Automating system administration by using RHEL System Roles

Consistent and repeatable configuration of RHEL deployments across multiple hosts with Red Hat Ansible Automation Platform playbooks
Red Hat Enterprise Linux 9 Automating system administration by using RHEL System Roles

Consistent and repeatable configuration of RHEL deployments across multiple hosts with Red Hat Ansible Automation Platform playbooks
Abstract

The Red Hat Enterprise Linux (RHEL) System Roles are a collection of Ansible roles, modules, and playbooks that help automate the consistent and repeatable administration of RHEL systems. With RHEL System Roles, you can efficiently manage large inventories of systems by running configuration playbooks from a single system.

  7.10. CONFIGURING INSIGHTS TAGS BY USING THE RHC SYSTEM ROLE .......... 43
  7.11. UNREGISTERING A SYSTEM BY USING THE RHC SYSTEM ROLE ................ 45

CHAPTER 8. CONFIGURING NETWORK SETTINGS BY USING RHEL SYSTEM ROLES ........... 46
  8.1. CONFIGURING AN ETHERNET CONNECTION WITH A STATIC IP ADDRESS BY USING THE NETWORK RHEL SYSTEM ROLE WITH AN INTERFACE NAME 46
  8.2. CONFIGURING AN ETHERNET CONNECTION WITH A STATIC IP ADDRESS BY USING THE NETWORK RHEL SYSTEM ROLE WITH A DEVICE PATH 47
8.3. CONFIGURING AN ETHERNET CONNECTION WITH A DYNAMIC IP ADDRESS BY USING THE NETWORK RHEL SYSTEM ROLE WITH AN INTERFACE NAME 49
8.4. CONFIGURING AN ETHERNET CONNECTION WITH A DYNAMIC IP ADDRESS BY USING THE NETWORK RHEL SYSTEM ROLE WITH A DEVICE PATH 50
8.5. CONFIGURING VLAN TAGGING BY USING THE NETWORK RHEL SYSTEM ROLE 52
8.6. CONFIGURING A NETWORK BRIDGE BY USING THE NETWORK RHEL SYSTEM ROLE 54
8.7. CONFIGURING A NETWORK BOND BY USING THE NETWORK RHEL SYSTEM ROLE 56
8.8. CONFIGURING AN IPOIB CONNECTION BY USING THE NETWORK RHEL SYSTEM ROLE 58
8.9. ROUTING TRAFFIC FROM A SPECIFIC SUBNET TO A DIFFERENT DEFAULT GATEWAY BY USING THE NETWORK RHEL SYSTEM ROLE 59
8.10. CONFIGURING A STATIC ETHERNET CONNECTION WITH 802.1X NETWORK AUTHENTICATION BY USING THE NETWORK RHEL SYSTEM ROLE 64
8.11. CONFIGURING A WIFI CONNECTION WITH 802.1X NETWORK AUTHENTICATION BY USING THE NETWORK RHEL SYSTEM ROLE 66
8.12. SETTING THE DEFAULT GATEWAY ON AN EXISTING CONNECTION BY USING THE NETWORK RHEL SYSTEM ROLE 68
8.13. CONFIGURING A STATIC ROUTE BY USING THE NETWORK RHEL SYSTEM ROLE 69
8.14. CONFIGURING AN ETHTOOL OFFLOAD FEATURE BY USING THE NETWORK RHEL SYSTEM ROLE 71
8.15. CONFIGURING AN ETHTOOL COALESCE SETTINGS BY USING THE NETWORK RHEL SYSTEM ROLE 73
8.16. INCREASING THE RING BUFFER SIZE TO REDUCE A HIGH PACKET DROP RATE BY USING THE NETWORK RHEL SYSTEM ROLE 75
8.17. NETWORK STATES FOR THE NETWORK RHEL SYSTEM ROLE 77

CHAPTER 9. CONFIGURING FIREWALLD BY USING RHEL SYSTEM ROLES ........................................ 79
9.1. INTRODUCTION TO THE FIREWALL RHEL SYSTEM ROLE 79
9.2. RESETTING THE FIREWALLD SETTINGS BY USING A RHEL SYSTEM ROLE 79
9.3. FORWARDING INCOMING TRAFFIC IN FIREWALLD FROM ONE LOCAL PORT TO A DIFFERENT LOCAL PORT BY USING A RHEL SYSTEM ROLE 81
9.4. MANAGING PORTS IN FIREWALLD BY USING A RHEL SYSTEM ROLE 82
9.5. CONFIGURING A FIREWALLD DMZ ZONE BY USING A RHEL SYSTEM ROLE 83

CHAPTER 10. CONFIGURING POSTFIX MTA BY USING RHEL SYSTEM ROLES .............................. 85
10.1. USING THE POSTFIX SYSTEM ROLE TO AUTOMATE BASIC POSTFIX MTA ADMINISTRATION 85
10.2. SELECTED VARIABLES FOR THE POSTFIX RHEL SYSTEM ROLE 86

CHAPTER 11. CONFIGURING SELINUX BY USING SYSTEM ROLES ............................................. 88
11.1. INTRODUCTION TO THE SELINUX SYSTEM ROLE 88
11.2. USING THE SELINUX SYSTEM ROLE TO APPLY SELINUX SETTINGS ON MULTIPLE SYSTEMS 89
11.3. MANAGING PORTS BY USING THE SELINUX RHEL SYSTEM ROLE 90

CHAPTER 12. MANAGING SYSTEMD UNITS BY USING THE SYSTEMD RHEL SYSTEM ROLE .......... 92
12.1. VARIABLES FOR THE SYSTEMD RHEL SYSTEM ROLE 92
12.2. DEPLOYING AND STARTING A SYSTEMD UNIT BY USING THE SYSTEMD SYSTEM ROLE 93
12.3. ADDITIONAL RESOURCES 93

CHAPTER 13. CONFIGURING LOGGING BY USING RHEL SYSTEM ROLES ..................................... 94
13.1. THE LOGGING SYSTEM ROLE 94
13.2. LOGGING SYSTEM ROLE PARAMETERS 94
13.3. APPLYING A LOCAL LOGGING SYSTEM ROLE 95
13.4. FILTERING LOGS IN A LOCAL LOGGING SYSTEM ROLE 97
13.5. APPLYING A REMOTE LOGGING SOLUTION USING THE LOGGING SYSTEM ROLE 99
13.6. USING THE LOGGING SYSTEM ROLE WITH TLS 101
   13.6.1. Configuring client logging with TLS 101
   13.6.2. Configuring server logging with TLS 104
13.7. USING THE LOGGING SYSTEM ROLES WITH RELP
13.7.1. Configuring client logging with RELP
13.7.2. Configuring server logging with RELP
13.8. ADDITIONAL RESOURCES

CHAPTER 14. CONFIGURING THE SYSTEMD JOURNAL BY USING THE JOURNALD RHEL SYSTEM ROLE
14.1. VARIABLES FOR THE JOURNALD RHEL SYSTEM ROLE
14.2. CONFIGURING PERSISTENT LOGGING BY USING THE JOURNALD SYSTEM ROLE
14.3. ADDITIONAL RESOURCES

CHAPTER 15. CONFIGURING SECURE COMMUNICATION BY USING THE SSH AND SSHD RHEL SYSTEM ROLES
15.1. SSH SERVER SYSTEM ROLE VARIABLES
15.2. CONFIGURING OPENSSH SERVERS USING THE SSHD SYSTEM ROLE
15.3. SSH SYSTEM ROLE VARIABLES
15.4. CONFIGURING OPENSSH CLIENTS USING THE SSH SYSTEM ROLE
15.5. USING THE SSHD SYSTEM ROLE FOR NON-EXCLUSIVE CONFIGURATION
15.6. OVERRIDING THE SYSTEM-WIDE CRYPTOGRAPHIC POLICY ON AN SSH SERVER BY USING SYSTEM ROLES

CHAPTER 16. CONFIGURING VPN CONNECTIONS WITH IPSEC BY USING THE VPN RHEL SYSTEM ROLE
16.1. CREATING A HOST-TO-HOST VPN WITH IPSEC USING THE VPN SYSTEM ROLE
16.2. CREATING AN OPPORTUNISTIC MESH VPN CONNECTION WITH IPSEC BY USING THE VPN SYSTEM ROLE
16.3. ADDITIONAL RESOURCES

CHAPTER 17. SETTING A CUSTOM CRYPTOGRAPHIC POLICY BY USING THE CRYPTO-POLICIES RHEL SYSTEM ROLE
17.1. CRYPTO_POLICIES SYSTEM ROLE VARIABLES AND FACTS
17.2. SETTING A CUSTOM CRYPTOGRAPHIC POLICY USING THE CRYPTO_POLICIES SYSTEM ROLE
17.3. ADDITIONAL RESOURCES

CHAPTER 18. CONFIGURING NBDE BY USING RHEL SYSTEM ROLES
18.1. INTRODUCTION TO THE NBDE_CLIENT AND NBDE_SERVER SYSTEM ROLES (CLEVIS AND TANG)
18.2. USING THE NBDE_SERVER SYSTEM ROLE FOR SETTING UP MULTIPLE TANG SERVERS
18.3. SETTING UP MULTIPLE CLEVIS CLIENTS BY USING THE NBDE_CLIENT RHEL SYSTEM ROLE

CHAPTER 19. REQUESTING CERTIFICATES USING RHEL SYSTEM ROLES
19.1. THE CERTIFICATE SYSTEM ROLE
19.2. REQUESTING A NEW SELF-SIGNED CERTIFICATE USING THE CERTIFICATE SYSTEM ROLE
19.3. REQUESTING A NEW CERTIFICATE FROM IDM CA USING THE CERTIFICATE SYSTEM ROLE
19.4. SPECIFYING COMMANDS TO RUN BEFORE OR AFTER CERTIFICATE ISSUANCE USING THE CERTIFICATE SYSTEM ROLE

CHAPTER 20. CONFIGURING AUTOMATIC CRASH DUMPS BY USING THE KDUMP RHEL SYSTEM ROLE
20.1. THE KDUMP RHEL SYSTEM ROLE
20.2. KDUMP ROLE PARAMETERS
20.3. CONFIGURING KDUMP USING RHEL SYSTEM ROLES

CHAPTER 21. MANAGING LOCAL STORAGE USING RHEL SYSTEM ROLES
21.1. INTRODUCTION TO THE STORAGE RHEL SYSTEM ROLE
21.2. PARAMETERS THAT IDENTIFY A STORAGE DEVICE IN THE STORAGE RHEL SYSTEM ROLE
21.3. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AN XFS FILE SYSTEM ON A BLOCK DEVICE
21.4. EXAMPLE ANSIBLE PLAYBOOK TO PERSISTENTLY MOUNT A FILE SYSTEM
21.5. EXAMPLE ANSIBLE PLAYBOOK TO MANAGE LOGICAL VOLUMES
21.6. EXAMPLE ANSIBLE PLAYBOOK TO ENABLE ONLINE BLOCK DISCARD
21.7. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AND MOUNT AN EXT4 FILE SYSTEM
21.8. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AND MOUNT AN EXT3 FILE SYSTEM
21.9. EXAMPLE ANSIBLE PLAYBOOK TO RESIZE AN EXISTING FILE SYSTEM ON LVM USING THE STORAGE RHEL SYSTEM ROLE
21.10. EXAMPLE ANSIBLE PLAYBOOK TO CREATE A SWAP VOLUME USING THE STORAGE RHEL SYSTEM ROLE
21.11. CONFIGURING A RAID VOLUME USING THE STORAGE SYSTEM ROLE
21.12. CONFIGURING AN LVM POOL WITH RAID USING THE STORAGE RHEL SYSTEM ROLE
21.13. CONFIGURING A STRIPE SIZE FOR RAID LVM VOLUMES USING THE STORAGE RHEL SYSTEM ROLE
21.14. EXAMPLE ANSIBLE PLAYBOOK TO COMPRESS AND DEDUPLICATE A VDO VOLUME ON LVM USING THE STORAGE RHEL SYSTEM ROLE
21.15. CREATING A LUKS2 ENCRYPTED VOLUME USING THE STORAGE RHEL SYSTEM ROLE
21.16. EXAMPLE ANSIBLE PLAYBOOK TO EXPRESS POOL VOLUME SIZES AS PERCENTAGE USING THE STORAGE RHEL SYSTEM ROLE
21.17. ADDITIONAL RESOURCES

CHAPTER 22. CONFIGURING TIME SYNCHRONIZATION BY USING THE TIMESYNC RHEL SYSTEM ROLE
22.1. THE TIMESYNC RHEL SYSTEM ROLE
22.2. APPLYING THE TIMESYNC SYSTEM ROLE FOR A SINGLE POOL OF SERVERS
22.3. APPLYING THE TIMESYNC SYSTEM ROLE ON CLIENT SERVERS
22.4. TIMESYNC SYSTEM ROLES VARIABLES

CHAPTER 23. MONITORING PERFORMANCE BY USING THE METRICS RHEL SYSTEM ROLE
23.1. INTRODUCTION TO THE METRICS SYSTEM ROLE
23.2. USING THE METRICS SYSTEM ROLE TO MONITOR YOUR LOCAL SYSTEM WITH VISUALIZATION
23.3. USING THE METRICS SYSTEM ROLE TO SET UP A FLEET OF INDIVIDUAL SYSTEMS TO MONITOR THEMSELVES
23.4. USING THE METRICS SYSTEM ROLE TO MONITOR A FLEET OF MACHINES CENTRALLY VIA YOUR LOCAL MACHINE
23.5. SETTING UP AUTHENTICATION WHILE MONITORING A SYSTEM USING THE METRICS SYSTEM ROLE
23.6. USING THE METRICS SYSTEM ROLE TO CONFIGURE AND ENABLE METRICS COLLECTION FOR SQL SERVER

CHAPTER 24. CONFIGURING A SYSTEM FOR SESSION RECORDING USING THE TLOG RHEL SYSTEM ROLE
24.1. THE TLOG SYSTEM ROLE
24.2. COMPONENTS AND PARAMETERS OF THE TLOG SYSTEM ROLE
24.3. DEPLOYING THE TLOG RHEL SYSTEM ROLE
24.4. DEPLOYING THE TLOG RHEL SYSTEM ROLE FOR EXCLUDING LISTS OF GROUPS OR USERS
24.5. RECORDING A SESSION USING THE DEPLOYED TLOG SYSTEM ROLE IN THE CLI
24.6. WATCHING A RECORDED SESSION USING THE CLI

CHAPTER 25. CONFIGURING A HIGH-AVAILABILITY CLUSTER BY USING THE HA_CLUSTER RHEL SYSTEM ROLE
25.1. HA_CLUSTER SYSTEM ROLE VARIABLES
25.2. SPECIFYING AN INVENTORY FOR THE HA_CLUSTER SYSTEM ROLE
25.2.1. Configuring node names and addresses in an inventory
25.2.2. Configuring watchdog and SBD devices in an inventory
25.3. CREATING PCSD TLS CERTIFICATES AND KEY FILES FOR A HIGH AVAILABILITY CLUSTER (RHEL 9.2 AND LATER)

CHAPTER 22. CONFIGURING TIME SYNCHRONIZATION BY USING THE TIMESYNC RHEL SYSTEM ROLE

CHAPTER 23. MONITORING PERFORMANCE BY USING THE METRICS RHEL SYSTEM ROLE

CHAPTER 24. CONFIGURING A SYSTEM FOR SESSION RECORDING USING THE TLOG RHEL SYSTEM ROLE

CHAPTER 25. CONFIGURING A HIGH-AVAILABILITY CLUSTER BY USING THE HA_CLUSTER RHEL SYSTEM ROLE
MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your feedback on our documentation. Let us know how we can improve it.

Submitting feedback through Jira (account required)

1. Log in to the Jira website.

2. Click Create in the top navigation bar

3. Enter a descriptive title in the Summary field.

4. Enter your suggestion for improvement in the Description field. Include links to the relevant parts of the documentation.

5. Click Create at the bottom of the dialogue.
RHEL System Roles is a collection of Ansible roles and modules. By using RHEL System Roles, you can remotely manage the system configurations of multiple RHEL systems across major versions of RHEL. To use it to configure systems, you must use the following components:

**Control node**
A control node is the system from which you run Ansible commands and playbooks. Your control node can be an Ansible Automation Platform, Red Hat Satellite, or a RHEL 9, 8, or 7 host. For more information, see [Preparing a control node on RHEL 9](#).

**Managed node**
Managed nodes are the servers and network devices that you manage with Ansible. Managed nodes are also sometimes called hosts. Ansible does not have to be installed on managed nodes. For more information, see [Preparing a managed node](#).

**Ansible playbook**
In a playbook, you define the configuration you want to achieve on your managed nodes or a set of steps for the system on the managed node to perform. Playbooks are Ansible’s configuration, deployment, and orchestration language.

**Inventory**
In an inventory file, you list the managed nodes and specify information such as IP address for each managed node. In the inventory, you can also organize the managed nodes by creating and nesting groups for easier scaling. An inventory file is also sometimes called a hostfile.

On Red Hat Enterprise Linux 9, you can use the following roles provided by the `rhel-system-roles` package, which is available in the AppStream repository:

Additional resources

- Red Hat Enterprise Linux (RHEL) System Roles
- `/usr/share/doc/rhel-system-roles/` provided by the `rhel-system-roles` package
CHAPTER 2. PREPARING A CONTROL NODE AND MANAGED NODES TO USE RHEL SYSTEM ROLES

Before you can use individual RHEL System Roles to manage services and settings, you must prepare the control node and managed nodes.

2.1. PREPARING A CONTROL NODE ON RHEL 9

Before using RHEL System Roles, you must configure a control node. This system then configures the managed hosts from the inventory according to the playbooks.

Prerequisites

- The system is registered to the Customer Portal.
- A Red Hat Enterprise Linux Server subscription is attached to the system.
- Optional: An Ansible Automation Platform subscription is attached to the system.

Procedure

1. Install the `rhel-system-roles` package:

   ```bash
   [root@control-node]# dnf install rhel-system-roles
   ```
   
   This command installs the `ansible-core` package as a dependency.

2. Create a user named `ansible` to manage and run playbooks:

   ```bash
   [root@control-node]# useradd ansible
   ```

3. Switch to the newly created `ansible` user:

   ```bash
   [root@control-node]# su - ansible
   ```
   
   Perform the rest of the procedure as this user.

4. Create an SSH public and private key:

   ```bash
   [ansible@control-node]$ ssh-keygen
   Generating public/private rsa key pair.
   Enter file in which to save the key (/home/ansible/.ssh/id_rsa):
   Enter passphrase (empty for no passphrase): <password>
   Enter same passphrase again: <password>
   ... 
   ```
   
   Use the suggested default location for the key file.

5. Optional: To prevent Ansible from prompting you for the SSH key password each time you establish a connection, configure an SSH agent.

6. Create the `~/.ansible.cfg` file with the following content:
inventory = /home/ansible/inventory
remote_user = ansible

[privilege_escalation]
become = True
become_method = sudo
become_user = root
become_ask_pass = True

NOTE
Settings in the ~/.ansible.cfg file have a higher priority and override settings from the global /etc/ansible/ansible.cfg file.

With these settings, Ansible performs the following actions:

- Manages hosts in the specified inventory file.
- Uses the account set in the remote_user parameter when it establishes SSH connections to managed nodes.
- Uses the sudo utility to execute tasks on managed nodes as the root user.
- Prompts for the root password of the remote user every time you apply a playbook. This is recommended for security reasons.

7. Create an ~/inventory file in INI or YAML format that lists the hostnames of managed hosts. You can also define groups of hosts in the inventory file. For example, the following is an inventory file in the INI format with three hosts and one host group named US:

managed-node-01.example.com

[US]
managed-node-02.example.com ansible_host=192.0.2.100
managed-node-03.example.com

Note that the control node must be able to resolve the hostnames. If the DNS server cannot resolve certain hostnames, add the ansible_host parameter next to the host entry to specify its IP address.

Next steps

- Prepare the managed nodes. For more information, see Preparing a managed node.

Additional resources

- Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories
- How to register and subscribe a system to the Red Hat Customer Portal using subscription-manager
- The ssh-keygen(1) man page
2.2. PREPARING A MANAGED NODE

Managed nodes are the systems listed in the inventory and which will be configured by the control node according to the playbook. You do not have to install Ansible on managed hosts.

Prerequisites

- You prepared the control node. For more information, see Preparing a control node on RHEL 9.
- You have SSH access from the control node.

**IMPORTANT**

Direct SSH access as the root user is a security risk. To reduce this risk, you will create a local user on this node and configure a sudo policy when preparing a managed node. Ansible on the control node can then use the local user account to log in to the managed node and run playbooks as different users, such as root.

Procedure

1. Create a user named ansible:

   ```
   [root@managed-node-01]# useradd ansible
   The control node later uses this user to establish an SSH connection to this host.
   ```

2. Set a password for the ansible user:

   ```
   [root@managed-node-01]# passwd ansible
   Changing password for user ansible.
   New password: <password>
   Retype new password: <password>
   passwd: all authentication tokens updated successfully.
   ```

   You must enter this password when Ansible uses sudo to perform tasks as the root user.

3. Install the ansible user’s SSH public key on the managed node:

   a. Log in to the control node as the ansible user, and copy the SSH public key to the managed node:

   ```
   [ansible@control-node]$ ssh-copy-id managed-node-01.example.com
   /usr/bin/ssh-copy-id: INFO: Source of key(s) to be installed:
   "~/home/ansible/.ssh/id_rsa.pub"
   The authenticity of host ‘managed-node-01.example.com (192.0.2.100)’ can’t be established.
   ECDSA key fingerprint is
   SHA256:9bZ33GJNODK3zbNhybokN/6Mq7hu3vpBXDrCxe7NAvo.
   ```
b. When prompted, connect by entering **yes**:

```
Are you sure you want to continue connecting (yes/no/[fingerprint])? yes
```

```
/usr/bin/ssh-copy-id: INFO: attempting to log in with the new key(s), to filter out any that are already installed
```

```
/usr/bin/ssh-copy-id: INFO: 1 key(s) remain to be installed -- if you are prompted now it is to install the new keys
```

c. When prompted, enter the password:

```
anansible@managed-node-01.example.com's password: <password>
```

```
Number of key(s) added: 1
```

```
Now try logging into the machine, with: "ssh '
```

```
and check to make sure that only the key(s) you wanted were added.
```

d. Verify the SSH connection by remotely executing a command on the control node:

```
[ansible@control-node]$ ssh <managed-node-01.example.com> whoami
ansible
```

4. Create a **sudo** configuration for the **ansible** user:

a. Create and edit the */etc/sudoers.d/ansible* file by using the **visudo** command:

```
[root@managed-node-01]# visudo /etc/sudoers.d/ansible
```

The benefit of using **visudo** over a normal editor is that this utility provides basic sanity checks and checks for parse errors before installing the file.

b. Configure a **sudoers** policy in the */etc/sudoers.d/ansible* file that meets your requirements, for example:

- To grant permissions to the **ansible** user to run all commands as any user and group on this host after entering the **ansible** user’s password, use:

```
ansible ALL=(ALL) ALL
```

- To grant permissions to the **ansible** user to run all commands as any user and group on this host without entering the **ansible** user’s password, use:

```
ansible ALL=(ALL) NOPASSWD: ALL
```

Alternatively, configure a more fine-granular policy that matches your security requirements. For further details on **sudoers** policies, see the **sudoers(5)** man page.

**Verification**

1. Verify that you can execute commands from the control node on an all managed nodes:

```
[ansible@control-node]$ ansible all -m ping
BECOME password: <password>
managed-node-01.example.com | SUCCESS => {
```
"ansible_facts": {
    "discovered_interpreter_python": "/usr/bin/python3"
},
"changed": false,
"ping": "pong"
}
...

The hard-coded all group dynamically contains all hosts listed in the inventory file.

2. Verify that privilege escalation works correctly by running the `whoami` utility on a managed host by using the Ansible `command` module:

```bash
[ansible@control-node]$ ansible managed-node-01.example.com -m command -a whoami
BECOME password: <password>
managed-node-01.example.com | CHANGED | rc=0 >>
root
```

If the command returns root, you configured `sudo` on the managed nodes correctly.

CHAPTER 3. INSTALLING AND USING COLLECTIONS

3.1. INTRODUCTION TO ANSIBLE COLLECTIONS

Ansible Collections are the new way of distributing, maintaining, and consuming automation. By combining multiple types of Ansible content such as playbooks, roles, modules, and plugins, you can benefit from improvements in flexibility and scalability.

The Ansible Collections are an option to the traditional RHEL System Roles format. Using the RHEL System Roles in the Ansible Collection format is almost the same as using it in the traditional RHEL System Roles format. The difference is that Ansible Collections use the concept of a fully qualified collection name (FQCN), which consists of a namespace and the collection name. The namespace we use is redhat and the collection name is rhel_system_roles. So, while the traditional RHEL System Roles format for the kernel_settings role is presented as rhel-system-roles.kernel_settings (with dashes), using the Collection fully qualified collection name for the kernel_settings role would be presented as redhat.rhel_system_roles.kernel_settings (with underscores).

The combination of a namespace and a collection name guarantees that the objects are unique. It also ensures that objects are shared across the Ansible Collections and namespaces without any conflicts.

Additional resources

- To use the Red Hat Certified Collections by accessing the Automation Hub, you must have an Ansible Automation Platform (AAP subscription).

3.2. COLLECTIONS STRUCTURE

Collections are a package format for Ansible content. The data structure is as below:

- docs/: local documentation for the collection, with examples, if the role provides the documentation
- galaxy.yml: source data for the MANIFEST.json that will be part of the Ansible Collection package
- playbooks/: playbooks are available here
  - tasks/: this holds 'task list files' for include_tasks/import_tasks usage
- plugins/: all Ansible plugins and modules are available here, each in its subdirectory
  - modules/: Ansible modules
  - modules_utils/: common code for developing modules
  - lookup/: search for a plugin
  - filter/: Jinja2 filter plugin
  - connection/: connection plugins required if not using the default
- roles/: directory for Ansible roles
- tests/: tests for the collection’s content
3.3. INSTALLING COLLECTIONS BY USING THE CLI

Collections are a distribution format for Ansible content that can include playbooks, roles, modules, and plugins.

You can install Collections through Ansible Galaxy, through the browser, or by using the command line.

Prerequisites

- Access and permissions to one or more managed nodes.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems.
  On the control node:
  - The ansible-core and rhel-system-roles packages are installed.
  - An inventory file which lists the managed nodes.

Procedure

- Install the collection via RPM package:

  ```sh
  # dnf install rhel-system-roles
  ```

  After the installation is finished, the roles are available as redhat.rhel_system_roles. <role_name>. Additionally, you can find the documentation for each role at /usr/share/ansible/collections/ansible_collections/redhat/rhel_system_roles/roles/<role_name>/README.md.

Verification steps

To verify the installation, run the kernel_settings role with check mode on your local host. However, the kernel_settings role does not work with the --check mode. To make it work, ensure to change the service task and the config task in your playbook to be skipped when in the --check mode. You must also use the --become parameter because it is necessary for the Ansible package module. However, the parameter will not change your system.

Enter the following command:

```sh
$ ansible-playbook -c local -i localhost, --check --become /usr/share/ansible/collections/ansible_collections/redhat/rhel_system_roles/tests/kernel_settings/tests_default.yml
```

The last line of the command output should contain the value failed=0.

**NOTE**

The comma after localhost is mandatory. You must add it even if there is only one host on the list. Without it, ansible-playbook would identify localhost as a file or a directory.

Additional resources

- The ansible-playbook man page.
The `-i` option of the `ansible-playbook` command

3.4. INSTALLING COLLECTIONS FROM AUTOMATION HUB

If you are using the Automation Hub, you can install the RHEL System Roles Collection hosted on the Automation Hub.

Prerequisites

- Access and permissions to one or more managed nodes.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems.
  
  On the control node:
  
  - The `ansible-core` and `rhel-system-roles` packages are installed.
  - An inventory file which lists the managed nodes.

Procedure

1. Define Red Hat Automation Hub as the default source for content in the `ansible.cfg` configuration file. See Configuring Red Hat Automation Hub as the primary source for content.

2. Install the `redhat.rhel_system_roles` collection from the Automation Hub:

   ```bash
   # ansible-galaxy collection install redhat.rhel_system_roles
   ``

   After the installation is finished, the roles are available as `redhat.rhel_system_roles.<role_name>`.

   Additionally, you can find the documentation for each role at `/usr/share/ansible/collections/ansible_collections/redhat/rhel_system_roles/roles/<role_name>/README.md`.

Verification steps

To verify the install, run the `kernel_settings` role with `check` mode on your local host. You must also use the `--become` parameter because it is necessary for the Ansible `package` module. However, the parameter will not change your system:

Run the following command:

```bash
$ ansible-playbook -c local -i localhost, --check --become /usr/share/ansible/collections/ansible_collections/redhat/rhel_system_roles/tests/kernel_settings/tests_default.yml
```

The last line of the command output should contain the value `failed=0`.

**NOTE**

The comma after `localhost` is mandatory. You must add it even if there is only one host on the list. Without it, `ansible-playbook` would identify `localhost` as a file or a directory.

Additional resources

- The `ansible-playbook` man page.
The `-i` option of the `ansible-playbook` command

3.5. DEPLOYING THE `tlog` RHEL SYSTEM ROLE USING COLLECTIONS

Following is an example using Collections to prepare and apply a playbook to deploy a logging solution on a set of separate machines.

Prerequisites

- A Galaxy collection is installed.

Procedure

1. Create a new `playbook.yml` file with the following content:

```yaml
---
- name: Deploy session recording
  hosts: all
  vars:
    tlog_scope_sssd: some
    tlog_users_sssd:
      - recordeduser
  roles:
    - redhat.rhel-system-roles.tlog
```

Where,

- **tlog_scope_sssd**:
  - `some` specifies you want to record only certain users and groups, not `all` or `none`.

- **tlog_users_sssd**:
  - `recordeduser` specifies the user you want to record a session from. Note that this does not add the user for you. You must set the user by yourself.

2. Optionally, verify the playbook syntax.

```bash
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```bash
# ansible-playbook -i IP_Address /path/to/file/playbook.yml -v
```

As a result, the playbook installs the `tlog` role on the system you specified. It also creates an SSSD configuration drop file that can be used by the users and groups that you define. SSSD parses and reads these users and groups to overlay `tlog` session as the shell user. Additionally, if the `cockpit` package is installed on the system, the playbook also installs the `cockpit-session-recording` package, which is a Cockpit module that allows you to view and play recordings in the web console interface.

Verification steps

1. Test the syntax of the `/etc/rsyslog.conf` file:
2. Verify that the system sends messages to the log.

3. To verify that the SSSD configuration drop file is created in the system, perform the following steps:

   a. Navigate to the folder where the SSSD configuration drop file is created:

      ```
      # cd /etc/sssd/conf.d/
      ```

   b. Check the file content:

      ```
      # cat sssd-session-recording.conf
      ```

      You can see that the file contains the parameters you set in the playbook.
CHAPTER 4. ANSIBLE IPMI MODULES IN RHEL

4.1. THE RHEL_MGMT COLLECTION

The Intelligent Platform Management Interface (IPMI) is a specification for a set of standard protocols to communicate with baseboard management controller (BMC) devices. The IPMI modules allow you to enable and support hardware management automation. The IPMI modules are available in:

- The rhel_mgmt Collection. The package name is ansible-collection-redhat-rhel_mgmt.
- The RHEL 8 AppStream, as part of the new ansible-collection-redhat-rhel_mgmt package.

The following IPMI modules are available in the rhel_mgmt collection:

- `ipmi_boot`: Management of boot device order
- `ipmi_power`: Power management for machine

The mandatory parameters used for the IPMI Modules are:

- `ipmi_boot` parameters:

<table>
<thead>
<tr>
<th>Module name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Hostname or ip address of the BMC</td>
</tr>
<tr>
<td>password</td>
<td>Password to connect to the BMC</td>
</tr>
<tr>
<td>bootdev</td>
<td>Device to be used on next boot</td>
</tr>
<tr>
<td></td>
<td>* network</td>
</tr>
<tr>
<td></td>
<td>* floppy</td>
</tr>
<tr>
<td></td>
<td>* hd</td>
</tr>
<tr>
<td></td>
<td>* safe</td>
</tr>
<tr>
<td></td>
<td>* optical</td>
</tr>
<tr>
<td></td>
<td>* setup</td>
</tr>
<tr>
<td></td>
<td>* default</td>
</tr>
<tr>
<td>User</td>
<td>Username to connect to the BMC</td>
</tr>
</tbody>
</table>

- `ipmi_power` parameters:

<table>
<thead>
<tr>
<th>Module name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>BMC Hostname or IP address</td>
</tr>
<tr>
<td>Module name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>password</td>
<td>Password to connect to the BMC</td>
</tr>
<tr>
<td>user</td>
<td>Username to connect to the BMC</td>
</tr>
<tr>
<td>State</td>
<td>Check if the machine is on the desired status</td>
</tr>
<tr>
<td></td>
<td>* on</td>
</tr>
<tr>
<td></td>
<td>* off</td>
</tr>
<tr>
<td></td>
<td>* shutdown</td>
</tr>
<tr>
<td></td>
<td>* reset</td>
</tr>
<tr>
<td></td>
<td>* boot</td>
</tr>
</tbody>
</table>

**4.2. INSTALLING THE RHEL MGMT COLLECTION USING THE CLI**

You can install the **rhel_mgmt** Collection using the command line.

**Prerequisites**

- The **ansible-core** package is installed.

**Procedure**

- Install the collection via RPM package:

  ```
  # yum install ansible-collection-redhat-rhel_mgmt
  ```

  After the installation is finished, the IPMI modules are available in the **redhat.rhel_mgmt** Ansible collection.

**Additional resources**

- The **ansible-playbook** man page.

**4.3. EXAMPLE USING THE IPMI_BOOT MODULE**

The following example shows how to use the **ipmi_boot** module in a playbook to set a boot device for the next boot. For simplicity, the examples use the same host as the Ansible control host and managed host, thus executing the modules on the same host where the playbook is executed.

**Prerequisites**

- The **rhel_mgmt** collection is installed.

- The **pyghmi** library in the **python3-pyghmi** package is installed in one of the following locations:
  - The host where you execute the playbook.
The managed host. If you use localhost as the managed host, install the `python3-pyghmi` package on the host where you execute the playbook instead.

- The IPMI BMC that you want to control is accessible via network from the host where you execute the playbook, or the managed host (if not using localhost as the managed host). Note that the host whose BMC is being configured by the module is generally different from the host where the module is executing (the Ansible managed host), as the module contacts the BMC over the network using the IPMI protocol.

- You have credentials to access BMC with an appropriate level of access.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   ---
   - name: Sets which boot device will be used on next boot
     hosts: localhost
     tasks:
       - redhat.rhel_mgmt.ipmi_boot:
         name: bmc.host.example.com
         user: admin_user
         password: basics
         bootdev: hd
   ```

2. Execute the playbook against localhost:

   ```
   # ansible-playbook playbook.yml
   ```

   As a result, the output returns the value “success”.

**4.4. EXAMPLE USING THE IPMI_POWER MODULE**

This example shows how to use the `ipmi_boot` module in a playbook to check if the system is turned on. For simplicity, the examples use the same host as the Ansible control host and managed host, thus executing the modules on the same host where the playbook is executed.

**Prerequisites**

- The `rhel_mgmt` collection is installed.

- The `pyghmi` library in the `python3-pyghmi` package is installed in one of the following locations:
  - The host where you execute the playbook.
  - The managed host. If you use localhost as the managed host, install the `python3-pyghmi` package on the host where you execute the playbook instead.

- The IPMI BMC that you want to control is accessible via network from the host where you execute the playbook, or the managed host (if not using localhost as the managed host). Note that the host whose BMC is being configured by the module is generally different from the host where the module is executing (the Ansible managed host), as the module contacts the BMC over the network using the IPMI protocol.

- You have credentials to access BMC with an appropriate level of access.
Procedure

1. Create a new `playbook.yml` file with the following content:

```yaml
---
- name: Turn the host on
  hosts: localhost
  tasks:
    - redhat.rhel_mgmt.ipmi_power:
      name: bmc.host.example.com
      user: admin_user
      password: basics
      state: on
```

2. Execute the playbook:

```bash
# ansible-playbook playbook.yml
```

The output returns the value "true".
CHAPTER 5. THE REDFISH MODULES IN RHEL

The Redfish modules for remote management of devices are now part of the **redhat.rhel_mgmt** Ansible collection. With the Redfish modules, you can easily use management automation on bare-metal servers and platform hardware by getting information about the servers or control them through an Out-Of-Band (OOB) controller, using the standard HTTPS transport and JSON format.

### 5.1. THE REDFISH MODULES

The **redhat.rhel_mgmt** Ansible collection provides the Redfish modules to support hardware management in Ansible over Redfish. The **redhat.rhel_mgmt** collection is available in the **ansible-collection-redhat-rhel_mgmt** package. To install it, see [Installing the redhat.rhel_mgmt Collection using the CLI](#).

The following Redfish modules are available in the **redhat.rhel_mgmt** collection:

1. **redfish_info**: The **redfish_info** module retrieves information about the remote Out-Of-Band (OOB) controller such as systems inventory.

2. **redfish_command**: The **redfish_command** module performs Out-Of-Band (OOB) controller operations like log management and user management, and power operations such as system restart, power on and off.

3. **redfish_config**: The **redfish_config** module performs OOB controller operations such as changing OOB configuration, or setting the BIOS configuration.

### 5.2. REDFISH MODULES PARAMETERS

The parameters used for the Redfish modules are:

<table>
<thead>
<tr>
<th><strong>redfish_info</strong> parameters:</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>baseuri</strong></td>
<td>(Mandatory) - Base URI of OOB controller.</td>
</tr>
<tr>
<td><strong>category</strong></td>
<td>(Mandatory) - List of categories to execute on OOB controller. The default value is [&quot;Systems&quot;].</td>
</tr>
<tr>
<td><strong>command</strong></td>
<td>(Mandatory) - List of commands to execute on OOB controller.</td>
</tr>
<tr>
<td><strong>username</strong></td>
<td>Username for authentication to OOB controller.</td>
</tr>
<tr>
<td><strong>password</strong></td>
<td>Password for authentication to OOB controller.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>redfish_command</strong> parameters:</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>baseuri</strong></td>
<td>(Mandatory) - Base URI of OOB controller.</td>
</tr>
<tr>
<td><strong>category</strong></td>
<td>(Mandatory) - List of categories to execute on OOB controller. The default value is [&quot;Systems&quot;].</td>
</tr>
<tr>
<td><strong>redfish_command parameters:</strong></td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>command</td>
<td>(Mandatory) - List of commands to execute on OOB controller.</td>
</tr>
<tr>
<td>username</td>
<td>Username for authentication to OOB controller.</td>
</tr>
<tr>
<td>password</td>
<td>Password for authentication to OOB controller.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>redfish_config parameters:</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseuri</td>
<td>(Mandatory) - Base URI of OOB controller.</td>
</tr>
<tr>
<td>category</td>
<td>(Mandatory) - List of categories to execute on OOB controller. The default value is [&quot;Systems&quot;].</td>
</tr>
<tr>
<td>command</td>
<td>(Mandatory) - List of commands to execute on OOB controller.</td>
</tr>
<tr>
<td>username</td>
<td>Username for authentication to OOB controller.</td>
</tr>
<tr>
<td>password</td>
<td>Password for authentication to OOB controller.</td>
</tr>
<tr>
<td>bios_attributes</td>
<td>BIOS attributes to update.</td>
</tr>
</tbody>
</table>

5.3. USING THE REDFISH_INFO MODULE

The following example shows how to use the `redfish_info` module in a playbook to get information about the CPU inventory. For simplicity, the example uses the same host as the Ansible control host and managed host, thus executing the modules on the same host where the playbook is executed.

**Prerequisites**

- The `redhat.rhel_mgmt` collection is installed.

- The `pyghmi` library in the `python3-pyghmi` package is installed on the managed host. If you use localhost as the managed host, install the `python3-pyghmi` package on the host where you execute the playbook.

- OOB controller access details.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

---
- name: Get CPU inventory
  hosts: localhost
  tasks:
    - redhat.rhel_mgmt.redfish_info:
      baseuri: "{{ baseuri }}"
      username: "{{ username }}"
      password: "{{ password }}"
      category: Systems
      command: GetCpuInventory
      register: result

2. Execute the playbook against localhost:

    # ansible-playbook playbook.yml

As a result, the output returns the CPU inventory details.

5.4. USING THE REDFISH_COMMAND MODULE

The following example shows how to use the `redfish_command` module in a playbook to turn on a system. For simplicity, the example uses the same host as the Ansible control host and managed host, thus executing the modules on the same host where the playbook is executed.

**Prerequisites**

- The `redhat.rhel_mgmt` collection is installed.
- The `pyghmi` library in the `python3-pyghmi` package is installed on the managed host. If you use localhost as the managed host, install the `python3-pyghmi` package on the host where you execute the playbook.
- OOB controller access details.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

```yaml
---
- name: Power on system
  hosts: localhost
  tasks:
    - redhat.rhel_mgmt.redfish_command:
      baseuri: "{{ baseuri }}"
      username: "{{ username }}"
      password: "{{ password }}"
      category: Systems
      command: PowerOn
```

2. Execute the playbook against localhost:

    # ansible-playbook playbook.yml

As a result, the system powers on.
5.5. USING THE REDFISH_CONFIG MODULE

The following example shows how to use the redfish_config module in a playbook to configure a system to boot with UEFI. For simplicity, the example uses the same host as the Ansible control host and managed host, thus executing the modules on the same host where the playbook is executed.

Prerequisites

- The redhat.rhel_mgmt collection is installed.
- The pyghmi library in the python3-pyghmi package is installed on the managed host. If you use localhost as the managed host, install the python3-pyghmi package on the host where you execute the playbook.
- OOB controller access details.

Procedure

1. Create a new playbook.yml file with the following content:

```yaml
---
- name: "Set BootMode to UEFI"
  hosts: localhost
  tasks:
    - redhat.rhel_mgmt.redfish_config:
      baseuri: "{{ baseuri }}"
      username: "{{ username }}"
      password: "{{ password }}"
      category: Systems
      command: SetBiosAttributes
      bios_attributes:
        BootMode: Uefi
```

2. Execute the playbook against localhost:

```bash
# ansible-playbook playbook.yml
```

As a result, the system boot mode is set to UEFI.
CHAPTER 6. CONFIGURING KERNEL PARAMETERS PERMANENTLY BY USING THE \texttt{KERNEL\_SETTINGS} RHEL SYSTEM ROLE

You can use the \texttt{kernel\_settings} role to configure kernel parameters on multiple clients at once. This solution:

- Provides a friendly interface with efficient input setting.
- Keeps all intended kernel parameters in one place.

After you run the \texttt{kernel\_settings} role from the control machine, the kernel parameters are applied to the managed systems immediately and persist across reboots.

\textbf{IMPORTANT}

Note that RHEL System Role delivered over RHEL channels are available to RHEL customers as an RPM package in the default AppStream repository. RHEL System Role are also available as a collection to customers with Ansible subscriptions over Ansible Automation Hub.

6.1. INTRODUCTION TO THE KERNEL\_SETTINGS ROLE

RHEL System Roles is a set of roles that provide a consistent configuration interface to remotely manage multiple systems.

RHEL System Roles were introduced for automated configurations of the kernel using the \texttt{kernel\_settings} System Role. The \texttt{rhel\_system\_roles} package contains this system role, and also the reference documentation.

To apply the kernel parameters on one or more systems in an automated fashion, use the \texttt{kernel\_settings} role with one or more of its role variables of your choice in a playbook. A playbook is a list of one or more plays that are human-readable, and are written in the YAML format.

With the \texttt{kernel\_settings} role you can configure:

- The kernel parameters using the \texttt{kernel\_settings\_sysctl} role variable
- Various kernel subsystems, hardware devices, and device drivers using the \texttt{kernel\_settings\_sysfs} role variable
- The CPU affinity for the \texttt{systemd} service manager and processes it forks using the \texttt{kernel\_settings\_systemd\_cpu\_affinity} role variable
- The kernel memory subsystem transparent hugepages using the \texttt{kernel\_settings\_transparent\_hugepages} and \texttt{kernel\_settings\_transparent\_hugepages\_defrag} role variables

Additional resources

- \texttt{README.md} and \texttt{README.html} files in the \texttt{/usr/share/doc/rhel-system-roles/kernel\_settings/} directory
- Working with playbooks
6.2. APPLYING SELECTED KERNEL PARAMETERS USING THE KERNEL_SETTINGS ROLE

Follow these steps to prepare and apply an Ansible playbook to remotely configure kernel parameters with persisting effect on multiple managed operating systems.

Prerequisites

- You have root permissions.
- Entitled by your RHEL subscription, you installed the ansible-core and rhel-system-roles packages on the control machine.
- An inventory of managed hosts is present on the control machine and Ansible is able to connect to them.

**IMPORTANT**

RHEL 8.0 - 8.5 provided access to a separate Ansible repository that contains Ansible Engine 2.9 for automation based on Ansible. Ansible Engine contains command-line utilities such as ansible, ansible-playbook; connectors such as docker and podman; and the entire world of plugins and modules. For information about how to obtain and install Ansible Engine, refer to How do I Download and Install Red Hat Ansible Engine?.

RHEL 8.6 and 9.0 has introduced Ansible Core (provided as ansible-core RPM), which contains the Ansible command-line utilities, commands, and a small set of built-in Ansible plugins. The AppStream repository provides ansible-core, which has a limited scope of support. You can learn more by reviewing Scope of support for the ansible-core package included in the RHEL 9 AppStream.

Procedure

1. Optionally, review the inventory file for illustration purposes:

   ```
   # cat /home/jdoe/<ansible_project_name>/inventory
   [testingservers]
   pdoe@192.168.122.98
   fdoe@192.168.122.226
   [db-servers]
   db1.example.com
   db2.example.com
   [webservers]
   web1.example.com
   web2.example.com
   192.0.2.42
   ```

   The file defines the [testingservers] group and other groups. It allows you to run Ansible more effectively against a specific set of systems.

2. Create a configuration file to set defaults and privilege escalation for Ansible operations.
Create a new YAML file and open it in a text editor, for example:

```
# vi /home/jdoe/<ansible_project_name>/.ansible.cfg
```

b. Insert the following content into the file:

```
[defaults]
inventory = ./inventory

[privilege_escalation]
become = true
become_method = sudo
become_user = root
become_ask_pass = true
```

The [defaults] section specifies a path to the inventory file of managed hosts. The [privilege_escalation] section defines that user privileges be shifted to root on the specified managed hosts. This is necessary for successful configuration of kernel parameters. When Ansible playbook is run, you will be prompted for user password. The user automatically switches to root by means of sudo after connecting to a managed host.

3. Create an Ansible playbook that uses the kernel_settings role.

a. Create a new YAML file and open it in a text editor, for example:

```
# vi /home/jdoe/<ansible_project_name>/kernel-roles.yml
```

This file represents a playbook and usually contains an ordered list of tasks, also called plays, that are run against specific managed hosts selected from your inventory file.

b. Insert the following content into the file:

```
---
- hosts: testingservers
  name: "Configure kernel settings"
  roles:
    - rhel-system-roles.kernel_settings
  vars:
    kernel_settings_sysctl:
      - name: fs.file-max
        value: 400000
      - name: kernel.threads-max
        value: 65536
    kernel_settings_sysfs:
      - name: /sys/class/net/lo/mtu
        value: 65000
    kernel_settings_transparent_hugepages: madvise
```

The name key is optional. It associates an arbitrary string with the play as a label and identifies what the play is for. The hosts key in the play specifies the hosts against which the play is run. The value or values for this key can be provided as individual names of managed hosts or as groups of hosts as defined in the inventory file.
The **vars** section represents a list of variables containing selected kernel parameter names and values to which they have to be set.

The **roles** key specifies what system role is going to configure the parameters and values mentioned in the **vars** section.

**NOTE**

You can modify the kernel parameters and their values in the playbook to fit your needs.

4. Optionally, verify that the syntax in your play is correct.

```
# ansible-playbook --syntax-check kernel-roles.yml
```

playbook: kernel-roles.yml

This example shows the successful verification of a playbook.

5. Execute your playbook.

```
# ansible-playbook kernel-roles.yml
...
```

BECOME password:

PLAY [Configure kernel settings]
..............................................................

PLAY RECAP
..............................................................

fdoe@192.168.122.226 : ok=10 changed=4 unreachable=0 failed=0 skipped=6 rescued=0 ignored=0
pdoe@192.168.122.98 : ok=10 changed=4 unreachable=0 failed=0 skipped=6 rescued=0 ignored=0

Before Ansible runs your playbook, you are going to be prompted for your password and so that a user on managed hosts can be switched to **root**, which is necessary for configuring kernel parameters.

The recap section shows that the play finished successfully (**failed=0**) for all managed hosts, and that 4 kernel parameters have been applied (**changed=4**).

6. Restart your managed hosts and check the affected kernel parameters to verify that the changes have been applied and persist across reboots.

**Additional resources**

- Preparing a control node and managed nodes to use RHEL System Roles

- README.html and README.md files in the **/usr/share/doc/rhel-system-roles/kernel_settings/** directory
CHAPTER 6. CONFIGURING KERNEL PARAMETERS PERMANENTLY BY USING THE KERNEL_SETTINGS RHEL SYSTEM ROLE

- Build Your Inventory
- Configuring Ansible
- Working With Playbooks
- Using Variables
- Roles
CHAPTER 7. USING THE RHC SYSTEM ROLE TO REGISTER THE SYSTEM

The **rhc** RHEL System Role enables administrators to automate the registration of multiple systems with Red Hat Subscription Management (RHSM) and Satellite servers. The role also supports Insights-related configuration and management tasks by using Ansible.

7.1. INTRODUCTION TO THE RHC SYSTEM ROLE

RHEL System Role is a set of roles that provides a consistent configuration interface to remotely manage multiple systems. The remote host configuration (**rhc**) System Role enables administrators to easily register RHEL systems to Red Hat Subscription Management (RHSM) and Satellite servers. By default, when you register a system by using the **rhc** System Role, the system is connected to Insights. Additionally, with the **rhc** System Role, you can:

- Configure connections to Red Hat Insights
- Enable and disable repositories
- Configure the proxy to use for the connection
- Configure insights remediations and, auto updates
- Set the release of the system
- Configure insights tags

7.2. REGISTERING A SYSTEM BY USING THE RHC SYSTEM ROLE

You can register your system to Red Hat by using the **rhc** RHEL System Role. By default, the **rhc** RHEL System Role connects the system to Red Hat Insights when you register it.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has **sudo** permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a vault to save the sensitive information:

   ```
   $ ansible-vault create secrets.yml
   New Vault password: password
   Confirm New Vault password: password
   ```

2. The **ansible-vault create** command creates an encrypted vault file and opens it in an editor. Enter the sensitive data you want to save in the vault, for example:
activationKey: activation_key
username: username
password: password

3. Save the changes, and close the editor. Ansible encrypts the data in the vault.
   You can later edit the data in the vault by using the `ansible-vault edit secrets.yml` command.

4. Optional: Display the vault content:

   ```
   $ ansible-vault view secrets.yml
   ```

5. Create a playbook file, for example `~/registration.yml`, and use one of the following options depending on the action you want to perform:

   a. To register by using an activation key and organization ID (recommended), use the following playbook:

   ```yaml
   ---
   - name: Registering system using activation key and organization ID
     hosts: managed-node-01.example.com
     vars_files:
       - secrets.yml
     vars:
       rhc_auth:
       activation_keys:
         keys:
           - "{{ activationKey }}"
       rhc_organization: organizationID
     roles:
       - role: rhel-system-roles.rhc
   ```

   b. To register by using a username and password, use the following playbook:

   ```yaml
   ---
   - name: Registering system with username and password
     hosts: managed-node-01.example.com
     vars_files:
       - secrets.yml
     vars:
       rhc_auth:
       login:
         username: "{{ username }}"
         password: "{{ password }}"
     roles:
       - role: rhel-system-roles.rhc
   ```

6. Run the playbook:

   ```
   # ansible-playbook ~/registration.yml --ask-vault-pass
   ```

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.rhc/README.md` file
7.3. REGISTERING A SYSTEM WITH SATELLITE BY USING THE RHC SYSTEM ROLE

When organizations use Satellite to manage systems, it is necessary to register the system through Satellite. You can remotely register your system with Satellite by using the rhc RHEL System Role.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a vault to save the sensitive information:

   $ ansible-vault create secrets.yml
   New Vault password: password
   Confirm New Vault password: password

2. The ansible-vault create command creates an encrypted file and opens it in an editor. Enter the sensitive data you want to save in the vault, for example:

   activationKey: activation_key

3. Save the changes, and close the editor. Ansible encrypts the data in the vault.
   You can later edit the data in the vault by using the ansible-vault edit secrets.yml command.

4. Optional: Display the vault content:

   $ ansible-vault view secrets.yml

5. Create a playbook file, for example ~/registration-sat.yml.

6. Use the following text in ~/registration-sat.yml to register the system by using an activation key and organization ID:

   ---
   - name: Register to the custom registration server and CDN
     hosts: managed-node-01.example.com
     vars_files:
     - secrets.yml
     vars:
     rhc_auth:
     login:
     activation_keys:
     keys:
     - "{{ activationKey }}"
     rhc_organization: organizationID
7. Run the playbook:

```
# ansible-playbook ~/registration-sat.yml --ask-vault-pass
```

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.rhc/README.md` file

### 7.4. DISABLING THE CONNECTION TO INSIGHTS AFTER THE REGISTRATION BY USING THE RHC SYSTEM ROLE

When you register a system by using the `rhc` RHEL System Role, the role by default, enables the connection to Red Hat Insights. You can disable it by using the `rhc` System Role, if not required.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- The system is already registered.

**Procedure**

1. Create a playbook file, for example `~/dis-insights.yml` and add the following content in it:

   ```yaml
   ---
   - name: Disable Insights connection
     hosts: managed-node-01.example.com
     vars:
       rhc_insights:
         state: absent
     roles:
       - role: rhel-system-roles.rhc
   
   2. Run the playbook:

   ```ruby
   # ansible-playbook ~/dis-insights.yml
   ```

   Additional resources
7.5. ENABLING REPOSITORIES BY USING THE RHC SYSTEM ROLE

You can remotely enable or disable repositories on managed nodes by using the `rhc` RHEL System Role.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- You have details of the repositories which you want to enable or disable on the managed nodes.
- You have registered the system.

**Procedure**

1. Create a playbook file, for example `~/configure-repos.yml`:
   
   a. To enable a repository:

   ```yaml
   ---
   - name: Enable repository
     hosts: managed-node-01.example.com
     vars:
       rhc_repositories:
       - {name: "RepositoryName", state: enabled}
     roles:
       - role: rhel-system-roles.rhc
   ```

   b. To disable a repository:

   ```yaml
   ---
   - name: Disable repository
     hosts: managed-node-01.example.com
     vars:
       rhc_repositories:
       - {name: "RepositoryName", state: disabled}
     roles:
       - role: rhel-system-roles.rhc
   ```

2. Run the playbook:

   ```sh
   # ansible-playbook ~/configure-repos.yml
   ```

**Additional resources**

- The `/usr/share/ansible/roles/rhel-system-roles.rhc/README.md` file
7.6. SETTING RELEASE VERSIONS BY USING THE RHC SYSTEM ROLE

You can limit the system to use only repositories for a particular minor RHEL version instead of the latest one. This way, you can lock your system to a specific minor RHEL version.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- You know the minor RHEL version to which you want to lock the system. Note that you can only lock the system to the RHEL minor version that the host currently runs or a later minor version.
- You have registered the system.

Procedure

1. Create a playbook file, for example `~/release.yml`:

```yaml
---
- name: Set Release
  hosts: managed-node-01.example.com
  vars:
    rhc_release: "8.6"
  roles:
    - role: rhel-system-roles.rhc
```

2. Run the playbook:

```
# ansible-playbook ~/release.yml
```

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.rhc/README.md` file

7.7. USING A PROXY SERVER WHEN REGISTERING THE HOST BY USING THE RHC SYSTEM ROLE

If your security restrictions allow access to the Internet only through a proxy server, you can specify the proxy’s settings in the playbook when you register the system using the `rhc` RHEL System Role.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a vault to save the sensitive information:

   ```bash
   $ ansible-vault create secrets.yml
   New Vault password: password
   Confirm New Vault password: password
   ```

2. The `ansible-vault create` command creates an encrypted file and opens it in an editor. Enter the sensitive data you want to save in the vault, for example:

   ```yaml
   username: username
   password: password
   proxy_username: proxyusernme
   proxy_password: proxypassword
   ```

3. Save the changes, and close the editor. Ansible encrypts the data in the vault.
   You can later edit the data in the vault by using the `ansible-vault edit secrets.yml` command.

4. Optional: Display the vault content:

   ```bash
   $ ansible-vault view secrets.yml
   ```

5. Create a playbook file, for example `~/configure-proxy.yml`:

   a. To register to the RHEL customer portal by using a proxy:

   ```yaml
   ---
   - name: Register using proxy
     hosts: managed-node-01.example.com
     vars_files:
       - secrets.yml
     vars:
       rhc_auth:
         login:
           username: "{{ username }}"
           password: "{{ password }}"
       rhc_proxy:
         hostname: proxy.example.com
         port: 3128
         username: "{{ proxy_username }}"
         password: "{{ proxy_password }}"
     roles:
       - role: rhel-system-roles.rhc
   ```

   b. To remove the proxy server from the configuration of the Red Hat Subscription Manager service:

   ```yaml
   ---
   - name: To stop using proxy server for registration
     hosts: managed-node-01.example.com
   ```
vars_files:
- secrets.yml
vars:
rhc_auth:
  login:
    username: "{{ username }}"
    password: "{{ password }}"
  rhc_proxy: ("state":"absent")
roles:
- role: rhel-system-roles.rhc

6. Run the playbook:

    # ansible-playbook ~/configure-proxy.yml --ask-vault-pass

Additional resources

- The /usr/share/ansible/roles/rhel-system-roles.rhc/README.md file

### 7.8. DISABLING AUTO UPDATES OF INSIGHTS RULES BY USING THE RHC SYSTEM ROLE

You can disable the automatic collection rule updates for Red Hat Insights by using the rhc RHEL System Role. By default, when you connect your system to Red Hat Insights, this option is enabled. You can disable it by using the rhc RHEL System Role.

**NOTE**

If you disable this feature, you risk using outdated rule definition files and not getting the most recent validation updates.

#### Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- You have registered the system.

#### Procedure

1. Create a vault to save the sensitive information:

    $ ansible-vault create secrets.yml
    New Vault password: password
    Confirm New Vault password: password
2. The `ansible-vault create` command creates an encrypted file and opens it in an editor. Enter the sensitive data you want to save in the vault, for example:

   ```
   username: username
   password: password
   ```

3. Save the changes, and close the editor. Ansible encrypts the data in the vault. You can later edit the data in the vault by using the `ansible-vault edit secrets.yml` command.

4. Optional: Display the vault content:

   ```
   $ ansible-vault view secrets.yml
   ```

5. Create a playbook file, for example `~/auto-update.yml` and add following content to it:

   ```yaml
   - name: Disable Red Hat Insights autoupdates
     hosts: managed-node-01.example.com
     vars_files:
     - secrets.yml
     vars:
     rhc_auth:
       login:
         username: "{{ username }}"
         password: "{{ password }}"
     rhc_insights:
       autoupdate: false
       state: present
     roles:
     - role: rhel-system-roles.rhc
   ```

6. Run the playbook:

   ```
   # ansible-playbook ~/auto-update.yml --ask-vault-pass
   ```

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.rhc/README.md` file

### 7.9. DISABLING INSIGHTS REMEDIATIONS BY USING THE RHC RHEL SYSTEM ROLE

You can configure systems to automatically update the dynamic configuration by using the `rhc` RHEL System Role. When you connect your system to Red Hat Insights, it is enabled by default. You can disable it, if not required.

**NOTE**

Enabling remediation with the `rhc` System Role ensures your system is ready to be remediated when connected directly to Red Hat. For systems connected to a Satellite, or Capsule, enabling remediation must be achieved differently. For more information about Red Hat Insights remediations, see `Red Hat Insights Remediations Guide`.
Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- You have Insights remediations enabled.
- You have registered the system.

Procedure

1. To enable the remediation, create a playbook file, for example `~/remediation.yml`:

   ```yaml
   ---
   - name: Disable remediation
     hosts: managed-node-01.example.com
     vars:
       rhc_insights:
         remediation: absent
         state: present
     roles:
       - role: rhel-system-roles.rhc
   
   # ansible-playbook ~/remediation.yml
   ```

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.rhc/README.md` file

7.10. CONFIGURING INSIGHTS TAGS BY USING THE RHC SYSTEM ROLE

You can use tags for system filtering and grouping. You can also customize tags based on the requirements.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
Procedure

1. Create a vault to save the sensitive information:

   ```
   $ ansible-vault create secrets.yml
   New Vault password: password
   Confirm New Vault password: password
   ```

2. The `ansible-vault create` command creates an encrypted file and opens it in an editor. Enter the sensitive data you want to save in the vault, for example:

   ```
   username: username
   password: password
   ```

3. Save the changes, and close the editor. Ansible encrypts the data in the vault. You can later edit the data in the vault by using the `ansible-vault edit secrets.yml` command.

4. Optional: Display the vault content:

   ```
   $ ansible-vault view secrets.yml
   ```

5. Create a playbook file, for example `~/tags.yml`, and add following content to it:

   ```yaml
   ---
   - name: Creating tags
     hosts: managed-node-01.example.com
     vars_files:
       - secrets.yml
     vars:
       rhc_auth:
         login: "{{ username }}"
         password: "{{ password }}"
     rhc_insights:
       tags:
         group: group-name-value
         location: location-name-value
         description:
           - RHEL8
           - SAP
         sample_key: value
       state: present
     roles:
       - role: rhel-system-roles.rhc
   ```

6. Run the playbook:

   ```
   # ansible-playbook ~/remediation.yml --ask-vault-pass
   ```

Additional resources

- The `~/.share/ansible/roles/rhel-system-roles.rhc/README.md` file
- For more information, see System Filtering and groups Red Hat Insights.
7.11. UNREGISTERING A SYSTEM BY USING THE RHC SYSTEM ROLE

You can unregister the system from Red Hat if you no longer need the subscription service.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- The system is already registered.

Procedure

1. To unregister, create a playbook file, for example, `~/unregister.yml` and add the following content to it:

```yaml
---
- name: Unregister the system
  hosts: managed-node-01.example.com
  vars:
    rhc_state: absent
  roles:
    - role: rhel-system-roles.rhc
```

2. Run the playbook:

```
# ansible-playbook ~/unregister.yml
```

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.rhc/README.md` file
CHAPTER 8. CONFIGURING NETWORK SETTINGS BY USING RHEL SYSTEM ROLES

Administrators can automate network-related configuration and management tasks by using the network RHEL System Role.

8.1. CONFIGURING AN ETHERNET CONNECTION WITH A STATIC IP ADDRESS BY USING THE NETWORK RHEL SYSTEM ROLE WITH AN INTERFACE NAME

You can remotely configure an Ethernet connection by using the network RHEL System Role.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- A physical or virtual Ethernet device exists in the server’s configuration.
- The managed nodes use NetworkManager to configure the network.

Procedure

1. Create a playbook file, for example ~/ethernet-static-IP.yml, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
  - name: Configure an Ethernet connection with static IP
    include_role:
    name: rhel-system-roles.network

  vars:
    network_connections:
      - name: enp1s0
        interface_name: enp1s0
        type: ethernet
        autoconnect: yes
        ip:
          address:
            - 192.0.2.1/24
            - 2001:db8:1::1/64
        gateway4: 192.0.2.254
        gateway6: 2001:db8:1::ffe
        dns:
```
These settings define an Ethernet connection profile for the `enp1s0` device with the following settings:

- A static IPv4 address - `192.0.2.1` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `192.0.2.254`
- An IPv6 default gateway - `2001:db8:1::fffe`
- An IPv4 DNS server - `192.0.2.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`

2. Validate the playbook syntax:

```bash
# ansible-playbook ~/ethernet-static-IP.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```bash
# ansible-playbook ~/ethernet-static-IP.yml
```

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file

8.2. CONFIGURING AN ETHERNET CONNECTION WITH A STATIC IP ADDRESS BY USING THE NETWORK RHEL SYSTEM ROLE WITH A DEVICE PATH

You can remotely configure an Ethernet connection using the `network` RHEL System Role.

You can identify the device path with the following command:

```bash
# udevadm info /sys/class/net/<device_name> | grep ID_PATH=
```

Perform this procedure on the Ansible control node.

**Prerequisites**

- You have prepared the control node and the managed nodes.
You are logged in to the control node as a user who can run playbooks on the managed nodes.

The account you use to connect to the managed nodes has `sudo` permissions on them.

The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

A physical or virtual Ethernet device exists in the server’s configuration.

The managed nodes use NetworkManager to configure the network.

**Procedure**

1. Create a playbook file, for example `~/ethernet-static-IP.yml`, with the following content:

   ```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure an Ethernet connection with static IP
      include_role:
        name: rhel-system-roles.network

  vars:
    network_connections:
      - name: example
        match:
          path:
            - pci-0000:00:02.0
            - /pci-0000:00:02.0
        type: ethernet
        autoconnect: yes
        ip:
          address:
            - 192.0.2.1/24
            - 2001:db8:1::1/64
        gateway4: 192.0.2.254
        gateway6: 2001:db8:1::ffe
        dns:
          - 192.0.2.200
          - 2001:db8:1::ffe
        dns_search:
          - example.com
        state: up
```

These settings define an Ethernet connection profile with the following settings:

- A static IPv4 address – **192.0.2.1** with a /24 subnet mask
- A static IPv6 address – **2001:db8:1::1** with a /64 subnet mask
- An IPv4 default gateway – **192.0.2.254**
- An IPv6 default gateway – **2001:db8:1::ffe**
- An IPv4 DNS server – **192.0.2.200**
- An IPv6 DNS server - 2001:db8:1::ffbb

- A DNS search domain - example.com

The *match* parameter in this example defines that Ansible applies the play to devices that match PCI ID 0000:00:0[1-3].0, but not 0000:00:02.0. For further details about special modifiers and wild cards you can use, see the *match* parameter description in the /usr/share/ansible/roles/rhel-system-roles.network/README.md file.

2. Validate the playbook syntax:

```sh
# ansible-playbook ~/ethernet-static-IP.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```sh
# ansible-playbook ~/ethernet-static-IP.yml
```

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file

8.3. CONFIGURING AN ETHERNET CONNECTION WITH A DYNAMIC IP ADDRESS BY USING THE NETWORK RHEL SYSTEM ROLE WITH AN INTERFACE NAME

You can remotely configure an Ethernet connection using the *network* RHEL System Role. For connections with dynamic IP address settings, NetworkManager requests the IP settings for the connection from a DHCP server.

Perform this procedure on the Ansible control node.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has *sudo* permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- A physical or virtual Ethernet device exists in the server’s configuration.
- A DHCP server is available in the network.
- The managed nodes use NetworkManager to configure the network.

**Procedure**

1. Create a playbook file, for example ~/ethernet-dynamic-IP.yml, with the following content:
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure an Ethernet connection with dynamic IP
      include_role:
        name: rhel-system-roles.network

  vars:
    network_connections:
      - name: enp1s0
        interface_name: enp1s0
        type: ethernet
        autoconnect: yes
        ip:
          dhcp4: yes
          auto6: yes
        state: up

These settings define an Ethernet connection profile for the `enp1s0` device. The connection retrieves IPv4 addresses, IPv6 addresses, default gateway, routes, DNS servers, and search domains from a DHCP server and IPv6 stateless address autoconfiguration (SLAAC).

2. Validate the playbook syntax:

```
# ansible-playbook ~/ethernet-dynamic-IP.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```
# ansible-playbook ~/ethernet-dynamic-IP.yml
```

Additional resources
- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file

8.4. CONFIGURING AN ETHERNET CONNECTION WITH A DYNAMIC IP ADDRESS BY USING THE NETWORK RHEL SYSTEM ROLE WITH A DEVICE PATH

You can remotely configure an Ethernet connection using the `network` RHEL System Role. For connections with dynamic IP address settings, NetworkManager requests the IP settings for the connection from a DHCP server.

You can identify the device path with the following command:

```
# udevadm info /sys/class/net/<device_name> | grep ID_PATH=
```

Perform this procedure on the Ansible control node.

Prerequisites
- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- A physical or virtual Ethernet device exists in the server’s configuration.
- A DHCP server is available in the network.
- The managed hosts use NetworkManager to configure the network.

Procedure

1. Create a playbook file, for example ~/.ethereum-dynamic-IP.yml, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure an Ethernet connection with dynamic IP
      include_role:
        name: rhel-system-roles.network
      vars:
        network_connections:
          - name: example
            match:
              path:
                - pci-0000:00:0[1-3].0
                - &!pci-0000:00:02.0
            type: ethernet
            autoconnect: yes
            ip:
              dhcp4: yes
              auto6: yes
            state: up

These settings define an Ethernet connection profile. The connection retrieves IPv4 addresses, IPv6 addresses, default gateway, routes, DNS servers, and search domains from a DHCP server and IPv6 stateless address autoconfiguration (SLAAC).

The match parameter in this example defines that Ansible applies the play to devices that match PCI ID 0000:00:0[1-3].0, but not 0000:00:02.0. For further details about special modifiers and wild cards you can use, see the match parameter description in the /usr/share/ansible/roles/rhel-system-roles.network/README.md file.

2. Validate the playbook syntax:

```
# ansible-playbook ~/.ethereum-dynamic-IP.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.
3. Run the playbook:

```
# ansible-playbook ~/ethernet-dynamic-IP.yml
```

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file

## 8.5. Configuring VLAN Tagging by Using the Network RHEL System Role

You can use the **network** RHEL System Role to configure VLAN tagging. This example adds an Ethernet connection and a VLAN with ID 10 on top of this Ethernet connection. As the child device, the VLAN connection contains the IP, default gateway, and DNS configurations.

Depending on your environment, adjust the play accordingly. For example:

- To use the VLAN as a port in other connections, such as a bond, omit the `ip` attribute, and set the IP configuration in the child configuration.

- To use team, bridge, or bond devices in the VLAN, adapt the `interface_name` and `type` attributes of the ports you use in the VLAN.

Perform this procedure on the Ansible control node.

**Prerequisites**

- You have prepared the control node and the managed nodes.

- You are logged in to the control node as a user who can run playbooks on the managed nodes.

- The account you use to connect to the managed nodes has **sudo** permissions on them.

- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**Procedure**

1. Create a playbook file, for example `~/vlan-ethernet.yml`, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure a VLAN that uses an Ethernet connection
      include_role:
        name: rhel-system-roles.network

  vars:
    network_connections:
      # Add an Ethernet profile for the underlying device of the VLAN
      - name: enp1s0
        type: ethernet
        interface_name: enp1s0
```
These settings define a VLAN to operate on top of the **enp1s0** device. The VLAN interface has the following settings:

- A static IPv4 address – **192.0.2.1** with a /24 subnet mask
- A static IPv6 address – **2001:db8:1::1** with a /64 subnet mask
- An IPv4 default gateway – **192.0.2.254**
- An IPv6 default gateway – **2001:db8:1::fffe**
- An IPv4 DNS server – **192.0.2.200**
- An IPv6 DNS server – **2001:db8:1::ffbb**
- A DNS search domain – **example.com**
- VLAN ID – **10**

The **parent** attribute in the VLAN profile configures the VLAN to operate on top of the **enp1s0** device. As the child device, the VLAN connection contains the IP, default gateway, and DNS configurations.

2. Validate the playbook syntax:

```yaml
# ansible-playbook ~/.vlan-ethernet.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:
8.6. CONFIGURING A NETWORK BRIDGE BY USING THE NETWORK RHEL SYSTEM ROLE

You can remotely configure a network bridge by using the network RHEL System Role.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.

- You are logged in to the control node as a user who can run playbooks on the managed nodes.

- The account you use to connect to the managed nodes has **sudo** permissions on them.

- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

- Two or more physical or virtual network devices are installed on the server.

Procedure

1. Create a playbook file, for example `~/bridge-ethernet.yml`, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure a network bridge that uses two Ethernet ports
      include_role:
        name: rhel-system-roles.network

  vars:
    network_connections:
      # Define the bridge profile
    - name: bridge0
      type: bridge
      interface_name: bridge0
      ip:
        address:
        - "192.0.2.1/24"
        - "2001:db8:1::1/64"
      gateway4: 192.0.2.254
      gateway6: 2001:db8:1::ffe
      dns:
        - 192.0.2.200
        - 2001:db8:1::ffbb
      dns_search:
```

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file

# ansible-playbook ~/vlan-ethernet.yml
These settings define a network bridge with the following settings:

- A static IPv4 address - **192.0.2.1** with a /24 subnet mask
- A static IPv6 address - **2001:db8:1::1** with a /64 subnet mask
- An IPv4 default gateway - **192.0.2.254**
- An IPv6 default gateway - **2001:db8:1::fffe**
- An IPv4 DNS server - **192.0.2.200**
- An IPv6 DNS server - **2001:db8:1::ffbb**
- A DNS search domain - **example.com**
- Ports of the bridge - **enp7s0** and **enp8s0**

**NOTE**

Set the IP configuration on the bridge and not on the ports of the Linux bridge.

2. Validate the playbook syntax:

```bash
# ansible-playbook ~/bridge-ethernet.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```bash
# ansible-playbook ~/bridge-ethernet.yml
```

Additional resources
8.7. CONFIGURING A NETWORK BOND BY USING THE NETWORK RHEL SYSTEM ROLE

You can remotely configure a network bond by using the `network` RHEL System Role.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- Two or more physical or virtual network devices are installed on the server.

Procedure

1. Create a playbook file, for example `~/bond-ethernet.yml`, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure a network bond that uses two Ethernet ports
      include_role:
        name: rhel-system-roles.network

  vars:
    network_connections:
      # Define the bond profile
      - name: bond0
        type: bond
        interface_name: bond0
        ip:
          address:
            - "192.0.2.1/24"
            - "2001:db8:1::1/64"
        gateway4: 192.0.2.254
        gateway6: 2001:db8:1::ffe
        dns:
          - 192.0.2.200
          - 2001:db8:1::ffbb
        dns_search:
          - example.com
        bond:
          mode: active-backup
          state: up
```

Red Hat Enterprise Linux 9 Automating system administration by using RHEL System Roles
These settings define a network bond with the following settings:

- A static IPv4 address - 192.0.2.1 with a /24 subnet mask
- A static IPv6 address - 2001:db8:1::1 with a /64 subnet mask
- An IPv4 default gateway - 192.0.2.254
- An IPv6 default gateway - 2001:db8:1::ffe
- An IPv4 DNS server - 192.0.2.200
- An IPv6 DNS server - 2001:db8:1::ffbb
- A DNS search domain - example.com
- Ports of the bond - enp7s0 and enp8s0
- Bond mode - active-backup

**NOTE**
Set the IP configuration on the bond and not on the ports of the Linux bond.

2. Validate the playbook syntax:

```
# ansible-playbook ~/bond-ethernet.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```
# ansible-playbook ~/bond-ethernet.yml
```

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file
8.8. CONFIGURING AN IPOIB CONNECTION BY USING THE NETWORK RHEL SYSTEM ROLE

You can use the network RHEL System Role to remotely create NetworkManager connection profiles for IP over InfiniBand (IPoIB) devices. For example, remotely add an InfiniBand connection for the mlx4_ib0 interface with the following settings by running an Ansible Playbook:

- An IPoIB device - mlx4_ib0.8002
- A partition key p_key - 0x8002
- A static IPv4 address - 192.0.2.1 with a /24 subnet mask
- A static IPv6 address - 2001:db8:1::1 with a /64 subnet mask

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- An InfiniBand device named mlx4_ib0 is installed in the managed nodes.
- The managed nodes use NetworkManager to configure the network.

Procedure

1. Create a playbook file, for example ~/IPoIB.yml, with the following content:

```yaml
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure IPoIB
      include_role:
        name: rhel-system-roles.network

  vars:
    network_connections:
      # InfiniBand connection mlx4_ib0
      - name: mlx4_ib0
        interface_name: mlx4_ib0
        type: infiniband

      # IPoIB device mlx4_ib0.8002 on top of mlx4_ib0
      - name: mlx4_ib0.8002
        type: infiniband
        autoconnect: yes
```

Red Hat Enterprise Linux 9 Automating system administration by using RHEL System Roles
infiniband:
  p_key: 0x8002
  transport_mode: datagram
  parent: mlx4_ib0
  ip:
    address:
      - 192.0.2.1/24
      - 2001:db8:1::1/64
    state: up

If you set a `p_key` parameter as in this example, do not set an `interface_name` parameter on the IPoIB device.

2. Validate the playbook syntax:

   # ansible-playbook ~/IPoIB.yml --syntax-check

   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

   # ansible-playbook ~/IPoIB.yml

Verification

1. On the `managed-node-01.example.com` host, display the IP settings of the `mlx4_ib0.8002` device:

   # ip address show mlx4_ib0.8002
   ...
   inet 192.0.2.1/24 brd 192.0.2.255 scope global noprefixroute ib0.8002
   valid_lft forever preferred_lft forever
   inet6 2001:db8:1::1/64 scope link tentative noprefixroute
   valid_lft forever preferred_lft forever

2. Display the partition key (P_Key) of the `mlx4_ib0.8002` device:

   # cat /sys/class/net/mlx4_ib0.8002/pkey
   0x8002

3. Display the mode of the `mlx4_ib0.8002` device:

   # cat /sys/class/net/mlx4_ib0.8002MODE
   datagram

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file

8.9. ROUTING TRAFFIC FROM A SPECIFIC SUBNET TO A DIFFERENT DEFAULT GATEWAY BY USING THE NETWORK RHEL SYSTEM ROLE
You can use policy-based routing to configure a different default gateway for traffic from certain subnets. For example, you can configure RHEL as a router that, by default, routes all traffic to internet provider A using the default route. However, traffic received from the internal workstations subnet is routed to provider B.

To configure policy-based routing remotely and on multiple nodes, you can use the RHEL network System Role. Perform this procedure on the Ansible control node.

This procedure assumes the following network topology:

![Network Topology Diagram]

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on the them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- The managed nodes uses the NetworkManager and firewalld services.
- The managed nodes you want to configure has four network interfaces:
  - The enp7s0 interface is connected to the network of provider A. The gateway IP in the provider’s network is 198.51.100.2, and the network uses a /30 network mask.
  - The enp1s0 interface is connected to the network of provider B. The gateway IP in the provider’s network is 192.0.2.2, and the network uses a /30 network mask.
  - The enp8s0 interface is connected to the 10.0.0.0/24 subnet with internal workstations.
  - The enp9s0 interface is connected to the 203.0.113.0/24 subnet with the company’s servers.
- Hosts in the internal workstations subnet use 10.0.0.1 as the default gateway. In the procedure, you assign this IP address to the enp8s0 network interface of the router.
Hosts in the server subnet use 203.0.113.1 as the default gateway. In the procedure, you assign this IP address to the enp9s0 network interface of the router.

Procedure

1. Create a playbook file, for example ~/pbr.yml, with the following content:

```yaml
---
- name: Configuring policy-based routing
  hosts: managed-node-01.example.com
  tasks:
    - name: Routing traffic from a specific subnet to a different default gateway
      include_role:
        name: rhel-system-roles.network
    vars:
      network_connections:
        - name: Provider-A
          interface_name: enp7s0
          type: ethernet
          autoconnect: True
          ip:
            address: 198.51.100.1/30
            gateway4: 198.51.100.2
          dns: 198.51.100.200
          state: up
          zone: external
        - name: Provider-B
          interface_name: enp1s0
          type: ethernet
          autoconnect: True
          ip:
            address: 192.0.2.1/30
            route:
              network: 0.0.0.0
              prefix: 0
              gateway: 192.0.2.2
              table: 5000
            state: up
            zone: external
        - name: Internal-Workstations
          interface_name: enp8s0
          type: ethernet
          autoconnect: True
          ip:
            address: 10.0.0.1/24
            route:
              network: 10.0.0.0
              prefix: 24
              table: 5000
```

CHAPTER 8. CONFIGURING NETWORK SETTINGS BY USING RHEL SYSTEM ROLES
2. Validate the playbook syntax:

```bash
# ansible-playbook ~/pbr.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```bash
# ansible-playbook ~/pbr.yml
```

**Verification**

1. On a RHEL host in the internal workstation subnet:
   a. Install the `traceroute` package:

   ```bash
   # dnf install traceroute
   ```

   b. Use the `traceroute` utility to display the route to a host on the internet:

   ```bash
   # traceroute redhat.com
   traceroute to redhat.com (209.132.183.105), 30 hops max, 60 byte packets
   1 10.0.0.1 (10.0.0.1)    0.337 ms  0.260 ms  0.223 ms
   2 192.0.2.1 (192.0.2.1) 0.884 ms  1.066 ms  1.248 ms
   ...
   ```

   The output of the command displays that the router sends packets over `192.0.2.1`, which is the network of provider B.

2. On a RHEL host in the server subnet:
   a. Install the `traceroute` package:

   ```bash
   # dnf install traceroute
   ```

   b. Use the `traceroute` utility to display the route to a host on the internet:

   ```bash
   ```

   ...
# traceroute redhat.com
traceroute to redhat.com (209.132.183.105), 30 hops max, 60 byte packets
1 203.0.113.1 (203.0.113.1) 2.179 ms 2.073 ms 1.944 ms
2 198.51.100.2 (198.51.100.2) 1.868 ms 1.798 ms 1.549 ms
...

The output of the command displays that the router sends packets over 198.51.100.2, which is the network of provider A.

3. On the RHEL router that you configured using the RHEL System Role:

a. Display the rule list:

```bash
# ip rule list
0: from all lookup local
5: from 10.0.0.0/24 lookup 5000
32766: from all lookup main
32767: from all lookup default
```

By default, RHEL contains rules for the tables `local`, `main`, and `default`.

b. Display the routes in table 5000:

```bash
# ip route list table 5000
0.0.0.0/0 via 192.0.2.2 dev enp1s0 proto static metric 100
10.0.0.0/24 dev enp8s0 proto static scope link src 192.0.2.1 metric 102
```

c. Display the interfaces and firewall zones:

```bash
# firewall-cmd --get-active-zones
external
  interfaces: enp1s0 enp7s0
trusted
  interfaces: enp8s0 enp9s0
```

d. Verify that the `external` zone has masquerading enabled:

```bash
# firewall-cmd --info-zone=external
external (active)
target: default
icmp-block-inversion: no
interfaces: enp1s0 enp7s0
sources:
services: ssh
ports:
protocols:
masquerade: yes
```

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
8.10. CONFIGURING A STATIC ETHERNET CONNECTION WITH 802.1X NETWORK AUTHENTICATION BY USING THE NETWORK RHEL SYSTEM ROLE

You can remotely configure an Ethernet connection with 802.1X network authentication by using the network RHEL System Role.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- The network supports 802.1X network authentication.
- The managed nodes use NetworkManager.
- The following files required for TLS authentication exist on the control node:
  - The client key is stored in the `/srv/data/client.key` file.
  - The client certificate is stored in the `/srv/data/client.crt` file.
  - The Certificate Authority (CA) certificate is stored in the `/srv/data/ca.crt` file.

Procedure

1. Create a playbook file, for example `~/enable-802.1x.yml`, with the following content:

```yaml
---
- name: Configure an Ethernet connection with 802.1X authentication
  hosts: managed-node-01.example.com
  tasks:
    - name: Copy client key for 802.1X authentication
      copy:
        src: "~/srv/data/client.key"
        dest: "/etc/pki/tls/private/client.key"
        mode: 0600

    - name: Copy client certificate for 802.1X authentication
      copy:
        src: "~/srv/data/client.crt"
        dest: "/etc/pki/tls/certs/client.crt"

    - name: Copy CA certificate for 802.1X authentication
      copy:
        src: "~/srv/data/ca.crt"
        dest: "/etc/pki/ca-trust/source/anchors/ca.crt"
```
These settings define an Ethernet connection profile for the **enp1s0** device with the following settings:

- A static IPv4 address - **192.0.2.1** with a **/24** subnet mask
- A static IPv6 address - **2001:db8:1::1** with a **/64** subnet mask
- An IPv4 default gateway - **192.0.2.254**
- An IPv6 default gateway - **2001:db8:1::ffe**
- An IPv4 DNS server - **192.0.2.200**
- An IPv6 DNS server - **2001:db8:1::ffbb**
- A DNS search domain - **example.com**
- 802.1X network authentication using the **TLS** Extensible Authentication Protocol (EAP)

2. Validate the playbook syntax:

```
# ansible-playbook ~/enable-802.1x.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:
# ansible-playbook ~/enable-802.1x.yml

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file

8.11. CONFIGURING A WIFI CONNECTION WITH 802.1X NETWORK AUTHENTICATION BY USING THE NETWORK RHEL SYSTEM ROLE

Using RHEL System Roles, you can automate the creation of a wifi connection. For example, you can remotely add a wireless connection profile for the *wlp1s0* interface using an Ansible Playbook. The created profile uses the 802.1X standard to authenticate the client to a wifi network. The playbook configures the connection profile to use DHCP. To configure static IP settings, adapt the parameters in the `ip` dictionary accordingly.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- The network supports 802.1X network authentication.
- You installed the `wpa_supplicant` package on the managed node.
- DHCP is available in the network of the managed node.
- The following files required for TLS authentication exist on the control node:
  - The client key is stored in the `/srv/data/client.key` file.
  - The client certificate is stored in the `/srv/data/client.crt` file.
  - The CA certificate is stored in the `/srv/data/ca.crt` file.

Procedure

1. Create a playbook file, for example `~/enable-802.1x.yml`, with the following content:

```yaml
---
- name: Configure a wifi connection with 802.1X authentication
  hosts: managed-node-01.example.com
  tasks:
    - name: Copy client key for 802.1X authentication
      copy:
        src: "/srv/data/client.key"
        dest: "/etc/pki/tls/private/client.key"
        mode: 0400
```
These settings define a wifi connection profile for the `wlp1s0` interface. The profile uses 802.1X standard to authenticate the client to the wifi network. The connection retrieves IPv4 addresses, IPv6 addresses, default gateway, routes, DNS servers, and search domains from a DHCP server and IPv6 stateless address autoconfiguration (SLAAC).

2. Validate the playbook syntax:

```bash
# ansible-playbook ~/enable-802.1x.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```bash
# ansible-playbook ~/enable-802.1x.yml
```

Additional resources
8.12. SETTING THE DEFAULT GATEWAY ON AN EXISTING CONNECTION BY USING THE NETWORK RHEL SYSTEM ROLE

You can use the network RHEL System Role to set the default gateway.

**IMPORTANT**

When you run a play that uses the network RHEL System Role and if the setting values do not match the values specified in the play, the role overrides the existing connection profile with the same name. To prevent resetting these values to their defaults, always specify the whole configuration of the network connection profile in the play, even if the configuration, for example the IP configuration, already exists.

Depending on whether it already exists, the procedure creates or updates the `enp1s0` connection profile with the following settings:

- A static IPv4 address - **198.51.100.20** with a /24 subnet mask
- A static IPv6 address - **2001:db8:1::1** with a /64 subnet mask
- An IPv4 default gateway - **198.51.100.254**
- An IPv6 default gateway - **2001:db8:1::fffe**
- An IPv4 DNS server - **198.51.100.200**
- An IPv6 DNS server - **2001:db8:1::ffbb**
- A DNS search domain - **example.com**

Perform this procedure on the Ansible control node.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has **sudo** permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**Procedure**

1. Create a playbook file, for example `~/ethernet-connection.yml`, with the following content:
name: rhel-system-roles.network

vars:
  network_connections:
    - name: enp1s0
      type: ethernet
      autoconnect: yes
      ip:
        address:
          - 198.51.100.20/24
          - 2001:db8:1::1/64
      gateway4: 198.51.100.254
      gateway6: 2001:db8:1::ffe
      dns:
        - 198.51.100.200
        - 2001:db8:1::ffbb
      dns_search:
        - example.com
      state: up

2. Validate the playbook syntax:

```
# ansible-playbook ~/ethernet-connection.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```
# ansible-playbook ~/ethernet-connection.yml
```

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file

### 8.13. Configuring a Static Route by Using the Network RHEL System Role

You can use the network RHEL System Role to configure static routes.

**IMPORTANT**

When you run a play that uses the network RHEL System Role and if the setting values do not match the values specified in the play, the role overrides the existing connection profile with the same name. To prevent resetting these values to their defaults, always specify the whole configuration of the network connection profile in the play, even if the configuration, for example the IP configuration, already exists.

Perform this procedure on the Ansible control node.

**Prerequisites**

- You have prepared the control node and the managed nodes.
• You are logged in to the control node as a user who can run playbooks on the managed nodes.

• The account you use to connect to the managed nodes has `sudo` permissions on them.

• The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example `~/add-static-routes.yml`, with the following content:

```
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure an Ethernet connection with static IP and additional routes
      include_role:
        name: rhel-system-roles.network

  vars:
    network_connections:
      - name: enp7s0
        type: ethernet
        autoconnect: yes
        ip:
        address:
          - 192.0.2.1/24
          - 2001:db8:1::1/64
        gateway4: 192.0.2.254
        gateway6: 2001:db8:1::ffe
        dns:
          - 192.0.2.200
          - 2001:db8:1::ffe
        dns_search:
          - example.com
        route:
          - network: 198.51.100.0
            prefix: 24
            gateway: 192.0.2.10
          - network: 2001:db8:2::
            prefix: 64
            gateway: 2001:db8:1::10
        state: up
```

Depending on whether it already exists, the procedure creates or updates the `enp7s0` connection profile with the following settings:

• A static IPv4 address - `192.0.2.1` with a `/24` subnet mask

• A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask

• An IPv4 default gateway - `192.0.2.254`

• An IPv6 default gateway - `2001:db8:1::ffe`

• An IPv4 DNS server - `192.0.2.200`
An IPv6 DNS server - 2001:db8:1::ffbb

A DNS search domain - example.com

Static routes:
- 198.51.100.0/24 with gateway 192.0.2.10
- 2001:db8:2::/64 with gateway 2001:db8:1::10

2. Validate the playbook syntax:

```
# ansible-playbook ~/add-static-routes.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```
# ansible-playbook ~/add-static-routes.yml
```

Verification

1. On the managed nodes:

   a. Display the IPv4 routes:

```
# ip -4 route
...
198.51.100.0/24 via 192.0.2.10 dev enp7s0
```

   b. Display the IPv6 routes:

```
# ip -6 route
...
2001:db8:2::/64 via 2001:db8:1::10 dev enp7s0 metric 1024 pref medium
```

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file

8.14. CONFIGURING AN ETHTOOL OFFLOAD FEATURE BY USING THE NETWORK RHEL SYSTEM ROLE

You can use the network RHEL System Role to configure ethtool features of a NetworkManager connection.
IMPORTANT

When you run a play that uses the network RHEL System Role and if the setting values do not match the values specified in the play, the role overrides the existing connection profile with the same name. To prevent resetting these values to their defaults, always specify the whole configuration of the network connection profile in the play, even if the configuration, for example the IP configuration, already exists.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example ~/configure-ethernet-device-with-ethtool-features.yml, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure an Ethernet connection with ethtool features
      include_role:
        name: rhel-system-roles.network

  vars:
    network_connections:
      - name: enp1s0
        type: ethernet
        autoconnect: yes
        ip:
          address:
            - 198.51.100.20/24
            - 2001:db8:1::1/64
        gateway4: 198.51.100.254
        gateway6: 2001:db8:1::ffe
        dns:
          - 198.51.100.200
          - 2001:db8:1::ffbb
        dns_search:
          - example.com
        ethtool:
          features:
            gro: "no"
```

Red Hat Enterprise Linux 9 Automating system administration by using RHEL System Roles
This playbook creates the **enp1s0** connection profile with the following settings, or updates it if the profile already exists:

- A static **IPv4** address - **198.51.100.20** with a /24 subnet mask
- A static **IPv6** address - **2001:db8:1::1** with a /64 subnet mask
- An **IPv4** default gateway - **198.51.100.254**
- An **IPv6** default gateway - **2001:db8:1::fffe**
- An **IPv4** DNS server - **198.51.100.200**
- An **IPv6** DNS server - **2001:db8:1::ffbb**
- A DNS search domain - **example.com**

- **ethtool** features:
  - Generic receive offload (GRO): disabled
  - Generic segmentation offload (GSO): enabled
  - TX stream control transmission protocol (SCTP) segmentation: disabled

2. Validate the playbook syntax:

```
# ansible-playbook ~/configure-ethernet-device-with-ethtool-features.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```
# ansible-playbook ~/configure-ethernet-device-with-ethtool-features.yml
```

## 8.15. Configuring an Ethtool Coalesce Settings by Using the Network RHEL System Role

You can use the `network` RHEL System Role to configure `ethtool` coalesce settings of a NetworkManager connection.
IMPORTANT

When you run a play that uses the network RHEL System Role and if the setting values do not match the values specified in the play, the role overrides the existing connection profile with the same name. To prevent resetting these values to their defaults, always specify the whole configuration of the network connection profile in the play, even if the configuration, for example the IP configuration, already exists.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example ~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure an Ethernet connection with ethtool coalesce settings
      include_role:
        name: rhel-system-roles.network
      vars:
        network_connections:
          - name: enp1s0
            type: ethernet
            autoconnect: yes
            ip:
              address:
                - 198.51.100.20/24
                - 2001:db8:1::1/64
              gateway4: 198.51.100.254
              gateway6: 2001:db8:1::ffe
              dns:
                - 198.51.100.200
                - 2001:db8:1::ffbb
              dns_search:
                - example.com
            ethtool:
              coalesce:
                rx_frames: 128
                tx_frames: 128
            state: up
```

Red Hat Enterprise Linux 9 Automating system administration by using RHEL System Roles

74
This playbook creates the `enp1s0` connection profile with the following settings, or updates it if the profile already exists:

- A static IPv4 address - 198.51.100.20 with a /24 subnet mask
- A static IPv6 address - 2001:db8:1::1 with a /64 subnet mask
- An IPv4 default gateway - 198.51.100.254
- An IPv6 default gateway - 2001:db8:1::ffe
- An IPv4 DNS server - 198.51.100.200
- An IPv6 DNS server - 2001:db8:1::ffbb
- A DNS search domain - example.com

**ethtool** coalesce settings:

- RX frames: 128
- TX frames: 128

2. Validate the playbook syntax:

```
# ansible-playbook ~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```
# ansible-playbook ~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml
```

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file

### 8.16. INCREASING THE RING BUFFER SIZE TO REDUCE A HIGH PACKET DROP RATE BY USING THE NETWORK RHEL SYSTEM ROLE

Increase the size of an Ethernet device’s ring buffers if the packet drop rate causes applications to report a loss of data, timeouts, or other issues.

Ring buffers are circular buffers where an overflow overwrites existing data. The network card assigns a transmit (TX) and receive (RX) ring buffer. Receive ring buffers are shared between the device driver and the network interface controller (NIC). Data can move from NIC to the kernel through either hardware interrupts or software interrupts, also called SoftIRQs.

The kernel uses the RX ring buffer to store incoming packets until the device driver can process them. The device driver drains the RX ring, typically by using SoftIRQs, which puts the incoming packets into a kernel data structure called an `sk_buff` or `skb` to begin its journey through the kernel and up to the application that owns the relevant socket.
The kernel uses the TX ring buffer to hold outgoing packets which should be sent to the network. These ring buffers reside at the bottom of the stack and are a crucial point at which packet drop can occur, which in turn will adversely affect network performance.

**IMPORTANT**

When you run a play that uses the `network` RHEL System Role and if the setting values do not match the values specified in the play, the role overrides the existing connection profile with the same name. To prevent resetting these values to their defaults, always specify the whole configuration of the network connection profile in the play, even if the configuration, for example the IP configuration, already exists.

Perform this procedure on the Ansible control node.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- You know the maximum ring buffer sizes that the device supports.

**Procedure**

1. Create a playbook file, for example `~/configure-ethernet-device-with-ring-buffer-sizes.yml`, with the following content:

```yaml
---
- name: Configure the network
  hosts: managed-node-01.example.com
  tasks:
    - name: Configure an Ethernet connection with increased ring buffer sizes
      include_role:
        name: rhel-system-roles.network
      vars:
        network_connections:
          - name: enp1s0
            type: ethernet
            autoconnect: yes
            ip:
              address:
                - 198.51.100.20/24
                - 2001:db8:1::1/64
              gateway4: 198.51.100.254
              gateway6: 2001:db8:1::ffe
              dns:
                - 198.51.100.200
                - 2001:db8:1::ffbb
              dns_search:
```

Red Hat Enterprise Linux 9 Automating system administration by using RHEL System Roles
This playbook creates the `enp1s0` connection profile with the following settings, or updates it if the profile already exists:

- A static IPv4 address - 198.51.100.20 with a /24 subnet mask
- A static IPv6 address - 2001:db8:1::1 with a /64 subnet mask
- An IPv4 default gateway - 198.51.100.254
- An IPv6 default gateway - 2001:db8:1::ffe
- An IPv4 DNS server - 198.51.100.200
- An IPv6 DNS server - 2001:db8:1::ffbb
- A DNS search domain - `example.com`
- Maximum number of ring buffer entries:
  - Receive (RX): 4096
  - Transmit (TX): 4096

2. Validate the playbook syntax:

```
ansible-playbook ~/configure-ethernet-device-with-ring-buffer-sizes.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```
ansible-playbook ~/configure-ethernet-device-with-ring-buffer-sizes.yml
```

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file

### 8.17. NETWORK STATES FOR THE NETWORK RHEL SYSTEM ROLE

The `network` RHEL system role supports state configurations in playbooks to configure the devices. For this, use the `network_state` variable followed by the state configurations.

Benefits of using the `network_state` variable in a playbook:

- Using the declarative method with the state configurations, you can configure interfaces, and the NetworkManager creates a profile for these interfaces in the background.
With the **network_state** variable, you can specify the options that you require to change, and all the other options will remain the same as they are. However, with the **network_connections** variable, you must specify all settings to change the network connection profile.

For example, to create an Ethernet connection with dynamic IP address settings, use the following `vars` block in your playbook:

<table>
<thead>
<tr>
<th>Playbook with state configurations</th>
<th>Regular playbook</th>
</tr>
</thead>
<tbody>
<tr>
<td>vars:</td>
<td>vars:</td>
</tr>
<tr>
<td>network_state:</td>
<td>network_connections:</td>
</tr>
<tr>
<td>interfaces:</td>
<td>- name: enp7s0</td>
</tr>
<tr>
<td>- name: enp7s0</td>
<td>interface_name: enp7s0</td>
</tr>
<tr>
<td>type: ethernet</td>
<td>type: ethernet</td>
</tr>
<tr>
<td>state: up</td>
<td>autoconnect: yes</td>
</tr>
<tr>
<td>ipv4:</td>
<td>ip:</td>
</tr>
<tr>
<td>enabled: true</td>
<td>dhcp4: yes</td>
</tr>
<tr>
<td>auto-dns: true</td>
<td>auto6: yes</td>
</tr>
<tr>
<td>auto-gateway: true</td>
<td>state: up</td>
</tr>
<tr>
<td>dhcp: true</td>
<td></td>
</tr>
<tr>
<td>ipv6:</td>
<td></td>
</tr>
<tr>
<td>enabled: true</td>
<td></td>
</tr>
<tr>
<td>auto-dns: true</td>
<td></td>
</tr>
<tr>
<td>auto-gateway: true</td>
<td></td>
</tr>
<tr>
<td>auto-routes: true</td>
<td></td>
</tr>
<tr>
<td>autoconf: true</td>
<td></td>
</tr>
<tr>
<td>dhcp: true</td>
<td></td>
</tr>
</tbody>
</table>

For example, to only change the connection status of dynamic IP address settings that you created as above, use the following `vars` block in your playbook:

<table>
<thead>
<tr>
<th>Playbook with state configurations</th>
<th>Regular playbook</th>
</tr>
</thead>
<tbody>
<tr>
<td>vars:</td>
<td>vars:</td>
</tr>
<tr>
<td>network_state:</td>
<td>network_connections:</td>
</tr>
<tr>
<td>interfaces:</td>
<td>- name: enp7s0</td>
</tr>
<tr>
<td>- name: enp7s0</td>
<td>interface_name: enp7s0</td>
</tr>
<tr>
<td>type: ethernet</td>
<td>type: ethernet</td>
</tr>
<tr>
<td>state: down</td>
<td>autoconnect: yes</td>
</tr>
<tr>
<td>ipv4:</td>
<td>ip:</td>
</tr>
<tr>
<td>ipv6:</td>
<td>dhcp4: yes</td>
</tr>
<tr>
<td>ipv6:</td>
<td>auto6: yes</td>
</tr>
</tbody>
</table>

CHAPTER 9. CONFIGURING FIREWALLD BY USING RHEL SYSTEM ROLES

You can use the `firewall` System Role to configure settings of the `firewalld` service on multiple clients at once. This solution:

- Provides an interface with efficient input settings.
- Keeps all intended `firewalld` parameters in one place.

After you run the `firewall` role on the control node, the System Role applies the `firewalld` parameters to the managed node immediately and makes them persistent across reboots.

### 9.1. INTRODUCTION TO THE FIREWALL RHEL SYSTEM ROLE

RHEL System Roles is a set of contents for the Ansible automation utility. This content together with the Ansible automation utility provides a consistent configuration interface to remotely manage multiple systems.

The `rhel-system-roles.firewall` role from the RHEL System Roles was introduced for automated configurations of the `firewalld` service. The `rhel-system-roles` package contains this System Role, and also the reference documentation.

To apply the `firewalld` parameters on one or more systems in an automated fashion, use the `firewall` System Role variable in a playbook. A playbook is a list of one or more plays that is written in the text-based YAML format.

You can use an inventory file to define a set of systems that you want Ansible to configure.

With the `firewall` role you can configure many different `firewalld` parameters, for example:

- Zones.
- The services for which packets should be allowed.
- Granting, rejection, or dropping of traffic access to ports.
- Forwarding of ports or port ranges for a zone.

Additional resources

- `README.md` and `README.html` files in the `/usr/share/doc/rhel-system-roles/firewall/` directory
- Working with playbooks
- How to build your inventory

### 9.2. RESETTING THE FIREWALLD SETTINGS BY USING A RHEL SYSTEM ROLE

With the `firewall` RHEL system role, you can reset the `firewalld` settings to their default state. If you add the `previous:replaced` parameter to the variable list, the System Role removes all existing user-defined settings and resets `firewalld` to the defaults. If you combine the `previous:replaced` parameter with
other settings, the **firewall** role removes all existing settings before applying new ones.

Perform this procedure on the Ansible control node.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has **sudo** permissions on the them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**Procedure**

1. Create a playbook file, for example `~/reset-firewalld.yml`, with the following content:

   ```yaml
   ---
   - name: Reset firewalld example
     hosts: managed-node-01.example.com
     tasks:
       - name: Reset firewalld
         include_role:
           name: rhel-system-roles.firewall

     vars:
       firewall:
         - previous: replaced
   
   # ansible-playbook ~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml --syntax-check
   
   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

2. Run the playbook:

   ```bash
   # ansible-playbook ~/reset-firewalld.yml
   
   Verification
   
   - Run this command as **root** on the managed node to check all the zones:

     ```bash
     # firewall-cmd --list-all-zones
     ```

**Additional resources**

- `/usr/share/ansible/roles/rhel-system-roles.firewall/README.md`
9.3. FORWARDING INCOMING TRAFFIC IN FIREWALLD FROM ONE LOCAL PORT TO A DIFFERENT LOCAL PORT BY USING A RHEL SYSTEM ROLE

With the firewall role you can remotely configure firewalld parameters with persisting effect on multiple managed hosts.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example ~/port_forwarding.yml, with the following content:

   ```yaml
   ---
   - name: Configure firewall
     hosts: managed-node-01.example.com
     tasks:
       - name: Forward incoming traffic on port 8080 to 443
         include_role:
           name: rhel-system-roles.firewall

       vars:
         firewall:
           - { forward_port: 8080/tcp; 443; state: enabled, runtime: true, permanent: true }
   
   # ansible-playbook ~/port_forwarding.yml --syntax-check
   
   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

2. Run the playbook:

   ```bash
   # ansible-playbook ~/port_forwarding.yml
   ```

Verification

- On the managed host, display the firewalld settings:

  ```bash
  # firewall-cmd --list-forward-ports
  ```
Additional resources

- /usr/share/ansible/roles/rhel-system-roles.firewall/README.md

9.4. MANAGING PORTS IN FIREWALLD BY USING A RHEL SYSTEM ROLE

You can use the RHEL firewall System Role to open or close ports in the local firewall for incoming traffic and make the new configuration persist across reboots. For example you can configure the default zone to permit incoming traffic for the HTTPS service.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on the them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example ~/opening-a-port.yml, with the following content:

```yaml
---
- name: Configure firewalld
  hosts: managed-node-01.example.com
  tasks:
    - name: Allow incoming HTTPS traffic to the local host
      include_role:
        name: rhel-system-roles.firewall

      vars:
        firewall:
          - port: 443/tcp
            service: http
            state: enabled
            runtime: true
            permanent: true
```

   The permanent: true option makes the new settings persistent across reboots.

2. Validate the playbook syntax:

   ```bash
   # ansible-playbook ~/opening-a-port.yml --syntax-check
   ```

   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

   ```bash
   # ansible-playbook ~/opening-a-port.yml
   ```
Verification

- On the managed node, verify that the 443/tcp port associated with the HTTPS service is open:

```bash
# firewall-cmd --list-ports
443/tcp
```

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.firewall/README.md`

9.5. CONFIGURING A FIREWALLD DMZ ZONE BY USING A RHEL SYSTEM ROLE

As a system administrator, you can use the firewall System Role to configure a dmz zone on the enp1s0 interface to permit HTTPS traffic to the zone. In this way, you enable external users to access your web servers.

Perform this procedure on the Ansible control node.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on the them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example `~/configuring-a-dmz.yml`, with the following content:

   ```yaml
   ---
   - name: Configure firewalld
     hosts: managed-node-01.example.com
     tasks:
       - name: Creating a DMZ with access to HTTPS port and masquerading for hosts in DMZ
         include_role:
           name: rhel-system-roles.firewall

           vars:
             firewall:
               - zone: dmz
                 interface: enp1s0
                 service: https
                 state: enabled
                 runtime: true
                 permanent: true
   
   2. Validate the playbook syntax:
# ansible-playbook ~/configuring-a-dmz.yml --syntax-check

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

# ansible-playbook ~/configuring-a-dmz.yml

**Verification**

- On the managed node, view detailed information about the `dmz` zone:

```
# firewall-cmd --zone=dmz --list-all
```

```
dmz (active)
target: default
icmp-block-inversion: no
**interfaces:** enp1s0
```

```
sources:
**services:** https ssh
```

```
ports:
protocols:
forward: no
masquerade: no
forward-ports:
source-ports:
icmp-blocks:
```

**Additional resources**

- `/usr/share/ansible/roles/rhel-system-roles.firewall/README.md`
10.1. USING THE POSTFIX SYSTEM ROLE TO AUTOMATE BASIC POSTFIX MTA ADMINISTRATION

You can install, configure and start the Postfix Mail Transfer Agent on the managed nodes by using the postfix RHEL System Role.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook that defines the postfix role:

   a. Create a new YAML file, for example ~/postfix-playbook.yml, and open it in a text editor, for example:

```
# vi postfix-playbook.yml
```

   b. Configure the relay_domains=$mydestination and relayhost=example.com variables:

```
- name: Manage postfix
  hosts: all
  vars:
    postfix_conf:
      relay_domains: $mydestination
      relayhost: example.com
  roles:
  - linux-system-roles.postfix
```

   c. If you want Postfix to use a different hostname than the fully-qualified domain name (FQDN) that is returned by the gethostname() function, add the myhostname parameter under the postfix_conf: line in the file:

```
myhostname = smtp.example.com
```

   d. If the domain name differs from the domain name in the myhostname parameter, add the mydomain parameter. Otherwise, the $myhostname minus the first component is used.
mydomain = <example.com>

e. Use `postfix_manage_firewall: true` variable to ensure that the SMTP port is open in the firewall on the servers. Manage the SMTP related ports, 25/tcp, 465/tcp, and 587/tcp. If the variable is set to `false`, the `postfix` role does not manage the firewall. The default is `false`.

**NOTE**

The `postfix_manage_firewall` variable is limited to adding ports. It cannot be used for removing ports. If you want to remove ports, use the `firewall` RHEL System Role directly.

f. If your scenario involves using non-standard ports, set the `postfix_manage_selinux: true` variable to ensure that the port is properly labeled for SELinux on the servers.

**NOTE**

The `postfix_manage_selinux` variable is limited to adding rules to the SELinux policy. It cannot remove rules from the policy. If you want to remove rules, use the `selinux` System Role directly.

2. Run the playbook on a specific inventory:

```
# ansible-playbook -i <inventory-file> </path/to/file/postfix-playbook.yml>
```

Where:

- `<inventory-file>` is the inventory file.
- `<postfix-playbook.yml>` is the playbook you use.

**Additional resources**

- For more details on RHEL System Roles, see the Introduction to RHEL System Roles.
- For more information about the Ansible automation controller and its functionality, see the Automation controller overview page.
- For more information about using Satellite as your RHEL System Roles control node, see Automating host configuration with Red Hat Satellite and RHEL System Roles.

### 10.2. SELECTED VARIABLES FOR THE POSTFIX RHEL SYSTEM ROLE

You can customize the configuration of the Postfix Mail Transfer Agent (MTA) by using variables of the `postfix` RHEL System Role.

Use the following variables for a basic configuration. See the documentation installed with the `rhel-system-roles` package for more variables.

**postfix_conf**

Use this variable to include key or value pairs of all the supported `postfix` configuration parameters. By default, `postfix_conf` does not have a value.
postfix_conf:
  relayhost: example.com

previous: replaced

Use this variable to remove any existing configuration and apply the desired configuration on top of a clean postfix installation:

postfix_conf:
  relayhost: example.com
  previous: replaced

postfix_check

Use this variable to determine whether a check has been executed before starting the postfix role to verify the configuration changes. The default value is true.
For example:

postfix_check: true

postfix_backup

Use this variable to create a single backup copy of the configuration by setting the variable to true. The default value is false.
To overwrite any previous backup, enter the following command:

# cp /etc/postfix/main.cf /etc/postfix/main.cf.backup

If the postfix_backup value is changed to true, you must also set the postfix_backup_multiple value to false:

postfix_backup: true
postfix_backup_multiple: false

postfix_backup_multiple

Use this variable to make a timestamped backup copy of the configuration by setting it to true. The default value is true.
To keep multiple backup copies, enter the following command:

# cp /etc/postfix/main.cf /etc/postfix/main.cf.$(date -Isec)

The postfix_backup_multiple:true setting overrides postfix_backup. If you want to use postfix_backup, you must set the postfix_backup_multiple:false.

postfix_manage_firewall

Use this variable to integrate the postfix role with the firewall role to manage port access. By default, the variable is set to false. If you want to automatically manage port access from the postfix role, set the variable to true.

postfix_manage_selinux

Use this variable to integrate the postfix role with the selinux role to manage port access. By default, the variable is set to false. If you want to automatically manage port access from the postfix role, set the variable to true.
CHAPTER 11. CONFIGURING SELINUX BY USING SYSTEM ROLES

You can configure and manage SELinux permissions on other systems by using the `selinux` RHEL System Role.

11.1. INTRODUCTION TO THE SELINUX SYSTEM ROLE

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems. You can perform the following actions by using the `selinux` System Role:

- Cleaning local policy modifications related to SELinux booleans, file contexts, ports, and logins.
- Setting SELinux policy booleans, file contexts, ports, and logins.
- Restoring file contexts on specified files or directories.
- Managing SELinux modules.

The following table provides an overview of input variables available in the `selinux` System Role.

Table 11.1. selinux System Role variables

<table>
<thead>
<tr>
<th>Role variable</th>
<th>Description</th>
<th>CLI alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>selinux_policy</code></td>
<td>Chooses a policy protecting targeted processes or Multi Level Security protection.</td>
<td><code>SELINUXTYPE</code> in <code>/etc/selinux/config</code></td>
</tr>
<tr>
<td><code>selinux_state</code></td>
<td>Switches SELinux modes.</td>
<td><code>setenforce</code> and <code>SELINUX</code> in <code>/etc/selinux/config</code></td>
</tr>
<tr>
<td><code>selinux_booleans</code></td>
<td>Enables and disables SELinux booleans.</td>
<td><code>setsebool</code></td>
</tr>
<tr>
<td><code>selinux_fcontexts</code></td>
<td>Adds or removes a SELinux file context mapping.</td>
<td><code>semanage fcontext</code></td>
</tr>
<tr>
<td><code>selinux_restore_dirs</code></td>
<td>Restores SELinux labels in the file-system tree.</td>
<td><code>restorecon -R</code></td>
</tr>
<tr>
<td><code>selinux_ports</code></td>
<td>Sets SELinux labels on ports.</td>
<td><code>semanage port</code></td>
</tr>
<tr>
<td><code>selinux_logins</code></td>
<td>Sets users to SELinux user mapping.</td>
<td><code>semanage login</code></td>
</tr>
<tr>
<td><code>selinux_modules</code></td>
<td>Installs, enables, disables, or removes SELinux modules.</td>
<td><code>semodule</code></td>
</tr>
</tbody>
</table>

The `/usr/share/doc/rhel-system-roles/selinux/example-selinux-playbook.yml` example playbook
installed by the `rhel-system-roles` package demonstrates how to set the targeted policy in enforcing mode. The playbook also applies several local policy modifications and restores file contexts in the `/tmp/test_dir/` directory.

For a detailed reference on `selinux` role variables, install the `rhel-system-roles` package, and see the README.md or README.html files in the `/usr/share/doc/rhel-system-roles/selinux/` directory.

Additional resources

- Introduction to RHEL System Roles

11.2. USING THE SELINUX SYSTEM ROLE TO APPLY SELINUX SETTINGS ON MULTIPLE SYSTEMS

With the `selinux` System Role, you can prepare and apply an Ansible playbook with your verified SELinux settings.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Prepare your playbook. You can either start from scratch or modify the example playbook installed as a part of the `rhel-system-roles` package:

   ```bash
   # cp /usr/share/doc/rhel-system-roles/selinux/example-selinux-playbook.yml <my-selinux-playbook.yml>
   # vi <my-selinux-playbook.yml>
   ```

2. Change the content of the playbook to fit your scenario. For example, the following part ensures that the system installs and enables the `selinux-local-1.pp` SELinux module:

   ```yaml
   selinux_modules:
   - { path: "selinux-local-1.pp", priority: "400" }
   ```

3. Save the changes, and exit the text editor.

4. Validate the playbook syntax:

   ```bash
   # ansible-playbook <my-selinux-playbook.yml> --syntax-check
   ```

   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

5. Run your playbook:
# ansible-playbook <my-selinux-playbook.yml>

## Additional resources

- For more information, install the `rhel-system-roles` package, and see the `/usr/share/doc/rhel-system-roles/selinux/` and `/usr/share/ansible/roles/rhel-system-roles.selinux/` directories.

- SELinux hardening with Ansible Knowledgebase article

### 11.3. MANAGING PORTS BY USING THE SELINUX RHEL SYSTEM ROLE

You can automate managing port access in SELinux consistently across multiple systems by using the `selinux` RHEL System Role. This might be useful, for example, when configuring an Apache HTTP server to listen on a different port. You can do this by creating a playbook with the `selinux` role that assigns the `http_port_t` SELinux type to a specific port number. After you run the playbook on the managed nodes, specific services defined in the SELinux policy can access this port.

You can automate managing port access in SELinux either by using the `seport` module, which is quicker than using the entire role, or by using the `selinux` role, which is more useful when you also make other changes in SELinux configuration. The methods are equivalent, in fact the `selinux` role uses the `seport` module when configuring ports. Each of the methods has the same effect as entering the command `semanage port -a -t http_port_t -p tcp <port_number>` on the managed node.

#### Prerequisites

- You have prepared the control node and the managed nodes.

- You are logged in to the control node as a user who can run playbooks on the managed nodes.

- The account you use to connect to the managed nodes has `sudo` permissions on them.

- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

- Optional: To verify port status by using the `semanage` command, the `policycoreutils-python-utils` package must be installed.

#### Procedure

- To configure just the port number without making other changes, use the `seport` module:

  ```yaml
  - name: Allow Apache to listen on tcp port <port_number>
    community.general.seport:
      ports: <port_number>
      proto: tcp
      setype: http_port_t
      state: present
  ```

  Replace `<port_number>` with the port number to which you want to assign the `http_port_t` type.

- For more complex configuration of the managed nodes that involves other customizations of SELinux, use the `selinux` role. Create a playbook file, for example, `~/selinux-custom-ports.yml`, and add the following content:

  ```yaml
  ```
---

- name: Modify SELinux port mapping example
  hosts: all
  vars:
    # Map tcp port <port_number> to the 'http_port_t' SELinux port type
    selinux_ports:
      - ports: <port_number>
        proto: tcp
        setype: http_port_t
        state: present

  tasks:
    - name: Include selinux role
      include_role:
        name: rhel-system-roles.selinux

Replace <port_number> with the port number to which you want to assign the http_port_t type.

Verification

- Verify that the port is assigned to the http_port_t type:

  # semanage port --list | grep http_port_t
  http_port_t tcp <port_number>, 80, 81, 443, 488, 8008, 8009, 8443, 9000
CHAPTER 12. MANAGING\textit{systemd} UNITS BY USING THE \textit{systemd} RHEL SYSTEM ROLE

With the \textit{systemd} System Role you can deploy unit files and manage \textit{systemd} units on multiple systems by using the Red Hat Ansible Automation Platform.

You can use the \texttt{systemd\_units} variable in \textit{systemd} System Role playbooks to gain insights into the status of \textit{systemd} units on a target system. The variable displays a list of dictionaries. Each dictionary entry describes the state and configuration of one \textit{systemd} unit present on the managed host. The \texttt{systemd\_units} variable is updated as the final step of task execution and captures the state after the role has run all tasks.

12.1. VARIABLES FOR THE \textit{systemd} RHEL SYSTEM ROLE

You can customize the behavior of the \textit{systemd} system and service manager by setting the following input variables for the \textit{systemd} RHEL System Role:

\texttt{systemd\_unit\_files}

Specifies a list of \textit{systemd} unit file names that you want to deploy to the target hosts.

\texttt{systemd\_unit\_file\_templates}

Specifies a list of \textit{systemd} unit file names that should be treated as templates. Each name should correspond to the Jinja template file. For example, for a \texttt{<name>\_service} unit file, you can either have the \texttt{<name>\_service} Jinja template file or the \texttt{<name>\_service.j2} Jinja template file. If your local template file has a \texttt{.j2} suffix, Ansible removes the suffix before creating the final unit file name.

\texttt{systemd\_dropins}

Specifies a list of \textit{systemd} drop-in configuration files to modify or enhance the behavior of a \textit{systemd} unit without making changes to the unit file directly.

When you set the \texttt{systemd\_dropins = <name>\_service.conf} variable in the playbook, Ansible takes the local \texttt{<name>\_service.conf} file and creates a drop-in file on the managed node named always \texttt{99-override.conf} and uses this drop-in file to modify the \texttt{<name>\_service systemd} unit.

\texttt{systemd\_started\_units}

Specifies the list of unit names that \textit{systemd} starts.

\texttt{systemd\_stopped\_units}

Use this variable to specify the list of unit names that \textit{systemd} should stop.

\texttt{systemd\_restarted\_units}

Specifies a list of unit names that \textit{systemd} should restart.

\texttt{systemd\_reloaded\_units}

Specifies a list of unit names that \textit{systemd} should reload.

\texttt{systemd\_enabled\_units}

Specifies a list of unit names that \textit{systemd} should enable.

\texttt{systemd\_disabled\_units}

Specifies a list of unit names that \textit{systemd} should disable.

\texttt{systemd\_masked\_units}

Specifies a list of unit names that \textit{systemd} should mask.

\texttt{systemd\_unmasked\_units}

Specifies a list of unit names that \textit{systemd} should unmask.
12.2. DEPLOYING AND STARTING A `systemd` UNIT BY USING THE `systemd` SYSTEM ROLE

You can apply the `systemd` RHEL System Role to perform tasks related to `systemd` unit management on the target hosts. You will set the `systemd` System Role variables in a playbook to define which unit files `systemd` manages, starts, and enables.

Prerequisites

- You have prepared the control node and the managed nodes
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   - name: Deploy and start systemd unit
     hosts: all
     vars:
       systemd_unit_files:
         - <name1>.service
         - <name2>.service
         - <name3>.service
       systemd_started_units:
         - <name1>.service
         - <name2>.service
         - <name3>.service
       systemd_enabled_units:
         - <name1>.service
         - <name2>.service
         - <name3>.service
     roles:
       - linux-system-roles.systemd
   
   2. Optional: Verify playbook syntax:

   ```
   # ansible-playbook --syntax-check playbook.yml -i inventory_file
   ```

3. Run the playbook on your inventory file:

   ```
   # ansible-playbook -i inventory_file /path/to/file/playbook.yml
   ```

12.3. ADDITIONAL RESOURCES

- The `ansible-playbook(1)` man page
CHAPTER 13. CONFIGURING LOGGING BY USING RHEL SYSTEM ROLES

As a system administrator, you can use the logging System Role to configure a RHEL host as a logging server to collect logs from many client systems.

13.1. THE LOGGING SYSTEM ROLE

With the logging System Role, you can deploy logging configurations on local and remote hosts.

Logging solutions provide multiple ways of reading logs and multiple logging outputs.

For example, a logging system can receive the following inputs:

- Local files
- systemd/journal
- Another logging system over the network

In addition, a logging system can have the following outputs:

- Logs stored in the local files in the /var/log directory
- Logs sent to Elasticsearch
- Logs forwarded to another logging system

With the logging System Role, you can combine the inputs and outputs to fit your scenario. For example, you can configure a logging solution that stores inputs from journal in a local file, whereas inputs read from files are both forwarded to another logging system and stored in the local log files.

13.2. LOGGING SYSTEM ROLE PARAMETERS

In a logging System Role playbook, you define the inputs in the logging_inputs parameter, outputs in the logging_outputs parameter, and the relationships between the inputs and outputs in the logging_flows parameter. The logging System Role processes these variables with additional options to configure the logging system. You can also enable encryption or an automatic port management.

NOTE

Currently, the only available logging system in the logging System Role is Rsyslog.

- logging_inputs: List of inputs for the logging solution.
  - name: Unique name of the input. Used in the logging_flows: inputs list and a part of the generated config file name.
  - type: Type of the input element. The type specifies a task type which corresponds to a directory name in roles/rsyslog/{tasks,vars}/inputs/.
    - basics: Inputs configuring inputs from systemd journal or unix socket.
      - kernel_message: Load imklog if set to true. Default to false.
- **use_imuxsock**: Use `imuxsock` instead of `imjournal`. Default to `false`.

- **ratelimit_burst**: Maximum number of messages that can be emitted within `ratelimit_interval`. Default to `20000` if `use_imuxsock` is false. Default to `200` if `use_imuxsock` is true.

- **ratelimit_interval**: Interval to evaluate `ratelimit_burst`. Default to `600 seconds` if `use_imuxsock` is false. Default to `0` if `use_imuxsock` is true. `0` indicates rate limiting is turned off.

- **persist_state_interval**: Journal state is persisted every value messages. Default to `10`. Effective only when `use_imuxsock` is false.

  - **files**: Inputs configuring inputs from local files.
  
  - **remote**: Inputs configuring inputs from the other logging system over network.
    
    - **state**: State of the configuration file. **present** or **absent**. Default to **present**.

- **logging_outputs**: List of outputs for the logging solution.

  - **files**: Outputs configuring outputs to local files.
  
  - **forwards**: Outputs configuring outputs to another logging system.
  
  - **remote_files**: Outputs configuring outputs from another logging system to local files.

- **logging_flows**: List of flows that define relationships between **logging_inputs** and **logging_outputs**. The **logging_flows** variable has the following keys:

  - **name**: Unique name of the flow
  
  - **inputs**: List of **logging_inputs** name values
  
  - **outputs**: List of **logging_outputs** name values.

- **logging_manage_firewall**: If set to **true**, the **logging** role uses the **firewall** role to automatically manage port access.

- **logging_manage_selinux**: If set to **true**, the **logging** role uses the **selinux** role to automatically manage port access.

**Additional resources**

- Documentation installed with the **rhel-system-roles** package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`

### 13.3. APPLYING A LOCAL LOGGING SYSTEM ROLE

Prepare and apply an Ansible playbook to configure a logging solution on a set of separate machines. Each machine records logs locally.

**Prerequisites**

- **You have prepared the control node and the managed nodes**.
You are logged in to the control node as a user who can run playbooks on the managed nodes.

- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**NOTE**

You do not have to have the `rsyslog` package installed, because the System Role installs `rsyslog` when deployed.

**Procedure**

1. Create a playbook file, for example, `~/logging-playbook.yml`, with the following content:

   ```yaml
   ---
   - name: Deploying basics input and implicit files output
     hosts: all
     roles:
       - rhel-system-roles.logging
     vars:
       logging_inputs:
         - name: system_input
           type: basics
       logging_outputs:
         - name: files_output
           type: files
       logging_flows:
         - name: flow1
           inputs: [system_input]
           outputs: [files_output]
   ```

2. Validate the playbook syntax:

   ```bash
   # ansible-playbook ~/logging-playbook.yml --syntax-check
   ```

   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

   ```bash
   # ansible-playbook ~/logging-playbook.yml
   ```

**Verification**

1. Test the syntax of the `/etc/rsyslog.conf` file:

   ```bash
   # rsyslogd -N 1
   rsyslogd: version 8.1911.0-6.el8, config validation run...
   ```

2. Verify that the system sends messages to the log:
a. Send a test message:

```
# logger test
```

b. View the `/var/log/messages` log, for example:

```
# cat /var/log/messages
Aug  5 13:48:31 <hostname> root[6778]: test
```

Where `<hostname>` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

### 13.4. FILTERING LOGS IN A LOCAL LOGGING SYSTEM ROLE

You can deploy a logging solution which filters the logs based on the `rsyslog` property-based filter.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**NOTE**

You do not have to have the `rsyslog` package installed, because the System Role installs `rsyslog` when deployed.

**Procedure**

1. Create a new playbook file, for example, `~/log-filter-playbook.yml`, with the following content:

```yaml
---
- name: Deploying files input and configured files output
  hosts: all
  roles:
    - linux-system-roles.logging
  vars:
    logging_inputs:
      - name: files_input
        type: basics
    logging_outputs:
      - name: files_output0
        type: files
        property: msg
        property_op: contains
        property_value: error
        path: /var/log/errors.log
      - name: files_output1
        type: files
```
Using this configuration, all messages that contain the `error` string are logged in `/var/log/errors.log`, and all other messages are logged in `/var/log/others.log`.

You can replace the `error` property value with the string by which you want to filter.

You can modify the variables according to your preferences.

2. Validate the playbook syntax:

   ```
   # ansible-playbook ~/log-filter-playbook.yml --syntax-check
   ```

   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

   ```
   # ansible-playbook ~/log-filter-playbook.yml
   ```

**Verification**

1. Test the syntax of the `/etc/rsyslog.conf` file:

   ```
   # rsyslogd -N 1
   rsyslogd: version 8.1911.0-6.el8, config validation run...
   ```

2. Verify that the system sends messages that contain the `error` string to the log:

   a. Send a test message:

      ```
      # logger error
      ```

   b. View the `/var/log/errors.log` log, for example:

      ```
      # cat /var/log/errors.log
      Aug  5 13:48:31 hostname root[6778]: error
      ```

      Where `hostname` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

**Additional resources**

- Documentation installed with the `rhel-system-roles` package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`
13.5. APPLYING A REMOTE LOGGING SOLUTION USING THE LOGGING SYSTEM ROLE

Follow these steps to prepare and apply a Red Hat Ansible Core playbook to configure a remote logging solution. In this playbook, one or more clients take logs from `systemd-journal` and forward them to a remote server. The server receives remote input from `remote_rsyslog` and `remote_files` and outputs the logs to local files in directories named by remote host names.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.

**NOTE**

You do not have to have the `rsyslog` package installed, because the System Role installs `rsyslog` when deployed.

Procedure

1. Create a playbook file, for example, `~/logging-playbook.yml`, with the following content:

```yaml
---
- name: Deploying remote input and remote_files output
  hosts: server
  roles:
    - rhel-system-roles.logging
  vars:
    logging_inputs:
    - name: remote_udp_input
      type: remote
      udp_ports: [601]
    - name: remote_tcp_input
      type: remote
      tcp_ports: [601]
    logging_outputs:
    - name: remote_files_output
      type: remote_files
    logging_flows:
    - name: flow_0
      inputs: [remote_udp_input, remote_tcp_input]
      outputs: [remote_files_output]
- name: Deploying basics input and forwards output
  hosts: clients
  roles:
    - rhel-system-roles.logging
  vars:
    logging_inputs:
    - name: basic_input
      type: basics
    logging_outputs:
```
- name: forward_output0
  type: forwards
  severity: info
  target: `<host1.example.com>`
  udp_port: 601
- name: forward_output1
  type: forwards
  facility: mail
  target: `<host1.example.com>`
  tcp_port: 601
logging_flows:
- name: flows0
  inputs: [basic_input]
  outputs: [forward_output0, forward_output1]

[basic_input]
[forward_output0, forward_output1]

Where `<host1.example.com>` is the logging server.

**NOTE**
You can modify the parameters in the playbook to fit your needs.

**WARNING**
The logging solution works only with the ports defined in the SELinux policy of the server or client system and open in the firewall. The default SELinux policy includes ports 601, 514, 6514, 10514, and 20514. To use a different port, modify the SELinux policy on the client and server systems.

2. Create a new inventory file `inventory.ini` that lists your servers and clients:

```ini
[servers]
server ansible_host=<host1.example.com>

[clients]
client ansible_host=<host2.example.com>
```

Where:
- `<host1.example.com>` is the logging server.
- `<host2.example.com>` is the logging client.

3. Validate the playbook syntax:

```bash
# ansible-playbook ~/logging-playbook.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.
4. Run the playbook on your inventory.

```
# ansible-playbook -i ~/inventory.ini ~/logging-playbook.yml
```

**Verification**

1. On both the client and the server system, test the syntax of the `/etc/rsyslog.conf` file:

```
# rsyslogd -N 1
rsyslogd: version 8.1911.0-6.el8, config validation run (level 1), master config /etc/rsyslog.conf
```

2. Verify that the client system sends messages to the server:
   a. On the client system, send a test message:
      
      ```
      # logger test
      ```
   b. On the server system, view the `/var/log/<host2.example.com>/messages` log, for example:

      ```
      # cat /var/log/<host2.example.com>/messages
      Aug 5 13:48:31 <host2.example.com> root[6778]: test
      ```
      
      Where `<host2.example.com>` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

**Additional resources**

- Preparing a control node and managed nodes to use RHEL System Roles
- Documentation installed with the `rhel-system-roles` package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`
- RHEL System Roles KB article

### 13.6. USING THE LOGGING SYSTEM ROLE WITH TLS

Transport Layer Security (TLS) is a cryptographic protocol designed to allow secure communication over the computer network.

As an administrator, you can use the `logging` RHEL System Role to configure a secure transfer of logs using Red Hat Ansible Automation Platform.

#### 13.6.1. Configuring client logging with TLS

You can use an Ansible playbook with the `logging` System Role to configure logging on RHEL clients and transfer logs to a remote logging system using TLS encryption.

This procedure creates a private key and certificate, and configures TLS on all hosts in the clients group in the Ansible inventory. The TLS protocol encrypts the message transmission for secure transfer of logs over the network.
NOTE

You do not have to call the certificate System Role in the playbook to create the certificate. The logging System Role calls it automatically.

In order for the CA to be able to sign the created certificate, the managed nodes must be enrolled in an IdM domain.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- The managed nodes are enrolled in an IdM domain.
- If the logging server you want to configure on the manage node runs RHEL 9.2 or later and the FIPS mode is enabled, clients must either support the Extended Master Secret (EMS) extension or use TLS 1.3. TLS 1.2 connections without EMS fail. For more information, see the TLS extension "Extended Master Secret" enforced Knowledgebase article.

Procedure

1. Create a playbook file, for example ~/tls-client-logging-playbook.yml, with the following content:

```yaml
---
- name: Deploying files input and forwards output with certs
  hosts: clients
  roles:
    - rhel-system-roles.logging
  vars:
    logging_certificates:
      - name: logging_cert
dns: ['localhost', 'www.example.com']
  ca: ipa
logging_pki_files:
  - ca_cert: /local/path/to/ca_cert.pem
cert: /local/path/to/logging_cert.pem
private_key: /local/path/to/logging_cert.pem
logging_inputs:
  - name: input_name
type: files
  input_log_path: /var/log/containers/*.log
logging_outputs:
  - name: output_name
type: forwards
target: your_target_host
tcp_port: 514
tls: true
  pki_authmode: x509/name
```
The playbook uses the following parameters:

**logging_certificates**

The value of this parameter is passed on to `certificate_requests` in the `certificate` role and used to create a private key and certificate.

**logging_pki_files**

Using this parameter, you can configure the paths and other settings that logging uses to find the CA, certificate, and key files used for TLS, specified with one or more of the following sub-parameters: `ca_cert`, `ca_cert_src`, `cert`, `cert_src`, `private_key`, `private_key_src`, and `tls`.

**NOTE**

If you are using `logging_certificates` to create the files on the target node, do not use `ca_cert_src`, `cert_src`, and `private_key_src`, which are used to copy files not created by `logging_certificates`.

**ca_cert**

Represents the path to the CA certificate file on the target node. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

**cert**

Represents the path to the certificate file on the target node. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

**private_key**

Represents the path to the private key file on the target node. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

**ca_cert_src**

Represents the path to the CA certificate file on the control node which is copied to the target host to the location specified by `ca_cert`. Do not use this if using `logging_certificates`.

**cert_src**

Represents the path to a certificate file on the control node which is copied to the target host to the location specified by `cert`. Do not use this if using `logging_certificates`.

**private_key_src**

Represents the path to a private key file on the control node which is copied to the target host to the location specified by `private_key`. Do not use this if using `logging_certificates`.

**tls**

Setting this parameter to `true` ensures secure transfer of logs over the network. If you do not want a secure wrapper, you can set `tls: false`.

2. Validate the playbook syntax:

```bash
# ansible-playbook ~/tls-client-logging-playbook.yml --syntax-check
```
Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

```bash
# ansible-playbook ~/tls-client-logging-playbook.yml
```

Additional resources

- Requesting certificates using RHEL System Roles.

13.6.2. Configuring server logging with TLS

You can use an Ansible playbook with the `logging` System Role to configure logging on RHEL servers and set them to receive logs from a remote logging system using TLS encryption.

This procedure creates a private key and certificate, and configures TLS on all hosts in the server group in the Ansible inventory.

**NOTE**

You do not have to call the `certificate` System Role in the playbook to create the certificate. The `logging` System Role calls it automatically.

In order for the CA to be able to sign the created certificate, the managed nodes must be enrolled in an IdM domain.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- The managed nodes are enrolled in an IdM domain.
- If the logging server you want to configure on the manage node runs RHEL 9.2 or later and the FIPS mode is enabled, clients must either support the Extended Master Secret (EMS) extension or use TLS 1.3. TLS 1.2 connections without EMS fail. For more information, see the TLS extension “Extended Master Secret” enforced Knowledgebase article.

Procedure

1. Create a playbook file, for example `~/tls-server-logging-playbook.yml`, with the following content:

```yaml
---
- name: Deploying remote input and remote_files output with certs
  hosts: server
  roles:
    - rhel-system-roles.logging
```
The playbook uses the following parameters:

**logging_certificates**

The value of this parameter is passed on to `certificate_requests` in the `certificate` role and used to create a private key and certificate.

**logging_pki_files**

Using this parameter, you can configure the paths and other settings that logging uses to find the CA, certificate, and key files used for TLS, specified with one or more of the following sub-parameters: `ca_cert`, `ca_cert_src`, `cert`, `cert_src`, `private_key`, `private_key_src`, and `tls`.

**NOTE**

If you are using `logging_certificates` to create the files on the target node, do not use `ca_cert_src`, `cert_src`, and `private_key_src`, which are used to copy files not created by `logging_certificates`.

**ca_cert**

Represents the path to the CA certificate file on the target node. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

**cert**

Represents the path to the certificate file on the target node. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

**private_key**

Represents the path to the private key file on the target node. Default path is `/etc/pki/tls/certs/server-key.pem` and the file name is set by the user.
Represents the path to the private key file on the target node. Default path is 
/etc/pki/tls/private/server-key.pem and the file name is set by the user.

cert_src
Represents the path to the CA certificate file on the control node which is copied to the 
target host to the location specified by ca_cert. Do not use this if using 
logging_certificates.

cert_src
Represents the path to a certificate file on the control node which is copied to the target 
host to the location specified by cert. Do not use this if using logging_certificates.

private_key_src
Represents the path to a private key file on the control node which is copied to the target 
host to the location specified by private_key. Do not use this if using logging_certificates.

tls
Setting this parameter to true ensures secure transfer of logs over the network. If you do not 
want a secure wrapper, you can set tls: false.

2. Validate the playbook syntax:

```
# ansible-playbook ~/tls-server-logging-playbook.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid 
configuration.

3. Run the playbook on your inventory file:

```
# ansible-playbook ~/tls-server-logging-playbook.yml
```

Additional resources

- Requesting certificates using RHEL System Roles.

13.7. USING THE LOGGING SYSTEM ROLES WITH RELP

Reliable Event Logging Protocol (RELP) is a networking protocol for data and message logging over the 
TCP network. It ensures reliable delivery of event messages and you can use it in environments that do 
not tolerate any message loss.

The RELP sender transfers log entries in form of commands and the receiver acknowledges them once they are processed. To ensure consistency, RELP stores the transaction number to each transferred 
command for any kind of message recovery.

You can consider a remote logging system in between the RELP Client and RELP Server. The RELP 
Client transfers the logs to the remote logging system and the RELP Server receives all the logs sent by 
the remote logging system.

Administrators can use the logging System Role to configure the logging system to reliably send and 
receive log entries.

13.7.1. Configuring client logging with RELP

You can use the logging System Role to configure logging in RHEL systems that are logged on a local 
machine and can transfer logs to the remote logging system with RELP by running an Ansible playbook.
This procedure configures RELP on all hosts in the clients group in the Ansible inventory. The RELP configuration uses Transport Layer Security (TLS) to encrypt the message transmission for secure transfer of logs over the network.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example ~/relp-client-logging-playbook.yml, with the following content:

```yaml
---
- name: Deploying basic input and relp output
  hosts: clients
  roles:
  - rhel-system-roles.logging
  vars:
    logging_inputs:
      - name: basic_input
        type: basics
    logging_outputs:
      - name: relp_client
        type: relp
        target: logging.server.com
        port: 20514
        tls: true
        ca_cert: /etc/pki/tls/certs/ca.pem
        cert: /etc/pki/tls/certs/client-cert.pem
        private_key: /etc/pki/tls/private/client-key.pem
        pki_authmode: name
        permitted_servers:
          - '*.server.example.com'
    logging_flows:
      - name: example_flow
        inputs: [basic_input]
        outputs: [relp_client]
```

The playbook uses following settings:

- **target**
  - This is a required parameter that specifies the host name where the remote logging system is running.

- **port**
  - Port number the remote logging system is listening.

- **tls**
Ensures secure transfer of logs over the network. If you do not want a secure wrapper you can set the `tls` variable to `false`. By default `tls` parameter is set to true while working with RELP and requires key/certificates and triplets `{ca_cert, cert, private_key}` and/or `{ca_cert_src, cert_src, private_key_src}`.

- If the `{ca_cert_src, cert_src, private_key_src}` triplet is set, the default locations `/etc/pki/tls/certs` and `/etc/pki/tls/private` are used as the destination on the managed node to transfer files from control node. In this case, the file names are identical to the original ones in the triplet.

- If the `{ca_cert, cert, private_key}` triplet is set, files are expected to be on the default path before the logging configuration.

- If both triplets are set, files are transferred from local path from control node to specific path of the managed node.

### ca_cert

Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

### cert

Represents the path to certificate. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

### private_key

Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

### ca_cert_src

Represents local CA certificate file path which is copied to the target host. If `ca_cert` is specified, it is copied to the location.

### cert_src

Represents the local certificate file path which is copied to the target host. If `cert` is specified, it is copied to the location.

### private_key_src

Represents the local key file path which is copied to the target host. If `private_key` is specified, it is copied to the location.

### pki_authmode

Accepts the authentication mode as `name` or `fingerprint`.

### permitted_servers

List of servers that will be allowed by the logging client to connect and send logs over TLS.

### inputs

List of logging input dictionary.

### outputs

List of logging output dictionary.

2. Validate the playbook syntax:

```
# ansible-playbook ~/relp-client-logging-playbook.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.
3. Run the playbook:

```bash
# ansible-playbook ~/relp-client-logging-playbook.yml
```

### 13.7.2. Configuring server logging with RELP

You can use the **logging** System Role to configure logging in RHEL systems as a server and can receive logs from the remote logging system with RELP by running an Ansible playbook.

This procedure configures RELP on all hosts in the **server** group in the Ansible inventory. The RELP configuration uses TLS to encrypt the message transmission for secure transfer of logs over the network.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has **sudo** permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**Procedure**

1. Create a playbook file, for example `~/relp-server-logging-playbook.yml`, with the following content:

```yaml
---
- name: Deploying remote input and remote_files output
  hosts: server
  roles:
    - rhel-system-roles.logging
  vars:
    logging_inputs:
      - name: relp_server
        type: relp
        port: 20514
        tls: true
        ca_cert: /etc/pki/tls/certs/ca.pem
        cert: /etc/pki/tls/certs/server-cert.pem
        private_key: /etc/pki/tls/private/server-key.pem
        pki_authmode: name
        permitted_clients:
          - '*example.client.com'
    logging_outputs:
      - name: remote_files_output
        type: remote_files
    logging_flows:
      - name: example_flow
        inputs: relp_server
        outputs: remote_files_output
```

The playbooks uses the following settings:
Port

Port number the remote logging system is listening.

tls

Ensures secure transfer of logs over the network. If you do not want a secure wrapper you can set the `tls` variable to `false`. By default `tls` parameter is set to `true` while working with RELP and requires key/certificates and triplets `{ca_cert, cert, private_key}` and/or `{ca_cert_src, cert_src, private_key_src}`:

- If the `{ca_cert_src, cert_src, private_key_src}` triplet is set, the default locations `/etc/pki/tls/certs` and `/etc/pki/tls/private` are used as the destination on the managed node to transfer files from control node. In this case, the file names are identical to the original ones in the triplet.
- If the `{ca_cert, cert, private_key}` triplet is set, files are expected to be on the default path before the logging configuration.
- If both triplets are set, files are transferred from local path from control node to specific path of the managed node.

c_a_cert

Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

cert

Represents the path to the certificate. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

private_key

Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

c_a_cert_src

Represents local CA certificate file path which is copied to the target host. If `ca_cert` is specified, it is copied to the location.

cert_src

Represents the local certificate file path which is copied to the target host. If `cert` is specified, it is copied to the location.

private_key_src

Represents the local key file path which is copied to the target host. If `private_key` is specified, it is copied to the location.

pki_authmode

Accepts the authentication mode as `name` or `fingerprint`.

permitted_clients

List of clients that will be allowed by the logging server to connect and send logs over TLS.

inputs

List of logging input dictionary.

outputs

List of logging output dictionary.

2. Validate the playbook syntax:
# ansible-playbook ~/relp-server-logging-playbook.yml --syntax-check

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:

    # ansible-playbook ~/relp-server-logging-playbook.yml

13.8. ADDITIONAL RESOURCES

- Preparing a control node and managed nodes to use RHEL System Roles

- Documentation installed with the `rhel-system-roles` package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`

- RHEL System Roles

- `ansible-playbook(1)` man page.
CHAPTER 14. CONFIGURING THE SYSTEMD JOURNAL BY USING THE JOURNALD RHEL SYSTEM ROLE

With the journald System Role you can automate the systemd journal, and configure persistent logging by using the Red Hat Ansible Automation Platform.

14.1. VARIABLES FOR THE JOURNALD RHEL SYSTEM ROLE

The journald System Role provides a set of variables for customizing the behavior of journald logging service. The role includes the following variables:

**journald_persistent**
- Use this boolean variable to configure journald for storing log files on disk in the /var/log/journal/ directory. When you set this variable to true, logs are stored on disk, otherwise, they are stored in volatile memory. The default value is false.

**journald_max_disk_size**
- Use this variable to specify the maximum size, in megabytes, that journal files can occupy on disk. Refer to the default sizing calculation described in journald.conf(5) man page.

**journald_max_files**
- Use this variable to specify the maximum number of journal files you want to keep while respecting the journald_max_disk_size setting for journal.

**journald_max_file_size**
- Use this variable to specify the maximum size, in megabytes, of a single journal file.

**journald_per_user**
- Use this boolean variable to configure journald for keeping log data separate for each user. The default value is true and the unprivileged users can read system logs from their own user services. Note that per-user journal files are only available when the journald_persistent variable is set to true.

**journald_compression**
- Use this boolean variable to apply compression to journald data objects that are larger than the default 512 bytes. The default value is true.

**journald_sync_interval**
- Use this variable to specify the time, in minutes, after which journald synchronizes the currently used journal file to disk. By default, the role does not alter the current value.

Additional resources

- The journald.conf(5) man page.

14.2. CONFIGURING PERSISTENT LOGGING BY USING THE JOURNALD SYSTEM ROLE

As a system administrator, you can configure persistent logging by using the journald System Role. The following example shows how to set up the journald System Role variables in a playbook to achieve the following goals:

- Configuring persistent logging
Specifying the maximum size of disk space for journal files
- Configuring journald to keep log data separate for each user
- Defining the synchronization interval

Prerequisites
- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure
1. Create a new playbook file, for example, ~/journald-log-playbook.yml, with the following content:

```yaml
---
- hosts: all
  vars:
    journald_persistent: true
    journald_max_disk_size: 2048
    journald_per_user: true
    journald_sync_interval: 1
  roles:
    - linux-system-roles.journald
---
```

As a result, the journald service stores your logs persistently on a disk to the maximum size of 2048 MB, and keeps log data separate for each user. The synchronization happens every minute.

2. Optional: Verify playbook syntax.

```bash
# ansible-playbook --syntax-check ~/journald-log-playbook.yml
```

3. Run the playbook on your inventory file:

```bash
# ansible-playbook ~/journald-log-playbook.yml
```

14.3. ADDITIONAL RESOURCES
- The journald.conf(5) man page
- The ansible-playbook(1) man page
CHAPTER 15. CONFIGURING SECURE COMMUNICATION BY USING THE SSH AND SSHD RHEL SYSTEM ROLES

As an administrator, you can use the sshd System Role to configure SSH servers and the ssh System Role to configure SSH clients consistently on any number of RHEL systems at the same time using the Ansible Core package.

15.1. SSH SERVER SYSTEM ROLE VARIABLES

In an sshd System Role playbook, you can define the parameters for the SSH configuration file according to your preferences and limitations.

If you do not configure these variables, the System Role produces an sshd_config file that matches the RHEL defaults.

In all cases, Booleans correctly render as yes and no in sshd configuration. You can define multi-line configuration items using lists. For example:

```yaml
sshd_ListenAddress:
  - 0.0.0.0
  - '::'
```

renders as:

```ini
ListenAddress 0.0.0.0
ListenAddress ::
```

Variables for the sshd System Role

- **sshd_enable**
  If set to false, the role is completely disabled. Defaults to true.

- **sshd_skip_defaults**
  If set to true, the System Role does not apply default values. Instead, you specify the complete set of configuration defaults by using either the sshd dictionary or sshd_<OptionName> variables. Defaults to false.

- **sshd_manage_service**
  If set to false, the service is not managed, which means it is not enabled on boot and does not start or reload. Defaults to true except when running inside a container or AIX, because the Ansible service module does not currently support enabled for AIX.

- **sshd_allow_reload**
  If set to false, sshd does not reload after a change of configuration. This can help with troubleshooting. To apply the changed configuration, reload sshd manually. Defaults to the same value as sshd_manage_service except on AIX, where sshd_manage_service defaults to false but sshd_allow_reload defaults to true.

- **sshd_install_service**
  If set to true, the role installs service files for the sshd service. This overrides files provided in the operating system. Do not set to true unless you are configuring a second instance and you also change the sshd_service variable. Defaults to false.
  The role uses the files pointed by the following variables as templates:
sshd_service_template_service (default: templates/sshd.service.j2)
sshd_service_template_at_service (default: templates/sshd@.service.j2)
sshd_service_template_socket (default: templates/sshd.socket.j2)

sshd_service
This variable changes the sshd service name, which is useful for configuring a second sshd service instance.

sshd
A dictionary that contains configuration. For example:

```
sshd:
  Compression: yes
  ListenAddress: 
    - 0.0.0.0
```

The sshd_config(5) lists all options for the sshd dictionary.

sshd_<OptionName>
You can define options by using simple variables consisting of the sshd_ prefix and the option name instead of a dictionary. The simple variables override values in the sshd dictionary. For example:

```
sshd_Compression: no
```

The sshd_config(5) lists all options for sshd.

sshd_manage_firewall
Set this variable to true if you are using a different port than the default port 22. When set to true, the sshd role uses the firewall role to automatically manage port access.

NOTE
The sshd_manage_firewall variable can only add ports. It cannot remove ports. To remove ports, use the firewall System Role directly. For more information about managing ports by using the firewall System Role, see Configuring ports by using System Roles.

sshd_manage_selinux
Set this variable to true if you are using a different port than the default port 22. When set to true, the sshd role uses the selinux role to automatically manage port access.

NOTE
The sshd_manage_selinux variable can only add ports. It cannot remove ports. To remove ports, use the selinux System Role directly.

sshd_match and sshd_match_1 to sshd_match_9
A list of dictionaries or just a dictionary for a Match section. Note that these variables do not override match blocks as defined in the sshd dictionary. All of the sources will be reflected in the resulting configuration file.
sshd_backup

When set to `false`, the original `sshd_config` file is not backed up. Default is `true`.

Secondary variables for the sshd System Role

You can use these variables to override the defaults that correspond to each supported platform.

**sshd_packages**

You can override the default list of installed packages using this variable.

**sshd_config_owner, sshd_config_group, and sshd_config_mode**

You can set the ownership and permissions for the `openssh` configuration file that this role produces using these variables.

**sshd_config_file**

The path where this role saves the `openssh` server configuration produced.

**sshd_config_namespace**

The default value of this variable is null, which means that the role defines the entire content of the configuration file including system defaults. Alternatively, you can use this variable to invoke this role from other roles or from multiple places in a single playbook on systems that do not support drop-in directory. The `sshd_skip_defaults` variable is ignored and no system defaults are used in this case. When this variable is set, the role places the configuration that you specify to configuration snippets in an existing configuration file under the given namespace. If your scenario requires applying the role several times, you need to select a different namespace for each application.

**NOTE**

Limitations of the `openssh` configuration file still apply. For example, only the first option specified in a configuration file is effective for most of the configuration options.

Technically, the role places snippets in "Match all" blocks, unless they contain other match blocks, to ensure they are applied regardless of the previous match blocks in the existing configuration file. This allows configuring any non-conflicting options from different roles invocations.

**sshd_binary**

The path to the `sshd` executable of `openssh`.

**sshd_service**

The name of the `sshd` service. By default, this variable contains the name of the `sshd` service that the target platform uses. You can also use it to set the name of the custom `sshd` service when the role uses the `sshd_install_service` variable.

**sshd_verify_hostkeys**

Defaults to `auto`. When set to `auto`, this lists all host keys that are present in the produced configuration file, and generates any paths that are not present. Additionally, permissions and file owners are set to default values. This is useful if the role is used in the deployment stage to verify the service is able to start on the first attempt. To disable this check, set this variable to an empty list `[]`.

**sshd_hostkey_owner, sshd_hostkey_group, sshd_hostkey_mode**

Use these variables to set the ownership and permissions for the host keys from `sshd_verify_hostkeys`.

**sshd_sysconfig**

On systems based on RHEL 8 and earlier versions, this variable configures additional details of the
sshd service. If set to true, this role manages also the /etc/sysconfig/sshd configuration file based on the sshd_sysconfig_override_crypto_policy and sshd_sysconfig_use_strong_rng variables. Defaults to false.

**sshd_sysconfig_override_crypto_policy**

In RHEL 8, setting it to true allows overriding the system-wide cryptographic policy by using the following configuration options in the sshd dictionary or in the sshd_<OptionName> format:

- Ciphers
- MACs
- GSSAPIKexAlgorithms
- GSSAPIKeyExchange (FIPS-only)
- KexAlgorithms
- HostKeyAlgorithms
- PubkeyAcceptedKeyTypes
- CASignatureAlgorithms
  Defaults to false.

In RHEL 9, this variable has no effect. Instead, you can override system-wide cryptographic policies by using the following configuration options in the sshd dictionary or in the sshd_<OptionName> format:

- Ciphers
- MACs
- GSSAPIKexAlgorithms
- GSSAPIKeyExchange (FIPS-only)
- KexAlgorithms
- HostKeyAlgorithms
- PubkeyAcceptedAlgorithms
- HostbasedAcceptedAlgorithms
- CASignatureAlgorithms
- RequiredRSASize

If you enter these options into custom configuration files in the drop-in directory defined in the sshd_config_file variable, use a file name that lexicographically precedes the /etc/ssh/sshd_config.d/50-redhat.conf file that includes the cryptographic policies.

**sshd_sysconfig_use_strong_rng**

On systems based on RHEL 8 and earlier versions, this variable can force sshd to reseed the openssl random number generator with the number of bytes given as the argument. The default is 0, which disables this functionality. Do not turn this on if the system does not have a hardware random number generator.
15.2. CONFIGURING OPENSSSH SERVERS USING THE sshd SYSTEM ROLE

You can use the sshd System Role to configure multiple SSH servers by running an Ansible playbook.

NOTE

You can use the sshd System Role with other System Roles that change SSH and SSHD configuration, for example the Identity Management RHEL System Roles. To prevent the configuration from being overwritten, make sure that the sshd role uses namespaces (RHEL 8 and earlier versions) or a drop-in directory (RHEL 9).

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Copy the example playbook for the sshd System Role:

```bash
# cp /usr/share/doc/rhel-system-roles/sshd/example-root-login-playbook.yml ~/sshd-playbook.yml
```

2. Open the copied playbook by using a text editor, for example:

```bash
# vim ~/sshd-playbook.yml
```

```yaml
---
- hosts: all
  tasks:
    - name: Configure sshd to prevent root and password login except from particular subnet
      include_role:
        name: rhel-system-roles.sshd
      vars:
        sshd:
          # root login and password login is enabled only from a particular subnet
          PermitRootLogin: no
          PasswordAuthentication: no
          Match:
            - Condition: "Address 192.0.2.0/24"
              PermitRootLogin: yes
              PasswordAuthentication: yes
```

The playbook configures the managed node as an SSH server configured so that:

- password and root user login is disabled
password and root user login is enabled only from the subnet 192.0.2.0/24

You can modify the variables according to your preferences. For more details, see sshd System Role variables.

3. Validate the playbook syntax:

```bash
# ansible-playbook --syntax-check ~/sshd-playbook.yml
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

4. Run the playbook:

```bash
# ansible-playbook ~/sshd-playbook.yml
```

...  

PLAY RECAP
**************************************************************************
localhost : ok=12 changed=2 unreachable=0 failed=0
skipped=10 rescued=0 ignored=0

Verification

1. Log in to the SSH server:

   ```bash
   $ ssh user1@10.1.1.1
   ```
   
   Where:
   
   - **user1** is a user on the SSH server.
   - **10.1.1.1** is the IP address of the SSH server.

2. Check the contents of the `sshd_config` file on the SSH server:

   ```bash
   $ cat /etc/ssh/sshd_config.d/00-ansible_system_role.conf
   #
   # Ansible managed
   #
   PasswordAuthentication no
   PermitRootLogin no
   Match Address 192.0.2.0/24
   PasswordAuthentication yes
   PermitRootLogin yes
   ```

3. Check that you can connect to the server as root from the 192.0.2.0/24 subnet:

   a. Determine your IP address:

   ```bash
   $ hostname -I
   192.0.2.1
   ```
If the IP address is within the 192.0.2.1 - 192.0.2.254 range, you can connect to the server.

b. Connect to the server as root:

```
$ ssh root@10.1.1.1
```

Additional resources

- `ansible-playbook(1)` man page.

### 15.3. `ssh` System Role Variables

In an `ssh` System Role playbook, you can define the parameters for the client SSH configuration file according to your preferences and limitations.

If you do not configure these variables, the System Role produces a global `ssh_config` file that matches the RHEL defaults.

In all cases, booleans correctly render as `yes` or `no` in `ssh` configuration. You can define multi-line configuration items using lists. For example:

```
LocalForward:
- 22 localhost:2222
- 403 localhost:4003
```

renders as:

```
LocalForward 22 localhost:2222
LocalForward 403 localhost:4003
```

**NOTE**

The configuration options are case sensitive.

**Variables for the `ssh` System Role**

**`ssh_user`**

You can define an existing user name for which the System Role modifies user-specific configuration. The user-specific configuration is saved in `~/.ssh/config` of the given user. The default value is null, which modifies global configuration for all users.

**`ssh_skip_defaults`**

Defaults to `auto`. If set to `auto`, the System Role writes the system-wide configuration file `/etc/ssh/ssh_config` and keeps the RHEL defaults defined there. Creating a drop-in configuration file, for example by defining the `ssh_drop_in_name` variable, automatically disables the `ssh_skip_defaults` variable.

**`ssh_drop_in_name`**

Defines the name for the drop-in configuration file, which is placed in the system-wide drop-in directory. The name is used in the template `/etc/ssh/ssh_config.d/{ssh_drop_in_name}.conf` to reference the configuration file to be modified. If the system does not support drop-in directory, the default value is null. If the system supports drop-in directories, the default value is `00-ansible`. 
WARNING
If the system does not support drop-in directories, setting this option will make the play fail.

The suggested format is **NN-name**, where **NN** is a two-digit number used for ordering the configuration files and **name** is any descriptive name for the content or the owner of the file.

**ssh**
A dict that contains configuration options and their respective values.

**ssh**\_**OptionName**
You can define options by using simple variables consisting of the **ssh** prefix and the option name instead of a dict. The simple variables override values in the **ssh** dict.

**ssh**\_additional\_packages
This role automatically installs the **openssh** and **openssh-clients** packages, which are needed for the most common use cases. If you need to install additional packages, for example, **openssh-keysign** for host-based authentication, you can specify them in this variable.

**ssh**\_config\_file
The path to which the role saves the configuration file produced. Default value:

- If the system has a drop-in directory, the default value is defined by the template `/etc/ssh/ssh_config.d/\{(ssh_drop_in_name).conf`.
- If the system does not have a drop-in directory, the default value is `/etc/ssh/ssh_config`.
- If the **ssh**\_user variable is defined, the default value is `~/.ssh/config`.

**ssh**\_config\_owner, **ssh**\_config\_group, **ssh**\_config\_mode
The owner, group and modes of the created configuration file. By default, the owner of the file is **root:root**, and the mode is **0644**. If **ssh**\_user is defined, the mode is **0600**, and the owner and group are derived from the user name specified in the **ssh**\_user variable.

### 15.4. CONFIGURING OPENSШ CLIENTS USING THE ssh SYSTEM ROLE

You can use the **ssh** System Role to configure multiple SSH clients by running an Ansible playbook.

**NOTE**
You can use the **ssh** System Role with other System Roles that change SSH and SSHD configuration, for example the Identity Management RHEL System Roles. To prevent the configuration from being overwritten, make sure that the **ssh** role uses a drop-in directory (default from RHEL 8).

**Prerequisites**

- You have prepared the control node and the managed nodes.
• You are logged in to the control node as a user who can run playbooks on the managed nodes.
• The account you use to connect to the managed nodes has `sudo` permissions on them.
• The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example `~/ssh-clients-playbook.yml`, with the following content:

```yaml
---
- hosts: all
  tasks:
  - name: "Configure ssh clients"
    include_role:
      name: rhel-system-roles.ssh
    vars:
      ssh_user: root
      ssh:
        Compression: true
        GSSAPIAuthentication: no
        ControlMaster: auto
        ControlPath: ~/.ssh/cm%C
      Host:
        - Condition: example
          Hostname: example.com
          User: user1
          ssh_ForwardX11: no
```

This playbook configures the `root` user’s SSH client preferences on the managed nodes with the following configurations:

• Compression is enabled.
• ControlMaster multiplexing is set to `auto`.
• The `<example>` alias for connecting to the `<example.com>` host is `<user1>`.
• The `<example>` host alias is created, which represents a connection to the `<example.com>` host with the `<user1>` user name.
• X11 forwarding is disabled.

Optionally, you can modify these variables according to your preferences. For more details, see `ssh System Role variables`.

2. Validate the playbook syntax:

```bash
# ansible-playbook --syntax-check ~/ssh-clients-playbook.yml
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook:
# ansible-playbook ~/ssh-clients-playbook.yml

## Verification

- Verify that the managed node has the correct configuration by opening the SSH configuration file in a text editor, for example:

  ```
  # vi ~root/.ssh/config
  ```

  After application of the example playbook shown above, the configuration file should have the following content:

  ```
  # Ansible managed
  Compression yes
  ControlMaster auto
  ControlPath ~/.ssh/.cm%C
  ForwardX11 no
  GSSAPIAuthentication no
  Host example
  Hostname example.com
  User user1
  ```

### 15.5. USING THE sshd SYSTEM ROLE FOR NON-EXCLUSIVE CONFIGURATION

Normally, applying the `sshd` System Role overwrites the entire configuration. This may be problematic if you have previously adjusted the configuration, for example, with a different System Role or playbook. To apply the `sshd` System Role for only selected configuration options while keeping other options in place, you can use the non-exclusive configuration.

In RHEL 8 and earlier, you can apply the non-exclusive configuration with a configuration snippet. For more information, see Using the SSH Server System Role for non-exclusive configuration in RHEL 8 documentation.

In RHEL 9, you can apply the non-exclusive configuration by using files in a drop-in directory. The default configuration file is already placed in the drop-in directory as `/etc/ssh/sshd_config.d/00-ansible_system_role.conf`

## Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
- A playbook for a different RHEL System Role.

## Procedure
1. Add a configuration snippet with the `sshd_config_file` variable to the playbook:

```yaml
---
- hosts: all
  tasks:
    - name: <Configure sshd to accept some useful environment variables>
      include_role:
        name: rhel-system-roles.sshd
      vars:
        sshd_config_file: /etc/ssh/sshd_config.d/<42-my-application>.conf
      sshd:
        # Environment variables to accept
        AcceptEnv:
          LANG
          LS_COLORS
          EDITOR
```

In the `sshd_config_file` variable, define the `.conf` file into which the `sshd` System Role writes the configuration options.

Use a two-digit prefix, for example `42-` to specify the order in which the configuration files will be applied.

When you apply the playbook to the inventory, the role adds the following configuration options to the file defined by the `sshd_config_file` variable.

```
# Ansible managed
# AcceptEnv LANG LS_COLORS EDITOR
```

**Verification**

- Optional: Verify playbook syntax.

```
# ansible-playbook --syntax-check <playbook.yml>
```

**Additional resources**

- `ansible-playbook(1)` man page.

**15.6. OVERRIDING THE SYSTEM-WIDE CRYPTOGRAPHIC POLICY ON AN SSH SERVER BY USING SYSTEM ROLES**

You can override the system-wide cryptographic policy on an SSH server by using the `sshd` RHEL System Role.

Perform this procedure on the Ansible control node.

**Prerequisites**

- You have prepared the control node and the managed nodes
You are logged in to the control node as a user who can run playbooks on the managed nodes.

The account you use to connect to the managed nodes has `sudo` permissions on them.

The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**Procedure**

1. Create a playbook that uses the required role:
   
   a. Create a new YAML file and open it in a text editor, for example:

   ```
   # vi <cryptographic-playbook.yml>
   ```

   b. Insert the following example:

   ```yaml
   ---
   - name: Overriding the system-wide cryptographic policy
     hosts: all
     become: true
     roles:
       - rhel_system_roles.sshd
     vars:
       sshd_sysconfig: true
       sshd_sysconfig_override_crypto_policy: true
       sshd_KexAlgorithms: ecdh-sha2-nistp521
       sshd_Ciphers: aes256-ctr
       sshd_MACs: hmac-sha2-512-etm@openssh.com
       sshd_HostKeyAlgorithms: rsa-sha2-512, rsa-sha2-256
   ```

   On RHEL 9 managed nodes, the system role writes the configuration into the `/etc/ssh/sshd_config.d/00-ansible_system_role.conf` file, where cryptographic options are applied automatically. You can change the file by using the `sshd_config_file` variable. However, to ensure the configuration is effective, use a file name that lexicographically precedes the `/etc/ssh/sshd_config.d/50-redhat.conf` file, which includes the configured crypto policies. For more information, see Examples of opting out of system-wide crypto policies.

   On RHEL 8 managed nodes, you must enable override by setting the `sshd_sysconfig_override_crypto_policy` and `sshd_sysconfig` variables to `true`.

   You can further customize the configuration on the SSH server by using the following variables of the `rhel_system_roles.sshd` RHEL System Role:

   **sshd_Ciphers**
   
   You can choose ciphers, for example, `aes128-ctr`, `aes192-ctr`, or `aes256-ctr`.

   **sshd_MACs**
   
   You can choose MACs, for example, `hmac-sha2-256`, `hmac-sha2-512`, or `hmac-sha1`.

   **sshd_HostKeyAlgorithms**
   
   You can choose a public key algorithm, for example, `ecdsa-sha2-nistp256`, `ecdsa-sha2-nistp384`, `ecdsa-sha2-nistp521`, `ssh-rsa`, or `ssh-dss`.

   **sshd_KexAlgorithms**
You can choose key exchange algorithms, for example, `ecdh-sha2-nistp256`, `ecdh-sha2-nistp384`, `ecdh-sha2-nistp521`, `diffie-hellman-group14-sha1`, or `diffie-hellman-group-exchange-sha256`. For more variables and their possible values, see the `sshd_config(5)` man page.

2. Run the playbook:

```bash
$ ansible-playbook <cryptographic-playbook.yml>
```

**Verification**

1. You can verify the success of the procedure by using the verbose SSH connection and check the defined variables in the following output:

```bash
$ ssh -vvv localhost
...
debug2: peer server KEXINIT proposal
debug2: KEX algorithms: ecdh-sha2-nistp521
debug2: host key algorithms: rsa-sha2-512, rsa-sha2-256
debug2: ciphers ctos: aes256-ctr
debug2: ciphers stoc: aes256-ctr
debug2: MACs ctos: hmac-sha2-512-etm@openssh.com
debug2: MACs stoc: hmac-sha2-512-etm@openssh.com
...
```
CHAPTER 16. CONFIGURING VPN CONNECTIONS WITH IPSEC BY USING THE *vpn* RHEL SYSTEM ROLE

With the *vpn* System Role, you can configure VPN connections on RHEL systems by using Red Hat Ansible Automation Platform. You can use it to set up host-to-host, network-to-network, VPN Remote Access Server, and mesh configurations.

For host-to-host connections, the role sets up a VPN tunnel between each pair of hosts in the list of *vpn* _connections_ using the default parameters, including generating keys as needed. Alternatively, you can configure it to create an opportunistic mesh configuration between all hosts listed. The role assumes that the names of the hosts under *hosts* are the same as the names of the hosts used in the Ansible inventory, and that you can use those names to configure the tunnels.

**NOTE**

The *vpn* RHEL System Role currently supports only Libreswan, which is an IPsec implementation, as the VPN provider.

### 16.1. CREATING A HOST-TO-HOST VPN WITH IPSEC USING THE *vpn* SYSTEM ROLE

You can use the *vpn* System Role to configure host-to-host connections by running an Ansible playbook on the control node, which configures all managed nodes listed in an inventory file.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has *sudo* permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**Procedure**

1. Create a playbook file, for example `~/vpn-playbook.yml`, with the following content:

   ```yaml
   - name: Host to host VPN
     hosts: <managed_node1>, <managed_node2>
     roles:
       - rhel-system-roles.vpn
     vars:
       vpn_connections:
         - hosts:
             <managed_node1>:
             <managed_node2>:
             vpn_manage_firewall: true
             vpn_manage_selinux: true
   ```

   This playbook configures the connection `<managed_node1>`-to-`<managed_node2>` using pre-shared key authentication with keys auto-generated by the system role. Because
**vpn_manage_firewall** and **vpn_manage_selinux** are both set to **true**, the **vpn** role uses the **firewall** and **selinux** roles to manage the ports used by the **vpn** role.

2. Optional: Configure connections from managed hosts to external hosts that are not listed in the inventory file by adding the following section to the **vpn_connections** list of hosts:

   ```yaml
   vpn_connections:
     - hosts:
       <managed_node1>:
       <managed_node2>:
       <external_node>:
          hostname: <192.0.2.2>
   ``

   This configures two additional connections: **<managed_node1>-to-<external_node>** and **<managed_node2>-to-<external_node>**.

   **NOTE**
   
   The connections are configured only on the managed nodes and not on the external node.

3. Optional: You can specify multiple VPN connections for the managed nodes by using additional sections within **vpn_connections**, for example, a control plane and a data plane:

   ```yaml
   - name: Multiple VPN
     hosts: <managed_node1>, <managed_node2>
     roles:
       - rhel-system-roles.vpn
     vars:
       vpn_connections:
         - name: control_plane_vpn
           hosts:
             <managed_node1>:
               hostname: 192.0.2.0 # IP for the control plane
             <managed_node2>:
               hostname: 192.0.2.1
         - name: data_plane_vpn
           hosts:
             <managed_node1>:
               hostname: 10.0.0.1 # IP for the data plane
             <managed_node2>:
               hostname: 10.0.0.2
   ``

4. Optional: You can modify the variables according to your preferences. For more details, see the **/usr/share/doc/rhel-system-roles/vpn/README.md** file.

5. Validate the playbook syntax:

   ```bash
   # ansible-playbook ~/vpn-playbook.yml --syntax-check
   ``

   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

6. Run the playbook:
# ansible-playbook ~/vpn-playbook.yml

**Verification**

1. On the managed nodes, confirm that the connection is successfully loaded:

   ```bash
   # ipsec status | grep <connection_name>
   ```

   Replace `<connection_name>` with the name of the connection from this node, for example `managed_node1-to-managed_node2`.

   **NOTE**

   By default, the role generates a descriptive name for each connection it creates from the perspective of each system. For example, when creating a connection between `managed_node1` and `managed_node2`, the descriptive name of this connection on `managed_node1` is `managed_node1-to-managed_node2` but on `managed_node2` the connection is named `managed_node2-to-managed_node1`.

2. On the managed nodes, confirm that the connection is successfully started:

   ```bash
   # ipsec trafficstatus | grep <connection_name>
   ```

3. Optional: If a connection does not successfully load, manually add the connection by entering the following command. This provides more specific information indicating why the connection failed to establish:

   ```bash
   # ipsec auto --add <connection_name>
   ```

   **NOTE**

   Any errors that may occur during the process of loading and starting the connection are reported in the `/var/log/pluto.log` file. Because these logs are hard to parse, manually add the connection to obtain log messages from the standard output instead.

---

### 16.2. CREATING AN OPPORTUNISTIC MESH VPN CONNECTION WITH IPSEC BY USING THE VPN RHEL SYSTEM ROLE

You can use the `vpn` System Role to configure an opportunistic mesh VPN connection that uses certificates for authentication by running an Ansible playbook on the control node, which will configure all the managed nodes listed in an inventory file.

Authentication with certificates is configured by defining the `auth_method: cert` parameter in the playbook. The `vpn` System Role assumes that the IPsec Network Security Services (NSS) crypto library, which is defined in the `/etc/ipsec.d` directory, contains the necessary certificates. By default, the node name is used as the certificate nickname. In this example, this is `managed_node1`. You can define different certificate names by using the `cert_name` attribute in your inventory.

In the following example procedure, the control node, which is the system from which you will run the Ansible playbook, shares the same classless inter-domain routing (CIDR) number as both of the
managed nodes (192.0.2.0/24) and has the IP address 192.0.2.7. Therefore, the control node falls under
the private policy which is automatically created for CIDR 192.0.2.0/24.

To prevent SSH connection loss during the play, a clear policy for the control node is included in the list
of policies. Note that there is also an item in the policies list where the CIDR is equal to default. This is
because this playbook overrides the rule from the default policy to make it private instead of private-or-
clear.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has sudo permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are
  listed in the Ansible inventory file.

Procedure

1. Create a playbook file, for example ~/mesh-vpn-playbook.yml, with the following content:

```yaml
- name: Mesh VPN
  hosts: managed_node1, managed_node2, managed_node3
  roles:
    - rhel-system-roles.vpn
  vars:
    vpn_connections:
      - opportunistic: true
        auth_method: cert
        policies:
          - policy: private
            cidr: default
          - policy: private-or-clear
            cidr: 195.51.100.0/24
          - policy: private
            cidr: 192.0.2.0/24
          - policy: clear
            cidr: 192.0.2.7/32
    vpn_manage_firewall: true
    vpn_manage_selinux: true
```

**NOTE**

Because `vpn_manage_firewall` and `vpn_manage_selinux` are both set to `true`,
the `vpn` role uses the `firewall` and `selinux` roles to manage the ports used by the `vpn` role.

2. Optional: You can modify the variables according to your preferences. For more details, see the

3. Validate the playbook syntax:

   ```bash
   # ansible-playbook ~/mesh-vpn-playbook.yml --syntax-check
   ```
Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

4. Run the playbook:

```
# ansible-playbook ~/mesh-vpn-playbook.yml
```

### 16.3. ADDITIONAL RESOURCES

- For details about the parameters used in the `vpn` System Role and additional information about the role, see the `/usr/share/doc/rhel-system-roles/vpn/README.md` file.

- For details about the `ansible-playbook` command, see the `ansible-playbook(1)` man page.
CHAPTER 17. SETTING A CUSTOM CRYPTOGRAPHIC POLICY BY USING THE CRYPTO-POLICIES RHEL SYSTEM ROLE

As an administrator, you can use the crypto_policies RHEL System Role to quickly and consistently configure custom cryptographic policies across many different systems using the Ansible Core package.

17.1. CRYPTO_POLICIES SYSTEM ROLE VARIABLES AND FACTS

In a crypto_policies System Role playbook, you can define the parameters for the crypto_policies configuration file according to your preferences and limitations.

If you do not configure any variables, the System Role does not configure the system and only reports the facts.

Selected variables for the crypto_policies System Role

crypto_policies_policy
  Determines the cryptographic policy the System Role applies to the managed nodes. For details about the different crypto policies, see System-wide cryptographic policies.

crypto_policies_reload
  If set to yes, the affected services, currently the ipsec, bind, and sshd services, reload after applying a crypto policy. Defaults to yes.

crypto_policies_reboot_ok
  If set to yes, and a reboot is necessary after the System Role changes the crypto policy, it sets crypto_policies_reboot_required to yes. Defaults to no.

Facts set by the crypto_policies System Role

crypto_policies_active
  Lists the currently selected policy.

crypto_policies_available_policies
  Lists all available policies available on the system.

crypto_policies_available_subpolicies
  Lists all available subpolicies available on the system.

Additional resources

- Creating and setting a custom system-wide cryptographic policy.

17.2. SETTING A CUSTOM CRYPTOGRAPHIC POLICY USING THE CRYPTO_POLICIES SYSTEM ROLE

You can use the crypto_policies System Role to configure a large number of managed nodes consistently from a single control node.

Prerequisites

- You have prepared the control node and the managed nodes.
You are logged in to the control node as a user who can run playbooks on the managed nodes.

- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**Procedure**

1. Create a playbook file, for example `~/crypto-playbook.yml`, with the following content:

```yaml
---
- hosts: all
  tasks:
    - name: Configure crypto policies
      include_role:
        name: rhel-system-roles.crypto_policies
        vars:
          - crypto_policies_policy: FUTURE
          - crypto_policies_reboot_ok: true
```

You can replace the `FUTURE` value with your preferred crypto policy, for example: `DEFAULT`, `LEGACY`, and `FIPS:OSPP`.

The `crypto_policies_reboot_ok: true` variable causes the system to reboot after the System Role changes the cryptographic policy.

For more details, see [crypto_policies System Role variables and facts](#).

2. Validate the playbook syntax:

```bash
# ansible-playbook ~/crypto-playbook.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

3. Run the playbook on your inventory file:

```bash
# ansible-playbook ~/crypto-playbook.yml
```

**Verification**

1. On the control node, create another playbook named, for example, `verify_playbook.yml`:

```yaml
- hosts: all
  tasks:
    - name: Verify active crypto policy
      include_role:
        name: rhel-system-roles.crypto_policies
      - debug:
        var: crypto_policies_active
```

This playbook does not change any configurations on the system, only reports the active policy on the managed nodes.
2. Run the playbook on the same inventory file:

```yaml
# ansible-playbook verify_playbook.yml

TASK [debug] **************************
ok: [host] => {
    "crypto_policies_active": "FUTURE"
}
```

The "crypto_policies_active": variable shows the policy active on the managed node.

17.3. ADDITIONAL RESOURCES

- `/usr/share/ansible/roles/rhel-system-roles.crypto_policies/README.md` file.
- `ansible-playbook(1)` man page.
- Preparing a control node and managed nodes to use RHEL System Roles.
18.1. INTRODUCTION TO THE \texttt{nbde\_client} AND \texttt{nbde\_server} SYSTEM ROLES (CLEVIS AND TANG)

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems.

You can use Ansible roles for automated deployments of Policy-Based Decryption (PBD) solutions using Clevis and Tang. The \texttt{rhel-system-roles} package contains these system roles, the related examples, and also the reference documentation.

The \texttt{nbde\_client} System Role enables you to deploy multiple Clevis clients in an automated way. Note that the \texttt{nbde\_client} role supports only Tang bindings, and you cannot use it for TPM2 bindings at the moment.

The \texttt{nbde\_client} role requires volumes that are already encrypted using LUKS. This role supports to bind a LUKS-encrypted volume to one or more Network-Bound (NBDE) servers - Tang servers. You can either preserve the existing volume encryption with a passphrase or remove it. After removing the passphrase, you can unlock the volume only using NBDE. This is useful when a volume is initially encrypted using a temporary key or password that you should remove after you provision the system.

If you provide both a passphrase and a key file, the role uses what you have provided first. If it does not find any of these valid, it attempts to retrieve a passphrase from an existing binding.

PBD defines a binding as a mapping of a device to a slot. This means that you can have multiple bindings for the same device. The default slot is slot 1.

The \texttt{nbde\_client} role provides also the \texttt{state} variable. Use the \texttt{present} value for either creating a new binding or updating an existing one. Contrary to a \texttt{clevis luks bind} command, you can use \texttt{state: present} also for overwriting an existing binding in its device slot. The \texttt{absent} value removes a specified binding.

Using the \texttt{nbde\_client} System Role, you can deploy and manage a Tang server as part of an automated disk encryption solution. This role supports the following features:

- Rotating Tang keys
- Deploying and backing up Tang keys

Additional resources

- For a detailed reference on Network-Bound Disk Encryption (NBDE) role variables, install the \texttt{rhel-system-roles} package, and see the \texttt{README.md} and \texttt{README.html} files in the \texttt{/usr/share/doc/rhel-system-roles/nbde\_client/} and \texttt{/usr/share/doc/rhel-system-roles/nbde\_server/} directories.

- For example system-roles playbooks, install the \texttt{rhel-system-roles} package, and see the \texttt{/usr/share/ansible/roles/rhel-system-roles.nbde\_server/examples/} directories.

- For more information about RHEL System Roles, see Preparing a control node and managed nodes to use RHEL System Roles.
18.2. USING THE NBDE_SERVER SYSTEM ROLE FOR SETTING UP MULTIPLE TANG SERVERS

Follow the steps to prepare and apply an Ansible playbook containing your Tang server settings.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

Procedure

1. Prepare your playbook containing settings for Tang servers. You can either start from the scratch, or use one of the example playbooks from the `/usr/share/ansible/roles/rhel-system-roles.nbde_server/examples/` directory.

   ```bash
   # cp /usr/share/ansible/roles/rhel-system-roles.nbde_server/examples/simple_deploy.yml ~/my-tang-playbook.yml
   ```

2. Edit the playbook and add the required parameters. The following example playbook ensures deploying of your Tang server and a key rotation:

   ```yaml
   ---
   - hosts: all
     vars:
       nbde_server_rotate_keys: yes
       nbde_server_manage_firewall: true
       nbde_server_manage_selinux: true
     roles:
       - rhel-system-roles.nbde_server
   ```

   **NOTE**
   
   When `nbde_server_manage_firewall` and `nbde_server_manage_selinux` are both set to `true`, the `nbde_server` role uses the `firewall` and `selinux` roles to manage the ports used by the `nbde_server` role.

3. Validate the playbook syntax:

   ```bash
   # ansible-playbook ~/my-tang-playbook.yml --syntax-check
   ```

   Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

4. Apply the finished playbook:

   ```bash
   ```
# ansible-playbook ~/my-tang-playbook.yml

**IMPORTANT**

To ensure that networking for a Tang pin is available during early boot by using the `grubby` tool on the systems where Clevis is installed:

```bash
# grubby --update-kernel=ALL --args="rd.neednet=1"
```

**Additional resources**

- For more information, install the `rhel-system-roles` package, and see the `/usr/share/doc/rhel-system-roles/nbde_server/` and `/usr/share/ansible/roles/rhel-system-roles.nbde_server/` directories.

### 18.3. SETTING UP MULTIPLE CLEVIS CLIENTS BY USING THE NBDE_CLIENT RHEL SYSTEM ROLE

With the `nbde_client` RHEL System Role, you can prepare and apply an Ansible playbook that contains your Clevis client settings on multiple systems.

**NOTE**

The `nbde_client` System Role supports only Tang bindings. This means that you cannot use it for TPM2 bindings at the moment.

**Prerequisites**

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The account you use to connect to the managed nodes has `sudo` permissions on them.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.

**Procedure**

1. Prepare your playbook that contains settings for Clevis clients. You can either start from the scratch, or use one of the example playbooks from the `/usr/share/ansible/roles/rhel-system-roles.nbde_client/examples/` directory.

   ```bash
   # cp /usr/share/ansible/roles/rhel-system-roles.nbde_client/examples/high_availability.yml ~/my-clevis-playbook.yml
   ```

2. Edit the playbook in a text editor of your choice, for example:

   ```bash
   # vi ~/my-clevis-playbook.yml
   ```
3. Add the required parameters. The following example playbook configures Clevis clients for automated unlocking of two LUKS-encrypted volumes when at least one of two Tang servers is available:

```yaml
---
- hosts: all

vars:
  nbde_client_bindings:
    - device: /dev/rhel/root
      encryption_key_src: /etc/luks/keyfile
      servers:
        - http://server1.example.com
        - http://server2.example.com
    - device: /dev/rhel/swap
      encryption_key_src: /etc/luks/keyfile
      servers:
        - http://server1.example.com
        - http://server2.example.com

roles:
- rhel-system-roles.nbde_client
```

4. Validate the playbook syntax:

```
# ansible-playbook ~/my-clevis-playbook.yml --syntax-check
```

Note that this command only validates the syntax and does not protect against a wrong but valid configuration.

5. Apply the finished playbook:

```
# ansible-playbook ~/my-clevis-playbook.yml
```
IMPORTANT

The current nbde_client System Role supports only scenarios with Dynamic Host Configuration Protocol (DHCP). To use NBDE for clients with static IP configuration, perform one of the following actions:

- Pass your network configuration to the dracut command, for example:

  ```
  # dracut -fv --regenerate-all --kernel-cmdline
  "ip=192.0.2.10::192.0.2.1:255.255.255.0::ens3:none"
  ```

- Alternatively, create a .conf file in the /etc/dracut.conf.d/ directory with the static network information, for example:

  ```
  # cat /etc/dracut.conf.d/static_ip.conf
  kernel_cmdline="ip=192.0.2.10::192.0.2.1:255.255.255.0::ens3:none"
  ```

  Then, regenerate the initial RAM disk image.

- You can also add the following snippet to your playbook:

  ```yaml
  tasks:
  - name: Configure a client with a static IP address during early boot
    ansible.builtin.command:
      cmd: grubby --update-kernel=ALL --
      args='GRUB_CMDLINE_LINUX_DEFAULT="ip={{ ansible_default_ipv4.address }}::{{ ansible_default_ipv4.gateway }}::{{ ansible_default_ipv4.netmask }}::{{ ansible_default_ipv4.alias }}:none"'
  ```

  In the previous snippet, replace the `<ansible_default_ipv4.*>` strings with IP addresses of your network, for example: `ip={{ 192.0.2.10 }}::{{ 192.0.2.1 }}::{255.255.255.0 }}::{{ ens3 }}:none`.

Additional resources

- For details about the parameters and additional information about the NBDE Client System Role, install the rhel-system-roles package, and see the /usr/share/doc/rhel-system-roles/nbde_client/ and /usr/share/ansible/roles/rhel-system-roles.nbde_client/ directories.

- Looking forward to Linux network configuration in the initial ramdisk (initrd) article on Red Hat Enable Sysadmin
CHAPTER 19. REQUESTING CERTIFICATES USING RHEL SYSTEM ROLES

You can use the certificate System Role to issue and manage certificates.

This chapter covers the following topics:

- The certificate System Role
- Requesting a new self-signed certificate using the certificate System Role
- Requesting a new certificate from IdM CA using the certificate System Role

19.1. THE CERTIFICATE SYSTEM ROLE

Using the certificate System Role, you can manage issuing and renewing TLS and SSL certificates using Ansible Core.

The role uses certmonger as the certificate provider, and currently supports issuing and renewing self-signed certificates and using the IdM integrated certificate authority (CA).

You can use the following variables in your Ansible playbook with the certificate System Role:

- **certificate_wait**
  
  to specify if the task should wait for the certificate to be issued.

- **certificate_requests**
  
  to represent each certificate to be issued and its parameters.

Additional resources

- See the `/usr/share/ansible/roles/rhel-system-roles.certificate/README.md` file.
- Preparing a control node and managed nodes to use RHEL System Roles

19.2. REQUESTING A NEW SELF-SIGNED CERTIFICATE USING THE CERTIFICATE SYSTEM ROLE

With the certificate System Role, you can use Ansible Core to issue self-signed certificates.

This process uses the certmonger provider and requests the certificate through the `getcert` command.

NOTE

By default, certmonger automatically tries to renew the certificate before it expires. You can disable this by setting the `auto_renew` parameter in the Ansible playbook to **no**.

Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.
**Procedure**

1. *Optional:* Create an inventory file, for example `inventory.file`:

   ```
   $ touch inventory.file
   ```

2. Open your inventory file and define the hosts on which you want to request the certificate, for example:

   ```
   [webserver]
   server.idm.example.com
   ```

3. Create a playbook file, for example `request-certificate.yml`:

   - Set `hosts` to include the hosts on which you want to request the certificate, such as `webserver`.

   - Set the `certificate_requests` variable to include the following:
     - Set the `name` parameter to the desired name of the certificate, such as `mycert`.
     - Set the `dns` parameter to the domain to be included in the certificate, such as `*.example.com`.
     - Set the `ca` parameter to `self-sign`.

   - Set the `rhel-system-roles.certificate` role under `roles`.

   This is the playbook file for this example:

   ```yaml
   ---
   - hosts: webserver
     vars:
       certificate_requests:
       - name: mycert
         dns: "*.example.com"
         ca: self-sign

     roles:
       - rhel-system-roles.certificate
   ```

4. Save the file.

5. Run the playbook:

   ```
   $ ansible-playbook -i inventory.file request-certificate.yml
   ```

**Additional resources**

- See the `/usr/share/ansible/roles/rhel-system-roles.certificate/README.md` file.
- See the `ansible-playbook(1)` man page.
19.3. REQUESTING A NEW CERTIFICATE FROM IDM CA USING THE CERTIFICATE SYSTEM ROLE

With the certificate System Role, you can use ansible-core to issue certificates while using an IdM server with an integrated certificate authority (CA). Therefore, you can efficiently and consistently manage the certificate trust chain for multiple systems when using IdM as the CA.

This process uses the certmonger provider and requests the certificate through the getcert command.

NOTE

By default, certmonger automatically tries to renew the certificate before it expires. You can disable this by setting the auto_renew parameter in the Ansible playbook to no.

Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the rhel-system-roles package installed on the system from which you want to run the playbook.

Procedure

1. Optional: Create an inventory file, for example inventory.file:

   $ touch inventory.file

2. Open your inventory file and define the hosts on which you want to request the certificate, for example:

   [webserver]
   server.idm.example.com

3. Create a playbook file, for example request-certificate.yml:

   - Set hosts to include the hosts on which you want to request the certificate, such as webserver.

   - Set the certificate_requests variable to include the following:
     - Set the name parameter to the desired name of the certificate, such as mycert.
     - Set the dns parameter to the domain to be included in the certificate, such as www.example.com.
     - Set the principal parameter to specify the Kerberos principal, such as HTTP/www.example.com@EXAMPLE.COM.
     - Set the ca parameter to ipa.

   - Set the rhel-system-roles.certificate role under roles.

This is the playbook file for this example:

---
- hosts: webserver
vars:
  certificate_requests:
    - name: mycert
dns: www.example.com
principal: HTTP/www.example.com@EXAMPLE.COM
ca: ipa

roles:
  - rhel-system-roles.certificate

4. Save the file.
5. Run the playbook:

   $ ansible-playbook -i inventory.file request-certificate.yml

Additional resources

- See the /usr/share/ansible/roles/rhel-system-roles.certificate/README.md file.
- See the ansible-playbook(1) man page.

19.4. SPECIFYING COMMANDS TO RUN BEFORE OR AFTER CERTIFICATE ISSUANCE USING THE CERTIFICATE SYSTEM ROLE

With the certificate Role, you can use Ansible Core to execute a command before and after a certificate is issued or renewed.

In the following example, the administrator ensures stopping the httpd service before a self-signed certificate for www.example.com is issued or renewed, and restarting it afterwards.

**NOTE**

By default, certmonger automatically tries to renew the certificate before it expires. You can disable this by setting the auto_renew parameter in the Ansible playbook to no.

Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the rhel-system-roles package installed on the system from which you want to run the playbook.

Procedure

1. Optional: Create an inventory file, for example inventory.file:

   $ touch inventory.file

2. Open your inventory file and define the hosts on which you want to request the certificate, for example:
3. Create a playbook file, for example `request-certificate.yml`:
   - Set **hosts** to include the hosts on which you want to request the certificate, such as `webserver`.
   - Set the **certificate_requests** variable to include the following:
     - Set the **name** parameter to the desired name of the certificate, such as `mycert`.
     - Set the **dns** parameter to the domain to be included in the certificate, such as `www.example.com`.
     - Set the **ca** parameter to the CA you want to use to issue the certificate, such as `self-sign`.
     - Set the **run_before** parameter to the command you want to execute before this certificate is issued or renewed, such as `systemctl stop httpd.service`.
     - Set the **run_after** parameter to the command you want to execute after this certificate is issued or renewed, such as `systemctl start httpd.service`.
   - Set the **rhel-system-roles.certificate** role under **roles**.
   
   This is the playbook file for this example:
   ```yaml
---
- hosts: webserver
  vars:
    certificate_requests:
      - name: mycert
        dns: www.example.com
        ca: self-sign
        run_before: systemctl stop httpd.service
        run_after: systemctl start httpd.service
  roles:
    - rhel-system-roles.certificate
```

4. Save the file.

5. Run the playbook:

   ```shell
   $ ansible-playbook -i inventory.file request-certificate.yml
   ```

**Additional resources**

- See the `/usr/share/ansible/roles/rhel-system-roles.certificate/README.md` file.
- See the `ansible-playbook(1)` man page.
CHAPTER 20. CONFIGURING AUTOMATIC CRASH DUMPS BY USING THE KDUMP RHEL SYSTEM ROLE

To manage kdump using Ansible, you can use the **kdump** role, which is one of the RHEL System Roles available in RHEL 9.

Using the **kdump** role enables you to specify where to save the contents of the system’s memory for later analysis.

For more information about RHEL System Roles and how to apply them, see [Introduction to RHEL System Roles](#).

### 20.1. THE KDUMP RHEL SYSTEM ROLE

The **kdump** System Role enables you to set basic kernel dump parameters on multiple systems.

### 20.2. KDUMP ROLE PARAMETERS

Use the mentioned role variables to set kernel dump parameters on multiple systems for RHEL System Roles.

<table>
<thead>
<tr>
<th>Role Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>kdump_target</code></td>
<td>An option to specify the target location to save the crash dump file (<code>vmcore</code>) to a location that is not in the root file system. If the type is <strong>raw</strong> or a <strong>filesystem</strong>, the target location points to a partition, such as device node name, <strong>label</strong>, or <strong>uuid</strong>.</td>
</tr>
<tr>
<td><code>kdump_path</code></td>
<td>The path to which <strong>vmcore</strong> is written. If <code>kdump_target</code> is not null, the path is relative to that dump target. Otherwise, it must be an absolute path in the root file system.</td>
</tr>
<tr>
<td><code>kdump_core_collector</code></td>
<td>A command to copy the crash dump (<strong>vmcore</strong>) file. If null, <strong>kdump</strong> uses the <strong>makedumpfile</strong> program with options that depend on the <code>kdump_target.type</code>.</td>
</tr>
<tr>
<td><code>kdump_system_action</code></td>
<td>An alternative operation to perform when <strong>kdump</strong> fails to save the core dump file (<strong>vmcore</strong>) to the primary target. The additional operations include <strong>reboot</strong>, <strong>halt</strong>, <strong>poweroff</strong>, and <strong>shell</strong>.</td>
</tr>
<tr>
<td><code>kdump_auto_reset_crashkernel</code></td>
<td>An option to reset the <strong>crashkernel</strong> value to a new default value. For example, reset <strong>crashkernel</strong> when <strong>kexec-tools</strong> updates the default <strong>crashkernel</strong> value to a new value or if existing kernels have the old default kernel <strong>crashkernel</strong> value.</td>
</tr>
</tbody>
</table>
### kdump_dracut_args
An option to pass additional `dracut` options when rebuilding `kdump initrd`.

### kdump_reboot_ok
An option to configure a `reboot` action if you run the role on a managed node that does not have sufficient memory reserved for the crash kernel, for example when the file `/sys/kernel/kexec_crash_size` contains 0 as the crash size, you might need to reboot the managed node to configure `kdump` again.

### Additional resources
- The `makedumpfile(8)` man page.
- For details about the parameters used in `kdump` and additional information about the `kdump` System Role, see the `/usr/share/ansible/roles/rhel-system-roles.kdump/README.md` file.

## 20.3. CONFIGURING KDUMP USING RHEL SYSTEM ROLES

You can set basic kernel dump parameters on multiple systems using the `kdump` System Role by running an Ansible playbook.

### WARNING

The `kdump` role replaces the kdump configuration of the managed hosts entirely by replacing the `/etc/kdump.conf` file. Additionally, if the `kdump` role is applied, all previous `kdump` settings are also replaced, even if they are not specified by the role variables, by replacing the `/etc/sysconfig/kdump` file.

### Prerequisites
- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.
- You have an inventory file which lists the systems on which you want to deploy `kdump`.

### Procedure
1. Create a new `playbook.yml` file with the following content:

```yaml
---
- hosts: kdump-test
  vars: 
```
kdump_path: /var/crash
roles:
- rhel-system-roles.kdump

2. Optional: Verify playbook syntax.

# ansible-playbook --syntax-check playbook.yml

3. Run the playbook on your inventory file:

# ansible-playbook -i inventory_file /path/to/file/playbook.yml

Additional resources

- For a detailed reference on **kdump** role variables, see the README.md or README.html files in the /usr/share/doc/rhel-system-roles/kdump directory.

- See [Preparing the control node and managed nodes to use RHEL System Roles](https://example.com)

- Documentation installed with the **rhel-system-roles** package /usr/share/ansible/roles/rhel-system-roles.kdump/README.html
CHAPTER 21. MANAGING LOCAL STORAGE USING RHEL SYSTEM ROLES

To manage LVM and local file systems (FS) using Ansible, you can use the **storage** role, which is one of the RHEL System Roles available in RHEL 9.

Using the **storage** role enables you to automate administration of file systems on disks and logical volumes on multiple machines and across all versions of RHEL starting with RHEL 7.7.

For more information about RHEL System Roles and how to apply them, see Introduction to RHEL System Roles.

21.1. INTRODUCTION TO THE STORAGE RHEL SYSTEM ROLE

The **storage** role can manage:

- File systems on disks which have not been partitioned
- Complete LVM volume groups including their logical volumes and file systems
- MD RAID volumes and their file systems

With the **storage** role, you can perform the following tasks:

- Create a file system
- Remove a file system
- Mount a file system
- Unmount a file system
- Create LVM volume groups
- Remove LVM volume groups
- Create logical volumes
- Remove logical volumes
- Create RAID volumes
- Remove RAID volumes
- Create LVM volume groups with RAID
- Remove LVM volume groups with RAID
- Create encrypted LVM volume groups
- Create LVM logical volumes with RAID

21.2. PARAMETERS THAT IDENTIFY A STORAGE DEVICE IN THE STORAGE RHEL SYSTEM ROLE
Your `storage` role configuration affects only the file systems, volumes, and pools that you list in the following variables.

**storage_volumes**

List of file systems on all unpartitioned disks to be managed. 
*storage_volumes* can also include *raid* volumes.

Partitions are currently unsupported.

**storage_pools**

List of pools to be managed.
Currently the only supported pool type is LVM. With LVM, pools represent volume groups (VGs). Under each pool there is a list of volumes to be managed by the role. With LVM, each volume corresponds to a logical volume (LV) with a file system.

### 21.3. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AN XFS FILE SYSTEM ON A BLOCK DEVICE

The example Ansible playbook applies the `storage` role to create an XFS file system on a block device using the default parameters.

---
- hosts: all
  vars:
    storage_volumes:
      - name: `barefs`
        type: disk
        disks:
          - `sdb`
        fs_type: xfs
        roles:
          - rhel-system-roles.storage

- The volume name (`barefs` in the example) is currently arbitrary. The `storage` role identifies the volume by the disk device listed under the `disks:` attribute.
- You can omit the `fs_type: xfs` line because XFS is the default file system in RHEL 9.
To create the file system on an LV, provide the LVM setup under the **disks** attribute, including the enclosing volume group. For details, see Example Ansible playbook to manage logical volumes. Do not provide the path to the LV device.

### Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

#### 21.4. EXAMPLE ANSIBLE PLAYBOOK TO PERSISTENTLY MOUNT A FILE SYSTEM

The example Ansible applies the **storage** role to immediately and persistently mount an XFS file system.

**Example 21.2. A playbook that mounts a file system on `/dev/sdb` to `/mnt/data**

```yaml
---
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
        disks:
          - sdb
        fs_type: xfs
        mount_point: /mnt/data
        mount_user: somebody
        mount_group: somegroup
        mount_mode: 0755
    roles:
      - rhel-system-roles.storage

- This playbook adds the file system to the `/etc/fstab` file, and mounts the file system immediately.

- If the file system on the `/dev/sdb` device or the mount point directory do not exist, the playbook creates them.

**Additional resources**

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

#### 21.5. EXAMPLE ANSIBLE PLAYBOOK TO MANAGE LOGICAL VOLUMES

The example Ansible playbook applies the **storage** role to create an LVM logical volume in a volume group.

**Example 21.3. A playbook that creates a mylv logical volume in the myvg volume group**

```yaml
---
- hosts: all
  vars:
```

---

Red Hat Enterprise Linux 9 Automating system administration by using RHEL System Roles

150
storage_pools:
  - name: myvg
disks:
    - sda
    - sdb
    - sdc
volumes:
  - name: mylv
    size: 2G
    fs_type: ext4
    mount_point: /mnt/data
roles:
  - rhel-system-roles.storage

- The **myvg** volume group consists of the following disks:
  - /dev/sda
  - /dev/sdb
  - /dev/sdc

- If the **myvg** volume group already exists, the playbook adds the logical volume to the volume group.

- If the **myvg** volume group does not exist, the playbook creates it.

- The playbook creates an Ext4 file system on the **mylv** logical volume, and persistently mounts the file system at **/mnt**.

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

### 21.6. EXAMPLE ANSIBLE PLAYBOOK TO ENABLE ONLINE BLOCK DISCARD

The example Ansible playbook applies the `storage` role to mount an XFS file system with online block discard enabled.

**Example 21.4. A playbook that enables online block discard on /mnt/data/**

```yaml
---
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
disks:
      - sdb
        fs_type: xfs
        mount_point: /mnt/data
```
mount_options: discard
roles:
  - rhel-system-roles.storage

Additional resources

- Example Ansible playbook to persistently mount a file system
- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.

21.7. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AND MOUNT AN EXT4 FILE SYSTEM

The example Ansible playbook applies the storage role to create and mount an Ext4 file system.

Example 21.5. A playbook that creates Ext4 on /dev/sdb and mounts it at /mnt/data

```yaml
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
        disks:
          - sdb
        fs_type: ext4
        fs_label: label-name
        mount_point: /mnt/data
  roles:
    - rhel-system-roles.storage
```

- The playbook creates the file system on the /dev/sdb disk.
- The playbook persistently mounts the file system at the /mnt/data directory.
- The label of the file system is label-name.

Additional resources

- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.

21.8. EXAMPLE ANSIBLE PLAYBOOK TO CREATE AND MOUNT AN EXT3 FILE SYSTEM

The example Ansible playbook applies the storage role to create and mount an Ext3 file system.

Example 21.6. A playbook that creates Ext3 on /dev/sdb and mounts it at /mnt/data

```yaml
- hosts: all
```
vars:
  storage_volumes:
    - name: barefs
      type: disk
disks:
  - sdb
    fs_type: ext3
    fs_label: label-name
    mount_point: /mnt/data
    mount_user: somebody
    mount_group: somegroup
    mount_mode: 0755
roles:
  - rhel-system-roles.storage

- The playbook creates the file system on the /dev/sdb disk.
- The playbook persistently mounts the file system at the /mnt/data directory.
- The label of the file system is label-name.

Additional resources

- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.

21.9. EXAMPLE ANSIBLE PLAYBOOK TO RESIZE AN EXISTING FILE SYSTEM ON LVM USING THE STORAGE RHEL SYSTEM ROLE

The example Ansible playbook applies the storage RHEL System Role to resize an LVM logical volume with a file system.

Example 21.7. A playbook that resizes existing mylv1 and myvl2 logical volumes in the myvg volume group

---
- hosts: all
  vars:
  storage_pools:
    - name: myvg
disks:
  - /dev/sda
  - /dev/sdb
- /dev/sdc
volumes:
- name: mylv1
  size: 10 GiB
  fs_type: ext4
  mount_point: /opt/mount1
- name: mylv2
  size: 50 GiB
  fs_type: ext4
  mount_point: /opt/mount2
- name: Create LVM pool over three disks
  include_role:
    name: rhel-system-roles.storage

- This playbook resizes the following existing file systems:
  - The Ext4 file system on the mylv1 volume, which is mounted at /opt/mount1, resizes to 10 GiB.
  - The Ext4 file system on the mylv2 volume, which is mounted at /opt/mount2, resizes to 50 GiB.

Additional resources
- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.

21.10. EXAMPLE ANSIBLE PLAYBOOK TO CREATE A SWAP VOLUME USING THE STORAGE RHEL SYSTEM ROLE

This section provides an example Ansible playbook. This playbook applies the storage role to create a swap volume, if it does not exist, or to modify the swap volume, if it already exist, on a block device using the default parameters.

Example 21.8. A playbook that creates or modify an existing XFS on /dev/sdb

---
- name: Create a disk device with swap
  - hosts: all
    vars:
      storage_volumes:
        - name: swap_fs
type: disk
disks:
  - /dev/sdb
size: 15 GiB
fs_type: swap
roles:
- rhel-system-roles.storage

- The volume name (swap_fs in the example) is currently arbitrary. The storage role identifies the volume by the disk device listed under the disks: attribute.
Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

21.11. CONFIGURING A RAID VOLUME USING THE STORAGE SYSTEM ROLE

With the `storage` System Role, you can configure a RAID volume on RHEL using Red Hat Ansible Automation Platform and Ansible-Core. Create an Ansible playbook with the parameters to configure a RAID volume to suit your requirements.

Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.
- You have an inventory file detailing the systems on which you want to deploy a RAID volume using the `storage` System Role.

Procedure

1. Create a new `playbook.yml` file with the following content:

```yaml
---
  - name: Configure the storage
    hosts: managed-node-01.example.com
    tasks:
      - name: Create a RAID on sdd, sde, sdf, and sdg
        include_role:
          name: rhel-system-roles.storage
        vars:
          storage_safe_mode: false
          storage_volumes:
            - name: data
              type: raid
              disks: [sdd, sde, sdf, sdg]
              raid_level: raid0
              raid_chunk_size: 32 KiB
              mount_point: /mnt/data
              state: present
```

**WARNING**

Device names might change in certain circumstances, for example, when you add a new disk to a system. Therefore, to prevent data loss, do not use specific disk names in the playbook.
2. Optional: Verify the playbook syntax:

```
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook:

```
# ansible-playbook -i inventory.file /path/to/file/playbook.yml
```

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file
- Preparing a control node and managed nodes to use RHEL System Roles

### 21.12. CONFIGURING AN LVM POOL WITH RAID USING THE `storage` RHEL SYSTEM ROLE

With the `storage` System Role, you can configure an LVM pool with RAID on RHEL using Red Hat Ansible Automation Platform. You can set up an Ansible playbook with the available parameters to configure an LVM pool with RAID.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.
- You have an inventory file detailing the systems on which you want to configure an LVM pool with RAID using the `storage` System Role.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

```yaml
- hosts: all
  vars:
    storage_safe_mode: false
    storage_pools:
      - name: my_pool
        type: lvm
        disks: [sdh, sdi]
        raid_level: raid1
        volumes:
          - name: my_volume
            size: "1 GiB"
            mount_point: "/mnt/app/shared"
            fs_type: xfs
            state: present
    roles:
      - name: rhel-system-roles.storage
```
NOTE

To create an LVM pool with RAID, you must specify the RAID type using the `raid_level` parameter.

2. Optional: Verify playbook syntax.

```
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```
# ansible-playbook -i inventory.file /path/to/file/playbook.yml
```

Additional resources

- The `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file.

### 21.13. CONFIGURING A STRIPE SIZE FOR RAID LVM VOLUMES USING THE STORAGE RHEL SYSTEM ROLE

With the `storage` System Role, you can configure a stripe size for RAID LVM volumes on RHEL using Red Hat Ansible Automation Platform. You can set up an Ansible playbook with the available parameters to configure an LVM pool with RAID.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.
- You have an inventory file detailing the systems on which you want to configure an LVM pool with RAID using the storage System Role.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

```yaml
hosts: all
vars:
  storage_safe_mode: false
  storage_pools:
  - name: my_pool
    type: lvm
    disks: [sdh, sdi]
    volumes:
      - name: my_volume
        size: "1 GiB"
        mount_point: "/mnt/app/shared"
        fs_type: xfs
        raid_level: raid1
        raid Stripe size: "256 KiB"
```
state: present
roles:
  - name: rhel-system-roles.storage

2. Optional: Verify playbook syntax:

```yaml
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```bash
# ansible-playbook -i inventory.file /path/to/file/playbook.yml
```

Additional resources

- Managing RAID
- The /usr/share/ansible/roles/rhel-system-roles.storage/README.md file.

21.14. EXAMPLE ANSIBLE PLAYBOOK TO COMPRESS AND DEDUPLICATE A VDO VOLUME ON LVM USING THE STORAGE RHEL SYSTEM ROLE

The example Ansible playbook applies the storage RHEL System Role to enable compression and deduplication of Logical Volumes (LVM) using Virtual Data Optimizer (VDO).

Example 21.9. A playbook that creates `mylv1` LVM VDO volume in the `myvg` volume group

```yaml
---
- name: Create LVM VDO volume under volume group 'myvg'
  hosts: all
  roles:
    - rhel-system-roles.storage
  vars:
    storage_pools:
      - name: myvg
    disks:
      - /dev/sdb
    volumes:
      - name: mylv1
        compression: true
        deduplication: true
        vdo_pool_size: 10 GiB
        size: 30 GiB
        mount_point: /mnt/app/shared
```

In this example, the `compression` and `deduplication` pools are set to true, which specifies that the VDO is used. The following describes the usage of these parameters:

- The `deduplication` is used to deduplicate the duplicated data stored on the storage volume.
- The compression is used to compress the data stored on the storage volume, which results in more storage capacity.
The vdo_pool_size specifies the actual size the volume takes on the device. The virtual size of VDO volume is set by the size parameter. NOTE: Because of the Storage role use of LVM VDO, only one volume per pool can use the compression and deduplication.

21.15. CREATING A LUKS2 ENCRYPTED VOLUME USING THE STORAGE RHEL SYSTEM ROLE

You can use the storage role to create and configure a volume encrypted with LUKS by running an Ansible playbook.

Prerequisites

- Access and permissions to one or more managed nodes, which are systems you want to configure with the crypto_policies System Role.
- An inventory file, which lists the managed nodes.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems. On the control node, the ansible-core and rhel-system-roles packages are installed.

IMPORTANT

RHEL 8.0–8.5 provided access to a separate Ansible repository that contains Ansible Engine 2.9 for automation based on Ansible. Ansible Engine contains command-line utilities such as ansible, ansible-playbook, connectors such as docker and podman, and many plugins and modules. For information about how to obtain and install Ansible Engine, see the How to download and install Red Hat Ansible Engine Knowledgebase article.

RHEL 8.6 and 9.0 have introduced Ansible Core (provided as the ansible-core package), which contains the Ansible command-line utilities, commands, and a small set of built-in Ansible plugins. RHEL provides this package through the AppStream repository, and it has a limited scope of support. For more information, see the Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories Knowledgebase article.

Procedure

1. Create a new playbook.yml file with the following content:

   ```yaml
   - hosts: all
     vars:
       storage_volumes:
         - name: barefs
           type: disk
           disks:
             - sdb
           fs_type: xfs
           fs_label: label-name
           mount_point: /mnt/data
           encryption: true
   ```
encryption_password: your-password
roles:
- rhel-system-roles.storage

You can also add the other encryption parameters such as encryption_key, encryption_cipher, encryption_key_size, and encryption_luks version in the playbook.yml file.

2. Optional: Verify playbook syntax:

```bash
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```bash
# ansible-playbook -i inventory.file /path/to/file/playbook.yml
```

**Verification**

1. View the encryption status:

```bash
# cryptsetup status sdb

/devmapper/sdb is active and is in use.
type: LUKS2
cipher: aes-xts-plain64
keysize: 512 bits
key location: keyring
device: /dev/sdb
[...]
```

2. Verify the created LUKS encrypted volume:

```bash
# cryptsetup luksDump /dev/sdb

Version: 2
Epoch: 6
Metadata area: 16384 [bytes]
Keyslots area: 33521664 [bytes]
UUID: a4c6be82-7347-4a91-a8ad-9479b72c9426
Label: (no label)
Subsystem: (no subsystem)
Flags: allow-discards

Data segments:
0: crypt
offset: 33554432 [bytes]
length: (whole device)
cipher: aes-xts-plain64
sector: 4096 [bytes]
[...]
```

3. View the cryptsetup parameters in the playbook.yml file, which the storage role supports:

```bash
# cat ~/playbook.yml
```
```yaml
- hosts: all
  vars:
    storage_volumes:
      - name: foo
        type: disk
        disks:
          - nvme0n1
        fs_type: xfs
        fs_label: label-name
        mount_point: /mnt/data
        encryption: true
        #encryption_password: passwdpasswd
        encryption_key: /home/passwd_key
        encryption_cipher: aes-xts-plain64
        encryption_key_size: 512
        encryption_luks_version: luks2

  roles:
    - rhel-system-roles.storage

Additional resources

- Encrypting block devices using LUKS
- /usr/share/ansible/roles/rhel-system-roles.storage/README.md

21.16. EXAMPLE ANSIBLE PLAYBOOK TO EXPRESS POOL VOLUME SIZES AS PERCENTAGE USING THE STORAGE RHEL SYSTEM ROLE

The example Ansible playbook applies the `storage` System Role to enable you to express Logical Manager Volumes (LVM) volume sizes as a percentage of the pool’s total size.

Example 21.10. A playbook that express volume sizes as a percentage of the pool’s total size

---
- name: Express volume sizes as a percentage of the pool’s total size
  hosts: all
  roles
    - rhel-system-roles.storage
  vars:
    storage_pools:
      - name: myvg
        disks:
          - /dev/sdb
        volumes:
          - name: data
            size: 60%
            mount_point: /opt/mount/data
          - name: web
            size: 30%
            mount_point: /opt/mount/web
          - name: cache
            size: 10%
            mount_point: /opt/cache/mount
This example specifies the size of LVM volumes as a percentage of the pool size, for example: "60%". Additionally, you can also specify the size of LVM volumes as a percentage of the pool size in a human-readable size of the file system, for example, "10g" or "50 GiB".

- /usr/share/ansible/roles/rhel-system-roles.storage/
CHAPTER 22. CONFIGURING TIME SYNCHRONIZATION BY USING THE TIMESYNC RHEL SYSTEM ROLE

With the timesync RHEL System Role, you can manage time synchronization on multiple target machines on RHEL using Red Hat Ansible Automation Platform.

22.1. THE TIMESYNC RHEL SYSTEM ROLE

You can manage time synchronization on multiple target machines using the timesync RHEL System Role.

The timesync role installs and configures an NTP or PTP implementation to operate as an NTP client or PTP replica in order to synchronize the system clock with NTP servers or grandmasters in PTP domains.

Note that using the timesync role also facilitates the Migrating to chrony, because you can use the same playbook on all versions of Red Hat Enterprise Linux starting with RHEL 6 regardless of whether the system uses ntp or chrony to implement the NTP protocol.

22.2. APPLYING THE TIMESYNC SYSTEM ROLE FOR A SINGLE POOL OF SERVERS

The following example shows how to apply the timesync role in a situation with just one pool of servers.

**WARNING**

The timesync role replaces the configuration of the given or detected provider service on the managed host. Previous settings are lost, even if they are not specified in the role variables. The only preserved setting is the choice of provider if the timesync_ntp_provider variable is not defined.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the rhel-system-roles package installed on the system from which you want to run the playbook.
- You have an inventory file which lists the systems on which you want to deploy timesync System Role.

**Procedure**

1. Create a new playbook.yml file with the following content:

```yaml
---
- hosts: timesync-test
  vars:
    timesync_ntp_servers:
```
- hostname: 2.rhel.pool.ntp.org
  pool: yes
  iburst: yes
roles:
  - rhel-system-roles.timesync

2. Optional: Verify playbook syntax.

# ansible-playbook --syntax-check playbook.yml

3. Run the playbook on your inventory file:

# ansible-playbook -i inventory_file /path/to/file/playbook.yml

### 22.3. APPLYING THE TIMESYNC SYSTEM ROLE ON CLIENT SERVERS

You can use the timesync role to enable Network Time Security (NTS) on NTP clients. Network Time Security (NTS) is an authentication mechanism specified for Network Time Protocol (NTP). It verifies that NTP packets exchanged between the server and client are not altered.

---

**WARNING**

The timesync role replaces the configuration of the given or detected provider service on the managed host. Previous settings are lost even if they are not specified in the role variables. The only preserved setting is the choice of provider if the timesync_ntp_provider variable is not defined.

**Prerequisites**

- You do not have to have Red Hat Ansible Automation Platform installed on the systems on which you want to deploy the timesync solution.
- You have the rhel-system-roles package installed on the system from which you want to run the playbook.
- You have an inventory file which lists the systems on which you want to deploy the timesync System Role.
- The chrony NTP provider version is 4.0 or later.

**Procedure**

1. Create a playbook.yml file with the following content:

```yaml
---
- hosts: timesync-test
  vars:
    timesync_ntp_servers:
      - hostname: ptbtime1.ptb.de
```
ptbtime1.ptb.de is an example of public server. You may want to use a different public server or your own server.

2. Optional: Verify playbook syntax.

```
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```
# ansible-playbook -i inventory_file /path/to/file/playbook.yml
```

**Verification**

1. Perform a test on the client machine:

```
# chronyc -N authdata
```

```
Name/IP address         Mode KeyID Type KLen Last Atmp  NAK Cook CLen
=====================================================================  
ptbtime1.ptb.de         NTS     1   15  256  157    0    0    8  100
```

2. Check that the number of reported cookies is larger than zero.

**Additional resources**

- [chrony.conf(5) man page](#)

### 22.4. TIMESYNC SYSTEM ROLES VARIABLES

You can pass the following variable to the `timesync` role:

- `timesync_ntp_servers`:

<table>
<thead>
<tr>
<th>Role variable settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname: host.example.com</td>
<td>Hostname or address of the server</td>
</tr>
<tr>
<td>minpoll: number</td>
<td>Minimum polling interval. Default: 6</td>
</tr>
<tr>
<td>maxpoll: number</td>
<td>Maximum polling interval. Default: 10</td>
</tr>
<tr>
<td>iburst: yes</td>
<td>Flag enabling fast initial synchronization. Default: no</td>
</tr>
<tr>
<td>pool: yes</td>
<td>Flag indicating that each resolved address of the hostname is a separate NTP server. Default: no</td>
</tr>
</tbody>
</table>
### Role variable settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nts: yes</td>
<td>Flag to enable Network Time Security (NTS). Default: no. Supported only with chrony &gt;= 4.0.</td>
</tr>
</tbody>
</table>

**Additional resources**

- For a detailed reference on `timesync` role variables, install the `rhel-system-roles` package, and see the README.md or README.html files in the `/usr/share/doc/rhel-system-roles/timesync` directory.
CHAPTER 23. MONITORING PERFORMANCE BY USING THE METRICS RHEL SYSTEM ROLE

As a system administrator, you can use the `metrics` RHEL System Role to monitor the performance of a system.

23.1. INTRODUCTION TO THE METRICS SYSTEM ROLE

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems. The `metrics` System Role configures performance analysis services for the local system and, optionally, includes a list of remote systems to be monitored by the local system. The `metrics` System Role enables you to use `pcp` to monitor your systems performance without having to configure `pcp` separately, as the set-up and deployment of `pcp` is handled by the playbook.

Table 23.1. metrics system role variables

<table>
<thead>
<tr>
<th>Role variable</th>
<th>Description</th>
<th>Example usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics_monitored_hosts</td>
<td>List of remote hosts to be analyzed by the target host. These hosts will have metrics recorded on the target host, so ensure enough disk space exists below <code>/var/log</code> for each host.</td>
<td>metrics_monitored_hosts: [&quot;webserver.example.com&quot;, &quot;database.example.com&quot;]</td>
</tr>
<tr>
<td>metrics_retention_days</td>
<td>Configures the number of days for performance data retention before deletion.</td>
<td>metrics_retention_days: 14</td>
</tr>
<tr>
<td>metrics_graph_service</td>
<td>A boolean flag that enables the host to be set up with services for performance data visualization via <code>pcp</code> and <code>grafana</code>. Set to false by default.</td>
<td>metrics_graph_service: no</td>
</tr>
<tr>
<td>metrics_query_service</td>
<td>A boolean flag that enables the host to be set up with time series query services for querying recorded <code>pcp</code> metrics via <code>redis</code>. Set to false by default.</td>
<td>metrics_query_service: no</td>
</tr>
<tr>
<td>metrics_provider</td>
<td>Specifies which metrics collector to use to provide metrics. Currently, <code>pcp</code> is the only supported metrics provider.</td>
<td>metrics_provider: &quot;pcp&quot;</td>
</tr>
<tr>
<td>metrics_manage_firewall</td>
<td>Uses the <code>firewall</code> role to manage port access directly from the <code>metrics</code> role. Set to false by default.</td>
<td>metrics_manage_firewall: true</td>
</tr>
<tr>
<td>Role variable</td>
<td>Description</td>
<td>Example usage</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>metrics_manage_selinux</td>
<td>Uses the <code>selinux</code> role to manage port access directly from the <code>metrics</code> role. Set to false by default.</td>
<td>metrics_manage_selinux: true</td>
</tr>
</tbody>
</table>

**NOTE**

For details about the parameters used in `metrics_connections` and additional information about the `metrics` System Role, see the `/usr/share/ansible/roles/rhel-system-roles.metrics/README.md` file.

### 23.2. USING THE METRICS SYSTEM ROLE TO MONITOR YOUR LOCAL SYSTEM WITH VISUALIZATION

This procedure describes how to use the `metrics` RHEL System Role to monitor your local system while simultaneously provisioning data visualization via Grafana.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to monitor.

**Procedure**

1. Configure `localhost` in the `/etc/ansible/hosts` Ansible inventory by adding the following content to the inventory:

   ```
   localhost ansible_connection=local
   ```

2. Create an Ansible playbook with the following content:

   ```yaml
   ---
   - name: Manage metrics
     hosts: localhost
     vars:
       metrics_graph_service: yes
       metrics_manage_firewall: true
       metrics_manage_selinux: true
     roles:
       - rhel-system-roles.metrics
   ```

3. Run the Ansible playbook:

   ```
   # ansible-playbook name_of_your_playbook.yml
   ```
Because the `metrics_graph_service` boolean is set to `value="yes"`, Grafana is automatically installed and provisioned with `pcp` added as a data source.

Because `metrics_manage_firewall` and `metrics_manage_selinux` are both set to `true`, the metrics role uses the `firewall` and `selinux` system roles to manage the ports used by the metrics role.

4. To view visualization of the metrics being collected on your machine, access the Grafana web interface as described in Accessing the Grafana web UI.

# 23.3. USING THE METRICS SYSTEM ROLE TO SET UP A FLEET OF INDIVIDUAL SYSTEMS TO MONITOR THEMSELVES

This procedure describes how to use the `metrics` System Role to set up a fleet of machines to monitor themselves.

## Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.
- You have the SSH connection established.

## Procedure

1. Add the name or IP address of the machines you want to monitor via the playbook to the `/etc/ansible/hosts` Ansible inventory file under an identifying group name enclosed in brackets:

   ```
   [remotes]
   webserver.example.com
   database.example.com
   ```

2. Create an Ansible playbook with the following content:

   ```
   ---
   - hosts: remotes
     vars:
       metrics_retention_days: 0
       metrics_manage_firewall: true
       metrics_manage_selinux: true
     roles:
       - rhel-system-roles.metrics
   ```

3. Run the Ansible playbook:
# ansible-playbook name_of_your_playbook.yml -k

Where the -k prompt for password to connect to remote system.

23.4. USING THE METRICS SYSTEM ROLE TO MONITOR A FLEET OF MACHINES CENTRALLY VIA YOUR LOCAL MACHINE

This procedure describes how to use the metrics System Role to set up your local machine to centrally monitor a fleet of machines while also provisioning visualization of the data via grafana and querying of the data via redis.

Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the rhel-system-roles package installed on the machine you want to use to run the playbook.

Procedure

1. Create an Ansible playbook with the following content:

```yaml
---
- hosts: localhost
  vars:
    metrics_graph_service: yes
    metrics_query_service: yes
    metrics_retention_days: 10
    metrics_monitored_hosts: ["database.example.com", "webserver.example.com"]
    metrics_manage_firewall: yes
    metrics_manage_selinux: yes
  roles:
    - rhel-system-roles.metrics
```

2. Run the Ansible playbook:

```bash
# ansible-playbook name_of_your_playbook.yml
```

NOTE

Because the metrics_graph_service and metrics_query_service booleans are set to value="yes", grafana is automatically installed and provisioned with pcp added as a data source with the pcp data recording indexed into redis, allowing the pcp querying language to be used for complex querying of the data. Because metrics_manage_firewall and metrics_manage_selinux are both set to true, the metrics role uses the firewall and selinux roles to manage the ports used by the metrics role.

3. To view a graphical representation of the metrics being collected centrally by your machine and to query the data, access the grafana web interface as described in Accessing the Grafana web UI.
23.5. Setting up Authentication While Monitoring a System Using the metrics System Role

PCP supports the **scram-sha-256** authentication mechanism through the Simple Authentication Security Layer (SASL) framework. The **metrics** RHEL System Role automates the steps to setup authentication using the **scram-sha-256** authentication mechanism. This procedure describes how to setup authentication using the **metrics** RHEL System Role.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the **rhel-system-roles** package installed on the machine you want to use to run the playbook.

**Procedure**

1. Include the following variables in the Ansible playbook you want to setup authentication for:

   ```
   ---
   vars:
   metrics_username: your_username
   metrics_password: your_password
   metrics_manage_firewall: true
   metrics_manage_selinux: true
   ```

   **NOTE**

   Because **metrics_manage_firewall** and **metrics_manage_selinux** are both set to **true**, the **metrics** role uses the **firewall** and **selinux** roles to manage the ports used by the **metrics** role.

2. Run the Ansible playbook:

   ```bash
   # ansible-playbook name_of_your_playbook.yml
   ```

**Verification steps**

- Verify the **sasl** configuration:

  ```bash
  # pminfo -f -h "pcp://ip_address?username=your_username" disk.dev.read
  Password:
  disk.dev.read
  inst [0 or "sda"] value 19540
  ```

  *ip_address* should be replaced by the IP address of the host.

23.6. Using the metrics System Role to Configure and Enable Metrics Collection for SQL Server

This procedure describes how to use the **metrics** RHEL System Role to automate the configuration and enabling of metrics collection for Microsoft SQL Server via **pcp** on your local system.
Prerequisites

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to monitor.
- You have installed Microsoft SQL Server for Red Hat Enterprise Linux and established a ‘trusted’ connection to an SQL server. See Install SQL Server and create a database on Red Hat.

Procedure

1. Configure `localhost` in the `/etc/ansible/hosts` Ansible inventory by adding the following content to the inventory:

   ```
   localhost ansible_connection=local
   ```

2. Create an Ansible playbook that contains the following content:

   ```yaml
   ---
   - hosts: localhost
     vars:
       metrics_from_mssql: true
       metrics_manage_firewall: true
       metrics_manage_selinux: true
     roles:
       - role: rhel-system-roles.metrics
   ```

   **NOTE**

   Because `metrics_manage_firewall` and `metrics_manage_selinux` are both set to `true`, the `metrics` role uses the `firewall` and `selinux` roles to manage the ports used by the `metrics` role.

3. Run the Ansible playbook:

   ```
   # ansible-playbook name_of_your_playbook.yml
   ```

Verification steps

- Use the `pcp` command to verify that SQL Server PMDA agent (mssql) is loaded and running:

   ```
   # pcp
   platform: Linux rhel82-2.local 4.18.0-167.el8.x86_64 #1 SMP Sun Dec 15 01:24:23 UTC 2019 x86_64
   hardware: 2 cpus, 1 disk, 1 node, 2770MB RAM
   timezone: PDT+7
   services: pmcd pmproxy
     pmcd: Version 5.0.2-1, 12 agents, 4 clients
     pmda: root pmcd proc pmproxy xfs linux nfsclient mmv kvm mssql
   ```
Additional resources

- For more information about using Performance Co-Pilot for Microsoft SQL Server, see this Red Hat Developers Blog post.
CHAPTER 24. CONFIGURING A SYSTEM FOR SESSION RECORDING USING THE TLOG RHEL SYSTEM ROLE

With the tlog RHEL System Role, you can configure a system for terminal session recording on RHEL using Red Hat Ansible Automation Platform.

24.1. THE TLOG SYSTEM ROLE

You can configure a RHEL system for terminal session recording on RHEL using the tlog RHEL System Role.

You can configure the recording to take place per user or user group by means of the SSSD service.

Additional resources

- For more details on session recording in RHEL, see Recording Sessions.

24.2. COMPONENTS AND PARAMETERS OF THE TLOG SYSTEM ROLE

The Session Recording solution has the following components:

- The tlog utility
- System Security Services Daemon (SSSD)
- Optional: The web console interface

The parameters used for the tlog RHEL System Role are:

<table>
<thead>
<tr>
<th>Role Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tlog_use_sssd (default: yes)</td>
<td>Configure session recording with SSSD, the preferred way of managing recorded users or groups</td>
</tr>
<tr>
<td>tlog_scope_sssd (default: none)</td>
<td>Configure SSSD recording scope - all / some / none</td>
</tr>
<tr>
<td>tlog_users_sssd (default: [])</td>
<td>YAML list of users to be recorded</td>
</tr>
<tr>
<td>tlog_groups_sssd (default: [])</td>
<td>YAML list of groups to be recorded</td>
</tr>
</tbody>
</table>

- For details about the parameters used in tlog and additional information about the tlog System Role, see the /usr/share/ansible/roles/rhel-system-roles.tlog/README.md file.

24.3. DEPLOYING THE TLOG RHEL SYSTEM ROLE

Follow these steps to prepare and apply an Ansible playbook to configure a RHEL system to log session recording data to the systemd journal.

Prerequisites
You have set SSH keys for access from the control node to the target system where the tlog System Role will be configured.

You have at least one system that you want to configure the tlog System Role.

The Ansible Core package is installed on the control machine.

The rhel-system-roles package is installed on the control machine.

**Procedure**

1. Create a new `playbook.yml` file with the following content:

   ```yaml
   ---
   - name: Deploy session recording
     hosts: all
     vars:
       tlog_scope_sssd: some
       tlog_users_sssd:
         - recorded-user
     roles:
       - rhel-system-roles.tlog
   ```

   Where,

   - **tlog_scope_sssd**:
     - *some* specifies you want to record only certain users and groups, not *all* or *none*.
   - **tlog_users_sssd**:
     - *recorded-user* specifies the user you want to record a session from. Note that this does not add the user for you. You must set the user by yourself.

2. Optionally, verify the playbook syntax.

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i IP_Address /path/to/file/playbook.yml -v
   ```

As a result, the playbook installs the tlog RHEL System Role on the system you specified. The role includes tlog-rec-session, a terminal session I/O logging program, that acts as the login shell for a user. It also creates an SSSD configuration drop file that can be used by the users and groups that you define. SSSD parses and reads these users and groups, and replaces their user shell with tlog-rec-session. Additionally, if the cockpit package is installed on the system, the playbook also installs the cockpit-session-recording package, which is a Cockpit module that allows you to view and play recordings in the web console interface.

**Verification steps**

To verify that the SSSD configuration drop file is created in the system, perform the following steps:

1. Navigate to the folder where the SSSD configuration drop file is created:
2. Check the file content:

```bash
# cd /etc/sssd/conf.d
# cat /etc/sssd/conf.d/sssd-session-recording.conf
```

You can see that the file contains the parameters you set in the playbook.

### 24.4. DEPLOYING THE `tlog` RHEL SYSTEM ROLE FOR EXCLUDING LISTS OF GROUPS OR USERS

You can use the `tlog` System Role to support the SSSD session recording configuration options `exclude_users` and `exclude_groups`. Follow these steps to prepare and apply an Ansible playbook to configure a RHEL system to exclude users or groups from having their sessions recorded and logged in the systemd journal.

#### Prerequisites

- You have set SSH keys for access from the control node to the target system on which you want to configure the `tlog` System Role.
- You have at least one system on which you want to configure the `tlog` System Role.
- The Ansible Core package is installed on the control machine.
- The `rhel-system-roles` package is installed on the control machine.

#### Procedure

1. Create a new `playbook.yml` file with the following content:

```yaml
---
- name: Deploy session recording excluding users and groups
  hosts: all
  vars:
    tlog_scope_sssd: all
    tlog_exclude_users_sssd:
      - jeff
      - james
    tlog_exclude_groups_sssd:
      - admins
  roles:
    - rhel-system-roles.tlog
```

Where,

- **tlog_scope_sssd**:
  - **all**: specifies that you want to record all users and groups.

- **tlog_exclude_users_sssd**:

- **tlog_exclude_groups_sssd**:
- user names: specifies the user names of the users you want to exclude from the session recording.

- **tlog_exclude_groups_sssd**:
  - **admins** specifies the group you want to exclude from the session recording.

2. Optionally, verify the playbook syntax;

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i IP_Address/path/to/file/playbook.yml -v
   ```

As a result, the playbook installs the **tlog** RHEL System Role on the system you specified. The role includes **tlog-rec-session**, a terminal session I/O logging program, that acts as the login shell for a user. It also creates an `/etc/sssd/conf.d/sssd-session-recording.conf` SSSD configuration drop file that can be used by users and groups except those that you defined as excluded. SSSD parses and reads these users and groups, and replaces their user shell with **tlog-rec-session**. Additionally, if the **cockpit** package is installed on the system, the playbook also installs the **cockpit-session-recording** package, which is a **Cockpit** module that allows you to view and play recordings in the web console interface.

**Verification steps**

To verify that the SSSD configuration drop file is created in the system, perform the following steps:

1. Navigate to the folder where the SSSD configuration drop file is created:

   ```bash
   # cd /etc/sssd/conf.d
   ```

2. Check the file content:

   ```bash
   # cat sssd-session-recording.conf
   ```

You can see that the file contains the parameters you set in the playbook.

**Additional resources**

- See the `/usr/share/doc/rhel-system-roles/tlog/` and `/usr/share/ansible/roles/rhel-system-roles.tlog/` directories.

- The [Recording a session using the deployed Terminal Session Recording System Role in the CLI](#).

### 24.5. RECORDING A SESSION USING THE DEPLOYED TLOG SYSTEM ROLE IN THE CLI

After you have deployed the **tlog** System Role in the system you have specified, you are able to record a user terminal session using the command-line interface (CLI).

**Prerequisites**

- You have deployed the **tlog** System Role in the target system.
● The SSSD configuration drop file was created in the `/etc/sssd/conf.d` directory. See Deploying the Terminal Session Recording RHEL System Role.

Procedure

1. Create a user and assign a password for this user:
   ```shell
   # useradd recorded-user
   # passwd recorded-user
   ```

2. Log in to the system as the user you just created:
   ```shell
   # ssh recorded-user@localhost
   ```

3. Type "yes" when the system prompts you to type yes or no to authenticate.

4. Insert the `recorded-user`’s password.
   The system displays a message about your session being recorded.

   **ATTENTION! Your session is being recorded!**

5. After you have finished recording the session, type:
   ```shell
   # exit
   ```
   The system logs out from the user and closes the connection with the localhost.

As a result, the user session is recorded, stored and you can play it using a journal.

Verification steps

To view your recorded session in the journal, do the following steps:

1. Run the command below:
   ```shell
   # journalctl -o verbose -r
   ```

2. Search for the `MESSAGE` field of the `tlog-rec` recorded journal entry.
   ```shell
   # journalctl -xel _EXE=/usr/bin/tlog-rec-session
   ```

24.6. WATCHING A RECORDED SESSION USING THE CLI

You can play a user session recording from a journal using the command-line interface (CLI).

Prerequisites

- You have recorded a user session. See Recording a session using the deployed tlog System Role in the CLI.

Procedure

1. On the CLI terminal, play the user session recording:
2. Search for the `tlog` recording:

```
$ /tlog-rec
```

You can see details such as:

- The username for the user session recording
- The `out_txt` field, a raw output encode of the recorded session
- The identifier number `TLOG_REC=ID_number`

3. Copy the identifier number `TLOG_REC=ID_number`.

4. Playback the recording using the identifier number `TLOG_REC=ID_number`.

```
# tlog-play -r journal -M TLOG_REC=ID_number
```

As a result, you can see the user session recording terminal output being played back.
CHAPTER 25. CONFIGURING A HIGH-AVAILABILITY CLUSTER BY USING THE HA_CLUSTER RHEL SYSTEM ROLE

With the ha_cluster System Role, you can configure and manage a high-availability cluster that uses the Pacemaker high availability cluster resource manager.

25.1. HA_CLUSTER SYSTEM ROLE VARIABLES

In an ha_cluster System Role playbook, you define the variables for a high availability cluster according to the requirements of your cluster deployment.

The variables you can set for an ha_cluster System Role are as follows:

ha_cluster_enable_repos
A boolean flag that enables the repositories containing the packages that are needed by the ha_cluster System Role. When this variable is set to true, the default value, you have active subscription coverage for RHEL and the RHEL High Availability Add-On on the systems that you will use as your cluster members or the System Role will fail.

ha_cluster_manage_firewall
(RHEL 9.2 and later) A boolean flag that determines whether the ha_cluster System Role manages the firewall. When ha_cluster_manage_firewall is set to true, the firewall high availability service and the fence-virt port are enabled. When ha_cluster_manage_firewall is set to false, the ha_cluster System Role does not manage the firewall. If your system is running the firewalld service, you must set the parameter to true in your playbook.

You can use the ha_cluster_manage_firewall parameter to add ports, but you cannot use the parameter to remove ports. To remove ports, use the firewall System Role directly.

As of RHEL 9.2, the firewall is no longer configured by default, because it is configured only when ha_cluster_manage_firewall is set to true.

ha_cluster_manage_selinux
(RHEL 9.2 and later) A boolean flag that determines whether the ha_cluster System Role manages the ports belonging to the firewall high availability service using the selinux System Role. When ha_cluster_manage_selinux is set to true, the ports belonging to the firewall high availability service are associated with the SELinux port type cluster_port_t. When ha_cluster_manage_selinux is set to false, the ha_cluster System Role does not manage SELinux.

If your system is running the selinux service, you must set this parameter to true in your playbook. Firewall configuration is a prerequisite for managing SELinux. If the firewall is not installed, the managing SELinux policy is skipped.

You can use the ha_cluster_manage_selinux parameter to add policy, but you cannot use the parameter to remove policy. To remove policy, use the selinux System Role directly.

ha_cluster_cluster_present
A boolean flag which, if set to true, determines that HA cluster will be configured on the hosts according to the variables passed to the role. Any cluster configuration not specified in the role and not supported by the role will be lost.

If ha_cluster_cluster_present is set to false, all HA cluster configuration will be removed from the target hosts.

The default value of this variable is true.
The following example playbook removes all cluster configuration on **node1** and **node2**

```yaml
- hosts: node1 node2
  vars:
    ha_cluster_cluster_present: false
  roles:
    - rhel-system-roles.ha_cluster
```

**ha_cluster_start_on_boot**

A boolean flag that determines whether cluster services will be configured to start on boot. The default value of this variable is **true**.

**ha_cluster_fence_agent_packages**

List of fence agent packages to install. The default value of this variable is **fence-agents-all, fence-virt**.

**ha_cluster_extra_packages**

List of additional packages to be installed. The default value of this variable is no packages.

This variable can be used to install additional packages not installed automatically by the role, for example custom resource agents.

It is possible to specify fence agents as members of this list. However, **ha_cluster_fence_agent_packages** is the recommended role variable to use for specifying fence agents, so that its default value is overridden.

**ha_cluster_hacluster_password**

A string value that specifies the password of the **hacluster** user. The **hacluster** user has full access to a cluster. To protect sensitive data, vault encrypt the password, as described in Encrypting content with Ansible Vault. There is no default password value, and this variable must be specified.

**ha_cluster_hacluster_qdevice_password**

(RHEL 9.3 and later) A string value that specifies the password of the **hacluster** user for a quorum device. This parameter is needed only if the **ha_cluster_quorum** parameter is configured to use a quorum device of type **net** and the password of the **hacluster** user on the quorum device is different from the password of the **hacluster** user specified with the **ha_cluster_hacluster_password** parameter. The **hacluster** user has full access to a cluster. To protect sensitive data, vault encrypt the password, as described in Encrypting content with Ansible Vault. There is no default value for this password.

**ha_cluster_corosync_key_src**

The path to Corosync **authkey** file, which is the authentication and encryption key for Corosync communication. It is highly recommended that you have a unique **authkey** value for each cluster. The key should be 256 bytes of random data.

If you specify a key for this variable, it is recommended that you vault encrypt the key, as described in Encrypting content with Ansible Vault.

If no key is specified, a key already present on the nodes will be used. If nodes do not have the same key, a key from one node will be distributed to other nodes so that all nodes have the same key. If no node has a key, a new key will be generated and distributed to the nodes.

If this variable is set, **ha_cluster_regenerate_keys** is ignored for this key.

The default value of this variable is null.
**ha_cluster_pacemaker_key_src**

The path to the Pacemaker authkey file, which is the authentication and encryption key for Pacemaker communication. It is highly recommended that you have a unique authkey value for each cluster. The key should be 256 bytes of random data.

If you specify a key for this variable, it is recommended that you vault encrypt the key, as described in Encrypting content with Ansible Vault.

If no key is specified, a key already present on the nodes will be used. If nodes do not have the same key, a key from one node will be distributed to other nodes so that all nodes have the same key. If no node has a key, a new key will be generated and distributed to the nodes.

If this variable is set, `ha_cluster_regenerate_keys` is ignored for this key.

The default value of this variable is null.

**ha_cluster_fence_virt_key_src**

The path to the fence-virt or fence-xvm pre-shared key file, which is the location of the authentication key for the fence-virt or fence-xvm fence agent.

If you specify a key for this variable, it is recommended that you vault encrypt the key, as described in Encrypting content with Ansible Vault.

If no key is specified, a key already present on the nodes will be used. If nodes do not have the same key, a key from one node will be distributed to other nodes so that all nodes have the same key. If no node has a key, a new key will be generated and distributed to the nodes. If the `ha_cluster` System Role generates a new key in this fashion, you should copy the key to your nodes’ hypervisor to ensure that fencing works.

If this variable is set, `ha_cluster_regenerate_keys` is ignored for this key.

The default value of this variable is null.

**ha_cluster_pcsd_public_key_src, ha_cluster_pcsd_private_key_src**

The path to the pcsd TLS certificate and private key. If this is not specified, a certificate-key pair already present on the nodes will be used. If a certificate-key pair is not present, a random new one will be generated.

If you specify a private key value for this variable, it is recommended that you vault encrypt the key, as described in Encrypting content with Ansible Vault.

If these variables are set, `ha_cluster_regenerate_keys` is ignored for this certificate-key pair.

The default value of these variables is null.

**ha_cluster_pcsd_certificates**

(RHEL 9.2 and later) Creates a pcsd private key and certificate using the certificate System Role. If your system is not configured with a pcsd private key and certificate, you can create them in one of two ways:

- Set the `ha_cluster_pcsd_certificates` variable. When you set the `ha_cluster_pcsd_certificates` variable, the certificate System Role is used internally and it creates the private key and certificate for pcsd as defined.

- Do not set the `ha_cluster_pcsd_public_key_src`, `ha_cluster_pcsd_private_key_src`, or the `ha_cluster_pcsd_certificates` variables. If you do not set any of these variables, the `ha_cluster` System Role will create pcsd certificates by means of pcsd itself. The value of
ha_cluster_pcsd_certificates is set to the value of the variable certificate_requests as specified in the certificate System Role. For more information about the certificate System Role, see Requesting certificates using RHEL System Roles.

The following operational considerations apply to the use of the ha_cluster_pcsd_certificate variable:

- Unless you are using IPA and joining the systems to an IPA domain, the certificate System Role creates self-signed certificates. In this case, you must explicitly configure trust settings outside of the context of RHEL System Roles. System Roles do not support configuring trust settings.

- When you set the ha_cluster_pcsd_certificates variable, do not set the ha_cluster_pcsd_public_key_src and ha_cluster_pcsd_private_key_src variables.

- When you set the ha_cluster_pcsd_certificates variable, ha_cluster_regenerate_keys is ignored for this certificate - key pair.

The default value of this variable is [].

For an example ha_cluster System Role playbook that creates TLS certificates and key files in a high availability cluster, see Creating pcsd TLS certificates and key files for a high availability cluster.

ha_cluster_regenerate_keys

A boolean flag which, when set to true, determines that pre-shared keys and TLS certificates will be regenerated. For more information about when keys and certificates will be regenerated, see the descriptions of the ha_cluster_corosync_key_src, ha_cluster_pacemaker_key_src, ha_cluster_fence_virt_key_src, ha_cluster_pcsd_public_key_src, and ha_cluster_pcsd_private_key_src variables.

The default value of this variable is false.

ha_cluster_pcs_permission_list

Configures permissions to manage a cluster using pcsd. The items you configure with this variable are as follows:

- **type** - user or group

- **name** - user or group name

- **allow_list** - Allowed actions for the specified user or group:
  - **read** - View cluster status and settings
  - **write** - Modify cluster settings except permissions and ACLs
  - **grant** - Modify cluster permissions and ACLs
  - **full** - Unrestricted access to a cluster including adding and removing nodes and access to keys and certificates

The structure of the ha_cluster_pcs_permission_list variable and its default values are as follows:

```yaml
ha_cluster_pcs_permission_list:
  - type: group
    name: hacluster
    allow_list:
```

CHAPTER 25. CONFIGURING A HIGH-AVAILABILITY CLUSTER BY USING THE HA_CLUSTER RHEL SYSTEM ROLE
The name of the cluster. This is a string value with a default of my-cluster.

(RHEL 9.1 and later) Sets the cluster transport method. The items you configure with this variable are as follows:

- **type** (optional) - Transport type: knet, udp, or udpu. The udp and udpu transport types support only one link. Encryption is always disabled for udp and udpu. Defaults to knet if not specified.

- **options** (optional) - List of name-value dictionaries with transport options.

- **links** (optional) - List of list of name-value dictionaries. Each list of name-value dictionaries holds options for one Corosync link. It is recommended that you set the linknumber value for each link. Otherwise, the first list of dictionaries is assigned by default to the first link, the second one to the second link, and so on.

- **compression** (optional) - List of name-value dictionaries configuring transport compression. Supported only with the knet transport type.

- **crypto** (optional) - List of name-value dictionaries configuring transport encryption. By default, encryption is enabled. Supported only with the knet transport type.

For a list of allowed options, see the pcs -h cluster setup help page or the setup description in the cluster section of the pcs(8) man page. For more detailed descriptions, see the corosync.conf(5) man page.

The structure of the ha_cluster_transport variable is as follows:

```yaml
ha_cluster_transport:
  type: knet
  options:
    - name: option1_name
      value: option1_value
    - name: option2_name
      value: option2_value
  links:
    -
      - name: option1_name
        value: option1_value
      - name: option2_name
        value: option2_value
      -
        - name: option1_name
          value: option1_value
        - name: option2_name
          value: option2_value
  compression:
    - name: option1_name
      value: option1_value
    - name: option2_name
      value: option2_value
```
value: option2_value
crypto:
- name: option1_name
  value: option1_value
- name: option2_name
  value: option2_value

For an example **ha_cluster** System Role playbook that configures a transport method, see [Configuring Corosync values in a high availability cluster](#).

**ha_cluster_totem**

(RHEL 9.1 and later) Configures Corosync totem. For a list of allowed options, see the `pcs -h cluster setup` help page or the `setup` description in the `cluster` section of the `pcs(8)` man page. For a more detailed description, see the `corosync.conf(5)` man page. The structure of the `ha_cluster_totem` variable is as follows:

```
ha_cluster_totem:
  options:
    - name: option1_name
      value: option1_value
    - name: option2_name
      value: option2_value
```

For an example **ha_cluster** System Role playbook that configures a Corosync totem, see [Configuring Corosync values in a high availability cluster](#).

**ha_cluster_quorum**

(RHEL 9.1 and later) Configures cluster quorum. You can configure the following items for cluster quorum:

- **options** (optional) - List of name-value dictionaries configuring quorum. Allowed options are: `auto_tie_breaker`, `last_man_standing`, `last_man_standing_window`, and `wait_for_all`. For information about quorum options, see the `votequorum(5)` man page.

- **device** (optional) - (RHEL 9.2 and later) Configures the cluster to use a quorum device. By default, no quorum device is used.
  - **model** (mandatory) - Specifies a quorum device model. Only `net` is supported
  - **model_options** (optional) - List of name-value dictionaries configuring the specified quorum device model. For model `net`, you must specify `host` and `algorithm` options. Use the `pcs-address` option to set a custom `pcsd` address and port to connect to the `qnetd` host. If you do not specify this option, the role connects to the default `pcsd` port on the `host`.
  - **generic_options** (optional) - List of name-value dictionaries setting quorum device options that are not model specific.
  - **heuristics_options** (optional) - List of name-value dictionaries configuring quorum device heuristics. For information about quorum device options, see the `corosync-qdevice(8)` man page. The generic options are `sync_timeout` and `timeout`. For model `net` options see the `quorum.device.net` section. For heuristics options, see the `quorum.device.heuristics` section.
To regenerate a quorum device TLS certificate, set the `ha_cluster_regenerate_keys` variable to `true`.

The structure of the `ha_cluster_quorum` variable is as follows:

```
ha_cluster_quorum:
  options:
    - name: option1_name
      value: option1_value
    - name: option2_name
      value: option2_value
  device:
    model: string
    model_options:
      - name: option1_name
        value: option1_value
      - name: option2_name
        value: option2_value
    generic_options:
      - name: option1_name
        value: option1_value
      - name: option2_name
        value: option2_value
    heuristics_options:
      - name: option1_name
        value: option1_value
      - name: option2_name
        value: option2_value
```

For an example `ha_cluster` System Role playbook that configures cluster quorum, see Configuring Corosync values in a high availability cluster. For an example `ha_cluster` System Role playbook that configures a cluster using a quorum device, see Configuring a high availability cluster using a quorum device.

**ha_cluster_sbd_enabled**

(RHEL 9.1 and later) A boolean flag which determines whether the cluster can use the SBD node fencing mechanism. The default value of this variable is `false`.

For an example `ha_cluster` System Role playbook that enables SBD, see Configuring a high availability cluster with SBD node fencing.

**ha_cluster_sbd_options**

(RHEL 9.1 and later) List of name-value dictionaries specifying SBD options. Supported options are:

- **delay-start** - defaults to `no`
- **startmode** - defaults to `always`
- **timeout-action** - defaults to `flush,reboot`
- **watchdog-timeout** - defaults to `5`

For information about these options, see the Configuration via environment section of the `sbd(8)` man page.
For an example `ha_cluster` System Role playbook that configures SBD options, see Configuring a high availability cluster with SBD node fencing.

When using SBD, you can optionally configure watchdog and SBD devices for each node in an inventory. For information about configuring watchdog and SBD devices in an inventory file, see Specifying an inventory for the `ha_cluster` System Role.

**ha_cluster_cluster_properties**

List of sets of cluster properties for Pacemaker cluster-wide configuration. Only one set of cluster properties is supported.

The structure of a set of cluster properties is as follows:

```yaml
ha_cluster_cluster_properties:
  - attrs:
    - name: property1_name
      value: property1_value
    - name: property2_name
      value: property2_value
```

By default, no properties are set.

The following example playbook configures a cluster consisting of `node1` and `node2` and sets the stonith-enabled and no-quorum-policy cluster properties.

```yaml
- hosts: node1 node2
  vars:
    ha_cluster_cluster_name: my-new-cluster
    ha_cluster_hacluster_password: password
    ha_cluster_cluster_properties:
      - attrs:
          - name: stonith-enabled
            value: 'true'
          - name: no-quorum-policy
            value: stop
  roles:
    - rhel-system-roles.ha_cluster
```

**ha_cluster_resource_primitives**

This variable defines pacemaker resources configured by the System Role, including stonith resources, including stonith resources. You can configure the following items for each resource:

- **id** (mandatory) - ID of a resource.
- **agent** (mandatory) - Name of a resource or stonith agent, for example `ocf:pacemaker:Dummy` or `stonith:fence_xvm`. It is mandatory to specify `stonith:` for stonith agents. For resource agents, it is possible to use a short name, such as `Dummy`, instead of `ocf:pacemaker:Dummy`. However, if several agents with the same short name are installed, the role will fail as it will be unable to decide which agent should be used. Therefore, it is recommended that you use full names when specifying a resource agent.
- **instance_attrs** (optional) - List of sets of the resource's instance attributes. Currently, only one set is supported. The exact names and values of attributes, as well as whether they are mandatory or not, depend on the resource or stonith agent.
• **meta attrs** (optional) - List of sets of the resource’s meta attributes. Currently, only one set is supported.

• **copy_operations_from_agent** (optional) - (RHEL 9.3 and later) Resource agents usually define default settings for resource operations, such as **interval** and **timeout**, optimized for the specific agent. If this variable is set to **true**, then those settings are copied to the resource configuration. Otherwise, clusterwide defaults apply to the resource. If you also define resource operation defaults for the resource with the **ha_cluster_resource_operation_defaults** role variable, you can set this to **false**. The default value of this variable is **true**.

• **operations** (optional) - List of the resource’s operations.
  
  o **action** (mandatory) - Operation action as defined by pacemaker and the resource or stonith agent.

  o **attrs** (mandatory) - Operation options, at least one option must be specified.

The structure of the resource definition that you configure with the **ha_cluster** System Role is as follows:

```
- id: resource-id
  agent: resource-agent
  instance_attrs:
    - attrs:
      - name: attribute1_name
        value: attribute1_value
      - name: attribute2_name
        value: attribute2_value
  meta_attrs:
    - attrs:
      - name: meta_attribute1_name
        value: meta_attribute1_value
      - name: meta_attribute2_name
        value: meta_attribute2_value
  copy_operations_from_agent: bool
  operations:
    - action: operation1-action
      attrs:
        - name: operation1_attribute1_name
          value: operation1_attribute1_value
        - name: operation1_attribute2_name
          value: operation1_attribute2_value
    - action: operation2-action
      attrs:
        - name: operation2_attribute1_name
          value: operation2_attribute1_value
        - name: operation2_attribute2_name
          value: operation2_attribute2_value
```

By default, no resources are defined.

For an example **ha_cluster** System Role playbook that includes resource configuration, see Configuring a high availability cluster with fencing and resources.

**ha_cluster_resource_groups**
This variable defines pacemaker resource groups configured by the System Role. You can configure the following items for each resource group:

- **id** (mandatory) - ID of a group.
- **resources** (mandatory) - List of the group’s resources. Each resource is referenced by its ID and the resources must be defined in the `ha_cluster_resource_primitives` variable. At least one resource must be listed.
- **meta_attrs** (optional) - List of sets of the group’s meta attributes. Currently, only one set is supported.

The structure of the resource group definition that you configure with the `ha_cluster` System Role is as follows:

```yaml
ha_cluster_resource_groups:
  - id: group-id
    resource_ids:
      - resource1-id
      - resource2-id
    meta_attrs:
      - attrs:
        - name: group_meta_attribute1_name
          value: group_meta_attribute1_value
        - name: group_meta_attribute2_name
          value: group_meta_attribute2_value
```

By default, no resource groups are defined.

For an example `ha_cluster` System Role playbook that includes resource group configuration, see Configuring a high availability cluster with fencing and resources.

**ha_cluster_resource_clones**

This variable defines pacemaker resource clones configured by the System Role. You can configure the following items for a resource clone:

- **resource_id** (mandatory) - Resource to be cloned. The resource must be defined in the `ha_cluster_resource_primitives` variable or the `ha_cluster_resource_groups` variable.
- **promotable** (optional) - Indicates whether the resource clone to be created is a promotable clone, indicated as `true` or `false`.
- **id** (optional) - Custom ID of the clone. If no ID is specified, it will be generated. A warning will be displayed if this option is not supported by the cluster.
- **meta_attrs** (optional) - List of sets of the clone’s meta attributes. Currently, only one set is supported.

The structure of the resource clone definition that you configure with the `ha_cluster` System Role is as follows:

```yaml
ha_cluster_resource_clones:
  - resource_id: resource-to-be-cloned
    promotable: true
    id: custom-clone-id
```
By default, no resource clones are defined.

For an example `ha_cluster` System Role playbook that includes resource clone configuration, see Configuring a high availability cluster with fencing and resources.

**ha_cluster_resource_defaults**

(RHEL 9.3 and later) This variable defines sets of resource defaults. You can define multiple sets of defaults and apply them to resources of specific agents using rules. The defaults you specify with the `ha_cluster_resource_defaults` variable do not apply to resources which override them with their own defined values.

Only meta attributes can be specified as defaults.

You can configure the following items for each defaults set:

- **id** (optional) - ID of the defaults set. If not specified, it is autogenerated.
- **rule** (optional) - Rule written using `pcs` syntax defining when and for which resources the set applies. For information on specifying a rule, see the `resource defaults set create` section of the `pcs(8)` man page.
- **score** (optional) - Weight of the defaults set.
- **attrs** (optional) - Meta attributes applied to resources as defaults.

The structure of the `ha_cluster_resource_defaults` variable is as follows:

```
ha_cluster_resource_defaults:
  meta_attrs:
    - id: defaults-set-1-id
      rule: rule-string
      score: score-value
      attrs:
        - name: meta_attribute1_name
          value: meta_attribute1_value
        - name: meta_attribute2_name
          value: meta_attribute2_value
    - id: defaults-set-2-id
      rule: rule-string
      score: score-value
      attrs:
        - name: meta_attribute3_name
          value: meta_attribute3_value
        - name: meta_attribute4_name
          value: meta_attribute4_value
```

For an example `ha_cluster` System Role playbook that configures resource defaults, see Configuring a high availability cluster with resource and resource operation defaults.
**ha_cluster_resource_operation_defaults**

(RHEL 9.3 and later) This variable defines sets of resource operation defaults. You can define multiple sets of defaults and apply them to resources of specific agents and specific resource operations using rules. The defaults you specify with the `ha_cluster_resource_operation_defaults` variable do not apply to resource operations which override them with their own defined values. By default, the `ha_cluster` System Role configures resources to define their own values for resource operations. For information about overriding these defaults with the `ha_cluster_resource_operations_defaults` variable, see the description of the `copy_operations_from_agent` item in `ha_cluster_resource_primitives`

Only meta attributes can be specified as defaults.

The structure of the `ha_cluster_resource_operations_defaults` variable is the same as the structure for the `ha_cluster_resource_defaults` variable, with the exception of how you specify a rule. For information about specifying a rule to describe the resource operation to which a set applies, see the `resource op defaults set create` section of the `pcs(8)` man page.

**ha_cluster_constraints_location**

This variable defines resource location constraints. Resource location constraints indicate which nodes a resource can run on. You can specify a resources specified by a resource ID or by a pattern, which can match more than one resource. You can specify a node by a node name or by a rule.

You can configure the following items for a resource location constraint:

- **resource** (mandatory) - Specification of a resource the constraint applies to.
- **node** (mandatory) - Name of a node the resource should prefer or avoid.
- **id** (optional) - ID of the constraint. If not specified, it will be autogenerated.
- **options** (optional) - List of name-value dictionaries.
  - **score** - Sets the weight of the constraint.
    - A positive `score` value means the resource prefers running on the node.
    - A negative `score` value means the resource should avoid running on the node.
    - A `score` value of `-INFINITY` means the resource must avoid running on the node.
    - If `score` is not specified, the score value defaults to `INFINITY`.

By default no resource location constraints are defined.

The structure of a resource location constraint specifying a resource ID and node name is as follows:

```plaintext
ha_cluster_constraints_location:
- resource:
  id: resource-id
  node: node-name
  id: constraint-id
  options:
    - name: score
      value: score-value
    - name: option-name
      value: option-value
```

The items that you configure for a resource location constraint that specifies a resource pattern are
the same items that you configure for a resource location constraint that specifies a resource ID, with the exception of the resource specification itself. The item that you specify for the resource specification is as follows:

- **pattern** (mandatory) - POSIX extended regular expression resource IDs are matched against.

The structure of a resource location constraint specifying a resource pattern and node name is as follows:

```yaml
ha_cluster_constraints_location:
  - resource:
    pattern: resource-pattern
    node: node-name
    id: constraint-id
  options:
    - name: score
      value: score-value
    - name: resource-discovery
      value: resource-discovery-value
```

You can configure the following items for a resource location constraint that specifies a resource ID and a rule:

- **resource** (mandatory) - Specification of a resource the constraint applies to.
  - id (mandatory) - Resource ID.
  - role (optional) - The resource role to which the constraint is limited: Started, Unpromoted, Promoted.

- **rule** (mandatory) - Constraint rule written using pcs syntax. For further information, see the **constraint location** section of the pcs(8) man page.

- Other items to specify have the same meaning as for a resource constraint that does not specify a rule.

The structure of a resource location constraint that specifies a resource ID and a rule is as follows:

```yaml
ha_cluster_constraints_location:
  - resource:
    id: resource-id
    role: resource-role
    rule: rule-string
    id: constraint-id
  options:
    - name: score
      value: score-value
    - name: resource-discovery
      value: resource-discovery-value
```

The items that you configure for a resource location constraint that specifies a resource pattern and a rule are the same items that you configure for a resource location constraint that specifies a resource ID and a rule, with the exception of the resource specification itself. The item that you specify for the resource specification is as follows:
• **pattern** (mandatory) - POSIX extended regular expression resource IDs are matched against.

The structure of a resource location constraint that specifies a resource pattern and a rule is as follows:

```yaml
ha_cluster_constraints_location:
  - resource:
      pattern: resource-pattern
      role: resource-role
      rule: rule-string
      id: constraint-id
      options:
        - name: score
          value: score-value
        - name: resource-discovery
          value: resource-discovery-value
```

For an example **ha_cluster** System Role playbook that creates a cluster with resource constraints, see Configuring a high availability cluster with resource constraints.

**ha_cluster_constraints_colocation**

This variable defines resource colocation constraints. Resource colocation constraints indicate that the location of one resource depends on the location of another one. There are two types of colocation constraints: a simple colocation constraint for two resources, and a set colocation constraint for multiple resources.

You can configure the following items for a simple resource colocation constraint:

• **resource_follower** (mandatory) - A resource that should be located relative to **resource_leader**.
  • **id** (mandatory) - Resource ID.
  • **role** (optional) - The resource role to which the constraint is limited: Started, Unpromoted, Promoted.

• **resource_leader** (mandatory) - The cluster will decide where to put this resource first and then decide where to put **resource_follower**.
  • **id** (mandatory) - Resource ID.
  • **role** (optional) - The resource role to which the constraint is limited: Started, Unpromoted, Promoted.

• **id** (optional) - ID of the constraint. If not specified, it will be autogenerated.

• **options** (optional) - List of name-value dictionaries.
  • **score** - Sets the weight of the constraint.
    • Positive **score** values indicate the resources should run on the same node.
    • Negative **score** values indicate the resources should run on different nodes.
    • A **score** value of +INFINITY indicates the resources must run on the same node.
A score value of -INFINITY indicates the resources must run on different nodes.

If score is not specified, the score value defaults to INFINITY.

By default no resource colocation constraints are defined. The structure of a simple resource colocation constraint is as follows:

```yaml
ha_cluster_constraints_colocation:
- resource_follower:
  id: resource-id1
  role: resource-role1
- resource_leader:
  id: resource-id2
  role: resource-role2
id: constraint-id
options:
  - name: score
    value: score-value
  - name: option-name
    value: option-value
```

You can configure the following items for a resource set colocation constraint:

- **resource_sets** (mandatory) - List of resource sets.
  - **resource_ids** (mandatory) - List of resources in a set.
  - **options** (optional) - List of name-value dictionaries fine-tuning how resources in the sets are treated by the constraint.
- **id** (optional) - Same values as for a simple colocation constraint.
- **options** (optional) - Same values as for a simple colocation constraint.

The structure of a resource set colocation constraint is as follows:

```yaml
ha_cluster_constraints_colocation:
- resource_sets:
  - resource_ids:
    - resource-id1
    - resource-id2
  options:
    - name: option-name
      value: option-value
id: constraint-id
options:
  - name: score
    value: score-value
  - name: option-name
    value: option-value
```

For an example ha_cluster System Role playbook that creates a cluster with resource constraints, see Configuring a high availability cluster with resource constraints.
This variable defines resource order constraints. Resource order constraints indicate the order in which certain resource actions should occur. There are two types of resource order constraints: a simple order constraint for two resources, and a set order constraint for multiple resources.

You can configure the following items for a simple resource order constraint:

- **resource_first** (mandatory) - Resource that the **resource_then** resource depends on.
  - **id** (mandatory) - Resource ID.
  - **action** (optional) - The action that must complete before an action can be initiated for the **resource_then** resource. Allowed values: **start**, **stop**, **promote**, **demote**.

- **resource_then** (mandatory) - The dependent resource.
  - **id** (mandatory) - Resource ID.
  - **action** (optional) - The action that the resource can execute only after the action on the **resource_first** resource has completed. Allowed values: **start**, **stop**, **promote**, **demote**.
  - **id** (optional) - ID of the constraint. If not specified, it will be autogenerated.
  - **options** (optional) - List of name-value dictionaries.

By default no resource order constraints are defined.

The structure of a simple resource order constraint is as follows:

```
ha_cluster_constraints_order:
- resource_first:
  id: resource-id1
  action: resource-action1
resource_then:
  id: resource-id2
  action: resource-action2
id: constraint-id
options:
- name: score
  value: score-value
- name: option-name
  value: option-value
```

You can configure the following items for a resource set order constraint:

- **resource_sets** (mandatory) - List of resource sets.
  - **resource_ids** (mandatory) - List of resources in a set.
  - **options** (optional) - List of name-value dictionaries fine-tuning how resources in the sets are treated by the constraint.

- **id** (optional) - Same values as for a simple order constraint.

- **options** (optional) - Same values as for a simple order constraint.

The structure of a resource set order constraint is as follows:

```
ha_cluster_constraints_order:
```
For an example **ha_cluster** System Role playbook that creates a cluster with resource constraints, see [Configuring a high availability cluster with resource constraints](#).

**ha_cluster_constraints_ticket**

This variable defines resource ticket constraints. Resource ticket constraints indicate the resources that depend on a certain ticket. There are two types of resource ticket constraints: a simple ticket constraint for one resource, and a ticket order constraint for multiple resources.

You can configure the following items for a simple resource ticket constraint:

- **resource** (mandatory) - Specification of a resource the constraint applies to.
  - **id** (mandatory) - Resource ID.
  - **role** (optional) - The resource role to which the constraint is limited: **Started**, **Unpromoted**, **Promoted**.

- **ticket** (mandatory) - Name of a ticket the resource depends on.

- **id** (optional) - ID of the constraint. If not specified, it will be autogenerated.

- **options** (optional) - List of name-value dictionaries.
  - **loss-policy** (optional) - Action to perform on the resource if the ticket is revoked.

By default no resource ticket constraints are defined.

The structure of a simple resource ticket constraint is as follows:

```
ha_cluster_constraints_ticket:
  - resource:
    id: resource-id
    role: resource-role
    ticket: ticket-name
    id: constraint-id
    options:
      - name: loss-policy
        value: loss-policy-value
      - name: option-name
        value: option-value
```

You can configure the following items for a resource set ticket constraint:
• **resource_sets** (mandatory) - List of resource sets.
  - **resource_ids** (mandatory) - List of resources in a set.
  - **options** (optional) - List of name-value dictionaries fine-tuning how resources in the sets are treated by the constraint.

• **ticket** (mandatory) - Same value as for a simple ticket constraint.

• **id** (optional) - Same value as for a simple ticket constraint.

• **options** (optional) - Same values as for a simple ticket constraint.

The structure of a resource set ticket constraint is as follows:

```yaml
ha_cluster_constraints_ticket:
  - resource_sets:
    - resource_ids:
      - resource-id1
      - resource-id2
    options:
      - name: option-name
        value: option-value
    ticket: ticket-name
    id: constraint-id
    options:
      - name: option-name
        value: option-value
```

For an example **ha_cluster** System Role playbook that creates a cluster with resource constraints, see Configuring a high availability cluster with resource constraints.

**ha_cluster_qnetd**

(RHEL 9.1 and later) This variable configures a **qnetd** host which can then serve as an external quorum device for clusters.

You can configure the following items for a **qnetd** host:

• **present** (optional) - If true, configure a **qnetd** instance on the host. If false, remove **qnetd** configuration from the host. The default value is false. If you set this true, you must set ha_cluster_cluster_present to false.

• **start_on_boot** (optional) - Configures whether the **qnetd** instance should start automatically on boot. The default value is true.

• **regenerate_keys** (optional) - Set this variable to true to regenerate the **qnetd** TLS certificate. If you regenerate the certificate, you must either re-run the role for each cluster to connect it to the **qnetd** host again or run pcs manually.

You cannot run **qnetd** on a cluster node because fencing would disrupt **qnetd** operation.

For an example **ha_cluster** System Role playbook that configures a cluster using a quorum device, see Configuring a cluster using a quorum device.

### 25.2. SPECIFYING AN INVENTORY FOR THE **HA_CLUSTER** SYSTEM ROLE
When configuring an HA cluster using the `ha_cluster` System Role playbook, you configure the names and addresses of the nodes for the cluster in an inventory.

### 25.2.1. Configuring node names and addresses in an inventory

For each node in an inventory, you can optionally specify the following items:

- **node_name** - the name of a node in a cluster.
- **pcs_address** - an address used by pcs to communicate with the node. It can be a name, FQDN or an IP address and it can include a port number.
- **corosync_addresses** - list of addresses used by Corosync. All nodes which form a particular cluster must have the same number of addresses and the order of the addresses matters.

The following example shows an inventory with targets `node1` and `node2`. `node1` and `node2` must be either fully qualified domain names or must otherwise be able to connect to the nodes as when, for example, the names are resolvable through the `/etc/hosts` file.

```yaml
all:
  hosts:
    node1:
      ha_cluster:
        node_name: node-A
        pcs_address: node1-address
        corosync_addresses:
          - 192.168.1.11
          - 192.168.2.11
    node2:
      ha_cluster:
        node_name: node-B
        pcs_address: node2-address:2224
        corosync_addresses:
          - 192.168.1.12
          - 192.168.2.12
```

### 25.2.2. Configuring watchdog and SBD devices in an inventory

(RHEL 9.1 and later) When using SBD, you can optionally configure watchdog and SBD devices for each node in an inventory. Even though all SBD devices must be shared to and accessible from all nodes, each node can use different names for the devices. Watchdog devices can be different for each node as well. For information about the SBD variables you can set in a System Role playbook, see the entries for `ha_cluster_sbd_enabled` and `ha_cluster_sbd_options` in `ha_cluster` System Role variables.

For each node in an inventory, you can optionally specify the following items:

- **sbd_watchdog_modules** (optional) - (RHEL 9.3 and later) Watchdog kernel modules to be loaded, which create `/dev/watchdog*` devices. Defaults to empty list if not set.
- **sbd_watchdog_modules_blocklist** (optional) - (RHEL 9.3 and later) Watchdog kernel modules to be unloaded and blocked. Defaults to empty list if not set.
- **sbd_watchdog** - Watchdog device to be used by SBD. Defaults to `/dev/watchdog` if not set.
- **sbd_devices** - Devices to use for exchanging SBD messages and for monitoring. Defaults to empty list if not set.

The following example shows an inventory that configures watchdog and SBD devices for targets **node1** and **node2**.

```yaml
all:
  hosts:
    node1:
      ha_cluster:
        sbd_watchdog_modules:
          - module1
          - module2
        sbd_watchdog: /dev/watchdog2
        sbd_devices:
          - /dev/vdx
          - /dev/vdy
    node2:
      ha_cluster:
        sbd_watchdog_modules:
          - module1
        sbd_watchdog_modules_blocklist:
          - module2
        sbd_watchdog: /dev/watchdog1
        sbd_devices:
          - /dev/vdw
          - /dev/vdz
```

For information about creating a high availability cluster that uses SBD fencing, see [Configuring a high availability cluster with SBD node fencing](#).

### 25.3. CREATING PCSD TLS CERTIFICATES AND KEY FILES FOR A HIGH AVAILABILITY CLUSTER (RHEL 9.2 AND LATER)

You can use the **ha_cluster** System Role to create TLS certificates and key files in a high availability cluster. When you run this playbook, the **ha_cluster** System Role uses the **certificate** System Role internally to manage TLS certificates.

**Prerequisites**

- The **ansible-core** and the **rhel-system-roles** packages are installed on the node from which you want to run the playbook.

**NOTE**

You do not need to have **ansible-core** installed on the cluster member nodes.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.
WARNING

The `ha_cluster` System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

Procedure

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the `ha_cluster` System Role.

2. Create a playbook file, for example `new-cluster.yml`.

   **NOTE**

   When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.

   The following example playbook file configures a cluster running the `firewalld` and `selinux` services and creates a self-signed `pcsd` certificate and private key files in `/var/lib/pcsd`. The `pcsd` certificate has the file name `FILENAME.crt` and the key file is named `FILENAME.key`.

   ```yaml
   - hosts: node1 node2
     vars:
       ha_cluster_cluster_name: my-new-cluster
       ha_cluster_hacluster_password: password
       ha_cluster_manage_firewall: true
       ha_cluster_manage_selinux: true
       ha_cluster_pcsd_certificates:
         - name: FILENAME
           common_name: "{{ ansible_hostname }}"
           ca: self-sign
     roles:
       - linux-system-roles.ha_cluster
   ```

3. Save the file.

4. Run the playbook, specifying the path to the inventory file `inventory` you created in Step 1.

   ```bash
   # ansible-playbook -i inventory new-cluster.yml
   ```

Additional resources

- Requesting certificates using RHEL System Roles

25.4. CONFIGURING A HIGH AVAILABILITY CLUSTER RUNNING NO RESOURCES

The following procedure uses the `ha_cluster` System Role, to create a high availability cluster with no fencing configured and which runs no resources.
Prerequisites

- You have **ansible-core** installed on the node from which you want to run the playbook.

  **NOTE**
  You do not need to have **ansible-core** installed on the cluster member nodes.

- You have the **rhel-system-roles** package installed on the system from which you want to run the playbook.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.

  **WARNING**
  The **ha_cluster** System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

Procedure

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the ha_cluster System Role.

2. Create a playbook file, for example **new-cluster.yml**.

   **NOTE**
   When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.

   The following example playbook file configures a cluster running the **firewalld** and **selinux** services with no fencing configured and which runs no resources.

   ```yaml
   - hosts: node1 node2
     vars:
       ha_cluster_cluster_name: my-new-cluster
       ha_cluster_hacluster_password: password
       ha_cluster_manage_firewall: true
       ha_cluster_manage_selinux: true

     roles:
       - rhel-system-roles.ha_cluster
   
   3. Save the file.

   4. Run the playbook, specifying the path to the inventory file **inventory** you created in Step 1.

     ```bash
     # ansible-playbook -i inventory new-cluster.yml
     ```
25.5. CONFIGURING A HIGH AVAILABILITY CLUSTER WITH FENCING AND RESOURCES

The following procedure uses the ha_cluster System Role to create a high availability cluster that includes a fencing device, cluster resources, resource groups, and a cloned resource.

Prerequisites

- You have ansible-core installed on the node from which you want to run the playbook.

  NOTE

  You do not need to have ansible-core installed on the cluster member nodes.

- You have the rhel-system-roles package installed on the system from which you want to run the playbook.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.

WARNING

The ha_cluster System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

Procedure

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the ha_cluster System Role.

2. Create a playbook file, for example new-cluster.yml.

  NOTE

  When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.

The following example playbook file configures a cluster running the firewalld and selinux services. The cluster includes fencing, several resources, and a resource group. It also includes a resource clone for the resource group.

- hosts: node1 node2
  vars:
    ha_cluster_cluster_name: my-new-cluster
    ha_cluster_hacluster_password: password
    ha_cluster_manage_firewall: true
    ha_cluster_manage_selinux: true
    ha_cluster_resource_primitives:
      - id: xvm-fencing
agent: 'stonith:fence_xvm'
instance_attrs:
  - attrs:
    - name: pcmk_host_list
      value: node1 node2
  - id: simple-resource
agent: 'ocf:pacemaker:Dummy'
- id: resource-with-options
  agent: 'ocf:pacemaker:Dummy'
instance_attrs:
  - attrs:
    - name: fake
      value: fake-value
    - name: passwd
      value: passwd-value
meta_attrs:
  - attrs:
    - name: target-role
      value: Started
    - name: is-managed
      value: 'true'
operations:
  - action: start
    attrs:
      - name: timeout
        value: '30s'
    - action: monitor
      attrs:
        - name: timeout
          value: '5'
        - name: interval
          value: '1min'
  - id: dummy-1
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-2
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-3
    agent: 'ocf:pacemaker:Dummy'
  - id: simple-clone
    agent: 'ocf:pacemaker:Dummy'
  - id: clone-with-options
    agent: 'ocf:pacemaker:Dummy'
h_cluster_resource_groups:
  - id: simple-group
    resource_ids:
    - dummy-1
    - dummy-2
    meta_attrs:
      - attrs:
        - name: target-role
          value: Started
        - name: is-managed
          value: 'true'
  - id: cloned-group
    resource_ids:
    - dummy-3
ha_cluster_resource_clones:
- resource_id: simple-clone
- resource_id: clone-with-options
  promotable: yes
  id: custom-clone-id
meta_attrs:
- attrs:
  - name: clone-max
    value: '2'
  - name: clone-node-max
    value: '1'
- resource_id: cloned-group
  promotable: yes
roles:
- rhel-system-roles.ha_cluster

3. Save the file.

4. Run the playbook, specifying the path to the inventory file inventory you created in Step 1.

   # ansible-playbook -i inventory new-cluster.yml

---

25.6. CONFIGURING A HIGH AVAILABILITY CLUSTER WITH RESOURCE AND RESOURCE OPERATION DEFAULTS

(RHEL 9.3 and later) The following procedure uses the ha_cluster System Role to create a high availability cluster that defines resource and resource operation defaults.

Prerequisites

- You have ansible-core installed on the node from which you want to run the playbook.

  **NOTE**
  
  You do not need to have ansible-core installed on the cluster member nodes.

- You have the rhel-system-roles package installed on the system from which you want to run the playbook.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.

**WARNING**

The ha_cluster System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.
Procedure

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the ha_cluster System Role.

2. Create a playbook file, for example `new-cluster.yml`.

   **NOTE**

   When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.

The following example playbook file configures a cluster running the `firewalld` and `selinux` services. The cluster includes resource and resource operation defaults.

```yaml
- hosts: node1 node2
  vars:
    ha_cluster_cluster_name: my-new-cluster
    ha_cluster_hacluster_password: password
    # Set a different 'resource-stickiness' value during # and outside work hours. This allows resources to # automatically move back to their most # preferred hosts, but at a time that # does not interfere with business activities.
    ha_cluster_resource_defaults:
      meta_attrs:
        - id: core-hours
          rule: date-spec hours=9-16 weekdays=1-5
          score: 2
          attr:
            - name: resource-stickiness
              value: INFINITY
        - id: after-hours
          score: 1
          attr:
            - name: resource-stickiness
              value: 0
      # Default the timeout on all 10-second-interval # monitor actions on IPaddr2 resources to 8 seconds.
    ha_cluster_resource_operation_defaults:
      meta_attrs:
        - rule: resource ::IPaddr2 and op monitor interval=10s
          score: INFINITY
          attr:
            - name: timeout
              value: 8s
      roles:
        - linux-system-roles.ha_cluster

3. Save the file.

4. Run the playbook, specifying the path to the inventory file `inventory` you created in Step 1.

   ```bash
   # ansible-playbook -i inventory new-cluster.yml
   ```
25.7. CONFIGURING A HIGH AVAILABILITY CLUSTER WITH RESOURCE CONSTRAINTS

The following procedure uses the `ha_cluster` System Role to create a high availability cluster that includes resource location constraints, resource colocation constraints, resource order constraints, and resource ticket constraints.

Prerequisites

- You have `ansible-core` installed on the node from which you want to run the playbook.

  **NOTE**
  
  You do not need to have `ansible-core` installed on the cluster member nodes.

- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.

**WARNING**

The `ha_cluster` System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

Procedure

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the `ha_cluster` System Role.

2. Create a playbook file, for example `new-cluster.yml`.

  **NOTE**
  
  When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.

The following example playbook file configures a cluster running the `firewalld` and `selinux` services. The cluster includes resource location constraints, resource colocation constraints, resource order constraints, and resource ticket constraints.

```yaml
- hosts: node1 node2
  vars:
    ha_cluster_cluster_name: my-new-cluster
    ha_cluster_hacluster_password: password
    ha_cluster_manage_firewall: true
    ha_cluster_manage_selinux: true
  # In order to use constraints, we need resources the constraints will apply
```
ha_cluster_resource_primitives:
  - id: xvm-fencing
    agent: 'stonith:fence_xvm'
    instance_attrs:
      - attrs:
        - name: pcmk_host_list
          value: node1 node2
  - id: dummy-1
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-2
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-3
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-4
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-5
    agent: 'ocf:pacemaker:Dummy'
  - id: dummy-6
    agent: 'ocf:pacemaker:Dummy'

# location constraints
ha_cluster_constraints_location:
  # resource ID and node name
  - resource:
    id: dummy-1

  - name: loss-policy
    value: fence

roles:
  - linux-system-roles.ha_cluster

3. Save the file.

4. Run the playbook, specifying the path to the inventory file `inventory` you created in Step 1.

```bash
# ansible-playbook -i inventory new-cluster.yml
```

### 25.8. CONFIGURING COROSYNC VALUES IN A HIGH AVAILABILITY CLUSTER

(RHEL 9.1 and later) The following procedure uses the `ha_cluster` System Role to create a high availability cluster that configures Corosync values.

**Prerequisites**

- You have `ansible-core` installed on the node from which you want to run the playbook.

  **NOTE**

  You do not need to have `ansible-core` installed on the cluster member nodes.

- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.

**WARNING**

The `ha_cluster` System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

**Procedure**

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the `ha_cluster` System Role.

2. Create a playbook file, for example `new-cluster.yml`. 
NOTE

When creating your playbook file for production, Vault encrypt the password, as described in Encrypting content with Ansible Vault.

The following example playbook file configures a cluster running the firewalld and selinux services that configures Corosync properties.

```yaml
- hosts: node1 node2
  vars:
    ha_cluster_cluster_name: my-new-cluster
    ha_cluster_hacluster_password: password
    ha_cluster_manage_firewall: true
    ha_cluster_manage_selinux: true
    ha_cluster_transport:
      type: knet
      options:
        - name: ip_version
          value: ipv4-6
        - name: link_mode
          value: active
      links:
        -
          - name: linknumber
            value: 1
          - name: link_priority
            value: 5
          -
          - name: linknumber
            value: 0
          - name: link_priority
            value: 10
      compression:
        - name: level
          value: 5
        - name: model
          value: zlib
      crypto:
        - name: cipher
          value: none
        - name: hash
          value: none
    ha_cluster_totem:
      options:
        - name: block_unlisted_ips
          value: 'yes'
        - name: send_join
          value: 0
    ha_cluster_quorum:
      options:
        - name: auto_tie_breaker
          value: 1
        - name: wait_for_all
          value: 1
```
roles:
- linux-system-roles.ha_cluster

3. Save the file.

4. Run the playbook, specifying the path to the inventory file `inventory` you created in Step 1.

```bash
# ansible-playbook -i inventory new-cluster.yml
```

### 25.9. CONFIGURING A HIGH AVAILABILITY CLUSTER WITH SBD NODE FENCING

(RHEL 9.1 and later) The following procedure uses the `ha_cluster` System Role to create a high availability cluster that uses SBD node fencing.

**Prerequisites**

- You have `ansible-core` installed on the node from which you want to run the playbook.

**NOTE**

You do not need to have `ansible-core` installed on the cluster member nodes.

- You have the `rhel-system-roles` package installed on the system from which you want to run the playbook.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.

**WARNING**

The `ha_cluster` System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

This playbook uses an inventory file that loads a watchdog module (supported in RHEL 9.3 and later) as described in Configuring watchdog and SBD devices in an inventory.

**Procedure**

1. Create an inventory file specifying the nodes in the cluster that configures watchdog and SBD devices, as described in Configuring watchdog and SBD devices in an inventory.

2. Create a playbook file, for example `new-cluster.yml`.
NOTE

When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.

The following example playbook file configures a cluster running the firewalld and selinux services that uses SBD fencing and creates the SBD Stonith resource. This playbook uses an inventory file that loads a watchdog module (supported in RHEL 9.3 and later) as described in Configuring watchdog and SBD devices in an inventory.

```yaml
- hosts: node1 node2
vars:
  ha_cluster_cluster_name: my-new-cluster
  ha_cluster_hacluster_password: password
  ha_cluster_manage_firewall: true
  ha_cluster_manage_selinux: true
  ha_cluster_sbd_enabled: yes
  ha_cluster_sbd_options:
    - name: delay-start
      value: 'no'
    - name: startmode
      value: always
    - name: timeout-action
      value: 'flush,reboot'
    - name: watchdog-timeout
      value: 30
  # Suggested optimal values for SBD timeouts:
  # watchdog-timeout * 2 = msgwait-timeout (set automatically)
  # msgwait-timeout * 1.2 = stonith-timeout
  ha_cluster_cluster_properties:
    - attrs:
      - name: stonith-timeout
        value: 72
  ha_cluster_resource_primitives:
    - id: fence_sbd
      agent: 'stonith:fence_sbd'
      instance_attrs:
        - attrs:
          - name: pcmk_delay_base
            value: 30

roles:
- linux-system-roles.ha_cluster

3. Save the file.

4. Run the playbook, specifying the path to the inventory file inventory you created in Step 1.

```ansible-playbook -i inventory new-cluster.yml```
25.10. CONFIGURING A HIGH AVAILABILITY CLUSTER USING A QUORUM DEVICE (RHEL 9.2 AND LATER)

To configure a high availability cluster with a separate quorum device by using the `ha_cluster` System Role, first set up the quorum device. After setting up the quorum device, you can use the device in any number of clusters.

25.10.1. Configuring a quorum device

To configure a quorum device using the `ha_cluster` System Role, follow these steps. Note that you cannot run a quorum device on a cluster node.

Prerequisites

- The `ansible-core` and the `rhel-system-roles` packages are installed on the node from which you want to run the playbook.

  **NOTE**
  You do not need to have `ansible-core` installed on the cluster member nodes.

- The system that you will use to run the quorum device has active subscription coverage for RHEL and the RHEL High Availability Add-On.

**WARNING**

The `ha_cluster` System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

Procedure

1. Create a playbook file, for example `qdev-playbook.yml`.

  **NOTE**
  When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.

The following example playbook file configures a quorum device on a system running the `firewalld` and `selinux` services.

```yaml
- hosts: nodeQ
  vars:
    ha_cluster_cluster_present: false
    ha_cluster_hacluster_password: password
    ha_cluster_manage_firewall: true
    ha_cluster_manage_selinux: true
    ha_cluster_qnetd:
```
present: true
roles:
  - linux-system-roles.ha_cluster

2. Save the file.

3. Run the playbook, specifying the host node for the quorum device.

   # ansible-playbook -i nodeQ, qdev-playbook.yml

25.10.2. Configuring a cluster to use a quorum device

To configure a cluster to use a quorum device, follow these steps.

Prerequisites

- You have ansible-core installed on the node from which you want to run the playbook.

  NOTE

  You do not need to have ansible-core installed on the cluster member nodes.

- You have the rhel-system-roles package installed on the system from which you want to run the playbook.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.

- You have configured a quorum device.

    WARNING

    The ha_cluster System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

Procedure

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the ha_cluster System Role.

2. Create a playbook file, for example new-cluster.yml.

    NOTE

    When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.
The following example playbook file configures a cluster running the `firewalld` and `selinux` services that uses a quorum device.

- hosts: node1 node2
  vars:
    ha_cluster_cluster_name: my-new-cluster
    ha_cluster_hacluster_password: password
    ha_cluster_manage_firewall: true
    ha_cluster_manage_selinux: true
    ha_cluster_quorum:
      device:
        model: net
        model_options:
          - name: host
            value: nodeQ
          - name: algorithm
            value: lms
  roles:
    - linux-system-roles.ha_cluster

3. Save the file.

4. Run the playbook, specifying the path to the inventory file `inventory` you created in Step 1.

```
# ansible-playbook -i inventory new-cluster.yml
```

### 25.11. CONFIGURING AN APACHE HTTP SERVER IN A HIGH AVAILABILITY CLUSTER WITH THE `ha_cluster` SYSTEM ROLE

This procedure configures an active/passive Apache HTTP server in a two-node Red Hat Enterprise Linux High Availability Add-On cluster using the `ha_cluster` System Role.

**Prerequisites**

- You have **ansible-core** installed on the node from which you want to run the playbook.

  **NOTE**
  
  You do not need to have **ansible-core** installed on the cluster member nodes.

- You have the **rhel-system-roles** package installed on the system from which you want to run the playbook.

- The systems that you will use as your cluster members have active subscription coverage for RHEL and the RHEL High Availability Add-On.

- Your system includes a public virtual IP address, required for Apache.

- Your system includes shared storage for the nodes in the cluster, using iSCSI, Fibre Channel, or other shared network block device.
- You have configured an LVM logical volume with an XFS file system, as described in Configuring an LVM volume with an XFS file system in a Pacemaker cluster.

- You have configured an Apache HTTP server, as described in Configuring an Apache HTTP Server.

- Your system includes an APC power switch that will be used to fence the cluster nodes.

## WARNING

The **ha_cluster** System Role replaces any existing cluster configuration on the specified nodes. Any settings not specified in the role will be lost.

### Procedure

1. Create an inventory file specifying the nodes in the cluster, as described in Specifying an inventory for the ha_cluster System Role.

2. Create a playbook file, for example `http-cluster.yml`.

### NOTE

When creating your playbook file for production, vault encrypt the password, as described in Encrypting content with Ansible Vault.

The following example playbook file configures a previously-created Apache HTTP server in an active/passive two-node HA cluster running the `firewalld` and `selinux` services.

This example uses an APC power switch with a host name of `zapc.example.com`. If the cluster does not use any other fence agents, you can optionally list only the fence agents your cluster requires when defining the `ha_cluster_fence_agent_packages` variable, as in this example.

```yaml
- hosts: z1.example.com z2.example.com
  roles:
    - rhel-system-roles.ha_cluster
  vars:
    ha_cluster_hacluster_password: password
    ha_cluster_cluster_name: my_cluster
    ha_cluster_manage_firewall: true
    ha_cluster_manage_selinux: true
    ha_cluster_fence_agent_packages:
    - fence-agents-apc-snmp
    ha_cluster_resource_primitives:
    - id: myapc
      agent: stonith:fence_apc_snmp
      instance_attrs:
      - attrs:
        - name: ipaddr
          value: zapc.example.com
        - name: pcmk_host_map
```

Red Hat Enterprise Linux 9 Automating system administration by using RHEL System Roles
value: z1.example.com:1;z2.example.com:2
- name: login
  value: apc
- name: passwd
  value: apc
- id: my_lvm
  agent: ocf:heartbeat:LVM-activate
  instance_attrs:
    - attrs:
        - name: vgname
          value: my_vg
        - name: vg_access_mode
          value: system_id
  - id: my_fs
    agent: Filesystem
    instance_attrs:
      - attrs:
          - name: device
            value: /dev/my_vg/my_lv
          - name: directory
            value: /var/www
          - name: fstype
            value: xfs
  - id: VirtualIP
    agent: IPaddr2
    instance_attrs:
      - attrs:
          - name: ip
            value: 198.51.100.3
          - name: cidr_netmask
            value: 24
      - id: Website
    agent: apache
    instance_attrs:
      - attrs:
          - name: configfile
            value: /etc/httpd/conf/httpd.conf
          - name: statusurl
            value: http://127.0.0.1/server-status

ha_cluster_resource_groups:
  - id: apachegroup
    resource_ids:
      - my_lvm
      - my_fs
      - VirtualIP
      - Website

3. Save the file.

4. Run the playbook, specifying the path to the inventory file inventory you created in Step 1.

   # ansible-playbook -i inventory http-cluster.yml

5. When you use the apache resource agent to manage Apache, it does not use systemd. Because of this, you must edit the logrotate script supplied with Apache so that it does not use systemctl to reload Apache.
Remove the following line in the `/etc/logrotate.d/httpd` file on each node in the cluster.

```
/bin/systemctl reload httpd.service > /dev/null 2>/dev/null || true
```

Replace the line you removed with the following three lines, specifying `/var/run/httpd-website.pid` as the PID file path where `website` is the name of the Apache resource. In this example, the Apache resource name is `Website`.

```
/usr/bin/test -f /var/run/httpd-Website.pid >/dev/null 2>/dev/null &&
/usr/bin/ps -q $(/usr/bin/cat /var/run/httpd-Website.pid) >/dev/null 2>/dev/null &&
/usr/sbin/httpd -f /etc/httpd/conf/httpd.conf -c "PidFile /var/run/httpd-Website.pid" -k graceful >
/dev/null 2>/dev/null || true
```

**Verification steps**

1. From one of the nodes in the cluster, check the status of the cluster. Note that all four resources are running on the same node, `z1.example.com`.
   If you find that the resources you configured are not running, you can run the `pcs resource debug-start resource` command to test the resource configuration.

```
[root@z1 ~]# pcs status
Cluster name: my_cluster
Last updated: Wed Jul 31 16:38:51 2013
Last change: Wed Jul 31 16:42:14 2013 via crm_attribute on z1.example.com
Stack: corosync
Current DC: z2.example.com (2) - partition with quorum
Version: 1.1.10-5.el7-9abei687
2 Nodes configured
6 Resources configured
Online: [ z1.example.com z2.example.com ]

Full list of resources:
myapc (stonith:fence_apc_snmp): Started z1.example.com
Resource Group: apachegroup
  my_lvm (ocf::heartbeat:LVM-activate): Started z1.example.com
  my_fs (ocf::heartbeat:Filesystem): Started z1.example.com
VirtualIP (ocf::heartbeat:IPaddr2): Started z1.example.com
Website (ocf::heartbeat:apache): Started z1.example.com

2. Once the cluster is up and running, you can point a browser to the IP address you defined as the `IPaddr2` resource to view the sample display, consisting of the simple word "Hello".

```
Hello
```

3. To test whether the resource group running on `z1.example.com` fails over to node `z2.example.com`, put node `z1.example.com` in `standby` mode, after which the node will no longer be able to host resources.

```
[root@z1 ~]# pcs node standby z1.example.com
```

4. After putting node `z1` in `standby` mode, check the cluster status from one of the nodes in the cluster. Note that the resources should now all be running on `z2`.

```
```
[root@z1 ~]# pcs status
Cluster name: my_cluster
Last updated: Wed Jul 31 17:16:17 2013
Last change: Wed Jul 31 17:18:34 2013 via crm_attribute on z1.example.com
Stack: corosync
Current DC: z2.example.com (2) - partition with quorum
Version: 1.1.10-5.el7-9abe687
2 Nodes configured
6 Resources configured

Node z1.example.com (1): standby
Online: [ z2.example.com ]

Full list of resources:

  myapc (stonith:fence_apc_snmp):       Started z1.example.com
Resource Group: apachegroup
  my_lvm   (ocf::heartbeat:LVM-activate):   Started z2.example.com
  my_fs    (ocf::heartbeat:Filesystem):    Started z2.example.com
  VirtualIP (ocf::heartbeat:IPaddr2):       Started z2.example.com
  Website  (ocf::heartbeat:apache):        Started z2.example.com

The web site at the defined IP address should still display, without interruption.

5. To remove z1 from standby mode, enter the following command.

   [root@z1 ~]# pcs node unstandby z1.example.com

NOTE

Removing a node from standby mode does not in itself cause the resources to
fail back over to that node. This will depend on the resource-stickiness value for
the resources. For information about the resource-stickiness meta attribute,
see Configuring a resource to prefer its current node.

25.12. ADDITIONAL RESOURCES

- Preparing a control node and managed nodes to use RHEL System Roles.

- Documentation installed with the rhel-system-roles package in /usr/share/ansible/roles/rhel-system-roles.logging/README.html

- RHEL System Roles KB article

- The ansible-playbook(1) man page.
CHAPTER 26. INSTALLING AND CONFIGURING WEB CONSOLE WITH THE COCKPIT RHEL SYSTEM ROLE

With the **cockpit** RHEL System Role, you can install and configure the web console in your system.

### 26.1. THE COCKPIT SYSTEM ROLE

You can use the **cockpit** System Role to automatically deploy and enable the web console and thus be able to manage your RHEL systems from a web browser.

### 26.2. VARIABLES FOR THE COCKPIT RHEL SYSTEM ROLE

The parameters used for the **cockpit** RHEL System Roles are:

<table>
<thead>
<tr>
<th>Role Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cockpit_packages</code>: (default: default)</td>
<td>Sets one of the predefined package sets: default, minimal, or full.</td>
</tr>
<tr>
<td></td>
<td>* <code>cockpit_packages</code>: (default: default) - most common pages and on-demand install UI</td>
</tr>
<tr>
<td></td>
<td>* <code>cockpit_packages</code>: (default: minimal) - just the Overview, Terminal, Logs, Accounts, and Metrics pages; minimal dependencies</td>
</tr>
<tr>
<td></td>
<td>* <code>cockpit_packages</code>: (default: full) - all available pages</td>
</tr>
<tr>
<td></td>
<td>Optionally, specify your own selection of cockpit packages you want to install.</td>
</tr>
<tr>
<td><code>cockpit_enabled</code>: (default:true)</td>
<td>Configures if the web console web server is enabled to start automatically at boot</td>
</tr>
<tr>
<td><code>cockpit_started</code>: (default:true)</td>
<td>Configures if the web console should be started</td>
</tr>
<tr>
<td><code>cockpit_config</code>: (default: nothing)</td>
<td>You can apply settings in the <code>/etc/cockpit/cockpit.conf</code> file. NOTE: The previous settings file will be lost.</td>
</tr>
<tr>
<td><code>cockpit_port</code>: (default: 9090)</td>
<td>The web console runs on port 9090 by default. You can change the port using this option.</td>
</tr>
<tr>
<td><code>cockpit_manage_firewall</code>: (default: false)</td>
<td>Allows the <strong>cockpit</strong> role to control the <strong>firewall</strong> role to add ports. It cannot be used for removing ports. If you want to remove ports, you will need to use the firewall system role directly.</td>
</tr>
</tbody>
</table>
### Role Variable Description

<table>
<thead>
<tr>
<th>Role Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cockpit_manage_selinux: (default: false)</td>
<td>Allows the cockpit role to configure SELinux using the selinux role. The default SELinux policy does not allow Cockpit to listen on anything other than port 9090. If you change the port, set this option to true so that the selinux role can set the correct port permissions (websm_port_t).</td>
</tr>
<tr>
<td>cockpit_certificates: (default: nothing)</td>
<td>Allows the cockpit role to generate new certificates using the certificate role. The value of cockpit_certificates is passed on to the certificate_requests variable of the certificate role. This role is called internally by the cockpit role and it generates the private key and certificate.</td>
</tr>
</tbody>
</table>
On the control node:

- The **ansible-core** and **rhel-system-roles** packages are installed.
- An inventory file exists that lists the managed nodes.

**Procedure**

1. Create a new **playbook.yml** file with the following content:

```yaml
---
- hosts: all
  tasks:
    - name: Install RHEL web console
      include_role:
        name: rhel-system-roles.cockpit
      vars:
        cockpit_packages: default
        #cockpit_packages: minimal
        #cockpit_packages: full
        cockpit_port:9050
        cockpit_manage_selinux: true
        cockpit_manage_firewall: true
        cockpit_certificates:
          - name: /etc/cockpit/ws-certs.d/01-certificate
            dns: ['localhost', 'www.example.com']
            ca: ipa
            group: cockpit-ws
```

2. Optional: Verify the playbook syntax:

   ```bash
   # ansible-playbook --syntax-check -i inventory_file playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i inventory_file /path/to/file/playbook.yml
   ```

**Additional resources**

- [Installing and enabling the web console](#).
- [Requesting certificates using RHEL System Roles](#).
CHAPTER 27. MANAGING CONTAINERS BY USING THE PODMAN RHEL SYSTEM ROLE

With the `podman` RHEL System Role, you can manage Podman configuration, containers, and `systemd` services that run Podman containers.

27.1. THE PODMAN RHEL SYSTEM ROLE

You can use the `podman` RHEL System Role to manage Podman configuration, containers, and `systemd` services which run Podman containers.

Additional resources

- For details about the parameters used in `podman` and additional information about the `podman` RHEL System Role, see the `/usr/share/ansible/roles/rhel-system-roles.podman/README.md` file.

27.2. VARIABLES FOR THE PODMAN RHEL SYSTEM ROLE

The parameters used for the `podman` RHEL System Role are the following:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>podman_kube_specs</code></td>
<td>Describes a Podman pod and the corresponding <code>systemd</code> unit.</td>
</tr>
<tr>
<td></td>
<td>* state: (default: created) - denotes an operation to be executed with <code>systemd</code> services and pods:</td>
</tr>
<tr>
<td></td>
<td>* created: create the pods and <code>systemd</code> service, but do not run them</td>
</tr>
<tr>
<td></td>
<td>* started: create the pods and <code>systemd</code> services, and start them</td>
</tr>
<tr>
<td></td>
<td>* absent: remove the pods and <code>systemd</code> services</td>
</tr>
<tr>
<td></td>
<td>* run_as_user: (default: <code>podman_run_as_user</code>) - a per-pod user. If you do not specify a user, it uses <code>root</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td>The user must already exist.</td>
</tr>
<tr>
<td></td>
<td>* run_as_group (default: <code>podman_run_as_group</code>) - a per-pod group. If you do not specify a user, it uses <code>root</code>.</td>
</tr>
</tbody>
</table>
The group must already exist.

- **systemd_unit_scope** (default: `podman_systemd_unit_scope`) - scope to use for the `systemd` unit. If you do not not specify, it uses `system` is for root containers, and `user` for user containers.

- **kube_file_src** - name of a Kubernetes YAML file on the controller node which will be copied to `kube_file` on the managed node. Do not specify the `kube_file_src` variable if you specify the `kube_file_content` variable. The `kube_file_content` takes precedence over `kube_file_src`.

- **kube_file_content** - string in Kubernetes YAML format or a dict in Kubernetes YAML format. It specifies the contents of `kube_file` on the managed node. Do not specify the `kube_file_content` variable if you specify `kube_file_src` variable. The `kube_file_content` takes precedence over `kube_file_src`.

- **kube_file** - a file name on the managed node that contains the Kubernetes specification of the container or pod. You typically do not have to specify the `kube_file` variable unless you need to copy the `kube_file` file to the managed node outside of the role. If you specify either `kube_file_src` or `kube_file_content`, you do not have to specify this. It is highly recommended to omit `kube_file` and instead specify either `kube_file_src` or `kube_file_content` and let the role manage the file path and name.
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>podman_quadlet_specs</td>
<td>List of Quadlet specifications.</td>
</tr>
</tbody>
</table>

Quadlet is defined by a name and type of a unit. Types of a unit can be the following: container, kube, network, volume. You can either pass in name and type explicitly, or the name and type will be derived from the file name given in file, file_src, or template_src.

- The root containers files are in /etc/containers/systemd/$name.$type on the managed node.

- The rootless containers files are in $HOME/.config/containers/systemd/$name.$type on the managed node.

When a Quadlet specification depends on some other file, for example quadlet.kube that depends on the Yaml file or a ConfigMap, then that file must be specified in the podman_quadlet_specs list before the file that uses it. For example, if you have a my-app.kube file:

```
[Kube]
ConfigMap=my-app-config.yml
Yaml=my-app.yml
...
```

Then you must specify my-app-config.yml and my-app.yml before my-app.kube:

---

**WARNING**

Quadlets work only with rootful containers on RHEL 8. Quadlets work with rootless containers only on RHEL 9.
### podman_quadlet_specs

- file_src: my-app-config.yml
- file_src: my-app.yml
- file_src: my-app.kube

Most of the parameters for each Quadlet specification are the same as for `podman_kube_spec` above, except that the `kube` parameters are not supported. The following parameters are supported:

- **name** - name of the unit. If you do not specify a name, it is derived from `file`, `file_src`, or `template_src`.
  - For example, if you specify `file_src: /path/to/my-container.container` then the `name` is `my-container`.

- **type** - type of a unit can be the following: `container`, `kube`, `network`, `volume`. If you do not specify a name, it is derived from `file`, `file_src`, or `template_src`.
  - For example, if you specify `file_src: /path/to/my-container.container` then the `type` is `container`.

**NOTE**

If this file is in the Quadlet unit format and has a valid Quadlet unit suffix, it is used as a Quadlet unit, otherwise, it is just copied.

- **file_src** - name of the file on the control node to copy to the managed node to use as the source of the Quadlet unit.

**NOTE**

If this file is in the Quadlet unit format and has a valid Quadlet unit suffix, it is used as a Quadlet unit, otherwise, it is just copied.

- **file** - name of the file on the managed node to use as the source of the Quadlet unit.

**NOTE**

If this file is in the Quadlet unit format and has a valid Quadlet unit suffix, it is used as a Quadlet unit, otherwise, it is just copied.
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_content</td>
<td>- the contents of a file to copy to the managed node, in string format. This is useful to pass in short files that can easily be specified inline. You must specify name and type.</td>
</tr>
<tr>
<td>template_src</td>
<td>- the name of the file on the control node which will be processed as a Jinja template file, then copied to the managed node to use as the source of the Quadlet unit.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td>If this file is in the Quadlet unit format and has a valid Quadlet unit suffix, it is used as a Quadlet unit, otherwise, it is just copied. If the file has a <code>.j2</code> suffix, that suffix will be removed to determine the quadlet file type.</td>
</tr>
<tr>
<td></td>
<td>* For example, if you specify:</td>
</tr>
<tr>
<td></td>
<td>```yaml</td>
</tr>
<tr>
<td></td>
<td>podman_quadlet_specs:</td>
</tr>
<tr>
<td></td>
<td>- template_src: my-app.container.j2</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>Then the local file <code>templates/my-app.container.j2</code> will be processed as a Jinja template file, then copied to <code>/etc/containers/systemd/my-app.container</code> as a Quadlet container unit specification on the managed node.</td>
</tr>
<tr>
<td>podman_secrets</td>
<td>List of secret specs in the same format as used by <code>podman_secret</code>, except that there is an additional field <code>run_as_user</code> used to create the secret in the account of a specified user. If this is not specified, then the secret will be created in the account specified by <code>podman_run_as_user</code>, and the default value of that is &quot;root&quot; Use Ansible Vault to encrypt the value of the <code>data</code> field.</td>
</tr>
</tbody>
</table>
### podman_create_host_directories

If true, the role ensures host directories specified in host mounts in `volumes.hostPath` specifications in the Kubernetes YAML given in `podman_kube_specs`. The default value is false.

**NOTE**

To ensure that the role manages the directories, you must specify directories as absolute paths for root containers, or paths relative to the home directory, for non-root containers.

The role applies its default ownership or permissions to the directories. If you need to set ownership or permissions, see `podman_host_directories`.

### podman_host_directories

It is a dict. If using `podman_create_host_directories` to tell the role to create host directories for volume mounts, and you need to specify permissions or ownership that apply to these created host directories, use `podman_host_directories`. Each key is the absolute path of the host directory to manage. The value is in the format of the parameters to the file module. If you do not specify a value, the role will use its built-in default values. If you want to specify a value to be used for all host directories, use the special key `DEFAULT`.

### podman_firewall

It is a list of dict. Specifies ports that you want the role to manage in the firewall. This uses the same format as used by the firewall RHEL System Role.

### podman_selinux_ports

It is a list of dict. Specifies ports that you want the role to manage the SELinux policy for ports used by the role. This uses the same format as used by the selinux RHEL System Role.
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>podman_run_as_user</td>
<td>Specifies the name of the user to use for all rootless containers. You can also specify per-container/unit/secret username with run_as_user in podman_kube_specs, podman_quadlet_specs, or podman_secrets.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td>The user must already exist.</td>

</tr>
</tbody>
</table>
### Additional resources

- For details about the parameters used in `podman` and additional information about the `podman` RHEL System Role, see the `/usr/share/ansible/roles/rhel-system-roles.podman/README.md` file.

---

### 27.3. ADDITIONAL RESOURCES

- For details about the parameters used in `podman` and additional information about the `podman` RHEL System Role, see the `/usr/share/ansible/roles/rhel-system-roles.podman/README.md` file.

- For details about the `ansible-playbook` command, see the `ansible-playbook(1)` man page.
With the `ad_integration` System Role, you can automate a direct integration of a RHEL system with Active Directory (AD) using Red Hat Ansible Automation Platform.

### 28.1. THE `ad_integration` SYSTEM ROLE

Using the `ad_integration` System Role, you can directly connect a RHEL system to Active Directory (AD).

The role uses the following components:

- **SSSD** to interact with the central identity and authentication source
- **`realm`** to detect available AD domains and configure the underlying RHEL system services, in this case SSSD, to connect to the selected AD domain

**NOTE**

The `ad_integration` role is for deployments using direct AD integration without an Identity Management (IdM) environment. For IdM environments, use the `ansible-freeipa` roles.

Additional resources

- Connecting RHEL systems directly to AD using SSSD.

### 28.2. VARIABLES FOR THE `ad_integration` RHEL SYSTEM ROLE

The `ad_integration` RHEL System Role uses the following parameters:

<table>
<thead>
<tr>
<th>Role Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ad_integration_realm</code></td>
<td>Active Directory realm, or domain name to join.</td>
</tr>
<tr>
<td><code>ad_integration_password</code></td>
<td>The password of the user used to authenticate with when joining the machine to the realm. Do not use plain text. Instead, use Ansible Vault to encrypt the value.</td>
</tr>
</tbody>
</table>
| `ad_integration_manage_crypto_policies` | If `true`, the `ad_integration` role will use `fedora.linux_system_roles.crypto_policies` as needed.  
Default: `false` |
<table>
<thead>
<tr>
<th>Role Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ad_integration_allow_rc4_crypto</td>
<td>If <code>true</code>, the <code>ad_integration</code> role will set the crypto policy to allow RC4 encryption. Providing this variable automatically sets <code>ad_integration_manage_crypto_policies</code> to <code>true</code>. Default: <code>false</code></td>
</tr>
<tr>
<td>ad_integration_timesync_source</td>
<td>Hostname or IP address of time source to synchronize the system clock with. Providing this variable automatically sets <code>ad_integration_manage_timesync</code> to <code>true</code>.</td>
</tr>
</tbody>
</table>

28.3. ADDITIONAL RESOURCES

- The `/usr/share/ansible/roles/rhel-system-roles.ad_integration/README.md` file.
- `man ansible-playbook(1)`
CHAPTER 29. INSTALLING AND CONFIGURING POSTGRESQL BY USING THE POSTGRESQL RHEL SYSTEM ROLE

As a system administrator, you can use the `postgresql` RHEL System Role to install, configure, manage, start, and improve performance of the PostgreSQL server.

29.1. INTRODUCTION TO THE POSTGRESQL RHEL SYSTEM ROLE

To install, configure, manage, and start the PostgreSQL server using Ansible, you can use the `postgresql` RHEL System Role.

You can also use the `postgresql` role to optimize the database server settings and improve performance.

The role supports the currently released and supported versions of PostgreSQL on RHEL 8 and RHEL 9 managed nodes.

Additional resources

- [Introduction to RHEL System Roles](#)
- Documentation installed with the `rhel-system-roles` package: the README.md or README.html files in the `/usr/share/doc/rhel-system-roles/postgresql/` directory
- [Using PostgreSQL](#)

29.2. CONFIGURING THE POSTGRESQL SERVER BY USING RHEL SYSTEM ROLES

You can use the `postgresql` RHEL System Role to install, configure, manage, and start the PostgreSQL server.

WARNING

The `postgresql` role replaces PostgreSQL configuration files in the `/var/lib/pgsql/data/` directory on the managed hosts. Previous settings are changed to those specified in the role variables, and lost if they are not specified in the role variables.

Prerequisites

- You have prepared the control node and the managed nodes.
- You are logged in to the control node as a user who can run playbooks on the managed nodes.
- The managed nodes or groups of managed nodes on which you want to run this playbook are listed in the Ansible inventory file.
Procedure

1. Create a new `postgresql-playbook.yml` file with the following content:

   ```yaml
   - name: Manage postgres
     hosts: all
     vars:
       postgresql_version: "13"
     roles:
       - rhel-system-roles.postgresql
   ```

2. Optional: Verify playbook syntax.

   ```
   # ansible-playbook --syntax-check postgresql-playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```
   # ansible-playbook -i inventory_file /path/to/file/postgresql-playbook.yml
   ```

Additional resources

- Preparing a control node and managed nodes to use RHEL System Roles
- Documentation installed with the `rhel-system-roles` package: the `README.md` or `README.html` files in the `/usr/share/doc/rhel-system-roles/postgresql/` directory
- `ansible-playbook(1)` man page

29.3. THE POSTGRESQL ROLE VARIABLES

You can use the following variables of the `postgresql` RHEL System Role to customize the PostgreSQL server behavior.

**postgresql_version**

You can set the version of the PostgreSQL server to any released and supported version of PostgreSQL on RHEL 8 and RHEL 9 managed nodes. For example:

```
postgresql_version: "13"
```

**postgresql_password**

Optionally, you can set a password for the `postgres` database superuser. By default, no password is set, and a database is accessible from the `postgres` system account through a UNIX socket. It is recommended to encrypt the password by using Ansible Vault. For example:

```
postgresql_password: !vault |
   $ANSIBLE_VAULT;1.2;AES256;dev
   ....
```

**postgresql_pg_hba_conf**

The content of the `postgresql_pg_hba_conf` variable replaces the default upstream configuration in the `/var/lib/pgsql/data/pg_hba.conf` file. For example:
**postgresql_pg_hba_conf**

- type: local
database: all
user: all
auth_method: peer
- type: host
database: all
user: all
address: '127.0.0.1/32'
auth_method: ident
- type: host
database: all
user: all
address: '::1/128'
auth_method: ident

**postgresql_server_conf**

The content of the `postgresql_server_conf` variable is added to the end of the `/var/lib/pgsql/data/postgresql.conf` file. As a result, the default settings are overwritten. For example:

```
postgresql_server_conf:
ssl: on
shared_buffers: 128MB
huge_pages: try
```

**postgresql_ssl_enable**

To set up an SSL/TLS connection, set the `postgresql_ssl_enable` variable to `true`:

```
pagisql_ssl_enable: true
```

and use one of the following approaches to provide a server certificate and a private key:

- Use the `postgresql_cert_name` variable if you want to use an existing certificate and private key.
- Use the `postgresql_certificates` variable to generate a new certificate.

**postgresql_cert_name**

If you want to use your own certificate and private key, use the `postgresql_cert_name` variable to specify the certificate name. You must keep both certificate and key files in the same directory and under the same name with the `.crt` and `.key` suffixes.
For example, if your certificate file is located in `/etc/certs/server.crt` and your private key in `/etc/certs/server.key`, set the `postgresql_cert_name` value to:

```
pagisql_cert_name: /etc/certs/server
```

**postgresql_certificates**

The `postgresql_certificates` variable requires a list of dict in the same format as used by the `redhat.rhel_system_roles.certificate` role. Specify the `postgresql_certificates` variable if you want the certificate role to generate certificates for the PostgreSQL server configured by the
PostgreSQL role. In the following example, a self-signed certificate `postgresql_cert.crt` is generated in the `/etc/pki/tls/certs/` directory. By default, no certificates are automatically generated ( []).

```yaml
postgresql_certificates:
  - name: postgresql_cert
dns: ['localhost', 'www.example.com']
  ca: self-sign
```

**postgresql_input_file**

To run an SQL script, define a path to your SQL file by using the `postgresql_input_file` variable:

```yaml
postgresql_input_file: "/tmp/mypath/file.sql"
```

**postgresql_server_tuning**

By default, the PostgreSQL system role enables server settings optimization based on system resources. To disable the tuning, set the `postgresql_server_tuning` variable to `false`:

```yaml
postgresql_server_tuning: false
```

Additional resources

- Documentation installed with the `rhel-system-roles` package: the `README.md` or `README.html` files in the `/usr/share/doc/rhel-system-roles/postgresql/` directory
