-Red Hat platforms. The UBI images are designed to be a foundation for cloud-native and web applications use cases developed in containers.

2.1. GENERAL CHARACTERISTICS OF RHEL CONTAINER IMAGES

Following characteristics apply to both RHEL base images and UBI images.

In general, RHEL container images are:

- **Supported**: Supported by Red Hat for use with containerized applications. They contain the same secured, tested, and certified software packages found in Red Hat Enterprise Linux.

- **Cataloged**: Listed in the Red Hat Container Catalog, with descriptions, technical details, and a health index for each image.

- **Updated**: Offered with a well-defined update schedule, to get the latest software, see Red Hat Container Image Updates article.

- **Tracked**: Tracked by Red Hat Product Errata to help understand the changes that are added into each update.

- **Reusable**: The container images need to be downloaded and cached in your production environment once. Each container image can be reused by all containers that include it as their foundation.

2.2. CHARACTERISTICS OF UBI IMAGES

The UBI images allow you to share container images with others. Four UBI images are offered: micro, minimal, standard, and init. Pre-build language runtime images and DNF repositories are available to build your applications.

Following characteristics apply to UBI images:

- **Built from a subset of RHEL content**: Red Hat Universal Base images are built from a subset of normal Red Hat Enterprise Linux content.

- **Redistributable**: UBI images allow standardization for Red Hat customers, partners, ISVs, and others. With UBI images, you can build your container images on a foundation of official Red Hat software that can be freely shared and deployed.
• **Provides a set of four base images** micro, minimal, standard, and init.

• **Provides a set of pre-built language runtime container images** The runtime images based on Application Streams provide a foundation for applications that can benefit from standard, supported runtimes such as python, perl, php, dotnet, nodejs, and ruby.

• **Provides a set of associated DNF repositories** DNF repositories include RPM packages and updates that allow you to add application dependencies and rebuild UBI container images.
  - The **ubi-8-baseos** repository holds the redistributable subset of RHEL packages you can include in your container.
  - The **ubi-8-appstream** repository holds Application streams packages that you can add to a UBI image to help you standardize the environments you use with applications that require particular runtimes.
  - **Adding UBI RPMs**: You can add RPM packages to UBI images from preconfigured UBI repositories. If you happen to be in a disconnected environment, you must allowlist the UBI Content Delivery Network (https://cdn-ubi.redhat.com) to use that feature. See the Connect to https://cdn-ubi.redhat.com solution for details.

• **Licensing**: You are free to use and redistribute UBI images, provided you adhere to the Red Hat Universal Base Image End User Licensing Agreement.

### Additional resources

- Introducing the Red Hat Universal Base Image
- Universal Base Images (UBI): Images, repositories, and packages
- All You Need to Know About Red Hat Universal Base Image
- FAQ – Universal Base Images

### 2.3. UNDERSTANDING THE UBI STANDARD IMAGES

The standard images (named **ubi**) are designed for any application that runs on RHEL. The key features of UBI standard images include:

- **init system**: All the features of the systemd initialization system you need to manage systemd services are available in the standard base images. These init systems let you install RPM packages that are pre-configured to start up services automatically, such as a Web server (**httpd**) or FTP server (**vsftpd**).

- **dnf**: You have access to free dnf repositories for adding and updating software. You can use the standard set of **dnf** commands (**dnf**, **dnf-config-manager**, **dnfdownloader**, and so on).

- **utilities**: Utilities include **tar**, **dmidecode**, **gzip**, **getfacl** and further acl commands, **dmsetup** and further device mapper commands, between other utilities not mentioned here.

### 2.4. UNDERSTANDING THE UBI INIT IMAGES

The UBI init images, named **ubi-init**, contain the systemd initialization system, making them useful for building images in which you want to run systemd services, such as a web server or file server. The init image contents are less than what you get with the standard images, but more than what is in the minimal images.
NOTE

Because the **ubi8-init** image builds on top of the **ubi8** image, their contents are mostly the same. However, there are a few critical differences:

- **ubi8-init**:
  - CMD is set to `/sbin/init` to start the systemd Init service by default
  - includes `ps` and process related commands (**procps-ng** package)
  - sets `SIGRTMIN+3` as the StopSignal, as systemd in **ubi8-init** ignores normal signals to exit (**SIGTERM** and **SIGKILL**), but will terminate if it receives `SIGRTMIN+3`

- **ubi8**:
  - CMD is set to `/bin/bash`
  - does not include `ps` and process related commands (**procps-ng** package)
  - does not ignore normal signals to exit (**SIGTERM** and **SIGKILL**)

2.5. UNDERSTANDING THE UBI MINIMAL IMAGES

The UBI minimal images, named **ubi-minimal** offer a minimized pre-installed content set and a package manager (**microdnf**). As a result, you can use a **Containerfile** while minimizing the dependencies included in the image.

The key features of UBI minimal images include:

- **Small size**: Minimal images are about 92M on disk and 32M, when compressed. This makes it less than half the size of the standard images.

- **Software installation (**microdnf**)**: Instead of including the fully-developed **dnf** facility for working with software repositories and RPM software packages, the minimal images includes the **microdnf** utility. The **microdnf** is a scaled-down version of **dnf** allowing you to enable and disable repositories, remove and update packages, and clean out cache after packages have been installed.

- **Based on RHEL packaging**: Minimal images incorporate regular RHEL software RPM packages, with a few features removed. Minimal images do not include initialization and service management system, such as systemd or System V init, Python run-time environment, and some shell utilities. You can rely on RHEL repositories for building your images, while carrying the smallest possible amount of overhead.

- **Modules for **microdnf** are supported**: Modules used with **microdnf** command let you install multiple versions of the same software, when available. You can use **microdnf module enable**, **microdnf module disable**, and **microdnf module reset** to enable, disable, and reset a module stream, respectively.
  - For example, to enable the **nodejs:14** module stream inside the UBI minimal container, enter:
    ```
    # microdnf module enable nodejs:14
    Downloading metadata...
    ...
    ```
2.6. UNDERSTANDING THE UBI MICRO IMAGES

The **ubi-micro** is the smallest possible UBI image, obtained by excluding a package manager and all of its dependencies which are normally included in a container image. This minimizes the attack surface of container images based on the **ubi-micro** image and is suitable for minimal applications, even if you use UBI Standard, Minimal, or Init for other applications. The container image without the Linux distribution packaging is called a Distroless container image.

2.7. USING THE UBI INIT IMAGES

This procedure shows how to build a container using a **Containerfile** that installs and configures a Web server (**httpd**) to start automatically by the systemd service (**/sbin/init**) when the container is run on a host system. The **podman build** command uses a **Containerfile** if found in the context directory, if it is not found the **podman build** command will use a **Containerfile**; otherwise any file can be specified with the **--file** option.

**Procedure**

1. Create a **Containerfile** with the following contents to a new directory:

   ```
   FROM registry.access.redhat.com/ubi8/ubi-init
   RUN dnf -y install httpd; dnf clean all; systemctl enable httpd; 
   RUN echo "Successful Web Server Test" > /var/www/html/index.html 
   RUN mkdir /etc/systemd/system/httpd.service.d/; echo -e '[Service]\nRestart=always' > /etc/systemd/system/httpd.service.d/httpd.conf 
   EXPOSE 80
   CMD [ "/sbin/init" ]
   ```

   The **Containerfile** installs the **httpd** package, enables the **httpd** service to start at boot time, creates a test file (**index.html**), exposes the Web server to the host (port 80), and starts the systemd init service (**/sbin/init**) when the container starts.

2. Build the container:

   ```
   # podman build --format=docker --tag mysysd .
   ```

3. Optional. If you want to run containers with systemd and SELinux is enabled on your system, you must set the **container_manage_cgroup** boolean variable:

   ```
   # setsebool -P container_manage_cgroup 1
   ```

4. Run the container named **mysysd_run**:

   ```
   # podman run -d --name=mysysd_run -p 80:80 mysysd
   ```
The **mysysd** image runs as the **mysysd_run** container as a daemon process, with port 80 from the container exposed to port 80 on the host system.

**NOTE**

In rootless mode, you have to choose host port number $\geq 1024$. For example:

```
$ podman run -d --name=mysysd -p 8081:80 mysysd
```

To use port numbers $< 1024$, you have to modify the `net.ipv4.ip_unprivileged_port_start` variable:

```
$ sudo sysctl net.ipv4.ip_unprivileged_port_start=80
```

5. Check that the container is running:

```
# podman ps
a282b0c2ad3d  localhost/mysysd:latest  /sbin/init  15 seconds ago  Up 14 seconds ago
 0.0.0.0:80->80/tcp  mysysd_run
```

6. Test the web server:

```
# curl localhost/index.html
Successful Web Server Test
```

**Additional resources**

- [Shortcomings of Rootless Podman](#)

### 2.8. USING THE UBI MICRO IMAGES

This procedure shows how to build a **ubi-micro** container image using the Buildah tool.

**Prerequisites**

- The **container-tools** module is installed.

```
# dnf module install -y container-tools
```

**Procedure**

1. Pull and build the `registry.access.redhat.com/ubi8/ubi-micro` image:

```
# microcontainer=$(buildah from registry.access.redhat.com/ubi9-beta/ubi-micro)
```

2. Mount a working container root filesystem:

```
# micromount=$(buildah mount $microcontainer)
```

3. Install the **httpd** service to the **micromount** directory:

```
# dnf install httpd
```
4. Unmount the root file system on the working container:

```
# buildah umount $microcontainer
```

5. Create the **ubi-micro-httpd** image from a working container:

```
# buildah commit $microcontainer ubi-micro-httpd
```

**Verification steps**

1. Display details about the **ubi-micro-httpd** image:

```
# podman images ubi-micro-httpd
localhost/ubi-micro-httpd latest 7c557e7f0e9f 22 minutes ago 151 MB
```
CHAPTER 3. WORKING WITH CONTAINER IMAGES

The Podman tool is designed to work with container images. You can use this tool to pull the image, inspect, tag, save, load, redistribute, and define the image signature.

3.1. CONTAINER REGISTRIES

A container registry is a repository or collection of repositories for storing container images and container-based application artifacts. The registries that Red Hat provides are:

- registry.redhat.io (requires authentication)
- registry.access.redhat.com (requires no authentication)
- registry.connect.redhat.com (holds Red Hat Partner Connect program images)

To get container images from a remote registry, such as Red Hat’s own container registry, and add them to your local system, use the podman pull command:

```
# podman pull <registry>[:<port>]/[<namespace>/]<name>:<tag>
```

where `<registry>[:<port>]/[<namespace>/]<name>:<tag>` is the name of the container image.

For example, the `registry.redhat.io/ubi8/ubi` container image is identified by:

- Registry server (`registry.redhat.io`)
- Namespace (`ubi8`)
- Image name (`ubi`)

If there are multiple versions of the same image, add a tag to explicitly specify the image name. By default, Podman uses the `:latest` tag, for example `ubi8/ubi:latest`.

Some registries also use `<namespace>` to distinguish between images with the same `<name>` owned by different users or organizations. For example:

<table>
<thead>
<tr>
<th>Namespace</th>
<th>Examples (<code>&lt;namespace&gt;/&lt;name&gt;</code>)</th>
</tr>
</thead>
<tbody>
<tr>
<td>organization</td>
<td>redhat/kubernetes, google/kubernetes</td>
</tr>
<tr>
<td>login (user name)</td>
<td>alice/application, bob/application</td>
</tr>
<tr>
<td>role</td>
<td>devel/database, test/database, prod/database</td>
</tr>
</tbody>
</table>

For details on the transition to registry.redhat.io, see Red Hat Container Registry Authentication. Before you can pull containers from registry.redhat.io, you need to authenticate using your RHEL Subscription credentials.

3.2. CONFIGURING CONTAINER REGISTRIES
You can find the list of container registries in the `registries.conf` configuration file. As a root user, edit the `/etc/containers/registries.conf` file to change the default system-wide search settings.

As a user, create the `$HOME/.config/containers/registries.conf` file to override the system-wide settings.

```
unqualified-search-registries = ["registry.fedoraproject.org", "registry.access.redhat.com", "docker.io"]
```

By default, the `podman pull` and `podman search` commands search for container images from registries listed in the `unqualified-search-registries` list in the given order.

**Configuring a local container registry**

You can configure a local container registry without the TLS verification. You have two options on how to disable TLS verification. First, you can use the `--tls-verify=false` option in Podman. Second, you can set `insecure=true` in the `registries.conf` file:

```
[[registry]]
location="localhost:5000"
insecure=true
```

**Blocking a registry, namespace, or image**

You can define registries the local system is not allowed to access. You can block a specific registry by setting `blocked=true`.

```
[[registry]]
location = "registry.example.org"
blocked = true
```

You can also block a namespace by setting the prefix to `prefix="registry.example.org/namespace"`. For example, pulling the image using the `podman pull registry.example.org/example/image:latest` command will be blocked, because the specified prefix is matched.

```
[[registry]]
location = "registry.example.org"
prefix="registry.example.org/namespace"
blocked = true
```

**NOTE**

`prefix` is optional, default value is the same as the `location` value.

You can block a specific image by setting `prefix="registry.example.org/namespace/image"`.

```
[[registry]]
location = "registry.example.org"
prefix="registry.example.org/namespace/image"
blocked = true
```

**Mirroring registries**

You can set a registry mirror in cases you cannot access the original registry. For example, you cannot connect to the internet, because you work in a highly-sensitive environment. You can specify
multiple mirrors that are contacted in the specified order. For example, when you run `podman pull registry.example.com/myimage:latest` command, the `mirror-1.com` is tried first, then `mirror-2.com`.

```yaml
[registry]
  location="registry.example.com"
[registry.mirror]
  location="mirror-1.com"
[registry.mirror]
  location="mirror-2.com"
```

Additional resources

- How to manage Linux container registries

### 3.3. SEARCHING FOR CONTAINER IMAGES

Using the `podman search` command you can search selected container registries for images. You can also search for images in the Red Hat Container Registry. The Red Hat Container Registry includes the image description, contents, health index, and other information.

**NOTE**

The `podman search` command is not a reliable way to determine the presence or existence of an image. The `podman search` behavior of the v1 and v2 Docker distribution API is specific to the implementation of each registry. Some registries may not support searching at all. Searching without a search term only works for registries that implement the v2 API. The same holds for the `docker search` command.

This section explains how to search for the `postgresql-10` images in the quay.io registry.

**Prerequisites**

- The registry is configured.

**Procedure**

1. Authenticate to the registry:

   ```
   # podman login quay.io
   ```

2. Search for the image:

   - To search for a particular image on a specific registry, enter:

   ```
   podman search quay.io/postgresql-10
   ```

<table>
<thead>
<tr>
<th>INDEX</th>
<th>NAME</th>
<th>DESCRIPTION</th>
<th>STARS</th>
<th>OFFICIAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMATED</td>
<td>registry.redhat.io/rhel8/postgresql-10</td>
<td>This container image ...</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>redhat.io</td>
<td>registry.redhat.io/rhscl/postgresql-10-rhel7</td>
<td>PostgreSQL is an ...</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

   - Alternatively, to display all images provided by a particular registry, enter:
# podman search quay.io/

- To search for the image name in all registries, enter:

  # podman search postgresql-10

To display the full descriptions, pass the `--no-trunc` option to the command.

Additional resources
- `podman-search` man page

## 3.4. PULLING IMAGES FROM REGISTRIES

Use the `podman pull` command to get the image to your local system.

**Procedure**

1. Log in to the registry.redhat.io registry:

   ```
   $ podman login registry.redhat.io
   Username: username
   Password: **********
   Login Succeeded!
   ```

2. Pull the registry.redhat.io/ubi8/ubi container image:

   ```
   $ podman pull registry.redhat.io/ubi8/ubi
   ```

**Verification steps**

- List all images pulled to your local system:

  ```
  $ podman images
  REPOSITORY                           TAG     IMAGE ID      CREATED      SIZE
  registry.redhat.io/ubi8/ubi          latest  3269c37eae33  7 weeks ago  208 MB
  ```

Additional resources
- `podman-pull` man page

## 3.5. CONFIGURING SHORT-NAME ALIASES

Red Hat recommends always to pull an image by its fully-qualified name. However, it is customary to pull images by short names. For instance, you can use `ubi8` instead of `registry.access.redhat.com/ubi8:latest`.

The `registries.conf` file allows to specify aliases for short names, giving administrators full control over where images are pulled from. Aliases are specified in the `[aliases]` table in the form “name” = “value”. You can see the lists of aliases in the `/etc/containers/registries.conf.d` directory. Red hat ships a set of aliases in this directory. For example, `podman pull ubi8` directly resolves to the right image, that is `registry.access.redhat.com/ubi8:latest`. 

25
For example:

```
unqualified-search-registries=["registry.fedoraproject.org", "quay.io"]
[aliases]
"fedora"="registry.fedoraproject.org/fedora"
```

The short-names modes are:

- **enforcing**: If no matching alias is found during the image pull, Podman prompts the user to choose one of the unqualified-search registries. If the selected image is pulled successfully, Podman automatically records a new short-name alias in the `$HOME/.cache/containers/short-name-aliases.conf` file (rootless user) or in the `/var/cache/containers/short-name-aliases.conf` (root user). If the user cannot be prompted (for example, stdin or stdout are not a TTY), Podman fails. Note that the `short-name-aliases.conf` file has precedence over the `registries.conf` file if both specify the same alias.

- **permissive**: Similar to enforcing mode, but Podman does not fail if the user cannot be prompted. Instead, Podman searches in all unqualified-search registries in the given order. Note that no alias is recorded.

- **disabled**: All unqualified-search registries are tried in a given order, no alias is recorded.

**NOTE**

Red Hat recommends using fully qualified image names including registry, namespace, image name, and tag. When using short names, there is always an inherent risk of spoofing. Add registries that are trusted, that is, registries that do not allow unknown or anonymous users to create accounts with arbitrary names. For example, a user wants to pull the example container image from `example.registry.com` registry. If `example.registry.com` is not first in the search list, an attacker could place a different example image at a registry earlier in the search list. The user would accidentally pull and run the attacker image rather than the intended content.

**Additional resources**

- [Container image short names in Podman](#)

### 3.6. PULLING CONTAINER IMAGES USING SHORT-NAME ALIASES

You can use secure short names to get the image to your local system. The following procedure describes how to pull a `fedora` or `nginx` container image.

**Procedure**

- Pull the container image:
  - Pull the `fedora` image:
    ```
    $ podman pull fedora
    Resolved “fedora” as an alias (/etc/containers/registries.conf.d/000-shortnames.conf)
    Trying to pull registry.fedoraproject.org/fedora:latest…
    ...
    Storing signatures
    ...
    ```
Alias is found and the `registry.fedoraproject.org/fedora` image is securely pulled. The `unqualified-search-registries` list is not used to resolve `fedora` image name.

- Pull the `nginx` image:

  ```bash
  $ podman pull nginx
  ? Please select an image:
  registry.access.redhat.com/nginx:latest
  registry.redhat.io/nginx:latest
  docker.io/library/nginx:latest
  docker.io/library/nginx:latest
  Trying to pull docker.io/library/nginx:latest...
  ... Storing signatures ...
  ```

  If no matching alias is found, you are prompted to choose one of the `unqualified-search-registries` list. If the selected image is pulled successfully, a new short-name alias is recorded locally, otherwise an error occurs.

**Verification**

- List all images pulled to your local system:

  ```bash
  $ podman images
  REPOSITORY                        TAG     IMAGE ID      CREATED        SIZE
  registry.fedoraproject.org/fedora latest 28317703decd 12 days ago 184 MB
  docker.io/library/nginx            latest 08b152afcafe 13 days ago 137 MB
  ```

**Additional resources**

- Container image short names in Podman

### 3.7. LISTING IMAGES

Use the `podman images` command to list images in your local storage.

**Prerequisites**

- A pulled image is available on the local system.

**Procedure**

- List all images in the local storage:

  ```bash
  $ podman images
  REPOSITORY                        TAG     IMAGE ID      CREATED        SIZE
  registry.access.redhat.com/ubi8/ubi latest 3269c37eae33 6 weeks ago 208 MB
  ```

**Additional resources**

- `podman-images` man page
3.8. INSPECTING LOCAL IMAGES

After you pull an image to your local system and run it, you can use the podman inspect command to investigate the image. For example, use it to understand what the image does and check what software is inside the image. The podman inspect command displays information on containers and images identified by name or ID.

Prerequisites

- A pulled image is available on the local system.

Procedure

- Inspect the registry.redhat.io/ubi8/ubi image:

```
$ podman inspect registry.redhat.io/ubi8/ubi
...
"Cmd": ["/bin/bash"],
"Labels": {
  "architecture": "x86_64",
  "build-date": "2020-12-10T01:59:40.343735",
  "com.redhat.build-host": "cpt-1002.osbs.prod.upshift.rdu2.redhat.com",
  "com.redhat.component": "ubi8-container",
  "com.redhat.license_terms": "https://www.redhat.com/...,
  "description": "The Universal Base Image is ..."
}
...
```

The "Cmd" key specifies a default command to run within a container. You can override this command by specifying a command as an argument to the podman run command. This ubi8/ubi container will execute the bash shell if no other argument is given when you start it with podman run. If an "Entrypoint" key was set, its value would be used instead of the "Cmd" value, and the value of "Cmd" is used as an argument to the Entrypoint command.

Additional resources

- podman-inspect man page

3.9. INSPECTING REMOTE IMAGES

Use the skopeo inspect command to display information about an image from a remote container registry before you pull the image to your system.

Procedure

- Inspect the registry.redhat.io/ubi8/ubi-init image:

```
# skopeo inspect docker://registry.redhat.io/ubi8/ubi-init
{
  "Name": "registry.redhat.io/ubi8/ubi8-init",
  "Digest": "sha256:c6d1e50ab...",
  "RepoTags": ["..."
```
"8.2-13-source",
"8.0-15",
"8.1-28",
...
"latest"
},
"Created": "2020-12-10T07:16:37.250312Z",
"DockerVersion": "1.13.1",
"Labels": {
"architecture": "x86_64",
"build-date": "2020-12-10T07:16:11.378348",
"com.redhat.build-host": "cpt-1007.osbs.prod.upshift.rdu2.redhat.com",
"com.redhat.component": "ubi8-init-container",
"com.redhat.license_terms": "https://www.redhat.com/en/about/red-hat-end-user-license-agreements#UBI",
"description": "The Universal Base Image Init is designed to run an init system as PID 1 for running multi-services inside a container

Additional resources
- skopeo-inspect man page

3.10. COPYING CONTAINER IMAGES

You can use the skopeo copy command to copy a container image from one registry to another. For example, you can populate an internal repository with images from external registries, or sync image registries in two different locations.

Procedure

- Copy the skopeo container image from docker://quay.io to docker://registry.example.com:

  $ skopeo copy docker://quay.io/skopeo/stable:latest
docker://registry.example.com/skopeo:latest

Additional resources
- skopeo-copy man page

3.11. COPYING IMAGE LAYERS TO A LOCAL DIRECTORY

You can use the skopeo copy command to copy the layers of a container image to a local directory.

Procedure

1. Create the /var/lib/images/nginx directory:

  $ mkdir -p /var/lib/images/nginx

2. Copy the layers of the docker://docker.io/nginx:latest image to the newly created directory:

  $ skopeo copy docker://docker.io/nginx:latest dir:/var/lib/images/nginx
Verification

- Display the content of the `/var/lib/images/nginx` directory:

  ```
  $ ls /var/lib/images/nginx
  08b11a3d692c1a2e15ae840f2c15c18308dc079aa5320e15d46b62015c0f6f3 ...
  4fcb23e29ba19bf305d0d4b35412625f0e351e82292ec7312f9e724cb6e31ff
  manifest.json
  version
  ```

Additional resources

- `skopeo-copy` man page

3.12. TAGGING IMAGES

Use the `podman tag` command to add an additional name to a local image. This additional name can consist of several parts: `registryhost/username/NAME:tag`.

Prerequisites

- A pulled image is available on the local system.

Procedure

1. List all images:

   ```
   $ podman images
   REPOSITORY                   TAG          IMAGE ID       CREATED          SIZE
   registry.redhat.io/ubi8/ubi  latest       3269c37ae33   7 weeks ago    208 MB
   ```

2. Assign the `myubi` name to the `registry.redhat.io/ubi8/ubi` image using either:

   - The image name:
     ```
     $ podman tag registry.redhat.io/ubi8/ubi myubi
     ```

   - The image ID:
     ```
     $ podman tag 3269c37ae33 myubi
     ```

   Both commands give you the same result.

3. List all images:

   ```
   $ podman images
   REPOSITORY                   TAG          IMAGE ID       CREATED          SIZE
   registry.redhat.io/ubi8/ubi  latest       3269c37ae33   2 months ago    208 MB
   localhost/myubi              latest       3269c37ae33   2 months ago    208 MB
   ```

Notice that the default tag is `latest` for both images. You can see all the image names are assigned to the single image ID 3269c37ae33.
4. Add the 8.4 tag to the \texttt{registry.redhat.io/ubi8/ubi} image using either:
   \begin{itemize}
   \item The image name:
     \begin{verbatim}
     $ podman tag registry.redhat.io/ubi8/ubi myubi:8.4
     \end{verbatim}
   \item The image ID:
     \begin{verbatim}
     $ podman tag 3269c37eae33 myubi:8.4
     \end{verbatim}
   \end{itemize}
   Both commands give you the same result.

5. List all images:
   \begin{verbatim}
   $ podman images
   \end{verbatim}
   \begin{tabular}{lllll}
   \texttt{REPOSITORY} & \texttt{TAG} & \texttt{IMAGE ID} & \texttt{CREATED} & \texttt{SIZE} \\
   \texttt{registry.redhat.io/ubi8/ubi} & latest 3269c37eae33 & 2 months ago & 208 MB \\
   \texttt{localhost/myubi} & latest 3269c37eae33 & 2 months ago & 208 MB \\
   \texttt{localhost/myubi} & 8.4 3269c37eae33 & 2 months ago & 208 MB \\
   \end{tabular}
   Notice that the default tag is \texttt{latest} for both images. You can see all the image names are assigned to the single image ID 3269c37eae33.

After tagging the \texttt{registry.redhat.io/ubi8/ubi} image, you have three options to run the container:
   \begin{itemize}
   \item by ID (\texttt{3269c37eae33})
   \item by name (\texttt{localhost/myubi:latest})
   \item by name (\texttt{localhost/myubi:8.4})
   \end{itemize}

3.13. SAVING AND LOADING IMAGES

Use the \texttt{podman save} command to save an image to a container archive. You can restore it later to another container environment or send it to someone else. You can use \texttt{--format} option to specify the archive format. The supported formats are:
   \begin{itemize}
   \item docker-archive
   \item oci-archive
   \item oci-dir (directory with oci manifest type)
   \item docker-dir (directory with v2s2 manifest type)
   \end{itemize}
   The default format is the \texttt{docker-dir} format.

Use the \texttt{podman load} command to load an image from the container image archive into the container storage.

Prerequisites
   \begin{itemize}
   \item A pulled image is available on the local system.
   \end{itemize}

Procedure
1. Save the `registry.redhat.io/rhel8/rsyslog` image as a tarball:
   - In the default `docker-dir` format:
     ```bash
     $ podman save -o myrsyslog.tar registry.redhat.io/rhel8/rsyslog:latest
     ```
   - In the `oci-archive` format, using the `--format` option:
     ```bash
     $ podman save -o myrsyslog-oci.tar --format=oci-archive registry.redhat.io/rhel8/rsyslog
     ```

   The `myrsyslog.tar` and `myrsyslog-oci.tar` archives are stored in your current directory. The next steps are performed with the `myrsyslog.tar` tarball.

2. Check the file type of `myrsyslog.tar`:
   ```bash
   $ file myrsyslog.tar
   myrsyslog.tar: POSIX tar archive
   ```

3. To load the `registry.redhat.io/rhel8/rsyslog:latest` image from the `myrsyslog.tar`:
   ```bash
   $ podman load -i myrsyslog.tar
   ...
   Loaded image(s): registry.redhat.io/rhel8/rsyslog:latest
   ```

3.14. REDISTRIBUTING UBI IMAGES

Use `podman push` command to push a UBI image to your own, or a third party, registry and share it with others. You can upgrade or add to that image from UBI dnf repositories as you like.

Prerequisites
- A pulled image is available on the local system.

Procedure

1. Optional: Add an additional name to the `ubi` image:
   ```bash
   # podman tag registry.redhat.io/ubi8/ubi registry.example.com:5000/ubi8/ubi
   ```

2. Push the `registry.example.com:5000/ubi8/ubi` image from your local storage to a registry:
   ```bash
   # podman push registry.example.com:5000/ubi8/ubi
   ```

   IMPORTANT
   While there are few restrictions on how you use these images, there are some restrictions about how you can refer to them. For example, you cannot call those images Red Hat certified or Red Hat supported unless you certify it through the Red Hat Partner Connect Program, either with Red Hat Container Certification or Red Hat OpenShift Operator Certification.

3.15. DEFAULT VERIFICATION OF THE IMAGE SIGNATURES
The policy YAML files for the Red Hat Container Registries
/etc/containers/registries.d/registry.access.redhat.com.yaml and
/etc/containers/registries.d/registry.redhat.io.yaml files are included in the containers-common
package which is included in the container-tools:latest module. Use the podman image trust
command to verify the container image signatures on RHEL.

Procedure

1. Update an existing trust scope for the registry.access.redhat.com:

   ```
   # podman image trust set -f /etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release
   registry.access.redhat.com
   ```

2. Optional. To verify the trust policy configuration, display the /etc/containers/policy.json file:

   ```
   ...
   "transports": {
     "docker": {
       "registry.access.redhat.com": [
         {
           "type": "signedBy",
           "keyType": "GPGKeys",
           "keyPath": "/etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release"
         }
       ],
       "registry.redhat.io": [
         {
           "type": "signedBy",
           "keyType": "GPGKeys",
           "keyPath": "/etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release"
         }
       ],
       ...
   }
   ...
   ```

3. Update an existing trust scope for the registry.redhat.io:

   ```
   # podman image trust set -f /etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release
   registry.redhat.io
   ```

4. Optional. To verify the trust policy configuration, display the /etc/containers/policy.json file:

   ```
   ...
   "transports": {
     "docker": {
       "registry.access.redhat.com": [],
       "registry.redhat.io": [
         {
           "type": "signedBy",
           "keyType": "GPGKeys",
           "keyPath": "/etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release"
         }
       ],
       ...
   }
   ```
**3.16. REMOVING IMAGES**

Use the `podman rmi` command to remove locally stored container images. You can remove an image by its ID or name.

**Procedure**

1. List all images on your local system:

   ```
   $ podman images
   REPOSITORY                              TAG     IMAGE ID      CREATED      SIZE
   registry.redhat.io/rhel8/rsyslog     latest  4b32d14201de  7 weeks ago  228 MB
   registry.redhat.io/ubi8/ubi          latest  3269c37eae33  7 weeks ago  208 MB
   localhost/myubi                      X.Y     3269c37eae33  7 weeks ago  208 MB
   ```

2. List all containers:

   ```
   $ podman ps -a
   CONTAINER ID  IMAGE                                    COMMAND          CREATED        STATUS PORTS   NAMES
   7ccd6001166e  registry.redhat.io/rhel8/rsyslog:latest  /bin/rsyslog.sh  6 seconds ago  Up 5 seconds ago          mysyslog
   ```

   To remove the `registry.redhat.io/rhel8/rsyslog` image, you have to stop all containers running from this image using the `podman stop` command. You can stop a container by its ID or name.

3. Stop the `mysyslog` container:

   ```
   $ podman stop mysyslog
   ```

4. Remove the `registry.redhat.io/rhel8/rsyslog` image:

   ```
   $ podman rmi registry.redhat.io/rhel8/rsyslog
   ```

   - To remove multiple images:

     ```
     $ podman rmi registry.redhat.io/rhel8/rsyslog registry.redhat.io/ubi8/ubi
     ```

   - To remove all images from your system:

     ```
     $ podman rmi -a
     ```

   - To remove images that have multiple names (tags) associated with them, add the `-f` option to remove them:

     ```
     $ podman rmi -f 1de7d7b3f531 1de7d7b3f531...
     ```
CHAPTER 4. WORKING WITH CONTAINERS

Containers represent a running or stopped process created from the files located in a decompressed container image. You can use the Podman tool to work with containers.

4.1. PODMAN RUN COMMAND

The `podman run` command runs a process in a new container based on the container image. If the container image is not already loaded then `podman run` pulls the image, and all image dependencies, from the repository in the same way running `podman pull image`, before it starts the container from that image. The container process has its own file system, its own networking, and its own isolated process tree.

The `podman run` command has the form:

```
podman run [options] image [command [arg ...]]
```

Basic options are:

- `--detach` (-d): Runs the container in the background and prints the new container ID.
- `--attach` (-a): Runs the container in the foreground mode.
- `--name` (-n): Assigns a name to the container. If a name is not assigned to the container with `--name` then it generates a random string name. This works for both background and foreground containers.
- `--rm`: Automatically remove the container when it exits. Note that the container will not be removed when it could not be created or started successfully.
- `--tty` (-t): Allocates and attaches the pseudo-terminal to the standard input of the container.
- `--interactive` (-i): For interactive processes, use `-i` and `-t` together to allocate a terminal for the container process. The `-i -t` is often written as `-it`.

4.2. RUNNING COMMANDS IN A CONTAINER FROM THE HOST

This procedure shows how to use the `podman run` command to display the type of operating system of the container.

**Prerequisites**

The Podman tool is installed.

```
# dnf module install -y container-tools
```

**Procedure**

1. Display the type of operating system of the container based on the `registry.access.redhat.com/ubi8/ubi` container image using the `cat /etc/os-release` command:

```
$ podman run --rm registry.access.redhat.com/ubi8/ubi cat /etc/os-release
NAME="Red Hat Enterprise Linux"
VERSION="8.2 (Ootpa)"
```
2. Optional: List all containers.

```bash
$ podman ps
CONTAINER ID  IMAGE   COMMAND  CREATED  STATUS  PORTS   NAMES

Because of the `--rm` option you should not see any container. The container was removed.
```

Additional resources

- `man podman-run`

### 4.3. RUNNING COMMANDS INSIDE THE CONTAINER

This procedure shows how you can use the `podman run` command to run a container interactively.

**Prerequisites**

- The Podman tool is installed.

```bash
# dnf module install -y container-tools
```

**Procedure**

1. Run the container named `myubi` based on the `registry.redhat.io/ubi8/ubi` image:

```bash
$ podman run --name=myubi -it registry.access.redhat.com/ubi8/ubi /bin/bash
[root@6ccffd0f6421 ~]#
```

   - The `-i` option creates an interactive session. Without the `-t` option, the shell stays open, but you cannot type anything to the shell.
   - The `-t` option opens a terminal session. Without the `-i` option, the shell opens and then exits.

2. Install the `procps-ng` package containing a set of system utilities (for example `ps`, `top`, `uptime`, and so on):

```bash
[root@6ccffd0f6421 ~]# dnf install procps-ng
```
3. Use the **ps -ef** command to list current processes:

```
# ps -ef
UID    PID   PPID  C   STIME TTY          TIME CMD
root   1   0      0 12:55 pts/0    00:00:00 /bin/bash
root  31   1      0 13:07 pts/0    00:00:00 ps -ef
```

4. Enter **exit** to exit the container and return to the host:

```
# exit
```

5. Optional: List all containers:

```
$ podman ps
CONTAINER ID   IMAGE                               COMMAND    CREATED       STATUS        PORTS NAMES
1984555a2c27   registry.redhat.io/ubi8/ubi:latest /bin/bash 21 minutes ago Exited (0) 21 minutes ago myubi
```

You can see that the container is in Exited status.

**Additional resources**
- **man podman-run**

### 4.4. LISTING CONTAINERS

Use the **podman ps** command to list the running containers on the system.

**Prerequisites**
- The Podman tool is installed.

```
# dnf module install -y container-tools
```

**Procedure**

1. Run the container based on **registry.redhat.io/rhel8/rsyslog** image:

```
$ podman run -d registry.redhat.io/rhel8/rsyslog
```

2. List all containers:

- To list all running containers:

```
$ podman ps
CONTAINER ID   IMAGE                               COMMAND    CREATED       STATUS        PORTS NAMES
74b1da000a11   rhel8/rsyslog /bin/rsyslog.sh 2 minutes ago Up About a minute musing_brown
```

- To list all containers, running or stopped:

```
If there are containers that are not running, but were not removed (\textit{--rm} option), the containers are present and can be restarted.

### Additional resources

- \texttt{man podman-ps}

### 4.5. STARTING CONTAINERS

If you run the container and then stop it, and not remove it, the container is stored on your local system ready to run again. You can use the \texttt{podman start} command to re-run the containers. You can specify the containers by their container ID or name.

#### Prerequisites

- The Podman tool is installed.
  
  \begin{verbatim}
  # dnf module install -y container-tools
  \end{verbatim}

- At least one container has been stopped.

#### Procedure

1. Start the \texttt{myubi} container:

   - In the non interactive mode:
     
     \begin{verbatim}
     $ podman start myubi
     \end{verbatim}

     Alternatively, you can use \texttt{podman start 1984555a2c27}.

   - In the interactive mode, use \texttt{-a \textit{(--attach)}} and \texttt{-t \textit{(--interactive)}} options to work with container bash shell:
     
     \begin{verbatim}
     $ podman start -a -i myubi
     \end{verbatim}

     Alternatively, you can use \texttt{podman start -a -i 1984555a2c27}.

2. Enter \texttt{exit} to exit the container and return to the host:

   \begin{verbatim}
   [root@6ccfd0f6421 /]# exit
   \end{verbatim}

### Additional resources

- \texttt{man podman-start}
4.6. INSPECTING CONTAINERS FROM THE HOST

Use the podman inspect command to inspect the metadata of an existing container in a JSON format. You can specify the containers by their container ID or name.

Prerequisites

- The Podman tool is installed.

  ```
  # dnf module install -y container-tools
  ```

Procedure

- Inspect the container defined by ID 64ad95327c74:
  
  - To get all metadata:
    ```
    $ podman inspect 64ad95327c74
    {
    "Id": "64ad95327c740ad9de468d551c50b6d906344027a0e645927256cd061049f681",
    "Created": "2021-03-02T11:23:54.591685515+01:00",
    "Path": "/bin/rsyslog.sh",
    "Args": [
    "/bin/rsyslog.sh"
    ],
    "State": {
    "OciVersion": "1.0.2-dev",
    "Status": "running",
    ...
    }
    }
    ```

  - To get particular items from the JSON file, for example, the StartedAt timestamp:
    ```
    $ podman inspect --format='{{.State.StartedAt}}' 64ad95327c74
    2021-03-02 11:23:54.945071961 +0100 CET
    ```

    The information is stored in a hierarchy. To see the container StartedAt timestamp (StartedAt is under State), use the --format option and the container ID or name.

Examples of other items you might want to inspect include:

- .Path to see the command run with the container
- .Args arguments to the command
- .ConfigExposedPorts TCP or UDP ports exposed from the container
- .State.Pid to see the process id of the container
- .HostConfigPortBindings port mapping from container to host

Additional resources

- man podman-inspect
4.7. MOUNTING DIRECTORY ON LOCALHOST TO THE CONTAINER

This procedure shows how you can make log messages from inside a container available to the host system by mounting the host /dev/log device inside the container.

Prerequisites

- The Podman tool is installed.
  
  # dnf module install -y container-tools

Procedure

1. Run the container named log_test and mount the host /dev/log device inside the container:

  # podman run --name="log_test" -v /dev/log:/dev/log --rm registry.redhat.io/ubi8/ubi logger "Testing logging to the host"

2. Use the journalctl utility to display logs:

  # journalctl -b | grep Testing

  Dec 09 16:55:00 localhost.localdomain root[14634]: Testing logging to the host

The --rm option removes the container when it exits.

Additional resources

- man podman-run

4.8. MOUNTING A CONTAINER FILESYSTEM

Use the podman mount command to mount a working container root filesystem in a location accessible from the host.

Prerequisites

- The Podman tool is installed.
  
  # dnf module install -y container-tools

Procedure

1. Run the container named mysyslog:

  # podman run -d --name=mysyslog registry.redhat.io/rhel8/rsyslog

2. Optional: List all containers:

  # podman ps -a

  CONTAINER ID  IMAGE                                    COMMAND          CREATED         STATUS

  PORTS   NAMES
3. Mount the **mysyslog** container:

   ```bash
   # podman mount mysyslog
   /var/lib/containers/storage/overlay/990b5c6ddcdeed4bde7b245885ce4544c553d108310e2b797
d7be46750894719/merged
   ```

4. Display the content of the mount point using **ls** command:

   ```bash
   # ls
   /var/lib/containers/storage/overlay/990b5c6ddcdeed4bde7b245885ce4544c553d108310e2b797
d7be46750894719/merged
   bin boot dev etc home lib lib64 lost+found media mnt opt proc root run sbin srv sys
    tmp usr var
   ```

5. Display the OS version:

   ```bash
   # cat
   /var/lib/containers/storage/overlay/990b5c6ddcdeed4bde7b245885ce4544c553d108310e2b797
d7be46750894719/merged/etc/os-release
   NAME="Red Hat Enterprise Linux"
   VERSION="8.3 (Ootpa)"
   ID="rhel"
   ID_LIKE="fedora"
   VERSION_ID="8.3"
   ```

Additional resources

- man podman-mount

### 4.9. RUNNING A SERVICE AS A DAEMON WITH A STATIC IP

The following example runs the **rsyslog** service as a daemon process in the background. The **--ip** option sets the container network interface to a particular IP address (for example, 10.88.0.44). After that, you can run the **podman inspect** command to check that you set the IP address properly.

**Prerequisites**

- The Podman tool is installed.

```
# dnf module install -y container-tools
```

**Procedure**

1. Set the container network interface to the IP address 10.88.0.44:

   ```bash
   # podman run -d --ip=10.88.0.44 registry.access.redhat.com/rhel7/rsyslog
   efdde5f0a8c723f70dd5cb5dc3d5039df3b962fae65575b08662e0d5b5f9fbe85
   ```

2. Check that the IP address is set properly:

   ```bash
   ```
# podman inspect efde5f0a8c723 | grep 10.88.0.44
"IPAddress": "10.88.0.44",

Additional resources

- man podman-run

4.10. EXECUTING COMMANDS INSIDE A RUNNING CONTAINER

Use the `podman exec` command to execute a command in a running container and investigate that container. The reason for using the `podman exec` command instead of `podman run` command is that you can investigate the running container without interrupting the container activity.

Prerequisites

- The Podman tool is installed.

  ```bash
  # dnf module install -y container-tools
  ```

- The container is running.

Procedure

1. Execute the `rpm -qa` command inside the `myrsyslog` container to list all installed packages:

   ```bash
   $ podman exec -it myrsyslog rpm -qa
   tzdata-2020d-1.el8.noarch
   python3-pip-wheel-9.0.3-18.el8.noarch
   redhat-release-8.3-1.0.el8.x86_64
   filesystem-3.8-3.el8.x86_64
   ...
   ```

2. Execute a `/bin/bash` command in the `myrsyslog` container:

   ```bash
   $ podman exec -it myrsyslog /bin/bash
   ```

3. Install the `procps-ng` package containing a set of system utilities (for example `ps`, `top`, `uptime`, and so on):

   ```bash
   # dnf install procps-ng
   ```

4. Inspect the container:

   - To list every process on the system:

     ```bash
     # ps -ef
     UID   PID  PPID  C   STIME TTY     TIME CMD
     root  1    0     0 10:23 ?    00:00:01 /usr/sbin/rsyslogd -n
     root 8    0 11:07 pts/0 00:00:00 /bin/bash
     root 47   8 11:13 pts/0 00:00:00 ps -ef
     ```

   - To display file system disk space usage:

     ```bash
     ```
To display system information:

```
# uname -r
4.18.0-240.10.1.el8_3.x86_64
```

To display amount of free and used memory in megabytes:

```
# free --mega
```

```
total        used        free      shared  buff/cache   available
Mem:       2818         615        1183          12         1020        1957
Swap:      3124           0        3124
```

Additional resources

- `man podman-exec`

### 4.11. SHARING FILES BETWEEN TWO CONTAINERS

You can use volumes to persist data in containers even when a container is deleted. Volumes can be used for sharing data among multiple containers. The volume is a folder which is stored on the host machine. The volume can be shared between the container and the host.

Main advantages are:

- Volumes can be shared among the containers.
- Volumes are easier to back up or migrate.
- Volumes do not increase the size of the containers.

**Prerequisites**

- The Podman tool is installed.

```
# dnf module install -y container-tools
```

**Procedure**

1. Create a volume:

```
$ podman volume create hostvolume
```

2. Display information about the volume:

```
$ podman volume inspect hostvolume
```
Notice that it creates a volume in the volumes directory. You can save the mount point path to the variable for easier manipulation: `$mntPoint=$(podman volume inspect hostvolume --format {{.Mountpoint}})`.

Notice that if you run `sudo podman volume create hostvolume`, then the mount point changes to `/var/lib/containers/storage/volumes/hostvolume/_data`.

3. Create a text file inside the directory using the path that is stored in the `mntPoint` variable:

   ```
   $ echo "Hello from host" >> $mntPoint/host.txt
   ```

4. List all files in the directory defined by the `mntPoint` variable:

   ```
   $ ls $mntPoint/
   ```

5. Run the container named `myubi1` and map the directory defined by the `hostvolume` volume name on the host to the `/containervolume1` directory on the container:

   ```
   $ podman run -it --name myubi1 -v hostvolume:/containervolume1
   registry.access.redhat.com/ubi8/ubi /bin/bash
   ```

   Note that if you use the volume path defined by the `mntPoint` variable (`-v $mntPoint:/containervolume1`), data can be lost when running `podman volume prune` command, which removes unused volumes. Always use `-v hostvolume_name:/containervolume_name`.

6. List the files in the shared volume on the container:

   ```
   # ls /containervolume1
   ```

   You can see the `host.txt` file which you created on the host.

7. Create a text file inside the `/containervolume1` directory:

   ```
   # echo "Hello from container 1" >> /containervolume1/container1.txt
   ```

8. Detach from the container with `CTRL+p` and `CTRL+q`.

9. List the files in the shared volume on the host, you should see two files:
At this point, you are sharing files between the container and host. To share files between two containers, run another container named `myubi2`.

10. Run the container named `myubi2` and map the directory defined by the `hostvolume` volume name on the host to the `/containervolume2` directory on the container:

```bash
$ podman run -it --name myubi2 -v hostvolume:/containervolume2
registry.access.redhat.com/ubi8/ubi  /bin/bash
```

11. List the files in the shared volume on the container:

```bash
# ls /containervolume2
container1.txt host.txt
```

You can see the `host.txt` file which you created on the host and `container1.txt` which you created inside the `myubi1` container.

12. Create a text file inside the `/containervolume2` directory:

```bash
# echo "Hello from container 2" >> /containervolume2/container2.txt
```

13. Detach from the container with `CTRL+p` and `CTRL+q`.

14. List the files in the shared volume on the host, you should see three files:

```bash
$ ls $mntPoint
container1.rxt  container2.txt host.txt
```

Additional resources

- `man podman-volume`

### 4.12. EXPORTING AND IMPORTING CONTAINERS

You can use the `podman export` command to export the file system of a running container to a tarball on your local machine. For example, if you have a large container that you use infrequently or one that you want to save a snapshot of in order to revert back to it later, you can use the `podman export` command to export a current snapshot of your running container into a tarball.

You can use the `podman import` command to import a tarball and save it as a filesystem image. Then you can run this filesystem image or you can use it as a layer for other images.

**Prerequisites**

- The Podman tool is installed.

```bash
# dnf module install -y container-tools
```

**Procedure**
1. Run the **myubi** container based on the `registry.access.redhat.com/ubi8/ubi` image:
   ```
   $ podman run -dt --name=myubi registry.access.redhat.com/ubi8/ubi
   ```

2. Optional: List all containers:
   ```
   $ podman ps -a
   CONTAINER ID  IMAGE                                    COMMAND          CREATED     STATUS
   PORTS   NAMES
   a6a6d4896142  registry.access.redhat.com/ubi8:latest   /bin/bash        7 seconds ago Up 7 seconds ago myubi
   ```

3. Attach to the **myubi** container:
   ```
   $ podman attach myubi
   ```

4. Create a file named **testfile**:
   ```
   [root@a6a6d4896142 /]# echo "hello" > testfile
   ```

5. Detach from the container with **CTRL+p** and **CTRL+q**.

6. Export the file system of the **myubi** as a **myubi-container.tar** on the local machine:
   ```
   $ podman export -o myubi.tar a6a6d4896142
   ```

7. Optional: List the current directory content:
   ```
   $ ls -l
   -rw-r--r--. 1 user user 210885120 Apr  6 10:50 myubi-container.tar
   ...  
   ```

8. Optional: Create a **myubi-container** directory, extract all files from the **myubi-container.tar** archive. List a content of the **myubi-directory** in a tree-like format:
   ```
   $ mkdir myubi-container
   $ tar -xf myubi-container.tar -C myubi-container
   $ tree -L 1 myubi-container
   ├── bin -> usr/bin
   │    ├── boot
   │    └── dev
   │         └── etc
   │             └── home
   │                 └── lib -> usr/lib
   │                     └── lib64 -> usr/lib64
   │                         └── lost+found
   │                             └── media
   │                                 └── mnt
   │                                     └── opt
   │                                         └── proc
   │                                             └── root
   │                                                 └── run
   │                                                     └── sbin -> usr/sbin
   ```
You can see that the `myubi-container.tar` contains the container file system.

9. Import the `myubi.tar` and saves it as a filesystem image:

   $ podman import myubi.tar myubi-imported
   Getting image source signatures
   Copying blob 277cab30fe96 done
   Copying config c296689a17 done
   Writing manifest to image destination
   Storing signatures
c296689a17da2f33bf9d16071911636d7ce4d63f329741db679c3f41537e7cbf

10. List all images:

    $ podman images
    REPOSITORY                              TAG     IMAGE ID      CREATED         SIZE
    docker.io/library/myubi-imported       latest  c296689a17da  51 seconds ago  211 MB

11. Display the content of the `testfile` file:

    $ podman run -it --name=myubi-imported docker.io/library/myubi-imported cat testfile
    hello

Additional resources

- `podman-export` man page
- `podman-import` man page

4.13. STOPPING CONTAINERS

Use the `podman stop` command to stop a running container. You can specify the containers by their container ID or name.

Prerequisites

- The Podman tool is installed.
  
  # dnf module install -y container-tools

- At least one container is running.

Procedure
• Stop the **myubi** container:
  
  - Using the container name:
    
    ```
    $ podman stop myubi
    ```
  - Using the container ID:
    
    ```
    $ podman stop 1984555a2c27
    ```

To stop a running container that is attached to a terminal session, you can enter the **exit** command inside the container.

The **podman stop** command sends a SIGTERM signal to terminate a running container. If the container does not stop after a defined period (10 seconds by default), Podman sends a SIGKILL signal.

You can also use the **podman kill** command to kill a container (SIGKILL) or send a different signal to a container. Here is an example of sending a SIGHUP signal to a container (if supported by the application, a SIGHUP causes the application to re-read its configuration files):

```
# podman kill --signal="SIGHUP" 74b1da000a11
74b1da000a114015886c557deec8bed9dfb80c888097aa83f30ca4074ff55fb2
```

**Additional resources**

- **man podman-stop**
- **man podman-kill**

### 4.14. REMOVING CONTAINERS

Use the **podman rm** command to remove containers. You can specify containers with the container ID or name.

**Prerequisites**

- The Podman tool is installed.
  
  ```
  # dnf module install -y container-tools
  ```
- At least one container has been stopped.

**Procedure**

1. List all containers, running or stopped:

```
$ podman ps -a
CONTAINER ID IMAGE COMMAND CREATED STATUS        PORTS NAMES
IS INFRA d65aec325a4 ubi8/ubi /bin/bash 3 secs ago Exited (0) 5 secs ago peaceful_hopper false
74b1da000a11 rhel8/rsyslog rsyslog.sh 2 mins ago Up About a minute musing_brown false
```
2. Remove the containers:

- To remove the `peaceful_hopper` container:

  ```bash
  $ podman rm peaceful_hopper
  ```

  Notice that the `peaceful_hopper` container was in Exited status, which means it was stopped and it can be removed immediately.

- To remove the `musing_brown` container, first stop the container and then remove it:

  ```bash
  $ podman stop musing_brown
  $ podman rm musing_brown
  ```

**NOTE**

- To remove multiple containers:

  ```bash
  $ podman rm clever_yonath furious_shockley
  ```

- To remove all containers from your local system:

  ```bash
  $ podman rm -a
  ```

Additional resources

- `man podman-rm`

### 4.15. THE RUNC CONTAINER RUNTIME

The runc container runtime is a lightweight, portable implementation of the Open Container Initiative (OCI) container runtime specification. The runc runtime shares a lot of low-level code with Docker but it is not dependent on any of the components of the Docker platform. The runc supports Linux namespaces, live migration, and has portable performance profiles.

It also provides full support for Linux security features such as SELinux, control groups (cgroups), seccomp, and others. You can build and run images with runc, or you can run OCI-compatible images with runc.

### 4.16. THE CRUN CONTAINER RUNTIME

The crun is a fast and low-memory footprint OCI container runtime written in C. The crun binary is up to 50 times smaller and up to twice as fast as the runc binary. Using crun, you can also set a minimal number of processes when running your container. The crun runtime also supports OCI hooks.

Additional features of crun include:

- Sharing files by group for rootless containers
- Controlling the stdout and stderr of OCI hooks
- Running older versions of systemd on cgroup v2
A C library that is used by other programs

- Extensibility
- Portability

Additional resources

- An introduction to crun, a fast and low-memory footprint container runtime

### 4.17. RUNNING CONTAINERS WITH RUNC AND CRUN

With runc or crun, containers are configured using bundles. A bundle for a container is a directory that includes a specification file named `config.json` and a root filesystem. The root filesystem contains the contents of the container.

**NOTE**

The `<runtime>` can be crun or runc.

**Procedure**

1. Pull the `registry.access.redhat.com/ubi8/ubi` container image:

   ```bash
   # podman pull registry.access.redhat.com/ubi8/ubi
   ```

2. Export the `registry.access.redhat.com/ubi8/ubi` image to the `rhel.tar` archive:

   ```bash
   # podman export $(podman create registry.access.redhat.com/ubi8/ubi) > rhel.tar
   ```

3. Create the `bundle/rootfs` directory:

   ```bash
   # mkdir -p bundle/rootfs
   ```

4. Extract the `rhel.tar` archive into the `bundle/rootfs` directory:

   ```bash
   # tar -C bundle/rootfs -xf rhel.tar
   ```

5. Create a new specification file named `config.json` for the bundle:

   ```bash
   # <runtime> spec -b bundle
   ```

   - The `-b` option specifies the bundle directory. The default value is the current directory.

6. Optional. Change the settings:

   ```bash
   # vi bundle/config.json
   ```

7. Create an instance of a container named `myubi` for a bundle:

   ```bash
   # <runtime> create -b bundle/ myubi
   ```
8. Start a **myubi** container:

```
# <runtime> start myubi
```

**NOTE**

The name of a container instance must be unique to the host. To start a new instance of a container: `# <runtime> start <container_name>`

**Verification**

- List containers started by `<runtime>`:

```
# <runtime> list
```

<table>
<thead>
<tr>
<th>ID</th>
<th>PID</th>
<th>STATUS</th>
<th>BUNDLE</th>
<th>CREATED</th>
<th>OWNER</th>
</tr>
</thead>
<tbody>
<tr>
<td>myubi</td>
<td>0</td>
<td>stopped</td>
<td>/root/bundle</td>
<td>2021-09-14T09:52:26.659714605Z</td>
<td>root</td>
</tr>
</tbody>
</table>

**Additional resources**

- **crun** man page
- **runc** man page
- An introduction to crun, a fast and low-memory footprint container runtime

### 4.18. TEMPORARILY CHANGING THE CONTAINER RUNTIME

You can use the **podman run** command with the **--runtime** option to change the container runtime.

**NOTE**

The `<runtime>` can be crun or runc.

**Prerequisites**

- The Podman tool is installed.

```
# dnf module install -y container-tools
```

**Procedure**

- Pull the **registry.access.redhat.com/ubi8/ubi** container image:

```
$ podman pull registry.access.redhat.com/ubi8/ubi
```

1. Change the container runtime using the **--runtime** option:

```
$ podman run --name=myubi -dt --runtime=<runtime> ubi8
bashe4654eb4df12ac0311f1d0f2657dc4ae6ff8eb0085bf114623b66cc664072e69b
```

2. Optional. List all images:
$ podman ps -a
CONTAINER ID  IMAGE                                   COMMAND  CREATED        STATUS PORTS NAMES
e4654eb4df12  registry.access.redhat.com/ubi8:latest  bash     4 seconds ago Up 4 seconds ago myubi

Verification

• Ensure that the OCI runtime is set to `<runtime>` in the myubi container:

$ podman inspect myubi --format "{{.OCIRuntime}}" <runtime>

Additional resources

• An introduction to crun, a fast and low-memory footprint container runtime

4.19. PERMANENTLY CHANGING THE CONTAINER RUNTIME

You can set the container runtime and its options in the `/etc/containers/containers.conf` configuration file as a root user or in the `$HOME/.config/containers/containers.conf` configuration file as a non-root user.

NOTE

The `<runtime>` can be crun or runc runtime.

Prerequisites

• The Podman tool is installed.

# dnf module install -y container-tools

Procedure

• Change the runtime in the `/etc/containers/containers.conf` file:

  # vim /etc/containers/containers.conf
  [engine]
  runtime = "<runtime>"

• Run the container named myubi:

  # podman run --name=myubi -dt ubi8 bash
  Resolved "ubi8" as an alias (/etc/containers/registries.conf.d/001-rhel-shortnames.conf)
  Trying to pull registry.access.redhat.com/ubi8:latest...
  ...
  Storing signatures

Verification

• Ensure that the OCI runtime is set to `<runtime>` in the `myubi` container:
Additional resources

- An introduction to crun, a fast and low-memory footprint container runtime
- containers.conf man page

4.20. CREATING SELINUX POLICIES FOR CONTAINERS

To generate SELinux policies for containers, use the UDICA tool. For more information, see Introduction to the udica SELinux policy generator.
CHAPTER 5. USING PODMAN IN HPC ENVIRONMENT

You can use Podman with Open MPI (Message Passing Interface) to run containers in a High Performance Computing (HPC) environment.

5.1. USING PODMAN WITH MPI

The example is based on the ring.c program taken from Open MPI. In this example, a value is passed around by all processes in a ring-like fashion. Each time the message passes rank 0, the value is decremented. When each process receives the 0 message, it passes it on to the next process and then quits. By passing the 0 first, every process gets the 0 message and can quit normally.

Procedure

1. Install Open MPI:
   $ sudo dnf install openmpi

2. To activate the environment modules, type:
   $ . /etc/profile.d/modules.sh

3. Load the mpi/openmpi-x86_64 module:
   $ module load mpi/openmpi-x86_64

   Optionally, to automatically load mpi/openmpi-x86_64 module, add this line to the .bashrc file:
   $ echo "module load mpi/openmpi-x86_64" >> .bashrc

4. To combine mpirun and podman, create a container with the following definition:
   $ cat Containerfile
   FROM registry.access.redhat.com/ubi8/ubi
   RUN dnf -y install openmpi-devel wget &&
       dnf clean all
   RUN wget https://raw.githubusercontent.com/open-mpi/ompi/master/test/simple/ring.c &&
       /usr/lib64/openmpi/bin/mpicc ring.c -o /home/ring &&
       rm -f ring.c

5. Build the container:
   $ podman build --tag=mpi-ring .

6. Start the container. On a system with 4 CPUs this command starts 4 containers:
   $ mpirun \
       --mca orte_tmpdir_base /tmp/podman-mpirun \ 
       podman run --env-host \ 
       -v /tmp/podman-mpirun:/tmp/podman-mpirun \
   Red Hat Enterprise Linux 9.0 Beta Building, running, and managing containers 54
As a result, `mpirun` starts up 4 Podman containers and each container is running one instance of the `ring` binary. All 4 processes are communicating over MPI with each other.

**Additional resources**

- [Podman in HPC environments](#)

### 5.2. THE MPRUN OPTIONS

The following `mpirun` options are used to start the container:

- `--mca orte_tmpdir_base /tmp/podman-mpirun` line tells Open MPI to create all its temporary files in `/tmp/podman-mpirun` and not in `/tmp`. If using more than one node this directory will be named differently on other nodes. This requires mounting the complete `/tmp` directory into the container which is more complicated.

The `mpirun` command specifies the command to start, the `podman` command. The following `podman` options are used to start the container:

- `run` command runs a container.
- `--env-host` option copies all environment variables from the host into the container.
- `--v /tmp/podman-mpirun:/tmp/podman-mpirun` line tells Podman to mount the directory where Open MPI creates its temporary directories and files to be available in the container.
- `--users=keep-id` line ensures the user ID mapping inside and outside the container.
- `--net=host --pid=host --ipc=host` line sets the same network, PID and IPC namespaces.
- `mpi-ring` is the name of the container.
- `/home/ring` is the MPI program in the container.

**Additional resources**

- [Podman in HPC environments](#)
CHAPTER 6. CREATING AND RESTORING CONTAINER CHECKPOINTS

Checkpoint/Restore In Userspace (CRIU) is a software that enables you to set a checkpoint on a running container or an individual application and store its state to disk. You can use data saved to restore the container after a reboot at the same point in time it was checkpointed.

6.1. CREATING AND RESTORING A CONTAINER CHECKPOINT LOCALLY

This example is based on a Python based web server which returns a single integer which is incremented after each request.

Procedure

1. Create a Python based server:

   ```python
   # cat counter.py
  #!/usr/bin/python3

   import http.server

   counter = 0

   class handler(http.server.BaseHTTPRequestHandler):
       def do_GET(s):
           global counter
           s.send_response(200)
           s.send_header('Content-type', 'text/html')
           s.end_headers()
           s.wfile.write(b'%d
' % counter)
           counter += 1

   server = http.server.HTTPServer(('', 8088), handler)
   server.serve_forever()
   ```

2. Create a container with the following definition:

   ```
   # cat Containerfile
   FROM registry.access.redhat.com/ubi8/ubi

   COPY counter.py /home/counter.py

   RUN useradd -ms /bin/bash counter

   RUN dnf -y install python3 && chmod 755 /home/counter.py

   USER counter
   ENTRYPOINT /home/counter.py
   ```

The container is based on the Universal Base Image (UBI 8) and uses a Python based server.
3. Build the container:

   ```
   # podman build . --tag counter
   ```

   Files `counter.py` and `Containerfile` are the input for the container build process (podman build). The built image is stored locally and tagged with the tag `counter`.

4. Start the container as root:

   ```
   # podman run --name criu-test --detach counter
   ```

5. To list all running containers, enter:

   ```
   # podman ps
   ```

<table>
<thead>
<tr>
<th>CONTAINER ID</th>
<th>IMAGE</th>
<th>COMMAND</th>
<th>CREATED</th>
<th>STATUS</th>
<th>PORTS</th>
<th>NAMES</th>
</tr>
</thead>
<tbody>
<tr>
<td>e4f82fd84d48</td>
<td>localhost/counter:latest</td>
<td>5 seconds ago</td>
<td>Up 4 seconds ago</td>
<td>criu-test</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

6. Display IP address of the container:

   ```
   # podman inspect criu-test --format "{{.NetworkSettings.IPAddress}}"
   10.88.0.247
   ```

7. Send requests to the container:

   ```
   # curl 10.88.0.247:8080
   0
   # curl 10.88.0.247:8080
   1
   ```

8. Create a checkpoint for the container:

   ```
   # podman container checkpoint criu-test
   ```

9. Reboot the system.

10. Restore the container:

    ```
    # podman container restore --keep criu-test
    ```

11. Send requests to the container:

    ```
    # curl 10.88.0.247:8080
    2
    # curl 10.88.0.247:8080
    3
    # curl 10.88.0.247:8080
    4
    ```

    The result now does not start at 0 again, but continues at the previous value.

This way you can easily save the complete container state through a reboot.

**Additional resources**
Adding checkpoint/restore support to Podman

6.2. REDUCING STARTUP TIME USING CONTAINER RESTORE

You can use container migration to reduce startup time of containers which require a certain time to initialize. Using a checkpoint, you can restore the container multiple times on the same host or on different hosts. This example is based on the container from the Creating and restoring a container checkpoint locally.

Procedure

1. Create a checkpoint of the container, and export the checkpoint image to a tar.gz file:

   # podman container checkpoint criu-test --export /tmp/chkpt.tar.gz

2. Restore the container from the tar.gz file:

   # podman container restore --import /tmp/chkpt.tar.gz --name counter1
   # podman container restore --import /tmp/chkpt.tar.gz --name counter2
   # podman container restore --import /tmp/chkpt.tar.gz --name counter3

   The --name (-n) option specifies a new name for containers restored from the exported checkpoint.

3. Display ID and name of each container:

   # podman ps -a --format "{{.ID}} {{.Names}}"
   a8b2e50d463c counter3
   faabc5c27362 counter2
   2ce648a11e5 counter1

4. Display IP address of each container:

   # podman inspect counter1 --format "{{.NetworkSettings.IPAddress}}"
   10.88.0.248

   # podman inspect counter2 --format "{{.NetworkSettings.IPAddress}}"
   10.88.0.249

   # podman inspect counter3 --format "{{.NetworkSettings.IPAddress}}"
   10.88.0.250

5. Send requests to each container:

   # curl 10.88.0.248:8080
   4
   # curl 10.88.0.249:8080
   4
   # curl 10.88.0.250:8080
   4

   Note, that the result is 4 in all cases, because you are working with different containers restored from the same checkpoint.
Using this approach, you can quickly start up stateful replicas of the initially checkpointed container.

Additional resources

- Container migration with Podman on RHEL

### 6.3. MIGRATING CONTAINERS AMONG SYSTEMS

This procedure shows the migration of running containers from one system to another, without losing the state of the applications running in the container. This example is based on the container from the Creating and restoring a container checkpoint locally section tagged with `counter`.

#### Prerequisites

The following steps are not necessary if the container is pushed to a registry as Podman will automatically download the container from a registry if it is not available locally. This example does not use a registry, you have to export previously built and tagged container (see Creating and restoring a container checkpoint locally section).

- Export previously built container:
  ```bash
  # podman save --output counter.tar counter
  ```

- Copy exported container image to the destination system (`other_host`):
  ```bash
  # scp counter.tar other_host:
  ```

- Import exported container on the destination system:
  ```bash
  # ssh other_host podman load --input counter.tar
  ```

Now the destination system of this container migration has the same container image stored in its local container storage.

#### Procedure

1. Start the container as root:
   ```bash
   # podman run --name criu-test --detach counter
   ```

2. Display IP address of the container:
   ```bash
   # podman inspect criu-test --format "{{.NetworkSettings.IPAddress}}"
   10.88.0.247
   ```

3. Send requests to the container:
   ```bash
   # curl 10.88.0.247:8080
   0
   # curl 10.88.0.247:8080
   1
   ```

4. Create a checkpoint of the container, and export the checkpoint image to a `tar.gz` file:
# podman container checkpoint criu-test --export /tmp/chkpt.tar.gz

5. Copy the checkpoint archive to the destination host:
   
   # scp /tmp/chkpt.tar.gz other_host:/tmp/

6. Restore the checkpoint on the destination host (*other_host*):

   # podman container restore --import /tmp/chkpt.tar.gz

7. Send a request to the container on the destination host (*other_host*):

   # curl 10.88.0.247:8080

As a result, the stateful container has been migrated from one system to another without losing its state.

**Additional resources**

- Container migration with Podman on RHEL
CHAPTER 7. WORKING WITH PODS

Containers are the smallest unit that you can manage with Podman, Skopeo and Buildah container tools. A Podman pod is a group of one or more containers. The Pod concept was introduced by Kubernetes. Podman pods are similar to the Kubernetes definition. Pods are the smallest compute units that you can create, deploy, and manage in OpenShift or Kubernetes environments. Every Podman pod includes an infra container. This container holds the namespaces associated with the pod and allows Podman to connect other containers to the pod. It allows you to start and stop containers within the pod and the pod will stay running. The default infra container on the `registry.access.redhat.com/ubi8/pause` image.

### 7.1. CREATING PODS

This procedure shows how to create a pod with one container.

**Prerequisites**

- The Podman tool is installed.

```
# dnf module install -y container-tools
```

**Procedure**

1. Create an empty pod:

```
$ podman pod create --name mypod
223df6b390b4ea87a090a4b52077b9b003187a6960bd37631ae9bc12c43aff
The pod is in the initial state Created.
```

The pod is in the initial state Created.

2. Optional: List all pods:

```
$ podman pod ps
POD ID     NAME    STATUS      CREATED                     # OF CONTAINERS   INFRA ID
223df6b390b4  mypod   Created    Less than a second ago   1               3afdcd93de3e
```

Notice that the pod has one container in it.

3. Optional: List all pods and containers associated with them:

```
$ podman ps -a --pod
CONTAINER ID     IMAGE                  COMMAND                CREATED             STATUS              PORTS
3afdcd93de3e  registry.access.redhat.com/ubi8/pause  Less than a second ago
Created    223df6b390b4-infra 223df6b390b4
```

You can see that the pod ID from `podman ps` command matches the pod ID in the `podman pod ps` command. The default infra container is based on the `registry.access.redhat.com/ubi8/pause` image.

4. Run a container named `myubi` in the existing pod named `mypod`:
5. Optional: List all pods:

```
$ podman pod ps
POD ID       NAME    STATUS    CREATED                  # OF CONTAINERS   INFRA ID
223df6b390b4   mypod   Running   Less than a second ago   2                 3afdcd93de3e
```

You can see that the pod has two containers in it.

6. Optional: List all pods and containers associated with them:

```
$ podman ps -a --pod
CONTAINER ID  IMAGE                                      COMMAND    CREATED
STATUS                     PORTS  NAMES               POD
5df5c48fea87  registry.access.redhat.com/ubi8/ubi:latest  /bin/bash  Less than a second ago
Up Less than a second ago  myubi               223df6b390b4
3afdcd93de3e  registry.access.redhat.com/ubi8/pause                                   Less than a
second ago  Up Less than a second ago  223df6b390b4-infra  223df6b390b4
```

Additional resources

- [podman-pod-create](#) man page

### 7.2. DISPLAYING POD INFORMATION

This procedure provides information on how to display pod information.

Prerequisites

- The Podman tool is installed.

```
# dnf module install -y container-tools
```

- The pod has been created. For details, see section Creating pods.

Procedure

- Display active processes running in a pod:

  - To display the running processes of containers in a pod, enter:

    ```
    $ podman pod top mypod
    USER   PID   PPID   %CPU    ELAPSED         TTY     TIME   COMMAND
    0      1     0      0.000   24.07743518s   ?       0s     /pause
    root   1     0      0.000   24.078146025s   pts/0   0s     /bin/bash
    ```

  - To display a live stream of resource usage stats for containers in one or more pods, enter:

    ```
    $ podman pod stats -a --no-stream
    ```
To display information describing the pod, enter:

```bash
$ podman pod inspect mypod
```

```
{
    "Id": "db99446fa9c6d10b973d1ce55a42a6850357e0cd447d9bac5627bb2516b5b19a",

    "CreateCommand": [
        "podman",
        "pod",
        "create",
        "--name",
        "mypod"
    ],
    "State": "Running",
    "Hostname": "mypod",
    "CreateCgroup": false,
    "CgroupParent": "/libpod_parent",
    "CgroupPath": "/libpod_parent/db99446fa9c6d10b973d1ce55a42a6850357e0cd447d9bac5627bb2516b5b19a",
    "CreateInfra": false,
    "InfraContainerID": "891c54f70783dcad596d888040700d93f3ead01921894bc19c10b0a03c738ff7",
    "SharedNamespaces": [
        "uts",
        "ipc",
        "net"
    ],
    "NumContainers": 2,
    "Containers": [
        {
            "Id": "891c54f70783dcad596d888040700d93f3ead01921894bc19c10b0a03c738ff7",
            "Name": "db99446fa9c6-infra",
            "State": "running"
        },
        {
            "Id": "effc5bcbfe505b522e3bf8fbb5705a39f94a455a66fd81e542bcc27d39727d2d",
            "Name": "myubi",
            "State": "running"
        }
    ]
}
```

You can see information about containers in the pod.

Additional resources
7.3. STOPPING PODS

You can stop one or more pods using the `podman pod stop` command.

**Prerequisites**

- The Podman tool is installed.
  ```
  # dnf module install -y container-tools
  ```
- The pod has been created. For details, see section Creating pods.

**Procedure**

1. Stop the pod **mypod**:

   ```
   $ podman pod stop mypod
   ```

2. Optional: List all pods and containers associated with them:

   ```
   $ podman ps -a --pod
   CONTAINER ID  IMAGE                               COMMAND    CREATED             STATUS
   PORTS   NAMES               POD ID        PODNAME
   5df5c48fea87  registry.redhat.io/ubi8/ubi:latest  /bin/bash  About a minute ago  Exited (0) 7
   seconds ago          myubi               223df6b390b4  mypod
   3afdd93de3e  registry.access.redhat.com/ubi8/pause                           About a minute ago
   Exited (0) 7 seconds ago          8a4e6527ac9d-infra  223df6b390b4  mypod
   ```

   You can see that the pod **mypod** and container **myubi** are in "Exited" status.

**Additional resources**

- `podman-pod-stop` man page

7.4. REMOVING PODS

You can remove one or more stopped pods and containers using the `podman pod rm` command.

**Prerequisites**

- The Podman tool is installed.
  ```
  # dnf module install -y container-tools
  ```
- The pod has been created. For details, see section Creating pods.
The pod has been stopped. For details, see section Stopping pods.

Procedure

1. Remove the pod `mypod`, type:

   ```
   $ podman pod rm mypod
   223df6b390b4ea87a090a4b5207f7b9b003187a6960bd37631ae9bc12c433aff
   ```

   Note that removing the pod automatically removes all containers inside it.

2. Optional: Check that all containers and pods were removed:

   ```
   $ podman ps
   $ podman pod ps
   ```

Additional resources

- `podman-pod-rm` man page
CHAPTER 8. ADDING SOFTWARE TO A RUNNING UBI CONTAINER

Red Hat Universal Base Images (UBIs) are built from a subset of the RHEL content. UBIs also provide a subset of RHEL packages that are freely available to install for use with UBI. To add or update software to a running container, you can use the dnf repositories that include RPM packages and updates. UBIs provide a set of pre-built language runtime container images such as Python, Perl, Node.js, Ruby, and so on.

To add packages from UBI repositories to running UBI containers:

- On UBI init and UBI standard images, use the `dnf` command.
- On UBI minimal images, use the `microdnf` command.

**NOTE**

Installing and working with software packages directly in running containers adds packages temporarily. The changes are not saved in the container image. To make package changes persistent, see section Building an image from a Containerfile with Buildah.

---

**NOTE**

When you add software to a UBI container, procedures differ for updating UBIs on a subscribed RHEL host or on an unsubscribed (or non-RHEL) system.

### 8.1. ADDING SOFTWARE TO A UBI CONTAINER ON A SUBSCRIBED HOST

If you are running a UBI container on a registered and subscribed RHEL host, the RHEL Base and AppStream repositories are enabled inside the standard UBI container, along with all the UBI repositories.

Additional resources

- Universal Base Images (UBI): Images, repositories, packages, and source code

### 8.2. ADDING SOFTWARE IN A STANDARD UBI CONTAINER

To add software inside the standard UBI container, disable non-UBI dnf repositories to ensure the containers you build can be redistributed.

**Procedure**

1. Pull and run the `registry.access.redhat.com/ubi8/ubi` image:
   ```sh
   $ podman run -it --name myubi registry.access.redhat.com/ubi8/ubi
   ```

2. Add a package to the `myubi` container.
   - To add a package that is in the UBI repository, disable all dnf repositories except for UBI repositories. For example, to add the `bzip2` package:
# dnf install --disablerepo=* --enablerepo=ubi-8-appstream --enablerepo=ubi-8-baseos bzip2

- To add a package that is not in the UBI repository, do not disable any repositories. For example, to add the `zsh` package:

```
# dnf install zsh
```

- To add a package that is in a different host repository, explicitly enable the repository you need. For example, to install the `python38-devel` package from the `codeready-builder-for-rhel-8-x86_64-rpms` repository:

```
# dnf install --enablerepo=codeready-builder-for-rhel-8-x86_64-rpms python38-devel
```

**Verification steps**

1. List all enabled repositories inside the container:

```
# dnf repolist
```

2. Ensure that the required repositories are listed.

3. List all installed packages:

```
# rpm -qa
```

4. Ensure that the required packages are listed.

**NOTE**

Installing Red Hat packages that are not inside the Red Hat UBI repositories can limit the ability to distribute the container outside of subscribed RHEL systems.

## 8.3. ADDING SOFTWARE IN A MINIMAL UBI CONTAINER

UBI dnf repositories are enabled inside UBI Minimal images by default.

**Procedure**

1. Pull and run the `registry.access.redhat.com/ubi8/ubi-minimal` image:

```
$ podman run -it --name myubimin registry.access.redhat.com/ubi8/ubi-minimal
```

2. Add a package to the `myubimin` container:

- To add a package that is in the UBI repository, do not disable any repositories. For example, to add the `bzip2` package:

```
# microdnf install bzip2
```

- To add a package that is in a different host repository, explicitly enable the repository you need. For example, to install the `python38-devel` package from the `codeready-builder-for-rhel-8-x86_64-rpms` repository:
# microdnf install --enablerepo=codeready-builder-for-rhel-8-x86_64-rpms python38-devel

**Verification steps**

1. List all enabled repositories inside the container:
   
   # microdnf repolist

2. Ensure that the required repositories are listed.

3. List all installed packages:
   
   # rpm -qa

4. Ensure that the required packages are listed.

**NOTE**

Installing Red Hat packages that are not inside the Red Hat UBI repositories can limit the ability to distribute the container outside of subscribed RHEL systems.

### 8.4. ADDING SOFTWARE TO A UBI CONTAINER ON A UNSUBSCRIBED HOST

You do not have to disable any repositories when adding software packages on unsubscribed RHEL systems.

**Procedure**

- Add a package to a running container based on the UBI standard or UBI init images. Do not disable any repositories. Use the `podman run` command to run the container. Then use the `dnf install` command inside a container.

  - For example, to add the `bzip2` package to the UBI standard based container:

    ```
    $ podman run -it --name myubi registry.access.redhat.com/ubi8/ubi
    # dnf install bzip2
    ```

1. For example, to add the `bzip2` package to the UBI init based container:

   ```
   $ podman run -it --name myubimin registry.access.redhat.com/ubi8/ubi-minimal
   # microdnf install bzip2
   ```

**Verification steps**

1. List all enabled repositories:

   - To list all enabled repositories inside the containers based on UBI standard or UBI init images:

     ```
     # dnf repolist
     ```
• To list all enabled repositories inside the containers based on UBI minimal containers:

  # microdnf repolist

2. Ensure that the required repositories are listed.

3. List all installed packages:

  # rpm -qa

4. Ensure that the required packages are listed.

### 8.5. BUILDING UBI-BASED IMAGES

You can create a UBI-based web server container from a **Containerfile** using the Buildah utility. You have to disable all non-UBI dnf repositories to ensure that your image contains only Red Hat software that you can redistribute.

**NOTE**

For UBI minimal images, use **microdnf** instead of **dnf**:

```bash
RUN microdnf update -y && rm -rf /var/cache/yum
RUN microdnf install httpd -y && microdnf clean all
```

**Procedure**

1. Create a **Containerfile**:

   ```bash
   FROM registry.access.redhat.com/ubi8/ubi
   USER root
   LABEL maintainer="John Doe"
   # Update image
   RUN dnf update --disablerepo=ubi-8-appstream --enablerepo=ubi-8-baseos
       --disablerepo=ubi-8-appstream --enablerepo=ubi-8-baseos -y&& rm -rf /var/cache/yum
   RUN dnf install httpd -y && rm -rf /var/cache/yum
   # Add default Web page and expose port
   RUN echo "The Web Server is Running" > /var/www/html/index.html
   EXPOSE 80
   # Start the service
   CMD ["-D", "FOREGROUND"]
   ENTRYPOINT ["/usr/sbin/httpd"]
   ```

2. Build the container image:

   ```bash
   # buildah bud -t johndoe/webserver .
   STEP 1: FROM registry.access.redhat.com/ubi8/ubi:latest
   STEP 2: USER root
   STEP 3: LABEL maintainer="John Doe"
   STEP 4: RUN dnf update --disablerepo=ubi-8-appstream --enablerepo=ubi-8-baseos
   # ...
Verification steps

1. Run the web server:

   ```
   # podman run -d --name=myweb -p 80:80 johndoe/webserver
   bbe98c71d18720d966e4567949888dc4fb86e3c7d304e785d5177168a5965f64
   ```

2. Test the web server:

   ```
   # curl http://localhost/index.html
   The Web Server is Running
   ```

8.6. USING APPLICATION STREAM RUNTIME IMAGES

Runtime images based on Application Streams offer a set of container images that you can use as the basis for your container builds.

Supported runtime images are Python, Ruby, s2-core, s2i-base, .NET Core, PHP. The runtime images are available in the Red Hat Container Catalog.

**NOTE**

Because these UBI images contain the same basic software as their legacy image counterparts, you can learn about those images from the Using Red Hat Software Collections Container Images guide.

Additional resources

- Red Hat Container Catalog
- Red Hat Container Image Updates

8.7. GETTING UBI CONTAINER IMAGE SOURCE CODE

Source code is available for all Red Hat UBI-based images in the form of downloadable container images. Source container images cannot be run, despite being packaged as containers. To install Red Hat source container images on your system, use the `skopeo` command, not the `podman pull` command.

Source container images are named based on the binary containers they represent. For example, for a particular standard RHEL UBI 8 container `registry.access.redhat.com/ubi8:8.1-397` append `-source` to get the source container image (`registry.access.redhat.com/ubi8:8.1-397-source`).

**Procedure**

1. Use the `skopeo copy` command to copy the source container image to a local directory:

   ```
   $ skopeo copy
   docker://registry.access.redhat.com/ubi8:8.1-397-source
   dir:~HOME/TEST
   ```
2. Use the `skopeo inspect` command to inspect the source container image:

```bash
$ skopeo inspect dir:$HOME/TEST
{
  "Digest": "sha256:7ab721ef3305271bb629a6db065c59bbbeb87bc53e7cbf88e2953a1217ba7322",
  "RepoTags": [],
  "Created": "2020-02-11T12:14:18.612461174Z",
  "DockerVersion": "",
  "Labels": null,
  "Architecture": "amd64",
  "Os": "linux",
  "Layers": [
    "sha256:1ae73d938ab9f11718d0f6a4148eb07d38ac1c0a70b1d3e751de8bf3c2c87fa",
    "sha256:9fe66685cb8712c47efe5ecc2eaa0797a0d5ff8b8b119c4bd4b400cc9e255421",
    "sha256:61b2527a4836a4efbb82df449c0556c0f769570a6c02e112f88f8bbc5d90166",
    ...
    "sha256:cc56c782b513e2b2dc22a777b69e13df4ab624dddb856c4d086206b46b9b9e5f",
    "sha256:dfc936fdada4e6c1ce677b306b7f8a83c96eb39dd955c481b8ea5b2a465b32",
  "sha256:feb6d2ae252402ea6afca8aa158a7d32c7e4572db0e6e5a5eab15d4e0777951e"
  ],
  "Env": null
}
```

3. Unpack all the content:

```bash
$ cd $HOME/TEST
$ for f in $(ls); do tar xvf $f; done
```

4. Check the results:

```bash
$ find blobs/ rpm_dir/
blobs/
blobs/sha256
blobs/sha256/10914f1ff060ce31388f5ab963871870535aaa5516295f5ad182384d60df82
rpm_dir/
rpm_dir/gzip-1.9-4.el8.src.rpm
```

If the results are correct, the image is ready to be used.

**NOTE**

It could take several hours after a container image is released for its associated source container to become available.

- **skopeo-copy** man page
- **skopeo-inspect** man page
CHAPTER 9. RUNNING SKOPEO, BUILDAH, AND PODMAN IN A CONTAINER

This chapter describes how you can run Skopeo, Buildah, and Podman in a container.

With Skopeo, you can inspect images on a remote registry without having to download the entire image with all its layers. You can also use Skopeo for copying images, signing images, syncing images, and converting images across different formats and layer compressions.

Buildah facilitates building OCI container images. With Buildah, you can create a working container, either from scratch or using an image as a starting point. You can create an image either from a working container or using the instructions in a Containerfile. You can mount and unmount a working container’s root filesystem.

With Podman, you can manage containers and images, volumes mounted into those containers, and pods made from groups of containers. Podman is based on a libpod library for container lifecycle management. The libpod library provides APIs for managing containers, pods, container images, and volumes.

Reasons to run Buildah, Skopeo, and Podman in a container:

- **CI/CD system:**
  - Podman and Skopeo: You can run a CI/CD system inside of Kubernetes or use OpenShift to build your container images, and possibly distribute those images across different container registries. To integrate Skopeo into a Kubernetes workflow, you need to run it in a container.
  
  - Buildah: You want to build OCI/container images within a Kubernetes or OpenShift CI/CD systems that are constantly building images. Previously, people used a Docker socket to connect to the container engine and perform a `docker build` command. This was the equivalent of giving root access to the system without requiring a password which is not secure. For this reason, Red Hat recommends using Buildah in a container.

- **Different versions:**
  - All: You are running an older OS on the host but you want to run the latest version of Skopeo, Buildah, or Podman. The solution is to run the container tools in a container. For example, this is useful for running the latest version of the container tools provided in RHEL 8 on a RHEL 7 container host which does not have access to the newest versions natively.

- **HPC environment:**
  - All: A common restriction in HPC environments is that non-root users are not allowed to install packages on the host. When you run Skopeo, Buildah, or Podman in a container, you can perform these specific tasks as a non-root user.

9.1. RUNNING SKOPEO IN A CONTAINER

This procedure demonstrates how to inspect a remote container image using Skopeo. Running Skopeo in a container means that the container root filesystem is isolated from the host root filesystem. To share or copy files between the host and container, you have to mount files and directories.

**Prerequisites**

- The container-tools module is installed.
# dnf module install -y container-tools

## Procedure

1. Log in to the registry.redhat.io registry:

   ```
   $ podman login registry.redhat.io
   Username: myuser@mycompany.com
   Password: ***********
   Login Succeeded!
   ```

2. Get the `registry.redhat.io/rhel8/skopeo` container image:

   ```
   $ podman pull registry.redhat.io/rhel8/skopeo
   ```

3. Inspect a remote container image `registry.access.redhat.com/ubi8/ubi` using Skopeo:

   ```
   $ podman run --rm registry.redhat.io/rhel8/skopeo skopeo inspect
   docker://registry.access.redhat.com/ubi8/ubi
   {
   "Name": "registry.access.redhat.com/ubi8/ubi",
   ...
   "Labels": {
   "architecture": "x86_64",
   ...
   "name": "ubi8",
   ...
   "summary": "Provides the latest release of Red Hat Universal Base Image 8.",
   "url": "https://access.redhat.com/containers/#/registry.access.redhat.com/ubi8/images/8.2-347",
   ...
   },
   "Architecture": "amd64",
   "Os": "linux",
   "Layers": [ ...
   ],
   "Env": [ 
   "PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin",
   "container=oci"
   ]
   }
   ```

   The `--rm` option removes the `registry.redhat.io/rhel8/skopeo` image after the container exits.

## Additional resources

- [How to run skopeo in a container](https://access.redhat.com/articles/running-skopeo) article

### 9.2. RUNNING SKOPEO IN A CONTAINER USING CREDENTIALS

Working with container registries requires an authentication to access and alter data. Skopeo supports various ways to specify credentials.
With this approach you can specify credentials on the command line using the `--cred` option.

Prerequisites

- The `container-tools` module is installed.

```
# dnf module install -y container-tools
```

Procedure

- Inspect a remote container image using Skopeo against a locked registry:

```
$ podman run --rm registry.redhat.io/rhel8/skopeo inspect --creds $USER:$PASSWORD docker://$IMAGE
```

Additional resources

- How to run skopeo in a container article

9.3. RUNNING SKOPEO IN A CONTAINER USING AUTHFILES

You can use an authentication file (authfile) to specify credentials. The `skopeo login` command logs into the specific registry and stores the authentication token in the authfile. The advantage of using authfiles is preventing the need to repeatedly enter credentials.

When running on the same host, all container tools such as Skopeo, Buildah, and Podman share the same authfile. When running Skopeo in a container, you have to either share the authfile on the host by volume-mounting the authfile in the container, or you have to reauthenticate within the container.

Prerequisites

- The `container-tools` module is installed.

```
# dnf module install -y container-tools
```

Procedure

- Inspect a remote container image using Skopeo against a locked registry:

```
$ podman run --rm -v $AUTHFILE:/auth.json registry.redhat.io/rhel8/skopeo inspect docker://$IMAGE
```

The `--v $AUTHFILE:/auth.json` option volume-mounts an authfile at /auth.json within the container. Skopeo can now access the authentication tokens in the authfile on the host and get secure access to the registry.

Other Skopeo commands work similarly, for example:

- Use the `skopeo-copy` command to specify credentials on the command line for the source and destination image using the `--source-creds` and `--dest-creds` options. It also reads the `/auth.json` authfile.
If you want to specify separate authfiles for the source and destination image, use the `--source-authfile` and `--dest-authfile` options and volume-mount those authfiles from the host into the container.

### Additional resources

- [How to run skopeo in a container](#)

### 9.4. COPYING CONTAINER IMAGES TO OR FROM THE HOST

Skopeo, Buildah, and Podman share the same local container-image storage. If you want to copy containers to or from the host container storage, you need to mount it into the Skopeo container.

**NOTE**

The path to the host container storage differs between root (`/var/lib/containers/storage`) and non-root users (`$HOME/.local/share/containers/storage`).

#### Prerequisites

- The `container-tools` module is installed.
  
  ```
  # dnf module install -y container-tools
  ```

#### Procedure

1. Copy the `registry.access.redhat.com/ubi8/ubi` image into your local container storage:

   ```
   $ podman run --privileged --rm -v $HOME/.local/share/containers/storage:/var/lib/containers/storage
   registry.redhat.io/rhel8/skopeo skopeo copy docker://registry.access.redhat.com/ubi8/ubi
   containers-storage:registry.access.redhat.com/ubi8/ubi
   ```

   - The `--privileged` option disables all security mechanisms. Red Hat recommends only using this option in trusted environments.
   - To avoid disabling security mechanisms, export the images to a tarball or any other path-based image transport and mount them in the Skopeo container:
     
     ```
     $ podman save --format oci-archive -o oci.tar $IMAGE
     $ podman run --rm -v oci.tar:/oci.tar registry.redhat.io/rhel8/skopeo copy oci-archive:/oci.tar $DESTINATION
     ```

2. Optional: List images in local storage:

   ```
   $ podman images
   REPOSITORY                              TAG IMAGE ID CREATED       SIZE
   registry.access.redhat.com/ubi8/ubi      latest ecbc6f53bba0 8 weeks ago 211 MB
   ```

#### Additional resources

- [How to run skopeo in a container](#)
9.5. RUNNING BUILDAH IN A CONTAINER

The procedure demonstrates how to run Buildah in a container and create a working container based on an image.

Prerequisites

- The `container-tools` module is installed.

```
# dnf module install -y container-tools
```

Procedure

1. Log in to the registry.redhat.io registry:

```
$ podman login registry.redhat.io
Username: myuser@mycompany.com
Password: ***********
Login Succeeded!
```

2. Pull and run the `registry.redhat.io/rhel8/buildah` image:

```
# podman run --rm --device /dev/fuse -it registry.redhat.io/rhel8/buildah  /bin/bash
```

- The `--rm` option removes the `registry.redhat.io/rhel8/buildah` image after the container exits.
- The `--device` option adds a host device to the container.

3. Create a new container using a `registry.access.redhat.com/ubi8` image:

```
# buildah from registry.access.redhat.com/ubi8
...(output truncated)
ubi8-working-container
```

4. Run the `ls /` command inside the `ubi8-working-container` container:

```
# buildah run --isolation=chroot ubi8-working-container ls /
bin boot dev etc home lib lib64 lost+found media mnt opt proc root run sbin srv
```

5. Optional: List all images in a local storage:

```
# buildah images
REPOSITORY                        TAG      IMAGE ID       CREATED       SIZE
registry.access.redhat.com/ubi8   latest   ecbc6f53bba0   5 weeks ago   211 MB
```

6. Optional: List the working containers and their base images:

```
# buildah containers
CONTAINER ID  BUILDER  IMAGE ID     IMAGE NAME                       CONTAINER NAME
0aaba7192762     *     ecbc6f53bba0 registry.access.redhat.com/ub... ubi8-working-container
```
7. Optional: Push the `registry.access.redhat.com/ubi8` image to the a local registry located on `registry.example.com`:

```bash
# buildah push ecbc6f53bba0 registry.example.com:5000/ubi8/ubi
```

Additional resources

- [Best practices for running Buildah in a container](#)

### 9.6. PRIVILEGED AND UNPRIVILEGED PODMAN CONTAINERS

By default, Podman containers are unprivileged and cannot, for example, modify parts of the operating system on the host. This is because by default a container is only allowed limited access to devices.

The following list emphasizes important properties of privileged containers. You can run the privileged container using the `podman run --privileged <image_name>` command.

- A privileged container is given the same access to devices as the user launching the container.
- A privileged container disables the security features that isolate the container from the host. Dropped Capabilities, limited devices, read-only mount points, Apparmor/SELinux separation, and Seccomp filters are all disabled.
- A privileged container cannot have more privileges than the account that launched them.

Additional resources

- [How to use the --privileged flag with container engines](#)
- [podman-run](#) man page

### 9.7. RUNNING PODMAN WITH EXTENDED PRIVILEGES

If you cannot run your workloads in a rootless environment, you need to run these workloads as a root user. Running a container with extended privileges should be done judiciously, because it disables all security features.

**Prerequisites**

- The `container-tools` module is installed.

  ```bash
  # dnf module install -y container-tools
  ```

**Procedure**

- Run the Podman container in the Podman container:

  ```bash
  $ podman run --privileged --name=privileged_podman
  registry.access.redhat.com/rhel8/podman podman run ubi8 echo hello
  Resolved "ubi8" as an alias (/etc/containers/registries.conf.d/001-rhel-shortnames.conf)
  Trying to pull registry.access.redhat.com/ubi8:latest...
  ...
  Storing signatures
  hello
  ```
• Run the outer container named `privileged_podman` based on the `registry.access.redhat.com/rhel8/podman` image.

• The `--privileged` option disables the security features that isolate the container from the host.

• Run `podman run ubi8 echo hello` command to create the inner container based on the `ubi8` image.

• Notice that the `ubi8` short image name was resolved as an alias. As a result, the `registry.access.redhat.com/ubi8:latest` image is pulled.

Verification

• List all containers:

```
$ podman ps -a
CONTAINER ID IMAGE COMMAND CREATED STATUS      PORTS NAMES
52537876caf4 registry.access.redhat.com/rhel8/podman podman run ubi8 e... 30 seconds ago   Exited (0) 13 seconds ago privileged_podman
```

Additional resources

• How to use Podman inside of a container

• `podman-run` man page

### 9.8. RUNNING PODMAN WITH LESS PRIVILEGES

You can run two nested Podman containers without the `--privileged` option. Running the container without the `--privileged` option is a more secure option.

This can be useful when you want to try out different versions of Podman in the most secure way possible.

Prerequisites

• The `container-tools` module is installed.

```
# dnf module install -y container-tools
```

Procedure

• Run two nested containers:

```
$ podman --name=unprivileged_podman --security-opt label=disable --user podman --device /dev/fuse registry.access.redhat.com/rhel8/podman podman run ubi8 echo hello
```

• Run the outer container named `unprivileged_podman` based on the `registry.access.redhat.com/rhel8/podman` image.
The `--security-opt label=disable` option disables SELinux separation on the host Podman. SELinux does not allow containerized processes to mount all of the file systems required to run inside a container.

The `--user podman` option automatically causes the Podman inside the outer container to run within the user namespace.

The `--device /dev/fuse` option uses the `fuse-overlayfs` package inside the container. This option adds `/dev/fuse` to the outer container, so that Podman inside the container can use it.

Run `podman run ubi8 echo hello` command to create the inner container based on the `ubi8` image.

Notice that the `ubi8` short image name was resolved as an alias. As a result, the `registry.access.redhat.com/ubi8:latest` image is pulled.

Verification

- List all containers:

```
$ podman ps -a
CONTAINER ID   IMAGE                            COMMAND               CREATED            STATUS             PORTS   NAMES
a47b26290f43   podman run ubi8 e... 30 seconds ago   Exited (0) 13 seconds ago
unprivileged_podman
```

9.9. BUILDING A CONTAINER INSIDE A PODMAN CONTAINER

This procedure shows how to run a container in a container using Podman. This example shows how to use Podman to build and run another container from within this container. The container will run "Moon-buggy", a simple text-based game.

Prerequisites

- The `container-tools` module is installed.

  ```
  # dnf module install -y container-tools
  ```

- You are logged in to the registry.redhat.io registry:

  ```
  # podman login registry.redhat.io
  ```

Procedure

1. Run the container based on `registry.redhat.io/rhel8/podman` image:

   ```
   # podman run --privileged --name podman_container -it registry.redhat.io/rhel8/podman /bin/bash
   ```

   - Run the outer container named `podman_container` based on the `registry.redhat.io/rhel8/podman` image.

   - The `--it` option specifies that you want to run an interactive bash shell within a container.
• The \texttt{--privileged} option disables the security features that isolate the container from the host.

2. Create a \textit{Containerfile} inside the \texttt{podman_container} container:

\begin{verbatim}
# vi Containerfile
FROM registry.access.redhat.com/ubi8/ubi
RUN dnf -y install moon-buggy && dnf clean all
CMD ["/usr/bin/moon-buggy"]
\end{verbatim}

The commands in the \textit{Containerfile} cause the following build command to:

• Build a container from the \texttt{registry.access.redhat.com/ubi8/ubi} image.
• Install the \texttt{epel-release-latest-8.noarch.rpm} package.
• Install the \texttt{moon-buggy} package.
• Set the container command.

3. Build a new container image named \texttt{moon-buggy} using the \textit{Containerfile}:

\begin{verbatim}
# podman build -t moon-buggy .
\end{verbatim}

4. Optional: List all images:

\begin{verbatim}
# podman images
REPOSITORY                  TAG      IMAGE ID      CREATED        SIZE
localhost/moon-buggy  latest  c97c58abb564  13 seconds ago  1.67 GB
registry.access.redhat.com/ubi8/ubi latest 4199acc88c6a  132seconds ago  213 MB
\end{verbatim}

5. Run a new container based on a \texttt{moon-buggy} container:

\begin{verbatim}
# podman run -it --name moon moon-buggy
\end{verbatim}

6. Optional: Tag the \texttt{moon-buggy} image:

\begin{verbatim}
# podman tag moon-buggy registry.example.com/moon-buggy
\end{verbatim}

7. Optional: Push the \texttt{moon-buggy} image to the registry:

\begin{verbatim}
# podman push registry.example.com/moon-buggy
\end{verbatim}

\textbf{Additional resources}

• Technology preview: Running a container inside a container article
CHAPTER 10. RUNNING SPECIAL CONTAINER IMAGES

This chapter provides information about some special types of container images. Some container images have built in labels called runlabels that allow you to run those containers with preset options and arguments. The podman container runlabel <label> command, allows you to execute the command defined in the <label> for the container image. Supported labels are install, run and uninstall.

10.1. OPENING PRIVILEGES TO THE HOST

There are several differences between privileged and non-privileged containers. For example, the toolbox container is a privileged container. Here are examples of privileges that may or may not be open to the host from a container:

- **Privileges**: A privileged container disables the security features that isolate the container from the host. You can run a privileged container using the podman run --privileged <image_name> command. You can, for example, delete files and directories mounted from the host that are owned by the root user.

- **Process tables**: You can use the podman run --privileged --pid=host <image_name> command to use the host PID namespace for the container. Then you can use the ps -e command within a privileged container to list all processes running on the host. You can pass a process ID from the host to commands that run in the privileged container (for example, kill <PID>).

- **Network interfaces**: By default, a container has only one external network interface and one loopback network interface. You can use the podman run --net=host <image_name> command to access host network interfaces directly from within the container.

- **Inter-process communications**: The IPC facility on the host is accessible from within the privileged container. You can run commands such as ipcs to see information about active message queues, shared memory segments, and semaphore sets on the host.

10.2. CONTAINER IMAGES WITH RUNLABELS

Some Red Hat images include labels that provide pre-set command lines for working with those images. Using the podman container runlabel <label> command, you can use the podman command to execute the command defined in the <label> for the image.

Existing runlabels include:

- **install**: Sets up the host system before executing the image. Typically, this results in creating files and directories on the host that the container can access when it is run later.

- **run**: Identifies podman command line options to use when running the container. Typically, the options will open privileges on the host and mount the host content the container needs to remain permanently on the host.

- **uninstall**: Cleans up the host system after you finish running the container.

10.3. RUNNING RSYSLOG WITH RUNLABELS

The rhel8/rsyslog container image is made to run a containerized version of the rsyslogd daemon. The rsyslog image contains the following runlabels: install, run and uninstall. The following procedure steps you through installing, running, and uninstalling the rsyslog image:
Procedure

1. Pull the `rsyslog` image:

   ```
   # podman pull registry.redhat.io/rhel8/rsyslog
   ```

2. Display the `install` runlabel for `rsyslog`:

   ```
   # podman container runlabel install --display rhel8/rsyslog
   command: podman run --rm --privileged -v /:/host -e HOST=/host -e IMAGE=registry.redhat.io/rhel8/rsyslog:latest -e NAME=rsyslog
   registry.redhat.io/rhel8/rsyslog:latest /bin/install.sh
   ```

   This shows that the command will open privileges to the host, mount the host root filesystem on `/host` in the container, and run an `install.sh` script.

3. Run the `install` runlabel for `rsyslog`:

   ```
   # podman container runlabel install rhel8/rsyslog
   command: podman run --rm --privileged -v /:/host -e HOST=/host -e IMAGE=registry.redhat.io/rhel8/rsyslog:latest -e NAME=rsyslog
   registry.redhat.io/rhel8/rsyslog:latest /bin/install.sh
   ```

   This creates files on the host system that the `rsyslog` image will use later.

4. Display the `run` runlabel for `rsyslog`:

   ```
   # podman container runlabel run --display rhel8/rsyslog
   command: podman run -d --privileged --name rsyslog --net=host --pid=host -v
   /etc/pki/rsyslog:/etc/pki/rsyslog -v /etc/syslog.conf:/etc/syslog.conf -v
   /etc/sysconfig/rsyslog:/etc/sysconfig/rsyslog -v /etc/rsyslog.d:/etc/rsyslog.d -v /var/log:/var/log
   -v /var/lib/rsyslog:/var/lib/rsyslog -v /run:/run -v /etc/machine-id:/etc/machine-id -v
   /etc/localtime:/etc/localtime -e IMAGE=registry.redhat.io/rhel8/rsyslog:latest -e
   NAME=rsyslog --restart=always registry.redhat.io/rhel8/rsyslog:latest /bin/rsyslog.sh
   ```

   This shows that the command opens privileges to the host and mount specific files and directories from the host inside the container, when it launches the `rsyslog` container to run the `rsyslogd` daemon.

5. Execute the `run` runlabel for `rsyslog`:

   ```
   # podman container runlabel run rhel8/rsyslog
   command: podman run -d --privileged --name rsyslog --net=host --pid=host -v
   /etc/pki/rsyslog:/etc/pki/rsyslog -v /etc/syslog.conf:/etc/syslog.conf -v
   /etc/sysconfig/rsyslog:/etc/sysconfig/rsyslog -v /etc/rsyslog.d:/etc/rsyslog.d -v /var/log:/var/log
   -v /var/lib/rsyslog:/var/lib/rsyslog -v /run:/run -v /etc/machine-id:/etc/machine-id -v
   /etc/localtime:/etc/localtime -e IMAGE=registry.redhat.io/rhel8/rsyslog:latest -e
   NAME=rsyslog --restart=always registry.redhat.io/rhel8/rsyslog:latest /bin/rsyslog.sh
   ```

   28a0d719ff179adcea81eb63cc90fcd09f1755d5edeb121399068a4ea59bd0f53
The rsyslog container opens privileges, mounts what it needs from the host, and runs the rsyslogd daemon in the background (-d). The rsyslogd daemon begins gathering log messages and directing messages to files in the /var/log directory.

6. Display the **uninstall** runlabel for rsyslog:

```
# podman container runlabel uninstall --display rhel8/rsyslog
command: podman run --rm --privileged -v /:/host -e HOST=/host -e IMAGE=registry.redhat.io/rhel8/rsyslog:latest -e NAME=rsyslog
registry.redhat.io/rhel8/rsyslog:latest /bin/uninstall.sh
```

7. Run the **uninstall** runlabel for rsyslog:

```
# podman container runlabel uninstall rhel8/rsyslog
command: podman run --rm --privileged -v /:/host -e HOST=/host -e IMAGE=registry.redhat.io/rhel8/rsyslog:latest -e NAME=rsyslog
registry.redhat.io/rhel8/rsyslog:latest /bin/uninstall.sh
```

**NOTE**

In this case, the **uninstall.sh** script just removes the /etc/logrotate.d/syslog file. It does not clean up the configuration files.
CHAPTER 11. PORTING CONTAINERS TO OPENSHIFT USING PODMAN

This chapter describes how to generate portable descriptions of containers and pods using the YAML ("YAML Ain’t Markup Language") format. The YAML is a text format used to describe the configuration data.

The YAML files are:

- Readable.
- Easy to generate.
- Portable between environments (for example between RHEL and OpenShift).
- Portable between programming languages.
- Convenient to use (no need to add all the parameters to the command line).

Reasons to use YAML files:

1. You can re-run a local orchestrated set of containers and pods with minimal input required which can be useful for iterative development.

2. You can run the same containers and pods on another machine. For example, to run an application in an OpenShift environment and to ensure that the application is working correctly. You can use `podman generate kube` command to generate a Kubernetes YAML file. Then, you can use `podman play` command to test the creation of pods and containers on your local system before you transfer the generated YAML files to the Kubernetes or OpenShift environment. Using the `podman play` command, you can also recreate pods and containers originally created in OpenShift or Kubernetes environments.

11.1. GENERATING A KUBERNETES YAML FILE USING PODMAN

This procedure describes how to create a pod with one container and generate the Kubernetes YAML file using the `podman generate kube` command.

Prerequisites

- The pod has been created. For details, see Creating pods.

Procedure

1. List all pods and containers associated with them:

   $$
   $ podman ps -a --pod
   CONTAINER ID  IMAGE                                          COMMAND       CREATED       STATUS                      PORTS               NAMES               POD
   5df5c48fea87  registry.access.redhat.com/ubi8/ubi:latest /bin/bash Less than a second ago Up Less than a second ago
   3afdc93de3e  k8s.gcr.io/pause:3.1                           Less than a second ago Up Less than a second ago
   $$

2. Use the pod name or ID to generate the Kubernetes YAML file:

   -
$ podman generate kube mypod > mypod.yaml

Note that the **podman generate** command does not reflect any Logical Volume Manager (LVM) logical volumes or physical volumes that might be attached to the container.

3. Display the **mypod.yaml** file:

```bash
$ cat mypod.yaml
# Generation of Kubernetes YAML is still under development!
#
# Save the output of this file and use kubectl create -f to import
# it into Kubernetes.
#
# Created with podman-1.6.4
apiVersion: v1
kind: Pod
metadata:
  creationTimestamp: "2020-06-09T10:31:56Z"
labels:
  app: mypod
  name: mypod
spec:
  containers:
    - command:
        - /bin/bash
eenv:
    - name: PATH
      value: /usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin
    - name: TERM
      value: xterm
    - name: HOSTNAME
      - name: container
      value: oci
image: registry.access.redhat.com/ubi8/ubi:latest
name: myubi
resources: {}
securityContext:
  allowPrivilegeEscalation: true
capabilities: {}
  privileged: false
  readOnlyRootFilesystem: false
tty: true
  workingDir: /
status: {}
```

**Additional resources**

- man podman-generate-kube
- Podman: Managing pods and containers in a local container runtime article

**11.2. Generating a Kubernetes YAML File in OpenShift Environment**
In the OpenShift environment, use the `oc create` command to generate the YAML files describing your application.

**Procedure**

- Generate the YAML file for your `myapp` application:

  ```
  $ oc create myapp --image=me/myapp:v1 -o yaml --dry-run > myapp.yaml
  ```

  The `oc create` command creates and run the `myapp` image. The object is printed using the `--dry-run` option and redirected into the `myapp.yaml` output file.

  **NOTE**
  
  In the Kubernetes environment, you can use the `kubectl create` command with the same flags.

11.3. STARTING CONTAINERS AND PODS WITH POEDMAN

With the generated YAML files, you can automatically start containers and pods in any environment. Note that the YAML files must not be generated by the Podman. The `podman play kube` command allows you to recreate pods and containers based on the YAML input file.

**Procedure**

1. Create the pod and the container from the `mypod.yaml` file:

   ```
   $ podman play kube mypod.yaml
   Pod:
   b8c5b99ba846ccf76c3e257e5761c2d8a5ca4d7fa3880531aelc79c0dacb22
   Container:
   848179395ebd33dd91d14ffbbde7ae273158d9695a081468f487af4e35688ece
   ```

2. List all pods:

   ```
   $ podman pod ps
   POD ID      NAME    STATUS     CREATED         # OF CONTAINERS   INFRA ID
   b8c5b99ba846 mypod    Running  19 seconds ago   2               aa4220eaf4bb
   ```

3. List all pods and containers associated with them:

   ```
   $ podman ps -a --pod
   CONTAINER ID    IMAGE                      COMMAND       CREATED         STATUS
   b8c5b99ba846  registry.access.redhat.com/ubi8/ubi:latest  /bin/bash    About a minute ago Up
   b8c5b99ba846  k8s.gcr.io/pause:3.1              About a minute ago Up
   ```

The pod IDs from `podman ps` command matches the pod ID from the `podman pod ps` command.

Additional resources
11.4. STARTING CONTAINERS AND PODS IN OPENSIFT ENVIRONMENT

You can use the `oc create` command to create pods and containers in the OpenShift environment.

Procedure

- Create a pod from the YAML file in the OpenShift environment:

  ```
  $ oc create -f mypod.yaml
  ```

**NOTE**

In the Kubernetes environment, you can use the `kubectl create` command with the same flags.
Podman (Pod Manager) is a fully featured container engine that is a simple daemonless tool. Podman provides a Docker-CLI comparable command line that eases the transition from other container engines and allows the management of pods, containers and images.

Podman was not originally designed to bring up an entire Linux system or manage services for such things as start-up order, dependency checking, and failed service recovery. That is the job of a full-blown initialization system like systemd. Red Hat has become a leader in integrating containers with systemd, so that OCI and Docker-formatted containers built by Podman can be managed in the same way that other services and features are managed in a Linux system. You can use the systemd initialization service to work with pods and containers. You can use the `podman generate systemd` command to generate a systemd unit file for containers and pods.

With systemd unit files, you can:

- Set up a container or pod to start as a systemd service.
- Define the order in which the containerized service runs and check for dependencies (for example making sure another service is running, a file is available or a resource is mounted).
- Control the state of the systemd system using the `systemctl` command.

This chapter provides you with information on how to generate portable descriptions of containers and pods using systemd unit files.

### 12.1. ENABLING SYSTEMD SERVICES

When enabling the service, you have different options.

**Procedure**

- Enable the service:
  - To enable a service at system start, no matter if user is logged in or not, enter:
    ```bash
    # systemctl enable <service>
    ```
    You have to copy the systemd unit files to the `/etc/systemd/system` directory.
  - To start a service at user login and stop it at user logout, enter:
    ```bash
    $ systemctl --user enable <service>
    ```
    You have to copy the systemd unit files to the `$HOME/.config/systemd/user` directory.
  - To enable users to start a service at system start and persist over logouts, enter:
    ```bash
    # loginctl enable-linger <username>
    ```

**Additional resources**

- `man systemctl`
12.2. GENERATING A SYSTEMD UNIT FILE USING PODMAN

Podman allows systemd to control and manage container processes. You can generate a systemd unit file for the existing containers and pods using `podman generate systemd` command. It is recommended to use `podman generate systemd` because the generated units files change frequently (via updates to Podman) and the `podman generate systemd` ensures that you get the latest version of unit files.

Procedure

1. Create a container (for example `myubi`):

   ```bash
   $ podman create --name myubi registry.access.redhat.com/ubi8:latest sleep infinity
   0280afe98bb75a5e713b28de4b7c5cb49f156f1cceb4a208f13f6e2f75cb453
   ```

2. Use the container name or ID to generate the systemd unit file and direct it into the `~/.config/systemd/user/container-myubi.service` file:

   ```bash
   $ podman generate systemd --name myubi > ~/.config/systemd/user/container-myubi.service
   ```

Verification steps

- Display the content of generated systemd unit file:

   ```bash
   $ cat ~/.config/systemd/user/container-myubi.service
   # container-myubi.service
   # autogenerated by Podman 3.3.1
   # Wed Sep 8 20:34:46 CEST 2021
   
   [Unit]
   Description=Podman container-myubi.service
   Documentation=man:podman-generate-systemd(1)
   Wants=network-online.target
   After=network-online.target
   RequiresMountsFor=/run/user/1000/containers
   
   [Service]
   Environment=PODMAN_SYSTEMD_UNIT=%n
   Restart=on-failure
   TimeoutStopSec=70
   ExecStart=/usr/bin/podman start myubi
   ExecStop=/usr/bin/podman stop -t 10 myubi
   ExecStopPost=/usr/bin/podman stop -t 10 myubi
   PIDFile=/run/user/1000/containers/overlay-containers/9683103f58a32192c84801f0be93446cb33c1ee7d9cdaa225b78049d7c5deea4/user data/conmon.pid
   Type=forking
   
   [Install]
   WantedBy=multi-user.target default.target
   ```
The **Restart=on-failure** line sets the restart policy and instructs systemd to restart when the service cannot be started or stopped cleanly, or when the process exits non-zero.

- The **ExecStart** line describes how we start the container.
- The **ExecStop** line describes how we stop and remove the container.

**Additional resources**

- [Running containers with Podman and shareable systemd services](#)

### 12.3. AUTO-GENERATING A SYSTEMD UNIT FILE USING PODMAN

By default, Podman generates a unit file for existing containers or pods. You can generate more portable systemd unit files using the `podman generate systemd --new`. The --new flag instructs Podman to generate unit files that create, start and remove containers.

**Procedure**

1. Pull the image you want to use on your system. For example, to pull the **httpd-24** image:

   ```bash
   # podman pull registry.access.redhat.com/ubi8/httpd-24
   ```

2. Optional. List all images available on your system:

   ```bash
   # podman images
   REPOSITORY                                TAG                  IMAGE ID      CREATED        SIZE
   registry.access.redhat.com/ubi8/httpd-24  latest               8594be0a0b57  2 weeks ago    462MB
   ```

3. Create the **httpd** container:

   ```bash
   # podman create --name httpd -p 8080:8080 registry.access.redhat.com/ubi8/httpd-24
cdb9f981cf143021b1679599d860026b13a7718775e46cc009eac85293710a4b1
   ```

4. Optional. Verify the container has been created:

   ```bash
   # podman ps -a
   CONTAINER ID  IMAGE                                            COMMAND               CREATED
   STATUS      PORTS                   NAMES
   cdb9f981cf14  registry.access.redhat.com/ubi8/httpd-24:latest /usr/bin/run-http...  5 minutes
   ago Created   0.0.0.0:8080->8080/tcp  httpd
   ```

5. Generate a systemd unit file for the **httpd** container:

   ```bash
   # podman generate systemd --new --files --name httpd
   /root/container-httpd.service
   ```

6. Display the content of the generated **container-httpd.service** systemd unit file:

   ```bash
   # cat /root/container-httpd.service
   # container-httpd.service
   # autogenerated by Podman 3.3.1
   ```
NOTE

Unit files generated using the --new option do not expect containers and pods to exist. Therefore, they perform the podman run command when starting the service (see the ExecStart line) instead of the podman start command. For example, see Section Generating a systemd unit file using Podman.

- The podman run command uses the following command-line options:
  - The --conmon-pidfile option points to a path to store the process ID for the conmon process running on the host. The conmon process terminates with the same exit status as the container, which allows systemd to report the correct service status and restart the container if needed.
  - The --cidfile option points to the path that stores the container ID.
  - The %t is the path to the run time directory root, for example /run/user/$UserID.
  - The %n is the full name of the service.

7. Copy unit files to /usr/lib/systemd/system for installing them as a root user:

```
# cp -Z container-httpd.service /etc/systemd/system
```

8. Enable and start the container-httpd.service:

```
# systemctl daemon-reload
# systemctl enable --now container-httpd.service
Created symlink /etc/systemd/system/multi-user.target.wants/container-httpd.service →
```
/etc/systemd/system/container-httpd.service. Created symlink /etc/systemd/system/default.target.wants/container-httpd.service → /etc/systemd/system/container-httpd.service.

Verification steps

- Check the status of the **container-httpd.service**:

  ```
  # systemctl status container-httpd.service
  ● container-httpd.service - Podman container-httpd.service
    Loaded: loaded (/etc/systemd/system/container-httpd.service; enabled; vendor preset: disabled)
    Active: active (running) since Tue 2021-08-24 09:53:40 EDT; 1min 5s ago
    Docs: man:podman-generate-systemd(1)
    Process: 493317 ExecStart=/usr/bin/podman run --conmon-pidfile /run/container-httpd.pid --cidfile /run/container-httpd.ctr-id --cgroups=no-conmon -d --repla>
    Process: 493315 ExecStartPre=/bin/rm -f /run/container-httpd.pid /run/container-httpd.ctr-id (code=exited, status=0/SUCCESS)
    Main PID: 493435 (conmon)
  ...
  ```

Additional resources

- [Improved Systemd Integration with Podman 2.0](#)
- [Managing services with systemd](#)

### 12.4. AUTO-STARTING CONTAINERS USING SYSTEMD

You can control the state of the systemd system and service manager using the **systemctl** command. This section shows the general procedure on how to enable, start, stop the service as a non-root user. To install the service as a root user, omit the **--user** option.

**Procedure**

1. Reload systemd manager configuration:

   ```
   # systemctl --user daemon-reload
   ```

2. Enable the service **container.service** and start it at boot time:

   ```
   # systemctl --user enable container.service
   ```

3. Start the service immediately:

   ```
   # systemctl --user start container.service
   ```

4. Check the status of the service:

   ```
   $ systemctl --user status container.service
   ● container.service - Podman container.service
     Loaded: loaded (/home/user/.config/systemd/user/container.service; enabled; vendor preset: enabled)
   ```
You can check if the service is enabled using the `systemctl is-enabled container.service` command.

### Verification steps

- List containers that are running or have exited:

  ```bash
  # podman ps
  CONTAINER ID  IMAGE                            COMMAND  CREATED         STATUS
  f20988d59920  registry.access.redhat.com/ubi8-minimal:latest  top      12 seconds ago  Up 11 seconds ago  funny_zhukovsky
  ```

### NOTE

To stop `container.service`, enter:

```bash
# systemctl --user stop container.service
```

### Additional resources

- `man systemctl`
- [Managing services with systemd](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/9/html/container_basics/chapters/managing-services-with-systemd)

### 12.5. AUTO-STARTING PODS USING SYSTEMD

You can start multiple containers as systemd services. Note that the `systemctl` command should only be used on the pod and you should not start or stop containers individually via `systemctl`, as they are managed by the pod service along with the internal infra-container.
Procedure

1. Create an empty pod, for example named `systemd-pod`:

   ```bash
   $ podman pod create --name systemd-pod
   11d4646ba41b1fffa51c108cbdf97cfab3213f7bd9b3e1ca52fe81b90fed5577
   ```

2. Optional. List all pods:

   ```bash
   $ podman pod ps
   POD ID       NAME         STATUS   CREATED         # OF CONTAINERS  INFRA ID
   11d4646ba41b systemd-pod  Created  40 seconds ago  1  8a428b257111
   11d4646ba41b1fffa51c108cbdf97cfab3213f7bd9b3e1ca52fe81b90fed5577
   ```

3. Create two containers in the empty pod. For example, to create `container0` and `container1` in `systemd-pod`:

   ```bash
   $ podman create --pod systemd-pod --name container0 registry.access.redhat.com/ubi8 top
   $ podman create --pod systemd-pod --name container1 registry.access.redhat.com/ubi8 top
   ```

4. Optional. List all pods and containers associated with them:

   ```bash
   $ podman ps -a --pod
   CONTAINER ID  IMAGE                                   COMMAND  CREATED        STATUS
   PORTS   NAMES               POD ID        PODNAME
   24666f47d9b2  registry.access.redhat.com/ubi8:latest  top      3 minutes ago  Created
   container0          3130f724e229  systemd-pod
   56eb1bf0cdfe  k8s.gcr.io/pause:3.2                             4 minutes ago  Created
   container1          3130f724e229-infra  3130f724e229  systemd-pod
   62118d170e43  registry.access.redhat.com/ubi8:latest  top      3 seconds ago  Created
   container1          3130f724e229  systemd-pod
   ```

5. Generate the systemd unit file for the new pod:

   ```bash
   $ podman generate systemd --files --name systemd-pod
   /home/user1/pod-systemd-pod.service
   /home/user1/container-container0.service
   /home/user1/container-container1.service
   ```

   Note that three systemd unit files are generated, one for the `systemd-pod` pod and two for the containers `container0` and `container1`.

6. Display `pod-systemd-pod.service` unit file:

   ```bash
   $ cat pod-systemd-pod.service
   # pod-systemd-pod.service
   # autogenerated by Podman 3.3.1
   # Wed Sep  8 20:49:17 CEST 2021
   [Unit]
   Description=Podman pod-systemd-pod.service
   Documentation=man:podman-generate-systemd(1)
   Wants=network-online.target
   After=network-online.target
   ```
The `Requires` line in the `[Unit]` section defines dependencies on `container-container0.service` and `container-container1.service` unit files. Both unit files will be activated.

- The `ExecStart` and `ExecStop` lines in the `[Service]` section start and stop the infrastructure container, respectively.

7. Display `container-container0.service` unit file:

```bash
$ cat container-container0.service
# container-container0.service
# autogenerated by Podman 3.3.1
# Wed Sep  8 20:49:17 CEST 2021

[Unit]
Description=Podman container-container0.service
Documentation=man:podman-generate-systemd(1)
Wants=network-online.target
After=network-online.target
RequiresMountsFor=/run/user/1000/containers
BindsTo=pod-systemd-pod.service
After=pod-systemd-pod.service

[Service]
Environment=PODMAN_SYSTEMD_UNIT=%n
Restart=on-failure
TimeoutStopSec=70
ExecStart=/usr/bin/podman start container0
ExecStop=/usr/bin/podman stop -t 10 container0
ExecStopPost=/usr/bin/podman stop -t 10 container0
PIDFile=/run/user/1000/containers/overlay-containers/4bcd7c8616ae5909b05317df4066fa90a64a067375af5996fdef9152f6d51f5/userdata/conmon.pid
Type=forking

[Install]
WantedBy=multi-user.target default.target
```
• The **BindsTo** line line in the **[Unit]** section defines the dependency on the **pod-systemd-pod.service** unit file

• The **ExecStart** and **ExecStop** lines in the **[Service]** section start and stop the **container0** respectively.

8. Display **container-container1.service** unit file:

```bash
$ cat container-container1.service
```

9. Copy all the generated files to **$HOME/.config/systemd/user** for installing as a non-root user:

```bash
$ cp pod-systemd-pod.service container-container0.service container-container1.service $HOME/.config/systemd/user
```

10. Enable the service and start at user login:

```bash
$ systemctl enable --user pod-systemd-pod.service
```

Note that the service stops at user logout.

**Verification steps**

• Check if the service is enabled:

```bash
$ systemctl is-enabled pod-systemd-pod.service
```

**Additional resources**

- **man podman-create**
- **man podman-generate-systemd**
- **man systemctl**
- **Running containers with Podman and shareable systemd services** article
- **Managing services with systemd** chapter

**12.6. AUTO-UPDATING CONTAINERS USING PODMAN**

The **podman auto-update** command allows you to automatically update containers according to their auto-update policy. The **podman auto-update** command updates services when the container image is updated on the registry. To use auto-updates, containers must be created with the **--label "io.containers.autoupdate=image"** label and run in a systemd unit generated by **podman generate systemd --new** command.

Podman searches for running containers with the "**io.containers.autoupdate**" label set to "**image**" and communicates to the container registry. If the image has changed, Podman restarts the corresponding
systemd unit to stop the old container and create a new one with the new image. As a result, the container, its environment, and all dependencies, are restarted.

**Prerequisites**

- The **container-tools** module is installed.

```
# dnf module install -y container-tools
```

**Procedure**

1. Start a **myubi** container based on the **registry.access.redhat.com/ubi8/ubi-init** image:

```
# podman run --label "io.containers.autoupdate=image" \
 --name myubi -dt registry.access.redhat.com/ubi8/ubi-init top \
 bc219740a210455fa27deacc96d50a9e20516492f1417507c13ce1533dbdcd9d
```

2. Optional: List containers that are running or have exited:

```
# podman ps -a
CONTAINER ID IMAGE COMMAND CREATED STATUS
76465a5e2933 registry.access.redhat.com/ubi8/ubi-init:latest top 24 seconds ago Up 23 seconds ago myubi
```

3. Generate a systemd unit file for the **myubi** container:

```
# podman generate systemd --new --files --name myubi \
/root/container-myubi.service
```

4. Copy unit files to **/usr/lib/systemd/system** for installing it as a root user:

```
# cp -Z ~/container-myubi.service /usr/lib/systemd/system
```

5. Reload systemd manager configuration:

```
# systemctl daemon-reload
```

6. Start and check the status of a container:

```
# systemctl start container-myubi.service
# systemctl status container-myubi.service
```

7. Auto-update the container:

```
# podman auto-update
```

**Additional resources**

Managing Services with systemd chapter

12.7. AUTO-UPDATING CONTAINERS USING SYSTEMD

As mentioned in section Auto-updating containers using Podman, you can update the container using the **podman auto-update** command. It integrates into custom scripts and can be invoked when needed. Another way to auto update the containers is to use the pre-installed **podman-auto-update.timer** and **podman-auto-update.service** systemd service. The **podman-auto-update.timer** can be configured to trigger auto updates at a specific date or time. The **podman-auto-update.service** can further be started by the **systemctl** command or be used as a dependency by other systemd services. As a result, auto updates based on time and events can be triggered in various ways to meet individual needs and use cases.

Prerequisites

- The **container-tools** module is installed.
  
  ```
  # dnf module install -y container-tools
  ```

Procedure

1. Display the **podman-auto-update.service** unit file:

   ```
   # cat /usr/lib/systemd/system/podman-auto-update.service
   
   [Unit]
   Description=Podman auto-update service
   Documentation=man:podman-auto-update(1)
   Wants=network.target
   After=network-online.target
   
   [Service]
   Type=oneshot
   ExecStart=/usr/bin/podman auto-update
   
   [Install]
   WantedBy=multi-user.target default.target
   ```

2. Display the **podman-auto-update.timer** unit file:

   ```
   # cat /usr/lib/systemd/system/podman-auto-update.timer
   
   [Unit]
   Description=Podman auto-update timer
   
   [Timer]
   OnCalendar=daily
   Persistent=true
   
   [Install]
   WantedBy=timers.target
   ```

In this example, the **podman auto-update** command is launched daily at midnight.
3. Enable the `podman-auto-update.timer` service at system start:

   ```
   # systemctl enable podman-auto-update.timer
   ```

4. Start the systemd service:

   ```
   # systemctl start podman-auto-update.timer
   ```

5. Optional: List all timers:

   ```
   # systemctl list-timers --all
   ```

<table>
<thead>
<tr>
<th>NEXT</th>
<th>LEFT</th>
<th>LAST</th>
<th>PASSED</th>
<th>UNIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wed 2020-12-09 00:00:00 CET</td>
<td>9h left</td>
<td>n/a</td>
<td>n/a</td>
<td>podman-auto-update.timer</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>podman-auto-update.service</td>
</tr>
</tbody>
</table>

   You can see that `podman-auto-update.timer` activates the `podman-auto-update.service`.

- [Running containers with Podman and shareable systemd services](#) article
- [Managing Services with systemd](#) chapter
CHAPTER 13. BUILDING CONTAINER IMAGES WITH BUILDAH

Buildah facilitates building OCI container images that meet the [OCI Runtime Specification](http://www.opencontainers.org). With Buildah, you can create a working container, either from scratch or using an image as a starting point. You can create an image either from a working container or using the instructions in a Containerfile. You can mount and unmount a working container's root filesystem.

### 13.1. THE BUILDAH TOOL

Using Buildah is different from building images with the docker command in the following ways:

- **No Daemon**
  - Buildah requires no container runtime.
- **Base image or scratch**
  - You can build an image based on another container or start with an empty image (scratch).
- **Build tools are external**
  - Buildah does not include build tools within the image itself. As a result, Buildah:
    - Reduces the size of built images.
    - Increases security of images by excluding software (e.g. gcc, make, and dnf) from the resulting image.
    - Allows to transport the images using fewer resources because of the reduced image size.

**Compatibility**

Buildah supports building container images with Dockerfiles allowing for an easy transition from Docker to Buildah.

**NOTE**

The default location Buildah uses for container storage is the same as the location the CRI-O container engine uses for storing local copies of images. As a result, the images pulled from a registry by either CRI-O or Buildah, or committed by the buildah command, are stored in the same directory structure. However, even though CRI-O and Buildah are currently able to share images, they cannot share containers.

**Additional resources**

- Buildah - a tool that facilitates building Open Container Initiative (OCI) container images
- Buildah Tutorial 1: Building OCI container images
- Buildah Tutorial 2: Using Buildah with container registries
- Building with Buildah: Dockerfiles, command line, or scripts
- How rootless Buildah works: Building containers in unprivileged environments

### 13.2. INSTALLING BUILDAH

Install the Buildah tool using the `dnf` command.
Procedure

- Install the Buildah tool:
  ```bash
  # dnf -y install buildah
  ```

Verification

- Display the help message:
  ```bash
  # buildah -h
  ```

13.3. GETTING IMAGES WITH BUILDAH

Use the `buildah from` command to create a new working container from scratch or based on a specified image as a starting point.

Procedure

- Create a new working container based on the `registry.redhat.io/ubi8/ubi` image:
  ```bash
  # buildah from registry.access.redhat.com/ubi8/ubi
  ```

Verification

1. List all images in local storage:

   ```bash
   # buildah images
   ```
   
<table>
<thead>
<tr>
<th>REPOSITORY</th>
<th>TAG</th>
<th>IMAGE ID</th>
<th>CREATED</th>
<th>SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>registry.access.redhat.com/ubi8/ubi</td>
<td>latest</td>
<td>272209ff0ae5</td>
<td>2 weeks ago</td>
<td>234 MB</td>
</tr>
</tbody>
</table>

2. List the working containers and their base images:

   ```bash
   # buildah containers
   ```

<table>
<thead>
<tr>
<th>CONTAINER ID</th>
<th>BUILDER</th>
<th>IMAGE ID</th>
<th>IMAGE NAME</th>
<th>CONTAINER NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>01eab9588ae1</td>
<td>*</td>
<td>272209ff0ae5</td>
<td>registry.access.redhat.com/ub...</td>
<td>ubi-working-container</td>
</tr>
</tbody>
</table>

Additional resources

- `buildah-from` man page
- `buildah-images` man page
- `buildah.containers` man page

13.4. RUNNING COMMANDS INSIDE OF THE CONTAINER
Use the **buildah run** command to execute a command from the container.

**Prerequisites**

- A pulled image is available on the local system.

**Procedure**

- Display the operating system version:

  ```
  # buildah run ubi-working-container cat /etc/redhat-release
  Red Hat Enterprise Linux release 8.4 (Ootpa)
  ```

**Additional resources**

- **buildah-run** man page

---

13.5. **BUILDING AN IMAGE FROM A CONTAINERFILE WITH BUILDAH**

Use the **buildah bud** command to build an image using instructions from a **Containerfile**.

**NOTE**

The **buildah bud** command uses a **Containerfile** if found in the context directory, if it is not found the **buildah bud** command uses a **Dockerfile**; otherwise any file can be specified with the **--file** option. The available commands that are usable inside a **Containerfile** and a **Dockerfile** are equivalent.

**Procedure**

1. Create a **Containerfile**:

   ```
   # cat Containerfile
   FROM registry.access.redhat.com/ubi8/ubi
   ADD myecho /usr/local/bin
   ENTRYPOINT "/usr/local/bin/myecho"
   ```

2. Create a **myecho** script:

   ```
   # cat myecho
   echo "This container works!"
   ```

3. Change the access permissions of **myecho** script:

   ```
   # chmod 755 myecho
   ```

4. Build the **myecho** image using **Containerfile** in the current directory:

   ```
   # buildah bud -t myecho .
   ```

   **STEP 1**: FROM registry.access.redhat.com/ubi8/ubi  
   **STEP 2**: ADD myecho /usr/local/bin  
   **STEP 3**: ENTRYPOINT "/usr/local/bin/myecho"
STEP 4: COMMIT myecho
... Storing signatures

Verification

1. List all images:

```
# buildah images
REPOSITORY       TAG IMAGE ID.CREATED       SIZE
localhost/myecho latest b28cd00741b3 About a minute ago 234 MB
```

2. Run the `myecho` container based on the `localhost/myecho` image:

```
# podman run --name=myecho localhost/myecho
This container works!
```

3. List all containers:

```
# podman ps -a
0d97517428d localhost/myecho 12 seconds ago Exited (0) 13 seconds ago myecho
```

**NOTE**
You can use the `podman history` command to display the information about each layer used in the image.

Additional resources

- `buildah-bud` man page

13.6. INSPECTING CONTAINERS AND IMAGES WITH BUILDAH

Use the `buildah inspect` command to display information about a container or image.

Prerequisites

- An image was built using instructions from Containerfile. For details, see section Building an image from a Containerfile with Buildah.

Procedure

- Inspect the image:
  - To inspect the myecho image, enter:

```
# buildah inspect localhost/myecho
{
  "Type": "buildah 0.0.1",
  "FromImage": "localhost/myecho:latest",
  "FromImageID": "b28cd00741b38c92382ee806e1653eae0a56402bcd2c8d31bdc836521bc267a4",
```
To inspect the working container from the `myecho` image:

i. Create a working container based on the `localhost/myecho` image:

```
# buildah from localhost/myecho
```

ii. Inspect the `myecho-working-container` container:

```
# buildah inspect ubi-working-container
{
  "Type": "buildah 0.0.1",
  "FromImage": "registry.access.redhat.com/ubi8/ubi:latest",
  "FromImageID": "272209ff0ae5fe54c119b9c32a25887e13625c9035a1599f6ba654aa7638262d",
  "FromImageDigest": "sha256:77623387101abefbf83161c7d5a0378379d0424b2244009282acb39d42f1fe13",
  "Config": ...
  "Container": "ubi-working-container",
  "ContainerID": "01eab9588ae15237661cd7c7b7661cd7efef8f9ae8a59585",
  "MountLabel": "system_u:system_r:container_t:s0:c162,c1000",
  "MountLabel": "system_u:object_r:container_file_t:s0:c162,c1000",
  ...
}
```

Additional resources

- `buildah-inspect` man page

13.7. MODIFYING A CONTAINER USING BUILDAH MOUNT

Use the `buildah inspect` command to display information about a container or image.

Prerequisites

- An image built using instructions from Containerfile. For details, see section Building an image from a Containerfile with Buildah.

Procedure
1. Create a working container based on the registry.access.redhat.com/ubi8/ubi image and save the name of the container to the `mycontainer` variable:

```
# mycontainer=$(buildah from localhost/myecho)
# echo $mycontainer
myecho-working-container
```

2. Mount the `myecho-working-container` container and save the mount point path to the `mymount` variable:

```
# mymount=$(buildah mount $mycontainer)
# echo $mymount
/var/lib/containers/storage/overlay/c1709df40031dda7c49e93575d9c8eebcaa5d8129033a58e5b6a95019684cc25/merged
```

3. Modify the `myecho` script and make it executable:

```
# echo 'echo "We modified this container."' >> $mymount/usr/local/bin/myecho
# chmod +x $mymount/usr/local/bin/myecho
```

4. Create the `myecho2` image from the `myecho-working-container` container:

```
# buildah commit $mycontainer containers-storage:myecho2
```

Verification

1. List all images in local storage:

```
# buildah images
REPOSITORY                              TAG       IMAGE ID       CREATED          SIZE
docker.io/library/myecho2              latest   4547d2c3e436   4 minutes ago    234 MB
localhost/myecho                        latest   b28cd00741b3   56 minutes ago   234 MB
```

2. Run the `myecho2` container based on the `docker.io/library/myecho2` image:

```
# podman run --name=myecho2 docker.io/library/myecho2
This container works!
We even modified it.
```

Additional resources

- `buildah-mount` man page
- `buildah-commit` man page

13.8. MODIFYING A CONTAINER USING BUILDAH COPY AND BUILDAH CONFIG

Use `buildah copy` command to copy files to a container without mounting it. You can then configure the container using the `buildah config` command to run the script you created by default.
Prerequisites

- An image built using instructions from Containerfile. For details, see section Building an image from a Containerfile with Buildah.

Procedure

1. Create a script named `newecho` and make it executable:

   ```
   # cat newecho
   echo "I changed this container"
   # chmod 755 newecho
   ```

2. Create a new working container:

   ```
   # buildah from myecho:latest
   myecho-working-container-2
   ```

3. Copy the newecho script to `/usr/local/bin` directory inside the container:

   ```
   # buildah copy myecho-working-container-2 newecho /usr/local/bin
   ```

4. Change the configuration to use the `newecho` script as the new entrypoint:

   ```
   # buildah config --entrypoint "/bin/sh -c /usr/local/bin/newecho" myecho-working-container-2
   ```

5. Optional. Run the `myecho-working-container-2` container which triggers the `newecho` script to be executed:

   ```
   # buildah run myecho-working-container-2 -- sh -c '/usr/local/bin/newecho'
   I changed this container
   ```

6. Commit the `myecho-working-container-2` container to a new image called `mynewecho`:

   ```
   # buildah commit myecho-working-container-2 containers-storage:mynewecho
   ```

Verification

- List all images in local storage:

   ```
   # buildah images
   REPOSITORY TAG IMAGE ID CREATED SIZE
docker.io/library/mynewecho latest fa2091a7d8b6 8 seconds ago 234 MB
   ```

Additional resources

- buildah-copy man page
- buildah-config man page
- buildah-commit man page
- buildah-run man page
13.9. CREATING IMAGES FROM SCRATCH WITH BUILDAH

Instead of starting with a base image, you can create a new container that holds only a minimal amount of container metadata.

When creating an image from scratch container, consider: A * You can copy the executable with no dependencies into the scratch image and make a few configuration settings to get a minimal container to work. * You must initialize an RPM database and add a release package in the container to use tools like dnf or rpm. * If you add a lot of packages, consider using the standard UBI or minimal UBI images instead of scratch images.

Procedure

This procedure adds a web service httpd to a container and configures it to run.

1. Create an empty container:

```
# buildah from scratch
working-container
```

2. Mount the `working-container` container and save the mount point path to the `scratchmnt` variable:

```
# scratchmnt=$(buildah mount working-container)
# echo $scratchmnt
/var/lib/containers/storage/overlay/be2eaecf9f74b6acfe4d0017dd5534fde06b2fa8de9ed875691f6ccc791c1836/merged
```

3. Initialize an RPM database within the scratch image and add the `redhat-release` package:

```
# dnf install -y --releasever=8 --installroot=$scratchmnt redhat-release
```

4. Install the `httpd` service to the `scratch` directory:

```
# dnf install -y --setopt=reposdir=/etc/yum.repos.d 
--installroot=$scratchmnt 
--setopt=cachedir=/var/cache/dnf httpd
```

5. Create the `$scratchmnt/var/www/html/index.html` file:

```
# mkdir -p $scratchmnt/var/www/html
# echo "Your httpd container from scratch works!" > $scratchmnt/var/www/html/index.html
```

6. Configure `working-container` to run the `httpd` daemon directly from the container:

```
# buildah config --cmd "/usr/sbin/httpd -DFOREGROUND" working-container
# buildah config --port 80/tcp working-container
# buildah commit working-container localhost/myhttpd:latest
```

Verification

1. List all images in local storage:
2. Run the `localhost/myhttpd` image and configure port mappings between the container and the host system:

   ```bash
   # podman run -p 8080:80 -d --name myhttpd 08da72792f60
   ```

3. Test the web server:

   ```bash
   # curl localhost:8080
   Your httpd container from scratch works!
   ```

Additional resources

- `buildah-config` man page
- `buildah-commit` man page

13.10. PUSHING CONTAINERS TO A PRIVATE REGISTRY

Use `buildah push` command to push an image from local storage to a public or private repository.

Prerequisites

- An image was built using instructions from Containerfile. For details, see section Building an image from a Containerfile with Buildah.

Procedure

1. Create the local registry on your machine:

   ```bash
   # podman run -d -p 5000:5000 registry:2
   ```

2. Push the `myecho:latest` image to the `localhost` registry:

   ```bash
   # buildah push --tls-verify=false myecho:latest localhost:5000/myecho:latest
   Getting image source signatures
   Copying blob sha256:e4efd0...
   ...
   Writing manifest to image destination
   Storing signatures
   ```

Verification

1. List all images in the `localhost` repository:

   ```bash
   # curl http://localhost:5000/v2/_catalog
   {"repositories":["myecho2"]}
   ```
# curl http://localhost:5000/v2/myecho2/tags/list
{"name":"myecho","tags":["latest"]}

2. Inspect the docker://localhost:5000/myecho:latest image:

```
# skopeo inspect --tls-verify=false docker://localhost:5000/myecho:latest | less
{
  "Name": "localhost:5000/myecho",
  "Digest": "sha256:8999ff6050...",
  "RepoTags": [
    "latest"
  ],
  "Created": "2021-06-28T14:44:05.919583964Z",
  "DockerVersion": "",
  "Labels": {
    "architecture": "x86_64",
    "authoritative-source-url": "registry.redhat.io",
    ...
  }
}
```

3. Pull the localhost:5000/myecho image:

```
# podman pull --tls-verify=false localhost:5000/myecho2
# podman run localhost:5000/myecho2
This container works!
```

Additional resources

- buildah-push man page

### 13.11. PUSHING CONTAINERS TO THE DOCKER HUB

Use your Docker Hub credentials to push and pull images from the Docker Hub with the buildah command.

**Prerequisites**

- An image built using instructions from Containerfile. For details, see section Building an image from a Containerfile with Buildah.

**Procedure**

1. Push the docker.io/library/myecho:latest to your Docker Hub. Replace username and password with your Docker Hub credentials:

```
# buildah push --creds username:password \
    docker.io/library/myecho:latest docker://testaccountXX/myecho:latest
```

**Verification**

- Get and run the docker.io/testaccountXX/myecho:latest image:
Using Podman tool:

```bash
# podman run docker.io/testaccountXX/myecho:latest
This container works!
```

Using Buildah and Podman tools:

```bash
# buildah from docker.io/testaccountXX/myecho:latest
myecho2-working-container-2
# podman run myecho-working-container-2
```

Additional resources

- `buildah-push` man page

### 13.12. REMOVING IMAGES WITH BUILDHAH

Use the `buildah rmi` command to remove locally stored container images. You can remove an image by its ID or name.

#### Procedure

1. List all images on your local system:

   ```bash
   # buildah images
   REPOSITORY                              TAG      IMAGE ID       CREATED          SIZE
   localhost/johndoe/webserver latest       dc5fccc610313 46 minutes ago  263 MB
   docker.io/library/mynewecho latest       fa2091a7d8b6 17 hours ago     234 MB
   docker.io/library/myecho2 latest         4547d2c3e436 6 days ago       234 MB
   localhost/myecho latest b28cd00741b3 6 days ago 234 MB
   localhost/ubi-micro-httpd latest c6a7678c4139 12 days ago 152 MB
   registry.access.redhat.com/ubi8/ubi latest 272209ff0ae5 3 weeks ago 234 MB
   ```

2. Remove the `localhost/myecho` image:

   ```bash
   # buildah rmi localhost/myecho
   ```

   - To remove multiple images:
     ```bash
     # buildah rmi docker.io/library/mynewecho docker.io/library/myecho2
     ```

   - To remove all images from your system:
     ```bash
     # buildah rmi -a
     ```

   - To remove images that have multiple names (tags) associated with them, add the `-f` option to remove them:
     ```bash
     # buildah rmi -f localhost/ubi-micro-httpd
     ```

#### Verification
• Ensure that images were removed:
  
  `# buildah images`

Additional resources

• `buildah-rmi` man page

13.13. REMOVING CONTAINERS WITH BUILDAH

Use the `buildah rm` command to remove containers. You can specify containers for removal with the container ID or name.

Prerequisites

• At least one container has been stopped.

Procedure

1. List all containers:

   `# buildah containers`

<table>
<thead>
<tr>
<th>CONTAINER ID</th>
<th>BUILDER</th>
<th>IMAGE ID</th>
<th>IMAGE NAME</th>
<th>CONTAINER NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>05387e29ab93</td>
<td>*</td>
<td>c37e14066ac7</td>
<td>docker.io/library/myecho:latest</td>
<td>myecho-working-container</td>
</tr>
</tbody>
</table>

2. Remove the myecho-working-container container:

   `# buildah rm myecho-working-container`

   05387e29ab93151cf52e9c85c573f3e8ab64af1592b1f9315db8a10a77d7c22

Verification

• Ensure that containers were removed:

  `# buildah containers`

Additional resources

• `buildah-rm` man page
CHAPTER 14. MONITORING CONTAINERS

This chapter focuses on useful Podman commands that allow you to manage a Podman environment, including determining the health of the container, displaying system and pod information, and monitoring Podman events.

14.1. PERFORMING A HEALTHCHECK ON A CONTAINER

The healthcheck allows you to determine the health or readiness of the process running inside the container. A healthcheck consists of five basic components:

- **Command**
  Podman executes the command inside the target container and waits for the exit code.

- **Retries**
  Defines the number of consecutive failed healthchecks that need to occur before the container is marked as "unhealthy". A successful healthcheck resets the retry counter.

- **Interval**
  Describes the time between running the healthcheck command. Note that small intervals cause your system to spend a lot of time running healthchecks. The large intervals cause struggles with catching time outs.

- **Start-period**
  Describes the time between when the container starts and when you want to ignore healthcheck failures.

- **Timeout**
  Describes the period of time the healthcheck must complete before being considered unsuccessful.

Healthchecks run inside the container. Healthcheck only make sense if you know what is a health state of the service and can differentiate between a successful and unsuccessful health check.

**Procedure**

1. Define a healthcheck:

   ```bash
   $ podman run -dt --name hc1 -p 8080:8080 --health-cmd='curl http://localhost:8080 || exit 1' --health-interval=0 registry.access.redhat.com/ubi8/httpd-24
   ```

   - The **--health-cmd** option sets a healthcheck command for the container.
The `-health-interval=0` option with 0 value indicates that you want to run healthcheck manually.

2. Run the healthcheck manually:

   ```
   $ podman healthcheck run hc1
   Healthy
   ```

3. Optionally, you can check the exit status of last command:

   ```
   $ echo $?
   0
   ```

   The "0" value means success.

Additional resources

- `man podman-run`
- Monitoring container vitality and availability with Podman article

14.2. DISPLAYING PODMAN SYSTEM INFORMATION

The `podman system` command allows you to manage the Podman systems. This section provides information on how to display Podman system information.

Procedure

- Display Podman system information:
  - To show Podman disk usage, enter:

    ```
    $ podman system df
    TYPE           TOTAL       ACTIVE      SIZE        RECLAIMABLE
    Images         3           2           1.085GB     233.4MB (0%)
    Containers     2           0           28.17kB     28.17kB (100%)
    Local Volumes  3           0           0B          0B (0%)
    ```

  - To show detailed information on space usage, enter:

    ```
    $ podman system df -v
    Images space usage:
    REPOSITORY                                TAG         IMAGE ID      CREATED     SIZE
    registry.access.redhat.com/ubi8           latest      b1e63aaae5cf  13 days     233.4MB
    233.4MB      0B           0
    registry.access.redhat.com/ubi8/httpd-24  latest      0d04740850e8  13 days     461.5MB
    0B           461.5MB      1
    registry.redhat.io/rhel8/podman           latest      dce10f591a2d  13 days     390.6MB
    233.4MB     157.2MB      1
    Containers space usage:
    ```
To display information about the host, current storage stats, and build of Podman, enter:

```
$ podman system info

- To remove all unused containers, images and volume data, enter:

  $ podman system prune

  WARNING! This will remove:
  - all stopped containers
  - all stopped pods
  - all dangling images
  - all build cache

  Are you sure you want to continue? [y/N] y

- The podman system prune command removes all unused containers (both dangling and unreferenced), pods and optionally, volumes from local storage.

- Use the --all option to delete all unused images. Unused images are dangling images and any image that does not have any containers based on it.

- Use the --volume option to prune volumes. By default, volumes are not removed to prevent important data from being deleted if there is currently no container using the volume.

Additional resources

- man podman-system-df
- man podman-system-info
- man podman-system-prune

14.3. PODMAN EVENT TYPES

You can monitor events that occur in Podman. Several event types exist and each event type reports different statuses.

The container event type reports the following statuses:
• attach
• checkpoint
• cleanup
• commit
• create
• exec
• export
• import
• init
• kill
• mount
• pause
• prune
• remove
• restart
• restore
• start
• stop
• sync
• unmount
• unpause

The pod event type reports the following statuses:

• create
• kill
• pause
• remove
• start
• stop
• unpause
The *image* event type reports the following statuses:

- prune
- push
- pull
- save
- remove
- tag
- untag

The *system* type reports the following statuses:

- refresh
- renumber

The *volume* type reports the following statuses:

- create
- prune
- remove

Additional resources

- *man podman-events*

### 14.4. MONITORING PODMAN EVENTS

You can monitor and print events that occur in Podman. Each event will include a timestamp, a type, a status, name (if applicable), and image (if applicable).

**Procedure**

- Show Podman events:
  - To show all Podman events, enter:

    ```bash
    $ podman events
    2020-05-14 10:33:42.312377447 -0600 CST container create 34503c192940 (image=registry.access.redhat.com/ubi8/ubi:latest, name=keen_colden)
    2020-05-14 10:33:46.958768077 -0600 CST container init 34503c192940 (image=registry.access.redhat.com/ubi8/ubi:latest, name=keen_colden)
    2020-05-14 10:33:46.973661968 -0600 CST container start 34503c192940 (image=registry.access.redhat.com/ubi8/ubi:latest, name=keen_colden)
    2020-05-14 10:33:50.833761479 -0600 CST container stop 34503c192940 (image=registry.access.redhat.com/ubi8/ubi:latest, name=keen_colden)
    2020-05-14 10:33:51.047104966 -0600 CST container cleanup 34503c192940 (image=registry.access.redhat.com/ubi8/ubi:latest, name=keen_colden)
    ```
To exit logging, press CTRL+c.

- To show only Podman create events, enter:

```bash
$ podman events --filter event=create
2020-05-14 10:36:01.375685062 -0600 CST container create 20dc581f6fbf
(image=registry.access.redhat.com/ubi8/ubi:latest)
2019-03-02 10:36:08.561188337 -0600 CST container create 58e7e002344c
(image=registry.access.redhat.com/ubi8/ubi-minimal:latest)
2019-03-02 10:36:29.978806894 -0600 CST container create d81e30f1310f
(image=registry.access.redhat.com/ubi8/ubi-init:latest)
```

CHAPTER 15. USING THE CONTAINER-TOOLS API

The new REST based Podman 2.0 API replaces the old remote API for Podman that used the varlink library. The new API works in both a rootful and a rootless environment.

The Podman v2.0 RESTful API consists of the Libpod API providing support for Podman, and Docker-compatible API. With this new REST API, you can call Podman from platforms such as cURL, Postman, Google’s Advanced REST client, and many others.

15.1. ENABLING THE PODMAN API USING SYSTEMD IN ROOT MODE

This procedure shows how to do the following:

1. Use systemd to activate the Podman API socket.
2. Use a Podman client to perform basic commands.

Prerequisites

- The `podman-remote` package is installed.

    # dnf install podman-remote

Procedure

1. Start the service immediately:

    # systemctl enable --now podman.socket

2. To enable the link to `var/lib/docker.sock` using the `docker-podman` package:

    # dnf install podman-docker

Verification steps

1. Display system information of Podman:

    # podman-remote info

2. Verify the link:

    # ls -al /var/run/docker.sock
    lrwxrwxrwx. 1 root root 23 Nov  4 10:19 /var/run/docker.sock -> /run/podman/podman.sock

15.2. ENABLING THE PODMAN API USING SYSTEMD IN ROOTLESS MODE

This procedure shows how to use systemd to activate the Podman API socket and podman API service.

Prerequisites

- The `podman-remote` package is installed.

  ```bash
  # dnf install podman-remote
  ```

Procedure

1. Enable and start the service immediately:

   ```bash
   $ systemctl --user enable --now podman.socket
   ```

2. Optional. To enable programs using Docker to interact with the rootless Podman socket:

   ```bash
   $ export DOCKER_HOST=unix:///run/user/<uid>/podman/podman.sock
   ```

Verification steps

1. Check the status of the socket:

   ```bash
   $ systemctl --user status podman.socket
   ● podman.socket - Podman API Socket
   Loaded: loaded (/usr/lib/systemd/user/podman.socket; enabled; vendor preset: enabled)
   Active: active (listening) since Mon 2021-08-23 10:37:25 CEST; 9min ago
   Docs: man:podman-system-service(1)
   Listen: /run/user/1000/podman/podman.sock (Stream)
   CGroup: /user.slice/user-1000.slice/user@1000.service/podman.socket
   ```

   The `podman.socket` is active and is listening at `/run/user/<uid>/podman.podman.sock`, where `<uid>` is the user’s ID.

2. Display system information of Podman:

   ```bash
   $ podman-remote info
   ```

15.3. RUNNING THE PODMAN API MANUALLY

This procedure describes how to run the Podman API. This is useful for debugging API calls, especially...
This procedure describes how to run the Podman API. This is useful for debugging API calls, especially when using the Docker compatibility layer.

**Prerequisites**

- The `podman-remote` package is installed.

```
# dnf install podman-remote
```

**Procedure**

1. Run the service for the REST API:

```
# podman system service -t 0 --log-level=debug
```

   - The value of 0 means no timeout. The default endpoint for a rootful service is `unix:/run/podman/podman.sock`.

   - The `--log-level <level>` option sets the logging level. The standard logging levels are `debug`, `info`, `warn`, `error`, `fatal`, and `panic`.

2. In another terminal, display system information of Podman. The `podman-remote` command, unlike the regular `podman` command, communicates through the Podman socket:

```
# podman-remote info
```

3. To troubleshoot the Podman API and display request and responses, use the `curl` command. To get the information about the Podman installation on the Linux server in JSON format:

```
# curl -s --unix-socket /run/podman/podman.sock http://d/v1.0.0/libpod/info | jq
```

   ```json
   {  
   "host": {  
   "arch": "amd64",  
   "buildahVersion": "1.15.0",  
   "cgroupVersion": "v1",  
   "conmon": {  
   "package": "conmon-2.0.18-1.module+el8.3.0+7084+c16098dd.x86_64",  
   "path": "/usr/bin/conmon",  
   "version": "conmon version 2.0.18, commit: 7fd3f71a21f8d3a7202e464252aeb1e942d17eb"  
   },  
   ...  
   "version": {  
   "APIVersion": 1,  
   "Version": "2.0.0",  
   "GoVersion": "go1.14.2",  
   "GitCommit": "",  
   "BuiltTime": "Thu Jan  1 01:00:00 1970",  
   "Built": 0,  
   "OsArch": "linux/amd64"  
   }
   }
   ```

A `jq` utility is a command-line JSON processor.
4. Pull the `registry.access.redhat.com/ubi8/ubi` container image:

```bash
# curl -X POST --unix-socket /run/podman/podman.sock -v 'http://d/v1.0.0/images/create?
fromImage=registry.access.redhat.com%2Fubi8%2Fubi'
* Trying /run/podman/podman.sock...
* Connected to d (/run/podman/podman.sock) port 80 (#0)
> POST /v1.0.0/images/create?fromImage=registry.access.redhat.com%2Fubi8%2Fubi
HTTP/1.1
> Host: d
> User-Agent: curl/7.61.1
> Accept: /
> HTTP/1.1 200 OK
< Content-Type: application/json
< Date: Tue, 20 Oct 2020 13:58:37 GMT
< Content-Length: 231
< {"status":"pulling image () from registry.access.redhat.com/ubi8/ubi:latest,
registry.redhat.io/ubi8/ubi:latest","error":null,"progress":null,"progressDetail":null},
"id":"ecbc6f53bba0d1923ca9e92b3f747da8353a070fccbae93625bd8b47dbee772e"
* Connection #0 to host d left intact
```

5. Display the pulled image:

```bash
# curl --unix-socket /run/podman/podman.sock -v 'http://d/v1.0.0/libpod/images/json' | jq
* Trying /run/podman/podman.sock...
* Connected to d (/run/podman/podman.sock) port 80 (0)
> GET /v1.0.0/libpod/images/json HTTP/1.1
> Host: d
> User-Agent: curl/7.61.1
> Accept: */*
> HTTP/1.1 200 OK
< Content-Type: application/json
< Date: Tue, 20 Oct 2020 13:59:55 GMT
< Transfer-Encoding: chunked
< 
< 100 12485 0 12485 0 2032k 0 --:--:-- --:--:-- --:--:-- 2438k
* Connection #0 to host d left intact
```
