Red Hat Enterprise Linux 9

Configuring and managing networking

A guide to configuring and managing networking in Red Hat Enterprise Linux 9

Last Updated: 2022-05-19
A guide to configuring and managing networking in Red Hat Enterprise Linux 9
Abstract

This document describes how to manage networking on Red Hat Enterprise Linux 9.
# Table of Contents

**MAKING OPEN SOURCE MORE INCLUSIVE** ................................................................. 9

**PROVIDING FEEDBACK ON RED HAT DOCUMENTATION** ................................. 10

**CHAPTER 1. CONSISTENT NETWORK INTERFACE DEVICE NAMING** .................. 11
  1.1. NETWORK INTERFACE DEVICE NAMING HIERARCHY .................................. 11
  1.2. HOW THE NETWORK DEVICE RENAMING WORKS ...................................... 12
  1.3. PREDICTABLE NETWORK INTERFACE DEVICE NAMES ON THE X86_64 PLATFORM EXPLAINED ............................................................. 13
  1.4. PREDICTABLE NETWORK INTERFACE DEVICE NAMES ON THE SYSTEM Z PLATFORM EXPLAINED ............................................................. 13
  1.5. DISABLING CONSISTENT INTERFACE DEVICE NAMING DURING THE INSTALLATION .......................................................... 14
  1.6. DISABLING CONSISTENT INTERFACE DEVICE NAMING ON AN INSTALLED SYSTEM .......................................................... 14
  1.7. CUSTOMIZING THE PREFIX OF ETHERNET INTERFACES .................................. 17
  1.8. ASSIGNING USER-DEFINED NETWORK INTERFACE NAMES USING UDEV RULES .......................................................... 18
  1.9. ASSIGNING USER-DEFINED NETWORK INTERFACE NAMES USING SYSTEMD LINK FILES .......................................................... 19
  1.10. ADDITIONAL RESOURCES .............................................................................. 20

**CHAPTER 2. GETTING STARTED WITH NETWORKMANAGER** ............................ 21
  2.1. BENEFITS OF USING NETWORKMANAGER .................................................. 21
  2.2. AN OVERVIEW OF UTILITIES AND APPLICATIONS YOU CAN USE TO MANAGE NETWORKMANAGER CONNECTIONS .......................................................... 21

**CHAPTER 3. CONFIGURING NETWORKMANAGER TO IGNORE CERTAIN DEVICES** .......................................................... 23
  3.1. PERMANENTLY CONFIGURING A DEVICE AS UNMANAGED IN NETWORKMANAGER .......................................................... 23
  3.2. TEMPORARILY CONFIGURING A DEVICE AS UNMANAGED IN NETWORKMANAGER .................................................................................. 24

**CHAPTER 4. USING NMTUI TO MANAGE NETWORK CONNECTIONS USING A TEXT-BASED INTERFACE** .......................................................... 25
  4.1. STARTING THE NMTUI UTILITY ...................................................................... 25
  4.2. ADDING A CONNECTION PROFILE USING NMTUI ......................................... 25
  4.3. APPLYING CHANGES TO A MODIFIED CONNECTION USING NMTUI .................................................................................. 28

**CHAPTER 5. GETTING STARTED WITH NMCLI** ................................................... 30
  5.1. THE DIFFERENT OUTPUT FORMATS OF NMCLI ............................................. 30
  5.2. USING TAB COMPLETION IN NMCLI ............................................................. 30
  5.3. FREQUENT NMCLI COMMANDS ..................................................................... 31

**CHAPTER 6. CONFIGURING AN ETHERNET CONNECTION** ............................. 32
  6.1. CONFIGURING A STATIC ETHERNET CONNECTION USING NMCLI .............. 32
  6.2. CONFIGURING A STATIC ETHERNET CONNECTION USING THE NMCLI INTERACTIVE EDITOR .................................................................................. 34
  6.3. CONFIGURING A STATIC ETHERNET CONNECTION USING NMSTATECTL .................................................................................. 37
  6.4. CONFIGURING A STATIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH THE INTERFACE NAME .................................................................................. 39
  6.5. CONFIGURING A STATIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH A DEVICE PATH .................................................................................. 41
  6.6. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING NMCLI .................................................................................. 43
  6.7. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING THE NMCLI INTERACTIVE EDITOR .................................................................................. 44
  6.8. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING NMSTATECTL .................................................................................. 47
  6.9. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH THE INTERFACE NAME .................................................................................. 48
  6.10. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH A DEVICE PATH .................................................................................. 49
  6.11. CONFIGURING AN ETHERNET CONNECTION USING CONTROL-CENTER .................................................................................. 51
  6.12. CONFIGURING AN ETHERNET CONNECTION USING NM-CONNECTION-EDITOR .................................................................................. 54
  6.13. CHANGING THE DHCP CLIENT OF NETWORKMANAGER .................................................................................. 57
  6.14. CONFIGURING THE DHCP BEHAVIOR OF A NETWORKMANAGER CONNECTION .................................................................................. 57

29.1. OVERVIEW OF QUEUING DISCIPLINES ........................................... 232
29.2. AVAILABLE QDISCS IN RHEL ..................................................... 232
29.3. INSPECTING QDISCS OF A NETWORK INTERFACE USING THE TC UTILITY 234
29.4. UPDATING THE DEFAULT QDISC ................................................ 235
29.5. TEMPORARILY SETTING THE CURRENT QDISK OF A NETWORK INTERFACE USING THE TC UTILITY 236
29.6. PERMANENTLY SETTING THE CURRENT QDISK OF A NETWORK INTERFACE USING NETWORKMANAGER ........................................... 236

CHAPTER 30. GETTING STARTED WITH MULTIPATH TCP ........................................... 238
30.1. MPTCP BENEFITS ........................................................................... 238
30.2. PREPARING RHEL TO ENABLE MPTCP SUPPORT .......................... 238
30.3. USING IPROUTE2 TO CONFIGURE AND ENABLE MULTIPLE PATHS FOR MPTCP APPLICATIONS ................................................ 239
30.4. MONITORING MPTCP SUB-FLOWS .............................................. 241
30.5. DISABLING MULTIPATH TCP IN THE KERNEL ................................. 244

CHAPTER 31. MANAGING THE MPTCPD SERVICE ........................................... 245
31.1. CONFIGURING MPTCPD ................................................................. 245
31.2. MANAGING APPLICATIONS WITH MPTCPIZE TOOL .................. 245
31.3. ENABLING MPTCP SOCKETS FOR A SERVICES USING THE MPTCPIZE UTILITY ................................................ 246

CHAPTER 32. CONFIGURING THE ORDER OF DNS SERVERS ........................... 247
32.1. HOW NETWORKMANAGER ORDERS DNS SERVERS IN /ETC/RESOLV.CONF ... 247
Default values of DNS priority parameters ............................................. 247
Valid DNS priority values: ................................................................. 247
32.2. SETTING A NETWORKMANAGER-WIDE DEFAULT DNS SERVER PRIORITY VALUE ........................................................................... 248
32.3. SETTING THE DNS PRIORITY OF A NETWORKMANAGER CONNECTION ......................................................................................... 249

CHAPTER 33. USING NETWORKMANAGER TO DISABLE IPV6 FOR A SPECIFIC CONNECTION ........................................... 250
33.1. DISABLING IPV6 ON A CONNECTION USING NMCLI ................. 250

CHAPTER 34. MONITORING AND TUNING THE RX RING BUFFER ................... 252
34.1. DISPLAYING THE NUMBER OF DROPPED PACKETS ....................... 252
34.2. INCREASING THE RX RING BUFFER TO REDUCE A HIGH PACKET DROP RATE ......................................................................................... 252

CHAPTER 35. CONFIGURING 802.3 LINK SETTINGS ........................................... 254
35.1. UNDERSTANDING AUTO-NEGOTIATION ....................................... 254
35.2. CONFIGURING 802.3 LINK SETTINGS USING THE NMCLI UTILITY ......................................................................................... 254

CHAPTER 36. CONFIGURING ETHTOOL OFFLOAD FEATURES .......................... 256
36.1. OFFLOAD FEATURES SUPPORTED BY NETWORKMANAGER .......... 256
36.2. CONFIGURING AN ETHTOOL OFFLOAD FEATURE USING NETWORKMANAGER ................................................ 258
36.3. USING RHEL SYSTEM ROLES TO SET ETHTOOL FEATURES ........ 258

CHAPTER 37. CONFIGURING ETHTOOL COALESCE SETTINGS ....................... 261
37.1. COALESCE SETTINGS SUPPORTED BY NETWORKMANAGER .......... 261
37.2. CONFIGURING ETHTOOL COALESCE SETTINGS USING NETWORKMANAGER ................................................ 262
37.3. USING RHEL SYSTEM ROLES TO CONFIGURE ETHTOOL COALESCE SETTINGS ................................................ 262

CHAPTER 38. USING MACSEC TO ENCRYPT LAYER-2 TRAFFIC IN THE SAME PHYSICAL NETWORK ........................ 265
38.1. CONFIGURING A MACSEC CONNECTION USING NMCLI ............. 265
38.2. ADDITIONAL RESOURCES .............................................................. 267

CHAPTER 39. USING DIFFERENT DNS SERVERS FOR DIFFERENT DOMAINS ........................ 268
39.1. SENDING DNS REQUESTS FOR A SPECIFIC DOMAIN TO A SELECTED DNS SERVER ................................................ 268

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Please let us know how we could make it better.

- For simple comments on specific passages:
  1. Make sure you are viewing the documentation in the Multi-page HTML format. In addition, ensure you see the Feedback button in the upper right corner of the document.
  2. Use your mouse cursor to highlight the part of text that you want to comment on.
  3. Click the Add Feedback pop-up that appears below the highlighted text.
  4. Follow the displayed instructions.

- For submitting feedback via Bugzilla, create a new ticket:
  1. Go to the Bugzilla website.
  2. As the Component, use Documentation.
  3. Fill in the Description field with your suggestion for improvement. Include a link to the relevant part(s) of documentation.
  4. Click Submit Bug.
CHAPTER 1. CONSISTENT NETWORK INTERFACE DEVICE NAMING

Red Hat Enterprise Linux provides methods for consistent and predictable device naming for network interfaces. These features help locating and differentiating network interfaces.

The kernel assigns names to network interfaces by concatenating a fixed prefix and a number that increases as the kernel initializes the network devices. For instance, `eth0` would represent the first device being probed on start-up. However, these names do not necessarily correspond to labels on the chassis. Modern server platforms with multiple network adapters can encounter non-deterministic and counter-intuitive naming of these interfaces. This affects both network adapters embedded on the system board and add-in adapters.

In Red Hat Enterprise Linux, the `udev` device manager supports a number of different naming schemes. By default, `udev` assigns fixed names based on firmware, topology, and location information. This has the following advantages:

- Device names are fully predictable.
- Device names stay fixed even if you add or remove hardware, because no re-enumeration takes place.
- Defective hardware can be seamlessly replaced.

1.1. NETWORK INTERFACE DEVICE NAMING HIERARCHY

If consistent device naming is enabled, which is the default in Red Hat Enterprise Linux, the `udev` device manager generates device names based on the following schemes:

<table>
<thead>
<tr>
<th>Scheme</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Device names incorporate firmware or BIOS-provided index numbers for onboard devices. If this information is not available or applicable, <code>udev</code> uses scheme 2.</td>
<td>eno1</td>
</tr>
<tr>
<td>2</td>
<td>Device names incorporate firmware or BIOS-provided PCI Express (PCIe) hot plug slot index numbers. If this information is not available or applicable, <code>udev</code> uses scheme 3.</td>
<td>ens1</td>
</tr>
<tr>
<td>3</td>
<td>Device names incorporate the physical location of the connector of the hardware. If this information is not available or applicable, <code>udev</code> uses scheme 5.</td>
<td>enp2s0</td>
</tr>
<tr>
<td>4</td>
<td>Device names incorporate the MAC address. Red Hat Enterprise Linux does not use this scheme by default, but administrators can optionally use it.</td>
<td>enx525400d5e0fb</td>
</tr>
<tr>
<td>5</td>
<td>The traditional unpredictable kernel naming scheme. If <code>udev</code> cannot apply any of the other schemes, the device manager uses this scheme.</td>
<td>eth0</td>
</tr>
</tbody>
</table>

By default, Red Hat Enterprise Linux selects the device name based on the `NamePolicy` setting in the `/usr/lib/systemd/network/99-default.link` file. The order of the values in `NamePolicy` is important.
Red Hat Enterprise Linux uses the first device name that is both specified in the file and that `udev` generated.

If you manually configured `udev` rules to change the name of kernel devices, those rules take precedence.

### 1.2. HOW THE NETWORK DEVICE RENAMING WORKS

By default, consistent device naming is enabled in Red Hat Enterprise Linux. The `udev` device manager processes different rules to rename the devices. The following list describes the order in which `udev` processes these rules and what actions these rules are responsible for:

1. The `/usr/lib/udev/rules.d/60-net.rules` file defines that the `/lib/udev/rename_device` helper utility searches for the `HWADDR` parameter in `/etc/sysconfig/network-scripts/ifcfg-*` files. If the value set in the variable matches the MAC address of an interface, the helper utility renames the interface to the name set in the `DEVICE` parameter of the file. This file only exists after installing the `initscripts` package.

2. The `/usr/lib/udev/rules.d/71-biosdevname.rules` file defines that the `biosdevname` utility renames the interface according to its naming policy, provided that it was not renamed in the previous step.

3. The `/usr/lib/udev/rules.d/75-net-description.rules` file defines that `udev` examines the network interface device and sets the properties in `udev`-internal variables that will be processed in the next step. Note that some of these properties might be undefined.

4. The `/usr/lib/udev/rules.d/80-net-setup-link.rules` file calls the `net_setup_link` `udev` built-in which then applies the policy. The following is the default policy that is stored in the `/usr/lib/systemd/network/99-default.link` file:

   ```
   [Link]
   NamePolicy=kernel database onboard slot path
   MACAddressPolicy=persistent
   ```

   With this policy, if the kernel uses a persistent name, `udev` does not rename the interface. If the kernel does not use a persistent name, `udev` renames the interface to the name provided by the hardware database of `udev`. If this database is not available, Red Hat Enterprise Linux falls back to the mechanisms described above.

   Alternatively, set the `NamePolicy` parameter in this file to `mac` for media access control (MAC) address-based interface names.

5. The `/usr/lib/udev/rules.d/80-net-setup-link.rules` file defines that `udev` renames the interface based on the `udev`-internal parameters in the following order:

   a. `ID_NET_NAME_ONBOARD`

   b. `ID_NET_NAME_SLOT`

   c. `ID_NET_NAME_PATH`

   If one parameter is not set, `udev` uses the next one. If none of the parameters are set, the interface is not renamed.

Steps 3 and 4 implement the naming schemes 1 to 4 described in [Network interface device naming hierarchy](#).
1.3. PREDICTABLE NETWORK INTERFACE DEVICE NAMES ON THE X86_64 PLATFORM EXPLAINED

When the consistent network device name feature is enabled, the udev device manager creates the names of devices based on different criteria. This section describes the naming scheme when Red Hat Enterprise Linux is installed on a x86_64 platform.

The interface name starts with a two-character prefix based on the type of interface:

- en for Ethernet
- wl for wireless LAN (WLAN)
- ww for wireless wide area network (WWAN)

Additionally, one of the following is appended to one of the above-mentioned prefix based on the schema the udev device manager applies:

- o<on-board_index_number>
- s<hot_plug_slot_index_number>[f<function>][d<device_id>]
  Note that all multi-function PCI devices have the [f<function>] number in the device name, including the function 0 device.
- x<MAC_address>
- [P<domain_number>]p<bus>s<slot>[f<function>][d<device_id>]
  The [P<domain_number>] part defines the PCI geographical location. This part is only set if the domain number is not 0.
- [P<domain_number>]p<bus>s<slot>[f<function>][u<usb_port>][...][c<config>][i<interface>]
  For USB devices, the full chain of port numbers of hubs is composed. If the name is longer than the maximum (15 characters), the name is not exported. If there are multiple USB devices in the chain, udev suppresses the default values for USB configuration descriptors (c1) and USB interface descriptors (i0).

1.4. PREDICTABLE NETWORK INTERFACE DEVICE NAMES ON THE SYSTEM Z PLATFORM EXPLAINED

When the consistent network device name feature is enabled, the udev device manager on the System z platform creates the names of devices based on the bus ID. The bus ID identifies a device in the s390 channel subsystem.

For a channel command word (CCW) device, the bus ID is the device number with a leading 0.n prefix where n is the subchannel set ID.

Ethernet interfaces are named, for example, enccw0.0.1234. Serial Line Internet Protocol (SLIP) channel-to-channel (CTC) network devices are named, for example, slccw0.0.1234.
Use the `znetconf -c` or the `lscss -a` commands to display available network devices and their bus IDs.

1.5. DISABLING CONSISTENT INTERFACE DEVICE NAMING DURING THE INSTALLATION

This section describes how to disable consistent interface device naming during the installation.

**WARNING**

Red Hat recommends not to disable consistent device naming and does not support this feature on hosts with more than one network interface. Disabling consistent device naming can cause different kind of problems. For example, if you add another network interface card to the system, the assignment of the kernel device names, such as `eth0`, is no longer fixed. Consequently, after a reboot, the Kernel can name the device differently.

**Procedure**

1. Boot the Red Hat Enterprise Linux 9 installation media.

2. In the boot manager, select Install Red Hat Enterprise Linux 9, and press the Tab key to edit the entry.

3. Append the `net.ifnames=0` parameter to the kernel command line:

```
vmlinuz... net.ifnames=0
```

4. Press Enter to start the installation.

**Additional resources**

- Is it safe to set net.ifnames=0 in RHEL 7 and RHEL 8?
- How to perform an in-place upgrade to RHEL 8 when using kernel NIC names on RHEL 7

1.6. DISABLING CONSISTENT INTERFACE DEVICE NAMING ON AN INSTALLED SYSTEM

This section describes how to disable consistent interface device naming on a RHEL system that is already installed.
WARNING

Red Hat recommends not to disable consistent device naming and does not support this feature on hosts with more than one network interface. Disabling consistent device naming can cause different kinds of problems. For example, if you add another network interface card to the system, the assignment of the kernel device names, such as `eth0`, is no longer fixed. Consequently, after a reboot, the Kernel can name the device differently.

Prerequisites

- The system uses consistent interface device naming, which is the default.

Procedure

1. Edit the `/etc/default/grub` file and append the `net.ifnames=0` parameter to the `GRUB_CMDLINE_LINUX` variable:
   ```
   GRUB_CMDLINE_LINUX="... net.ifnames=0"
   ```

2. Rebuild the `grub.cfg` file:
   - On a system with UEFI boot mode:
     ```
     # grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg
     ```
   - On a system with legacy boot mode:
     ```
     # grub2-mkconfig -o /boot/grub2/grub.cfg
     ```

3. Display the current profile names and the associated device names:
   ```
   # nmcli -f NAME,DEVICE,FILENAME connection show
   NAME    DEVICE     FILENAME
   System enp1s0   enp1s0 /etc/sysconfig/network-scripts/ifcfg-enp1s0
   System enp7s0   enp7s0 /etc/NetworkManager/system-connections/enp7s0.nmconnection
   ```
   Note which profile name and configuration file is associated with each device.

4. Remove `HWADDR` parameters from all connection profiles:
   ```
   # sed -i '/^HWADDR=/d' /etc/sysconfig/network-scripts/ifcfg-enp1s0
   /etc/NetworkManager/system-connections/enp7s0.nmconnection
   ```

5. Display the MAC addresses that are associated with the Ethernet devices:
   ```
   # ip link show
   ...
   2: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
   ```
mode DEFAULT group default qlen 1000
link/ether 00:53:00:c5:98:1c brd ff:ff:ff:ff:ff:ff
3: enp7s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
   mode DEFAULT group default qlen 1000
   link/ether 00:53:00:b6:87:c6 brd ff:ff:ff:ff:ff:ff

6. Reboot the host:

   # reboot

7. After the reboot, display the Ethernet devices and identify the new interface name based on the
   MAC address:

   # ip link show

   ... 2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
   
   mode DEFAULT group default qlen 1000
   
   link/ether 00:53:00:b6:87:c6 brd ff:ff:ff:ff:ff:ff
   
   3: eth1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
   
   mode DEFAULT group default qlen 1000
   
   link/ether 00:53:00:c5:98:1c brd ff:ff:ff:ff:ff:ff

   If you compare the current output with the previous one:

   - Interface enp7s0 (MAC address 00:53:00:b6:87:c6) is now named eth0.
   - Interface enp1s0 (MAC address 00:53:00:c5:98:1c) is now named eth1.

8. Rename the configuration file:

   # mv /etc/NetworkManager/system-connections/enp7s0.nmconnection
   /etc/NetworkManager/system-connections/eth0.nmconnection

   # mv /etc/sysconfig/network-scripts/ifcfg-enp1s0
   /etc/sysconfig/network-scripts/ifcfg-eth1

9. Reload NetworkManager:

   # nmcli connection reload

10. If no profile name is set in the configuration files, NetworkManager uses a default value. To
    determine the current profile name after you renamed and reloaded the connections, enter:

   # nmcli -f NAME,DEVICE,FILENAME connection show

   NAME       FILENAME
   System enp7s0 /etc/NetworkManager/system-connections/eth0.nmconnection
   System enp1s0 /etc/sysconfig/network-scripts/ifcfg-eth1

   You require the profile names in the next step.

11. Rename the NetworkManager connection profiles and update the interface name in each
    profile:

   # nmcli connection modify "System enp7s0" connection.id eth0 connection.interface-name eth0
12. Reactivate the NetworkManager connections:

```bash
# nmcli connection up eth0
# nmcli connection up eth1
```

### 1.7. CUSTOMIZING THE PREFIX OF ETHERNET INTERFACES

You can customize the prefix of Ethernet interface names during the Red Hat Enterprise Linux installation.

**IMPORTANT**

Red Hat does not support customizing the prefix using the `prefixdevname` utility on already deployed systems.

After the RHEL installation, the `udev` service names Ethernet devices `<prefix>.<index>`. For example, if you select the prefix `net`, RHEL names Ethernet interfaces `net0`, `net1`, and so on.

**Prerequisites**

- The prefix you want to set meets the following requirements:
  - It consists of ASCII characters.
  - It is an alpha-numeric string.
  - It is shorter than 16 characters.
  - It does not conflict with any other well-known prefix used for network interface naming, such as `eth`, `eno`, `ens`, and `em`.

**Procedure**

1. Boot the Red Hat Enterprise Linux installation media.
2. In the boot manager:
   a. Select the `Install Red Hat Enterprise Linux <version>` entry, and press `Tab` to edit the entry.
   b. Append `net.ifnames.prefix=<prefix>` to the kernel options.
   c. Press `Enter` to start the installer.
3. Install Red Hat Enterprise Linux.

**Verification**

- After the installation, display the Ethernet interfaces:

  ```bash
  # ip link show
  ```
1.8. ASSIGNING USER-DEFINED NETWORK INTERFACE NAMES USING UDEV RULES

The udev device manager supports a set of rules to customize the interface names.

Procedure

1. Display all network interfaces and their MAC addresses:

```
# ip link list
```

2. Create the file `/etc/udev/rules.d/70-custom-ifnames.rules` with the following contents:

```
SUBSYSTEM=="net",ACTION=="add",ATTR{address}=="b4:96:91:14:ae:58",ATTR{type }=="1",NAME="provider0"
SUBSYSTEM=="net",ACTION=="add",ATTR{address}=="b4:96:91:14:ae:5a",ATTR{type }=="1",NAME="provider1"
SUBSYSTEM=="net",ACTION=="add",ATTR{address}=="00:90:fa:6a:7d:90",ATTR{type }=="1",NAME="dmz"
```

These rules match the MAC address of the network interfaces and rename them to the name given in the NAME property. In these examples, ATTR{type} parameter value 1 defines that the interface is of type Ethernet.

Verification

1. Reboot the system.

```
# reboot
```

2. Verify that interface names for each MAC address match the value you set in the NAME parameter of the rule file:

```
# ip link show
```
CHAPTER 1. CONSISTENT NETWORK INTERFACE DEVICE NAMING

provider0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT group default qlen 1000
    link/ether b4:96:91:14:ae:58 brd ff:ff:ff:ff:ff:ff
    altname enp6s0f0
provider1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT group default qlen 1000
    link/ether b4:96:91:14:ae:5a brd ff:ff:ff:ff:ff:ff
    altname enp6s0f1
dmz: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT group default qlen 1000
    link/ether 00:90:fa:6a:7d:90 brd ff:ff:ff:ff:ff:ff
    altname enp4s0f0

Additional resources

- udev(7) man page
- udevadm(8) man page
- /usr/src/kernels/<kernel_version>/include/uapi/linux/if_arp.h provided by the kernel-doc package

1.9. ASSIGNING USER-DEFINED NETWORK INTERFACE NAMES USING SYSTEMD LINK FILES

Create a naming scheme by renaming network interfaces to provider0.

Procedure

1. Display all interfaces names and their MAC addresses:

    # ip link show

    enp6s0f0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP mode DEFAULT group default qlen 1000
        link/ether b4:96:91:14:ae:58 brd ff:ff:ff:ff:ff:ff
    enp6s0f1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP mode DEFAULT group default qlen 1000
        link/ether b4:96:91:14:ae:5a brd ff:ff:ff:ff:ff:ff
    enp4s0f0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP mode DEFAULT group default qlen 1000
        link/ether 00:90:fa:6a:7d:90 brd ff:ff:ff:ff:ff:ff

2. For naming the interface with MAC address b4:96:91:14:ae:58 to provider0, create the /etc/systemd/network/70-custom-ifnames.link file with following contents:

    [Match]
    MACAddress=b4:96:91:14:ae:58

    [Link]
    Name=provider0
This link file matches a MAC address and renames the network interface to the name set in the **Name** parameter.

**Verification**

1. Reboot the system:

   ```
   # reboot
   ```

2. Verify that the device with the MAC address you specified in the link file has been assigned to **provider0**:

   ```
   # ip link show
   ```

   ```
   provider0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP mode DEFAULT group default qlen 1000
   link/ether b4:96:91:14:ae:58 brd ff:ff:ff:ff:ff:ff
   ```

**Additional resources**

- [systemd.link(5) man page](systemd.link(5)

### 1.10. ADDITIONAL RESOURCES

- See the [udev(7) man page](udev(7) for details about the **udev** device manager.)
CHAPTER 2. GETTING STARTED WITH NETWORKMANAGER

By default, RHEL uses NetworkManager to manage the network configuration and connections.

2.1. BENEFITS OF USING NETWORKMANAGER

The main benefits of using NetworkManager are:

- Offering an API through D-Bus which allows to query and control network configuration and state. In this way, networking can be checked and configured by multiple applications ensuring a synced and up-to-date networking status. For example, the RHEL web console, which monitors and configures servers through a web browser, uses the NetworkManager D-BUS interface to configure networking, as well as the Gnome GUI, the nmcli and the nm-connection-editor tools. Each change made in one of these tools is detected by all the others.

- Making Network management easier: NetworkManager ensures that network connectivity works. When it detects that there is no network configuration in a system but there are network devices, NetworkManager creates temporary connections to provide connectivity.

- Providing easy setup of connection to the user: NetworkManager offers management through different tools – GUI, nmtui, nmcli.

- Supporting configuration flexibility. For example, configuring a WiFi interface, NetworkManager scans and shows the available wifi networks. You can select an interface, and NetworkManager displays the required credentials providing automatic connection after the reboot process. NetworkManager can configure network aliases, IP addresses, static routes, DNS information, and VPN connections, as well as many connection-specific parameters. You can modify the configuration options to reflect your needs.

- Maintaining the state of devices after the reboot process and taking over interfaces which are set into managed mode during restart.

- Handling devices which are not explicitly set unmanaged but controlled manually by the user or another network service.

Additional resources

- Managing systems using the RHEL 9 web console.

2.2. AN OVERVIEW OF UTILITIES AND APPLICATIONS YOU CAN USE TO MANAGE NETWORKMANAGER CONNECTIONS

You can use the following utilities and applications to manage NetworkManager connections:

- **nmcli**: A command-line utility to manage connections.

- **nmtui**: A curses-based text user interface (TUI). To use this application, install the NetworkManager-tui package.

- **nm-connection-editor**: A graphical user interface (GUI) for NetworkManager-related tasks. To start this application, enter `nm-connection-editor` in a terminal of a GNOME session.

- **control-center**: A GUI provided by the GNOME shell for desktop users. Note that this application supports less features than `nm-connection-editor`. 
- The **network connection icon** in the GNOME shell: This icon represents network connection states and serves as visual indicator for the type of connection you are using.

**Additional resources**

- **Using nmtui to manage network connections using a text-based interface**
- **Getting started with nmcli**
CHAPTER 3. CONFIGURING NETWORKMANAGER TO IGNORE CERTAIN DEVICES

By default, NetworkManager manages all devices except the loopback device. However, you can set certain devices as unmanaged to configure that NetworkManager ignores these devices. With this setting, you can manually manage these devices, for example, using a script.

3.1. PERMANENTLY CONFIGURING A DEVICE AS UNMANAGED IN NETWORKMANAGER

You can configure devices as unmanaged based on several criteria, such as the interface name, MAC address, or device type. This procedure describes how to permanently set the enp1s0 interface as unmanaged in NetworkManager.

To temporarily configure network devices as unmanaged, see Temporarily configuring a device as unmanaged in NetworkManager.

Procedure

1. Optional: Display the list of devices to identify the device you want to set as unmanaged:

   # nmcli device status
   DEVICE TYPE STATE CONNECTION
   enp1s0 ethernet disconnected --
   ...

2. Create the /etc/NetworkManager/conf.d/99-unmanaged-devices.conf file with the following content:

   [keyfile]
   unmanaged-devices=interface-name:enp1s0

   To set multiple devices as unmanaged, separate the entries in the unmanaged-devices parameter with semicolon:

   [keyfile]
   unmanaged-devices=interface-name:interface_1;interface-name:interface_2;...

3. Reload the NetworkManager service:

   # systemctl reload NetworkManager

Verification steps

- Display the list of devices:

   # nmcli device status
   DEVICE TYPE STATE CONNECTION
   enp1s0 ethernet unmanaged --
   ...

   The unmanaged state next to the enp1s0 device indicates that NetworkManager does not
The unmanaged state next to the enp1s0 device indicates that NetworkManager does not manage this device.

Additional resources

- The Device List Format section in the NetworkManager.conf(5) man page.

### 3.2. TEMPORARILY CONFIGURING A DEVICE AS UNMANAGED IN NETWORKMANAGER

You can configure devices as unmanaged based on several criteria, such as the interface name, MAC address, or device type. This procedure describes how to temporarily set the enp1s0 interface as unmanaged in NetworkManager.

Use this method, for example, for testing purposes. To permanently configure network devices as unmanaged, see Permanently configuring a device as unmanaged in NetworkManager.

**Procedure**

1. Optional: Display the list of devices to identify the device you want to set as unmanaged:

   ```bash
   # nmcli device status
   DEVICE   TYPE      STATE         CONNECTION
   enp1s0   ethernet  disconnected  --
   ...
   ```

2. Set the enp1s0 device to the unmanaged state:

   ```bash
   # nmcli device set enp1s0 managed no
   ```

**Verification steps**

- Display the list of devices:

  ```bash
  # nmcli device status
  DEVICE   TYPE      STATE         CONNECTION
  enp1s0   ethernet  unmanaged     --
  ...
  ```

  The unmanaged state next to the enp1s0 device indicates that NetworkManager does not manage this device.

**Additional resources**

- The Device List Format section in the NetworkManager.conf(5) man page
CHAPTER 4. USING NMTUI TO MANAGE NETWORK CONNECTIONS USING A TEXT-BASED INTERFACE

The nmtui application is a text user interface (TUI) for NetworkManager. The following section provides how you can configure a network interface using nmtui.

NOTE

The nmtui application does not support all connection types. In particular, you cannot add or modify VPN connections or Ethernet connections that require 802.1X authentication.

4.1. STARTING THE NMTUI UTILITY

This procedure describes how to start the NetworkManager text user interface, nmtui.

Prerequisites

• The NetworkManager-tui package is installed.

Procedure

1. To start nmtui, enter:

```
# nmtui
```

2. To navigate:

• Use the cursors or press Tab to step forwards and press Shift+Tab to step back through the options.

• Use Enter to select an option.

• Use the Space bar to toggle the status of check boxes.

4.2. ADDING A CONNECTION PROFILE USING NMTUI
The `nmtui` application provides a text user interface to NetworkManager. This procedure describes how to add a new connection profile.

**Prerequisites**

- The `NetworkManager-tui` package is installed.

**Procedure**

1. Start the NetworkManager text user interface utility:
   ```
   # nmtui
   ```

2. Select the **Edit a connection** menu entry, and press **Enter**.

3. Select the **Add** button, and press **Enter**.

4. Select **Ethernet**, and press **Enter**.

5. Fill the fields with the connection details.
6. Select **OK** to save the changes.

7. Select **Back** to return to the main menu.

8. Select **Activate a connection**, and press **Enter**.

9. Select the new connection entry, and press **Enter** to activate the connection.

10. Select **Back** to return to the main menu.

11. Select **Quit**.

**Verification steps**

1. Display the status of the devices and connections:
# nmcli device status

<table>
<thead>
<tr>
<th>DEVICE</th>
<th>TYPE</th>
<th>STATE</th>
<th>CONNECTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>enp1s0</td>
<td>ethernet</td>
<td>connected</td>
<td>Example-Connection</td>
</tr>
</tbody>
</table>

2. To display all settings of the connection profile:

```bash
# nmcli connection show Example-Connection
```

- **connection.id:** Example-Connection
- **connection.uuid:** b6cdfa1c-e4ad-46e5-af8b-a75f06b79f76
- **connection.stable-id:** --
- **connection.type:** 802-3-ethernet
- **connection.interface-name:** enp1s0

If the configuration on the disk does not match the configuration on the device, starting or restarting NetworkManager creates an in-memory connection that reflects the configuration of the device. For further details and how to avoid this problem, see NetworkManager duplicates a connection after restart of NetworkManager service.

### Additional resources

- Testing basic network settings
- [nmtui(1) man page](https://manpages.debian.org/buster/man/netconnect.html)

### 4.3. APPLYING CHANGES TO A MODIFIED CONNECTION USING NMTUI

After you modified a connection in **nmtui**, you must reactivate the connection. Note that reactivating a connection in **nmtui** temporarily deactivates the connection.

#### Prerequisites

- The connection profile does not have the auto-connect setting enabled.

#### Procedure

1. In the main menu, select the **Activate a connection** menu entry:
2. Select the modified connection.

3. On the right, select the **Deactivate** button, and press **Enter**:

![Image of network connection interface showing Deactivate button](image1)

4. Select the connection again.

5. On the right, select the **Activate** button, and press **Enter**:

![Image of network connection interface showing Activate button](image2)
CHAPTER 5. GETTING STARTED WITH NMCLI

This section describes general information about the nmcli utility.

5.1. THE DIFFERENT OUTPUT FORMATS OF NMCLI

The nmcli utility supports different options to modify the output of nmcli commands. Using these options, you can display only the required information. This simplifies processing the output in scripts.

By default, the nmcli utility displays its output in a table-like format:

```
# nmcli device
DEVICE TYPE STATE CONNECTION
enp1s0 ethernet connected enp1s0
lo loopback unmanaged --
```

Using the -f option, you can display specific columns in a custom order. For example, to display only the DEVICE and STATE column, enter:

```
# nmcli -f DEVICE,STATE device
DEVICE STATE
enp1s0 connected
lo unmanaged
```

The -t option enables you to display the individual fields of the output in a colon-separated format:

```
# nmcli -t device
enp1s0:ethernet:connected:enp1s0
lo:loopback:unmanaged:
```

Combining the -f and -t to display only specific fields in colon-separated format can be helpful when you process the output in scripts:

```
# nmcli -f DEVICE,STATE -t device
enp1s0:connected
lo:unmanaged
```

5.2. USING TAB COMPLETION IN NMCLI

If the bash-completion package is installed on your host, the nmcli utility supports tab completion. This enables you to auto-complete option names and to identify possible options and values.

For example, if you type nmcli con and press Tab, then the shell automatically completes the command to nmcli connection.

For the completion, the options or value you have typed must be unique. If it is not unique, then nmcli displays all possibilities. For example, if you type nmcli connection d and press Tab, then the command shows command delete and down as possible options.

You can also use tab completion to display all properties you can set in a connection profile. For example, if you type nmcli connection modify connection_name and press Tab, the command shows the full list of available properties.
5.3. FREQUENT NMCLI COMMANDS

The following is an overview about frequently-used `nmcli` commands.

- To display the list connection profiles, enter:

  ```
  # nmcli connection show
  NAME  UUID                                  TYPE      DEVICE
  enp1s0 45224a39-606f-4bf7-b3dc-d088236c15ee  ethernet  enp1s0
  ```

- To display the settings of a specific connection profile, enter:

  ```
  # nmcli connection show connection_name
  connection.id: enp1s0
  connection.uuid: 45224a39-606f-4bf7-b3dc-d088236c15ee
  connection.stable-id: --
  connection.type: 802-3-ethernet
  ```

- To modify properties of a connection, enter:

  ```
  # nmcli connection modify connection_name property value
  ```
  You can modify multiple properties using a single command if you pass multiple `property value` combinations to the command.

- To display the list of network devices, their state, and which connection profiles use the device, enter:

  ```
  # nmcli device
  DEVICE  TYPE      STATE         CONNECTION
  enp1s0  ethernet  connected     enp1s0
  enp8s0  ethernet  disconnected  --
  enp7s0  ethernet  unmanaged    --
  ```

- To activate a connection, enter:

  ```
  # nmcli connection up connection_name
  ```

- To deactivate a connection, enter:

  ```
  # nmcli connection down connection_name
  ```
CHAPTER 6. CONFIGURING AN ETHERNET CONNECTION

This section describes different ways how to configure an Ethernet connection with static and dynamic IP addresses.

6.1. CONFIGURING A STATIC ETHERNET CONNECTION USING NMCLI

This procedure describes adding an Ethernet connection with the following settings using the `nmcli` utility:

- A static IPv4 address - **192.0.2.1** with a /24 subnet mask
- A static IPv6 address - **2001:db8:1::1** with a /64 subnet mask
- An IPv4 default gateway - **192.0.2.254**
- An IPv6 default gateway - **2001:db8:1::ffe**
- An IPv4 DNS server - **192.0.2.200**
- An IPv6 DNS server - **2001:db8:1::ffbb**
- A DNS search domain - **example.com**

Procedure

1. Add a new NetworkManager connection profile for the Ethernet connection:

   ```
   # nmcli connection add con-name Example-Connection ifname enp7s0 type ethernet
   ```

   The further steps modify the **Example-Connection** connection profile you created.

2. Set the IPv4 address:

   ```
   # nmcli connection modify Example-Connection ipv4.addresses 192.0.2.1/24
   ```

3. Set the IPv6 address:

   ```
   # nmcli connection modify Example-Connection ipv6.addresses 2001:db8:1::1/64
   ```

4. Set the IPv4 and IPv6 connection method to **manual**:

   ```
   # nmcli connection modify Example-Connection ipv4.method manual
   # nmcli connection modify Example-Connection ipv6.method manual
   ```

5. Set the IPv4 and IPv6 default gateways:

   ```
   # nmcli connection modify Example-Connection ipv4.gateway 192.0.2.254
   # nmcli connection modify Example-Connection ipv6.gateway 2001:db8:1::ffe
   ```

6. Set the IPv4 and IPv6 DNS server addresses:
# nmcli connection modify Example-Connection ipv4.dns "192.0.2.200"
# nmcli connection modify Example-Connection ipv6.dns "2001:db8:1::ffbb"

To set multiple DNS servers, specify them space-separated and enclosed in quotes.

7. Set the DNS search domain for the IPv4 and IPv6 connection:

   # nmcli connection modify Example-Connection ipv4.dns-search example.com
   # nmcli connection modify Example-Connection ipv6.dns-search example.com

8. Activate the connection profile:

   # nmcli connection up Example-Connection
   Connection successfully activated (D-Bus active path: /org/freedesktop/NetworkManager/ActiveConnection/13)

**Verification steps**

1. Display the status of the devices and connections:

   # nmcli device status

   DEVICE      TYPE      STATE      CONNECTION
   enp7s0      ethernet  connected  Example-Connection

2. To display all settings of the connection profile:

   # nmcli connection show Example-Connection
   connection.id:       Example-Connection
   connection.uuid:     b6cdfa1c-e4ad-46e5-af8b-a75f06b79f76
   connection.stable-id: --
   connection.type:     802-3-ethernet
   connection.interface-name: enp7s0
   ...

3. Use the `ping` utility to verify that this host can send packets to other hosts.
   - Ping an IP address in the same subnet.
     - For IPv4:
       ```
       # ping 192.0.2.3
       ```
     - For IPv6:
       ```
       # ping 2001:db8:1::2
       ```

     If the command fails, verify the IP and subnet settings.

   - Ping an IP address in a remote subnet.
     - For IPv4:
       ```
       # ping 198.162.3.1
       ```
     - For IPv6:
4. Use the `host` utility to verify that name resolution works. For example:

```
# host client.example.com
```

If the command returns any error, such as `connection timed out` or `no servers could be reached`, verify your DNS settings.

**Troubleshooting steps**

1. If the connection fails or if the network interface switches between an up and down status:
   - Make sure that the network cable is plugged-in to the host and a switch.
   - Check whether the link failure exists only on this host or also on other hosts connected to the same switch the server is connected to.
   - Verify that the network cable and the network interface are working as expected. Perform hardware diagnosis steps and replace defect cables and network interface cards.
   - If the configuration on the disk does not match the configuration on the device, starting or restarting NetworkManager creates an in-memory connection that reflects the configuration of the device. For further details and how to avoid this problem, see NetworkManager duplicates a connection after restart of NetworkManager service

**Additional resources**

- `nm-settings(5)`, `nmcli` and `nmcli(1)` man pages
- Configuring NetworkManager to avoid using a specific profile to provide a default gateway

**6.2. CONFIGURING A STATIC ETHERNET CONNECTION USING THE NMCLI INTERACTIVE EDITOR**

This procedure describes adding an Ethernet connection with the following settings using the `nmcli` interactive mode:

- A static IPv4 address - `192.0.2.1` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `192.0.2.254`
- An IPv6 default gateway - `2001:db8:1::ffe`
• An IPv4 DNS server - 192.0.2.200
• An IPv6 DNS server - 2001:db8:1::ffbb
• A DNS search domain - example.com

Procedure

1. To add a new NetworkManager connection profile for the Ethernet connection, and starting the interactive mode, enter:

```
# nmcli connection edit type ethernet con-name Example-Connection
```

2. Set the network interface:

```
nmcli> set connection.interface-name enp7s0
```

3. Set the IPv4 address:

```
nmcli> set ipv4.addresses 192.0.2.1/24
```

4. Set the IPv6 address:

```
nmcli> set ipv6.addresses 2001:db8:1::1/64
```

5. Set the IPv4 and IPv6 connection method to manual:

```
nmcli> set ipv4.method manual
nmcli> set ipv6.method manual
```

6. Set the IPv4 and IPv6 default gateways:

```
nmcli> set ipv4.gateway 192.0.2.254
nmcli> set ipv6.gateway 2001:db8:1::fffe
```

7. Set the IPv4 and IPv6 DNS server addresses:

```
nmcli> set ipv4.dns 192.0.2.200
nmcli> set ipv6.dns 2001:db8:1::ffbb
```

To set multiple DNS servers, specify them space-separated and enclosed in quotes.

8. Set the DNS search domain for the IPv4 and IPv6 connection:

```
nmcli> set ipv4.dns-search example.com
nmcli> set ipv6.dns-search example.com
```

9. Save and activate the connection:

```
nmcli> save persistent
```

Saving the connection with ‘autoconnect=yes’. That might result in an immediate activation of the connection.

Do you still want to save? (yes/no) [yes] yes
10. Leave the interactive mode:

```
nmcli> quit
```

**Verification steps**

1. Display the status of the devices and connections:

```
# nmcli device status
DEVICE      TYPE      STATE      CONNECTION
enp7s0       ethernet  connected  Example-Connection
```

2. To display all settings of the connection profile:

```
# nmcli connection show Example-Connection
connection.id:         Example-Connection
connection.uuid:       b6cd1a1c-e4ad-46f5-af8b-a75f06b79f76
connection.stable-id:  --
connection.type:       802-3-ethernet
connection.interface-name: enp7s0
```

3. Use the `ping` utility to verify that this host can send packets to other hosts.

- Ping an IP address in the same subnet.
  For IPv4:
  ```
  # ping 192.0.2.3
  ```
  For IPv6:
  ```
  # ping 2001:db8:1::2
  ```
  If the command fails, verify the IP and subnet settings.
- Ping an IP address in a remote subnet.
  For IPv4:
  ```
  # ping 198.162.3.1
  ```
  For IPv6:
  ```
  # ping 2001:db8:2::1
  ```
  - If the command fails, ping the default gateway to verify settings.
    For IPv4:
    ```
    # ping 192.0.2.254
    ```
    For IPv6:
# ping 2001:db8:1::fff3

4. Use the `host` utility to verify that name resolution works. For example:

```bash
# host client.example.com
```

If the command returns any error, such as `connection timed out` or `no servers could be reached`, verify your DNS settings.

**Troubleshooting steps**

1. If the connection fails or if the network interface switches between an up and down status:
   - Make sure that the network cable is plugged-in to the host and a switch.
   - Check whether the link failure exists only on this host or also on other hosts connected to the same switch the server is connected to.
   - Verify that the network cable and the network interface are working as expected. Perform hardware diagnosis steps and replace defect cables and network interface cards.

If the configuration on the disk does not match the configuration on the device, starting or restarting NetworkManager creates an in-memory connection that reflects the configuration of the device. For further details and how to avoid this problem, see NetworkManager duplicates a connection after restart of NetworkManager service.

**Additional resources**

- `nm-settings(5)` man page
- `nmcli(1)` man page
- Configuring NetworkManager to avoid using a specific profile to provide a default gateway

### 6.3. CONFIGURING A STATIC ETHERNET CONNECTION USING NMSTATECTL

This procedure describes how to configure an Ethernet connection for the `enp7s0` device with the following settings using the `nmstatectl` utility:

- A static IPv4 address - `192.0.2.1` with the `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with the `/64` subnet mask
- An IPv4 default gateway - `192.0.2.254`
- An IPv6 default gateway - `2001:db8:1::ffe`
- An IPv4 DNS server - `192.0.2.200`
- An IPv6 DNS server - `2001:db8:1::fbb`
- A DNS search domain - `example.com`
The `nmstatectl` utility ensures that, after setting the configuration, the result matches the configuration file. If anything fails, `nmstatectl` automatically rolls back the changes to avoid leaving the system in an incorrect state.

The procedure defines the interface configuration in YAML format. Alternatively, you can also specify the configuration in JSON format.

**Prerequisites**

- The `nmstate` package is installed.

**Procedure**

1. Create a YAML file, for example `~/create-ethernet-profile.yml`, with the following contents:

```yaml
---
interfaces:
- name: enp7s0
  type: ethernet
  state: up
  ipv4:
    enabled: true
    address:
    - ip: 192.0.2.1
      prefix-length: 24
    dhcp: false
  ipv6:
    enabled: true
    address:
    - ip: 2001:db8:1::1
      prefix-length: 64
    autoconf: false
    dhcp: false
  routes:
    config:
    - destination: 0.0.0.0/0
      next-hop-address: 192.0.2.254
      next-hop-interface: enp7s0
    - destination: ::/0
      next-hop-address: 2001:db8:1::fffe
      next-hop-interface: enp7s0
  dns-resolver:
    config:
    search:
    - example.com
    server:
    - 192.0.2.200
    - 2001:db8:1::ffbe
```

2. Apply the settings to the system:

```
# nmstatectl apply ~/create-ethernet-profile.yml
```

**Verification steps**
1. Display the status of the devices and connections:

```bash
# nmcli device status
DEVICE      TYPE      STATE      CONNECTION
enp7s0      ethernet  connected  enp7s0
```

2. Display all settings of the connection profile:

```bash
# nmcli connection show enp7s0
connection.id:       enp7s0
connection.uuid:     b6cdfa1c-e4ad-46e5-af8b-a75f06b79f76
connection.stable-id: --
connection.type:     802-3-ethernet
connection.interface-name: enp7s0
```

3. Display the connection settings in YAML format:

```bash
# nmstatectl show enp7s0
```

Additional resources

- `nmstatectl(8)` man page
- `/usr/share/doc/nmstate/examples/`

### 6.4. CONFIGURING A STATIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH THE INTERFACE NAME

This procedure describes how to use the Networking RHEL System Role to remotely add an Ethernet connection for the `enp7s0` interface with the following settings by running an Ansible playbook:

- A static IPv4 address - \textbf{192.0.2.1} with a /24 subnet mask
- A static IPv6 address - \textbf{2001:db8:1::1} with a /64 subnet mask
- An IPv4 default gateway - \textbf{192.0.2.254}
- An IPv6 default gateway - \textbf{2001:db8:1::fffe}
- An IPv4 DNS server - \textbf{192.0.2.200}
- An IPv6 DNS server - \textbf{2001:db8:1::ffbb}
- A DNS search domain - \textbf{example.com}

Run this procedure on the Ansible control node.

Prerequisites

- The `ansible-core` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.
The host uses NetworkManager to configure the network.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/ethernet-static-IP.yml` playbook with the following content:

   ```yaml
   ---
   - name: Configure an Ethernet connection with static IP
     hosts: node.example.com
     become: true
     tasks:
     - include_role:
       name: rhel-system-roles.network

     vars:
     network_connections:
     - name: enp7s0
       interface_name: enp7s0
       type: ethernet
       autoconnect: yes
       ip:
         address:
         - 192.0.2.1/24
         - 2001:db8:1::1/64
       gateway4: 192.0.2.254
       gateway6: 2001:db8:1::fffe
       dns:
       - 192.0.2.200
       - 2001:db8:1::ffbb
       dns_search:
       - example.com
     state: up
   ```

3. Run the playbook:

   - To connect as `root` user to the managed host, enter:
     ```
     # ansible-playbook -u root ~/ethernet-static-IP.yml
     ```
   - To connect as a user to the managed host, enter:
     ```
     # ansible-playbook -u user_name --ask-become-pass ~/ethernet-static-IP.yml
     ```

     The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

     If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

**Additional resources**
6.5. CONFIGURING A STATIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH A DEVICE PATH

This procedure describes how to use RHEL System Roles to remotely add an Ethernet connection with static IP address for devices that match a specific device path by running an Ansible playbook.

You can identify the device path with the following command:

```
# udevadm info /sys/class/net/<device_name> | grep ID_PATH=
```

This procedure sets the following settings to the device that matches the PCI ID `0000:00:0[1-3].0` expression, but not `0000:00:02.0`:

- A static IPv4 address - `192.0.2.1` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `192.0.2.254`
- An IPv6 default gateway - `2001:db8:1::ffe`
- An IPv4 DNS server - `192.0.2.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`

Run this procedure on the Ansible control node.

**Prerequisites**

- The `ansible-core` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.
- The host uses NetworkManager to configure the network.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/ethernet-dynamic-IP.yml` playbook with the following content:

   ```yaml
   ---
   - name: Configure an Ethernet connection with dynamic IP
     hosts: node.example.com
   ```
become: true

vars:
  network_connections:
  - name: example
    match:
      path:
        - pci-0000:00:0[1-3].0
        - &/pci-0000:00:02.0
    type: ethernet
    autoconnect: yes
    ip:
      address:
        - 192.0.2.1/24
        - 2001:db8:1::/64
    gateway4: 192.0.2.254
    gateway6: 2001:db8:1::fffe
    dns:
      - 192.0.2.200
      - 2001:db8:1::ffbb
    dns_search:
      - example.com
    state: up

The `match` parameter in this example defines that Ansible applies the play to devices that match PCI ID `0000:00:0[1-3].0`, but not `0000:00:02.0`. For further details about special modifiers and wildcards you can use, see the `match` parameter description in the `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file.

3. Run the playbook:

   - To connect as root user to the managed host, enter:

     ```bash
     # ansible-playbook -u root ~/ethernet-dynamic-IP.yml
     ```

   - To connect as a user to the managed host, enter:

     ```bash
     # ansible-playbook -u user_name --ask-become-pass ~/ethernet-dynamic-IP.yml
     ```

     The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts
     for the `sudo` password of the user defined in the `--ask-become-pass` option.

     If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed
     host as the user that is currently logged in to the control node.

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
- `ansible-playbook(1)` man page
6.6. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING NMCLI

This procedure describes adding a dynamic Ethernet connection using the `nmcli` utility. With this setting, NetworkManager requests the IP settings for this connection from a DHCP server.

Prerequisites

- A DHCP server is available in the network.

Procedure

1. Add a new NetworkManager connection profile for the Ethernet connection:

   ```
   # nmcli connection add con-name Example-Connection ifname enp7s0 type ethernet
   ```

2. Optionally, change the host name NetworkManager sends to the DHCP server when using the `Example-Connection` profile:

   ```
   # nmcli connection modify Example-Connection ipv4.dhcp-hostname Example
   ipv6.dhcp-hostname Example
   ```

3. Optionally, change the client ID NetworkManager sends to an IPv4 DHCP server when using the `Example-Connection` profile:

   ```
   # nmcli connection modify Example-Connection ipv4.dhcp-client-id client-ID
   ```

   Note that there is no `dhcp-client-id` parameter for IPv6. To create an identifier for IPv6, configure the `dhclient` service.

Verification steps

1. Display the status of the devices and connections:

   ```
   # nmcli device status
   DEVICE      TYPE      STATE      CONNECTION
   enp7s0      ethernet  connected  Example-Connection
   ```

2. To display all settings of the connection profile:

   ```
   # nmcli connection show Example-Connection
   connection.id: Example-Connection
   connection.uuid: b6cd1a1c-e4ad-46e5-af8b-a75f06b79f76
   connection.stable-id: --
   connection.type: 802-3-ethernet
   connection.interface-name: enp7s0
   ... 
   ```

3. Use the `ping` utility to verify that this host can send packets to other hosts.

   - Ping an IP address in the same subnet.

     For IPv4:
4. Use the `host` utility to verify that name resolution works. For example:

```bash
# host client.example.com
```

If the command returns any error, such as connection timed out or no servers could be reached, verify your DNS settings.

Additional resources

- `dhclient(8)` man page
- `nm-settings(5)`
- `nmcli(1)` man page
- NetworkManager duplicates a connection after restart of NetworkManager service

6.7. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING THE NMCLI INTERACTIVE EDITOR

This procedure describes adding an dynamic Ethernet connection using the interactive editor of the `nmcli` utility. With this setting, NetworkManager requests the IP settings for this connection from a DHCP server.

Prerequisites
A DHCP server is available in the network.

**Procedure**

1. To add a new NetworkManager connection profile for the Ethernet connection, and starting the interactive mode, enter:
   ```
   # nmcli connection edit type ethernet con-name Example-Connection
   ```

2. Set the network interface:
   ```
   nmcli> set connection.interface-name enp7s0
   ```

3. Optionally, change the host name NetworkManager sends to the DHCP server when using the `Example-Connection` profile:
   ```
   nmcli> set ipv4.dhcp-hostname Example
   nmcli> set ipv6.dhcp-hostname Example
   ```

4. Optionally, change the client ID NetworkManager sends to an IPv4 DHCP server when using the `Example-Connection` profile:
   ```
   nmcli> set ipv4.dhcp-client-id client-ID
   ```
   Note that there is no `dhcp-client-id` parameter for IPv6. To create an identifier for IPv6, configure the `dhclient` service.

5. Save and activate the connection:
   ```
   nmcli> save persistent
   Saving the connection with 'autoconnect=yes'. That might result in an immediate activation of the connection.
   Do you still want to save? (yes/no) [yes] yes
   ```

6. Leave the interactive mode:
   ```
   nmcli> quit
   ```

**Verification steps**

1. Display the status of the devices and connections:
   ```
   # nmcli device status
   DEVICE TYPE STATE CONNECTION
   enp7s0 ethernet connected Example-Connection
   ```

2. To display all settings of the connection profile:
   ```
   # nmcli connection show Example-Connection
   connection.id: Example-Connection
   connection.uuid: b6cda1e4-ad54-18b9a75f06b79f76
   connection.stable-id: --
   ```
3. Use the `ping` utility to verify that this host can send packets to other hosts.

- Ping an IP address in the same subnet.
  For IPv4:

  ```
  # ping 192.0.2.3
  ```

  For IPv6:

  ```
  # ping 2001:db8:1::2
  ```

  If the command fails, verify the IP and subnet settings.

- Ping an IP address in a remote subnet.
  For IPv4:

  ```
  # ping 198.162.3.1
  ```

  For IPv6:

  ```
  # ping 2001:db8:2::1
  ```

  If the command fails, ping the default gateway to verify settings.
  For IPv4:

  ```
  # ping 192.0.2.254
  ```

  For IPv6:

  ```
  # ping 2001:db8:1::fff3
  ```

4. Use the `host` utility to verify that name resolution works. For example:

```
# host client.example.com
```

If the command returns any error, such as `connection timed out` or `no servers could be reached`, verify your DNS settings.

- `dhclient(8)` man page
- `nm-settings(5)`
- `nmcli(1)` man page
- NetworkManager duplicates a connection after restart of NetworkManager service
6.8. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING NMSTATECTL

This procedure describes how to add a dynamic Ethernet for the `enp7s0` device using the `nmstatectl` utility. With the settings in this procedure, NetworkManager requests the IP settings for this connection from a DHCP server.

The `nmstatectl` utility ensures that, after setting the configuration, the result matches the configuration file. If anything fails, `nmstatectl` automatically rolls back the changes to avoid leaving the system in an incorrect state.

The procedure defines the interface configuration in YAML format. Alternatively, you can also specify the configuration in JSON format.

Prerequisites

- The `nmstate` package is installed.

Procedure

1. Create a YAML file, for example `~/create-ethernet-profile.yml`, with the following contents:

   ```yaml
   ---
   interfaces:
   - name: enp7s0
     type: ethernet
     state: up
     ipv4:
       enabled: true
       auto-dns: true
       auto-gateway: true
       auto-routes: true
       dhcp: true
     ipv6:
       enabled: true
       auto-dns: true
       auto-gateway: true
       auto-routes: true
       autoconf: true
       dhcp: true
   ```

2. Apply the settings to the system:

   ```
   # nmstatectl apply ~/create-ethernet-profile.yml
   ```

Verification steps

1. Display the status of the devices and connections:

   ```
   # nmcli device status
   DEVICE   TYPE     STATE       CONNECTION
   enp7s0   ethernet  connected  enp7s0
   ```

2. Display all settings of the connection profile:
3. Display the connection settings in YAML format:

```
# nmstatectl show enp7s0
```

### Additional resources

- `nmstatectl(8)` man page
- `/usr/share/doc/nmstate/examples/`

## 6.9. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH THE INTERFACE NAME

This procedure describes how to use RHEL System Roles to remotely add a dynamic Ethernet connection for the `enp7s0` interface by running an Ansible playbook. With this setting, the network connection requests the IP settings for this connection from a DHCP server. Run this procedure on the Ansible control node.

### Prerequisites

- A DHCP server is available in the network.
- The `ansible-core` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.
- The host uses NetworkManager to configure the network.

### Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

```
node.example.com
```

2. Create the `~/.ethernet-dynamic-IP.yml` playbook with the following content:

```
---
- name: Configure an Ethernet connection with dynamic IP
  hosts: node.example.com
  become: true
  tasks:
    - include_role:
        name: rhel-system-roles.network
```
vars:
  network_connections:
  - name: enp7s0
    interface_name: enp7s0
    type: ethernet
    autoconnect: yes
    ip:
      dhcp4: yes
      auto6: yes
    state: up

3. Run the playbook:

   - To connect as root user to the managed host, enter:

     ```
     # ansible-playbook -u root ~/ethernet-dynamic-IP.yml
     ```

   - To connect as a user to the managed host, enter:

     ```
     # ansible-playbook -u user_name --ask-become-pass ~/ethernet-dynamic-IP.yml
     ```

     The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

     If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file

- ansible-playbook(1) man page

6.10. CONFIGURING A DYNAMIC ETHERNET CONNECTION USING RHEL SYSTEM ROLES WITH A DEVICE PATH

This procedure describes how to use RHEL System Roles to remotely add a dynamic Ethernet connection for devices that match a specific device path by running an Ansible playbook. With dynamic IP settings, the network connection requests the IP settings for this connection from a DHCP server. Run this procedure on the Ansible control node.

You can identify the device path with the following command:

```
# udevadm info /sys/class/net/<device_name> | grep ID_PATH=
```

Prerequisites

- A DHCP server is available in the network.

- The ansible-core and rhel-system-roles packages are installed on the control node.

- If you use a different remote user than root when you run the playbook, this user has appropriate sudo permissions on the managed node.
- The host uses NetworkManager to configure the network.

Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/ethernet-dynamic-IP.yml` playbook with the following content:

   ```yaml
   ---
   - name: Configure an Ethernet connection with dynamic IP
     hosts: node.example.com
     become: true
     tasks:
       - include_role:
           name: rhel-system-roles.network
     vars:
       network_connections:
         - name: example
           match:
             path:
               - pci-0000:00:0[1-3].0
               - &!pci-0000:00:02.0
             type: ethernet
             autoconnect: yes
             ip:
               dhcp4: yes
               auto6: yes
             state: up
   ```

   The `match` parameter in this example defines that Ansible applies the play to devices that match PCI ID `0000:00:0[1-3].0`, but not `0000:00:02.0`. For further details about special modifiers and wild cards you can use, see the `match` parameter description in the `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file.

3. Run the playbook:

   - To connect as `root` user to the managed host, enter:
     ```
     # ansible-playbook -u root ~/ethernet-dynamic-IP.yml
     ```

   - To connect as a user to the managed host, enter:
     ```
     # ansible-playbook -u user_name --ask-become-pass ~/ethernet-dynamic-IP.yml
     ```

     The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

     If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

Additional resources
6.11. CONFIGURING AN ETHERNET CONNECTION USING CONTROL-CENTER

Ethernet connections are the most frequently used connections types in physical or virtual machines. This section describes how to configure this connection type in the GNOME control-center:

Note that control-center does not support as many configuration options as the nm-connection-editor application or the nmcli utility.

Prerequisites

- A physical or virtual Ethernet device exists in the server’s configuration.
- GNOME is installed.

Procedure

1. Press the Super key, enter Settings, and press Enter.
2. Select Network in the navigation on the left.
3. Click the + button next to the Wired entry to create a new profile.
4. Optional: Set a name for the connection on the Identity tab.
5. On the IPv4 tab, configure the IPv4 settings. For example, select method Manual, set a static IPv4 address, network mask, default gateway, and DNS server:
6. On the IPv6 tab, configure the IPv6 settings. For example, select method Manual, set a static IPv6 address, network mask, default gateway, and DNS server:

<table>
<thead>
<tr>
<th>Identity</th>
<th>IPv4</th>
<th>IPv6</th>
<th>Security</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv6 Method</td>
<td>Manual</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Addresses**

<table>
<thead>
<tr>
<th>Address</th>
<th>Netmask</th>
<th>Gateway</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.0.2.1</td>
<td>24</td>
<td>192.0.2.254</td>
</tr>
</tbody>
</table>

**DNS**

<table>
<thead>
<tr>
<th>Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.0.2.1</td>
</tr>
</tbody>
</table>

Separate IP addresses with commas

7. Click the Add button to save the connection. The GNOME control-center automatically activates the connection.
Verification steps

1. Display the status of the devices and connections:

```
# nmcli device status
DEVICE   TYPE      STATE      CONNECTION
enp7s0    ethernet  connected  Example-Connection
```

2. To display all settings of the connection profile:

```
# nmcli connection show Example-Connection
connection.id:   Example-Connection
connection.uuid: b6cdfa1c-e4ad-46e5-af8b-a75f06b79f76
connection.stable-id: --
connection.type:   802-3-ethernet
connection.interface-name: enp7s0
```

3. Use the `ping` utility to verify that this host can send packets to other hosts.

   - Ping an IP address in the same subnet.
     For IPv4:
     
     ```
     # ping 192.0.2.3
     ```
     
     For IPv6:
     
     ```
     # ping 2001:db8:1::2
     ```

     If the command fails, verify the IP and subnet settings.

   - Ping an IP address in a remote subnet.
     For IPv4:
     
     ```
     # ping 198.162.3.1
     ```
     
     For IPv6:
     
     ```
     # ping 2001:db8:2::1
     ```

     - If the command fails, ping the default gateway to verify settings.
       For IPv4:
       
       ```
       # ping 192.0.2.254
       ```
       
       For IPv6:
       
       ```
       # ping 2001:db8:1::ffe
       ```

4. Use the `host` utility to verify that name resolution works. For example:

```
# host client.example.com
```
If the command returns any error, such as connection timed out or no servers could be reached, verify your DNS settings.

Troubleshooting steps

1. If the connection fails or if the network interface switches between an up and down status:
   - Make sure that the network cable is plugged-in to the host and a switch.
   - Check whether the link failure exists only on this host or also on other hosts connected to the same switch the server is connected to.
   - Verify that the network cable and the network interface are working as expected. Perform hardware diagnosis steps and replace defect cables and network interface cards.

Additional Resources

- If the connection does not have a default gateway, see Configuring NetworkManager to avoid using a specific profile to provide a default gateway.

6.12. CONFIGURING AN ETHERNET CONNECTION USING NM-CONNECTION-EDITOR

Ethernet connections are the most frequently used connection types in physical or virtual servers. This section describes how to configure this connection type using the nm-connection-editor application.

Prerequisites

- A physical or virtual Ethernet device exists in the server’s configuration.
- GNOME is installed.

Procedure

1. Open a terminal, and enter:

   ```
   $ nm-connection-editor
   ```

2. Click the + button to add a new connection.

3. Select the Ethernet connection type, and click Create.

4. On the General tab:
   a. To automatically enable this connection when the system boots or when you restart the NetworkManager service:
      i. Select Connect automatically with priority.
      ii. Optional: Change the priority value next to Connect automatically with priority. If multiple connection profiles exist for the same device, NetworkManager enables only one profile. By default, NetworkManager activates the last-used profile that has auto-connect enabled. However, if you set priority values in the profiles, NetworkManager activates the profile with the highest priority.
b. Clear the **All users may connect to this network** check box if the profile should be available only to the user that created the connection profile.

5. On the **Ethernet** tab, select a device and, optionally, further Ethernet-related settings.

6. On the **IPv4 Settings** tab, configure the IPv4 settings. For example, set a static IPv4 address, network mask, default gateway, and DNS server:
7. On the **IPv6 Settings** tab, configure the IPv6 settings. For example, set a static IPv6 address, network mask, default gateway, and DNS server:

![IPv6 Settings configuration](image)

8. Save the connection.

**Verification steps**

1. Use the **ping** utility to verify that this host can send packets to other hosts.

   - Ping an IP address in the same subnet.
     For IPv4:

     ```
     # ping 192.0.2.3
     ```

     For IPv6:

     ```
     # ping 2001:db8:1::2
     ```

     If the command fails, verify the IP and subnet settings.

   - Ping an IP address in a remote subnet.
     For IPv4:

     ```
     # ping 198.162.3.1
     ```

     For IPv6:

     ```
     # ping 2001:db8:2::1
     ```

     If the command fails, ping the default gateway to verify settings.
     For IPv4:

     ```
     # ping 192.0.2.254
     ```

     For IPv6:

     ```
     # ping 2001:db8:1::fff3
     ```

   - Use the **host** utility to verify that name resolution works. For example:
# host client.example.com

If the command returns any error, such as connection timed out or no servers could be reached, verify your DNS settings.

Additional Resources

- If the connection does not have a default gateway, see Configuring NetworkManager to avoid using a specific profile to provide a default gateway.

### 6.13. CHANGING THE DHCP CLIENT OF NETWORKMANAGER

By default, NetworkManager uses its internal DHCP client. However, if you require a DHCP client with features that the built-in client does not provide, you can alternatively configure NetworkManager to use dhclient.

Note that RHEL does not provide dhcpcd and, therefore, NetworkManager can not use this client.

**Procedure**

1. Create the `/etc/NetworkManager/conf.d/dhcp-client.conf` file with the following content:

   ```
   [main]
   dhcp=dhclient
   ```

   You can set the dhcp parameter to internal (default) or dhclient.

2. If you set the dhcp parameter to dhclient, install the dhcp-client package:

   ```
   # dnf install dhcp-client
   ```

3. Restart NetworkManager:

   ```
   # systemctl restart NetworkManager
   ```

   Note that the restart temporarily interrupts all network connections.

**Verification**

- Search in the `/var/log/messages` log file for an entry similar to the following:

  ```
  Apr 26 09:54:19 server NetworkManager[27748]: <info> [1650959659.8483] dhcp-init: Using DHCP client 'dhclient'
  ```

  This log entry confirms that NetworkManager uses dhclient as DHCP client.

**Additional resources**

- NetworkManager.conf(5) man page

### 6.14. CONFIGURING THE DHCP BEHAVIOR OF A NETWORKMANAGER CONNECTION
A Dynamic Host Configuration Protocol (DHCP) client requests the dynamic IP address and corresponding configuration information from a DHCP server each time a client connects to the network.

When you configured a connection to retrieve an IP address from a DHCP server, the NetworkManager requests an IP address from a DHCP server. By default, the client waits 45 seconds for this request to be completed. When a DHCP connection is started, a dhcp client requests an IP address from a DHCP server.

Prerequisites
- A connection that uses DHCP is configured on the host.

Procedure
1. Set the `ipv4.dhcp-timeout` and `ipv6.dhcp-timeout` properties. For example, to set both options to 30 seconds, enter:

   ```bash
   # nmcli connection modify connection_name ipv4.dhcp-timeout 30 ipv6.dhcp-timeout 30
   ```

   Alternatively, set the parameters to `infinity` to configure that NetworkManager does not stop trying to request and renew an IP address until it is successful.

2. Optional: Configure the behavior if NetworkManager does not receive an IPv4 address before the timeout:

   ```bash
   # nmcli connection modify connection_name ipv4.may-fail value
   ```

   If you set the `ipv4.may-fail` option to:
   - `yes`, the status of the connection depends on the IPv6 configuration:
     - If the IPv6 configuration is enabled and successful, NetworkManager activates the IPv6 connection and no longer tries to activate the IPv4 connection.
     - If the IPv6 configuration is disabled or not configured, the connection fails.
   - `no`, the connection is deactivated. In this case:
     - If the `autoconnect` property of the connection is enabled, NetworkManager retries to activate the connection as many times as set in the `autoconnect-retries` property. The default is 4.
     - If the connection still cannot acquire a DHCP address, auto-activation fails. Note that after 5 minutes, the auto-connection process starts again to acquire an IP address from the DHCP server.

3. Optional: Configure the behavior if NetworkManager does not receive an IPv6 address before the timeout:

   ```bash
   # nmcli connection modify connection_name ipv6.may-fail value
   ```

Additional resources

Red Hat Enterprise Linux 9 Configuring and managing networking
6.15. CONFIGURING MULTIPLE ETHERNET INTERFACES USING A SINGLE CONNECTION PROFILE BY INTERFACE NAME

In most cases, one connection profile contains the settings of one network device. However, NetworkManager also supports wildcards when you set the interface name in connection profiles. If a host roams between Ethernet networks with dynamic IP address assignment, you can use this feature to create a single connection profile that you can use for multiple Ethernet interfaces.

Prerequisites

- DHCP is available in the network
- The host has multiple Ethernet adapters
- No connection profile exists on the host

Procedure

1. Add a connection profile that applies to all interface names starting with `enp`:

```
# nmcli connection add con-name Example connection.multi-connect multiple
match.interface-name enp* type ethernet
```

Verification steps

1. Display all settings of the single connection profile:

```
# nmcli connection show Example
```

```
connection.id:                      Example
... connection.multi-connect:       3 (multiple)
match.interface-name:              `enp*`
...                               
```

3 indicates the number of interfaces active on the connection profile at the same time, and not the number of network interfaces in the connection profile. The connection profile uses all devices that match the pattern in the `match.interface-name` parameter and, therefore, the connection profiles have the same Universally Unique Identifier (UUID).

2. Display the status of the connections:

```
# nmcli connection show
```

```
NAME                    UUID                    TYPE     DEVICE
... Example 6f22402e-c0cc-49cf-b702-eaf0cd5ea7d1  ethernet  enp7s0
Example 6f22402e-c0cc-49cf-b702-eaf0cd5ea7d1  ethernet  enp8s0
Example 6f22402e-c0cc-49cf-b702-eaf0cd5ea7d1  ethernet  enp9s0
```
6.16. CONFIGURING A SINGLE CONNECTION PROFILE FOR MULTIPLE ETHERNET INTERFACES USING PCI IDS

The PCI ID is a unique identifier of the devices connected to the system. The connection profile adds multiple devices by matching interfaces based on a list of PCI IDs. You can use this procedure to connect multiple device PCI IDs to the single connection profile.

Prerequisites

- DHCP server is available in the network
- The host has multiple Ethernet adapters
- No connection profile exists on system

Procedure

1. Identify the device path. For example, to display the device paths of all interfaces starting with `enp`, enter:

   ```bash
   udevadm info /sys/class/net/enp* | grep ID_PATH=
   ...
   E: ID_PATH=pci-0000:07:00.0
   E: ID_PATH=pci-0000:08:00.0
   ```

2. Add a connection profile that applies to all PCI IDs matching the `0000:00:0[7-8].0` expression:

   ```bash
   nmcli connection add type ethernet connection.multi-connect multiple match.path "pci-0000:07:00.0 pci-0000:08:00.0" con-name Example
   ```

Verification steps

1. Display the status of the connection:

   ```bash
   nmcli connection show
   ```

<table>
<thead>
<tr>
<th>NAME</th>
<th>UUID</th>
<th>TYPE</th>
<th>DEVICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>9cee0958-512f-4203-9d3d-b57af1d88466</td>
<td>ethernet</td>
<td>enp7s0</td>
</tr>
<tr>
<td>Example</td>
<td>9cee0958-512f-4203-9d3d-b57af1d88466</td>
<td>ethernet</td>
<td>enp8s0</td>
</tr>
</tbody>
</table>
   
2. To display all settings of the connection profile:

   ```bash
   nmcli connection show Example
   ```
This connection profile uses all devices with a PCI ID which match the pattern in the `match.path` parameter and, therefore, the connection profiles have the same Universally Unique Identifier (UUID).

**Additional resources**

- **nmcli(1)** man page
- **nm-settings(5)** man page
CHAPTER 7. MANAGING WI-FI CONNECTIONS

This section describes how to configure and manage Wi-Fi connections.

7.1. SETTING THE WIRELESS REGULATORY DOMAIN

In Red Hat Enterprise Linux, the `crda` package contains the Central Regulatory Domain Agent that provides the kernel with the wireless regulatory rules for a given jurisdiction. It is used by certain `udev` scripts and should not be run manually unless debugging `udev` scripts. The kernel runs `crda` by sending a `udev` event upon a new regulatory domain change. Regulatory domain changes are triggered by the Linux wireless subsystem (IEEE-802.11). This subsystem uses the `regulatory.bin` file to keep its regulatory database information.

The `setregdomain` utility sets the regulatory domain for your system. `Setregdomain` takes no arguments and is usually called through system script such as `udev` rather than manually by the administrator. If a country code look-up fails, the system administrator can define the `COUNTRY` environment variable in the `/etc/sysconfig/regdomain` file.

Additional resources

- `setregdomain(1)` man page
- `crda(8)` man page
- `regulatory.bin(5)` man page
- `iw(8)` man page

7.2. CONFIGURING A WI-FI CONNECTION USING NMCLI

This procedure describes how to configure a Wi-fi connection profile using `nmcli`.

Prerequisites

- The `nmcli` utility to be installed.
- Make sure that the WiFi radio is on (default):

  ```
  $ nmcli radio wifi on
  ```

Procedure

1. To create a Wi-Fi connection profile with static IP configuration:

  ```
  $ nmcli con add con-name MyCafe ifname wlan0 type wifi ssid MyCafe ip4 192.0.2.101/24 gw4 192.0.2.1
  ```

2. Set a DNS server. For example, to set `192.0.2.1` as the DNS server:

  ```
  $ nmcli con modify con-name MyCafe ipv4.dns "192.0.2.1"
  ```

3. Optionally, set a DNS search domain. For example, to set the search domain to `example.com`:
$ nmcli con modify con-name MyCafe ipv4.dns-search "example.com"

4. To check a specific property, for example `mtu`:

$ nmcli connection show id MyCafe | grep mtu
  802-11-wireless.mtu: auto

5. To change the property of a setting:

$ nmcli connection modify id MyCafe wireless.mtu 1350

6. To verify the change:

$ nmcli connection show id MyCafe | grep mtu
  802-11-wireless.mtu: 1350

Verification steps

1. Use the `ping` utility to verify that this host can send packets to other hosts.
   - Ping an IP address in the same subnet. For example:

     # ping 192.0.2.103

     If the command fails, verify the IP and subnet settings.

   - Ping an IP address in a remote subnet. For example:

     # ping 198.51.16.3

     - If the command fails, ping the default gateway to verify settings.

     # ping 192.0.2.1

2. Use the `host` utility to verify that name resolution works. For example:

   # host client.example.com

   If the command returns any error, such as `connection timed out` or `no servers could be reached`, verify your DNS settings.

Additional resources

- `nm-settings(5)` man page
- `NetworkManager duplicates a connection after restart of NetworkManager service`.

### 7.3. Configuring a Wi-Fi Connection Using Control-Center

When you connect to a **Wi-Fi**, the network settings are prefilled depending on the current network connection. This means that the settings will be detected automatically when the interface connects to a network.
This procedure describes how to use control-center to manually configure the Wi-Fi settings.

Procedure

1. Press the Super key to enter the Activities Overview, type Wi-Fi and press Enter. In the left-hand-side menu entry you see the list of available networks.

2. Select the gear wheel icon to the right of the Wi-Fi connection name that you want to edit, and the editing connection dialog appears. The Details menu window shows the connection details where you can make further configuration.

Options

a. If you select Connect automatically, NetworkManager auto-connects to this connection whenever NetworkManager detects that it is available. If you do not want NetworkManager to connect automatically, clear the check box. Note that when the check box is clear, you have to select that connection manually in the network connection icon’s menu to cause it to connect.

b. To make a connection available to other users, select the Make available to other users check box.

c. You can also control the background data usage by changing the Restrict background data usage option.

NOTE

To delete a Wi-Fi connection, click the Forget Connection red box.

3. Select the Identity menu entry to see the basic configuration options.

SSID – The Service Set Identifier (SSID) of the access point (AP).

BSSID – The Basic Service Set Identifier (BSSID) is the MAC address, also known as a hardware address, of the specific wireless access point you are connecting to when in Infrastructure mode. This field is blank by default, and you are able to connect to a wireless access point by SSID without having to specify its BSSID. If the BSSID is specified, it will force the system to associate to a specific access point only. For ad-hoc networks, the BSSID is generated randomly by the mac80211 subsystem when the ad-hoc network is created. It is not displayed by NetworkManager.

MAC address – The MAC address allows you to associate a specific wireless adapter with a specific connection (or connections).

Cloned Address – A cloned MAC address to use in place of the real hardware address. Leave blank unless required.

4. For further IP address configuration, select the IPv4 and IPv6 menu entries.

By default, both IPv4 and IPv6 are set to automatic configuration depending on current network settings. This means that addresses such as the local IP address, DNS address, and other settings will be detected automatically when the interface connects to a network. If a DHCP server assigns the IP configuration in this network, this is sufficient, but you can also provide static configuration in the IPv4 and IPv6 Settings. In the IPv4 and IPv6 menu entries, you can see the following settings:

- IPv4 Method
- **Automatic (DHCP)** — Choose this option if the network you are connecting to uses Router Advertisements (RA) or a DHCP server to assign dynamic IP addresses. You can see the assigned IP address in the Details menu entry.

- **Link-Local Only** — Choose this option if the network you are connecting to does not have a DHCP server and you do not want to assign IP addresses manually. Random addresses will be assigned as per RFC 3927 with prefix 169.254/16.

- **Manual** — Choose this option if you want to assign IP addresses manually.

- **Disable** — IPv4 is disabled for this connection.

- **DNS**
  - If **Automatic** is ON, and no DHCP server is available that assigns DNS servers to this connection, switch it to **OFF** to enter the IP address of a DNS server separating the IPs by comma.

- **Routes**
  - Note that in the Routes section, when **Automatic** is ON, routes from Router Advertisements (RA) or DHCP are used, but you can also add additional static routes. When **OFF**, only static routes are used.
    - **Address** — Enter the IP address of a remote network, sub-net, or host.
    - **Netmask** — The netmask or prefix length of the IP address entered above.
    - **Gateway** — The IP address of the gateway leading to the remote network, sub-net, or host entered above.
    - **Metric** — A network cost, a preference value to give to this route. Lower values will be preferred over higher values.

- **Use this connection only for resources on its network**
  - Select this check box to prevent the connection from becoming the default route.

Alternatively, to configure IPv6 settings in a Wi-Fi connection, select the IPv6 menu entry:

- **IPv6 Method**
  - **Automatic** — Choose this option to use IPv6 Stateless Address AutoConfiguration (SLAAC) to create an automatic, stateless configuration based on the hardware address and Router Advertisements (RA).
  - **Automatic, DHCP only** — Choose this option to not use RA, but request information from DHCPv6 directly to create a stateful configuration.
  - **Link-Local Only** — Choose this option if the network you are connecting to does not have a DHCP server and you do not want to assign IP addresses manually. Random addresses will be assigned as per RFC 4862 with prefix FE80::0.
  - **Manual** — Choose this option if you want to assign IP addresses manually.
  - **Disable** — IPv6 is disabled for this connection.

- The DNS, Routes, Use this connection only for resources on its network fields are common to IPv4 settings.

5. To configure Security settings in a Wi-Fi connection, select the Security menu entry.
WARNING

Do not connect to Wi-Fi networks without encryption or which support only the insecure WEP or WPA standards.

The following configuration options are available:

- **Security**
  - **None** – Encryption is disabled, and data is transferred in plain text over the network.
  - **WEP 40/128-bit Key** – Wired Equivalent Privacy (WEP), from the IEEE 802.11 standard. Uses a single pre-shared key (PSK).
  - **WEP 128-bit Passphrase** – An MD5 hash of the passphrase to derive a WEP key.
  - **Dynamic WEP (802.1X)** – WEP keys are changed dynamically.
  - **LEAP** – Lightweight Extensible Authentication Protocol, from Cisco Systems.
  - **WPA & WPA2 Personal** – Wi-Fi Protected Access (WPA), from the draft IEEE 802.11i standard. Wi-Fi Protected Access 2 (WPA2), from the 802.11i-2004 standard. Personal mode uses a pre-shared key (WPA-PSK).
  - **WPA & WPA2 Enterprise** – WPA and WPA 2 for use with a RADIUS authentication server to provide IEEE 802.1X network access control.
  - **WPA3 Personal** – Wi-Fi Protected Access 3 (WPA3) Personal uses Simultaneous Authentication of Equals (SAE) instead of pre-shared keys (PSK) to prevent dictionary attacks. WPA3 uses perfect forward secrecy.

- **Password** – Enter the password to be used in the authentication process.

6. Once you have finished the configuration, click the **Apply** button to save it.

**NOTE**

When you add a new connection by clicking the **plus** button, **NetworkManager** creates a new configuration file for that connection and then opens the same dialog that is used for editing an existing connection. The difference between these dialogs is that an existing connection profile has a **Details** menu entry.

### 7.4. CONNECTING TO A WI-FI NETWORK WITH NMCLI

This procedure describes how to connect to a **wireless** connection using the **nmcli** utility.

**Prerequisites**

- The **nmcli** utility to be installed.
- Make sure that the WiFi radio is on (default):
$ nmcli radio wifi on

Procedure

1. To refresh the available Wi-Fi connection list:

   $ nmcli device wifi rescan

2. To view the available Wi-Fi access points:

   $ nmcli dev wifi list

   IN-USE  SSID      MODE   CHAN   RATE     SIGNAL   BARS  SECURITY
   ...
   MyCafe    Infra 3  405 Mbit/s  85  ▂▄▆█ WPA1 WPA2

3. To connect to a Wi-Fi connection using nmcli:

   $ nmcli dev wifi connect SSID-Name password wireless-password

   For example:

   $ nmcli dev wifi connect MyCafe password wireless-password

   Note that if you want to disable the Wi-Fi state:

   $ nmcli radio wifi off

7.5. CONNECTING TO A HIDDEN WI-FI NETWORK USING NMCLI

All access points have a Service Set Identifier (SSID) to identify them. However, an access point may be configured not to broadcast its SSID, in which case it is hidden, and will not show up in NetworkManager's list of Available networks.

This procedure shows how you can connect to a hidden network using the nmcli tool.

Prerequisites

- The nmcli utility to be installed.
- To know the SSID, and password of the Wi-Fi connection.
- Make sure that the WiFi radio is on (default):

  $ nmcli radio wifi on

Procedure

- Connect to the SSID that is hidden:

  $ nmcli dev wifi connect SSID_Name password wireless_password hidden yes
7.6. CONNECTING TO A WI-FI NETWORK USING THE Gnome GUI

This procedure describes how you can connect to a wireless network to get access to the Internet.

Procedure

1. Open the Gnome Shell network connection icon menu from the top right-hand corner of the screen.
2. Select Wi-Fi Not Connected.
3. Click the Select Network option.
4. Click the name of the network to which you want to connect, and then click Connect.
   Note that if you do not see the network, the network might be hidden.
5. If the network is protected by a password or encryption keys are required, enter the password and click Connect.
   Note that if you do not know the password, contact the administrator of the Wi-Fi network.
6. If the connection is successful, the name of the network is visible in the connection icon menu and the wireless indicator is on the top right-hand corner of the screen.

Additional resources

- Configuring a Wi-Fi connection using the control center.

7.7. CONFIGURING 802.1X NETWORK AUTHENTICATION ON AN EXISTING WI-FI CONNECTION USING NMCLI

Using the nmcli utility, you can configure the client to authenticate itself to the network. This procedure describes how to configure Protected Extensible Authentication Protocol (PEAP) authentication with the Microsoft Challenge-Handshake Authentication Protocol version 2 (MSCHAPv2) in an existing NetworkManager Wi-Fi connection profile named wlp1s0.

Prerequisites

1. The network must have 802.1X network authentication.
2. The Wi-Fi connection profile exists in NetworkManager and has a valid IP configuration.
3. If the client is required to verify the certificate of the authenticator, the Certificate Authority (CA) certificate must be stored in the /etc/pki/ca-trust/source/anchors/ directory.
4. The wpa_supplicant package is installed.

Procedure

1. Set the Wi-Fi security mode to wpa-eap, the Extensible Authentication Protocol (EAP) to peap, the inner authentication protocol to mschapv2, and the user name:

```bash
# nmcli connection modify wlp1s0 wireless-security.key-mgmt wpa-eap 802-1x.eap peap 802-1x.phase2-auth mschapv2 802-1x.identity user_name
```
Note that you must set the `wireless-security.key-mgmt, 802-1x.eap, 802-1x.phase2-auth, and 802-1x.identity` parameters in a single command.

2. Optionally, store the password in the configuration:

   ```bash
   # nmcli connection modify wpl1s0 802-1x.password password
   ```

   **IMPORTANT**

   By default, NetworkManager stores the password in clear text in the `~/.sysconfig/network-scripts/keys-connection_name` file, that is readable only by the root user. However, clear text passwords in a configuration file can be a security risk.

   To increase the security, set the `802-1x.password-flags` parameter to `0x1`. With this setting, on servers with the GNOME desktop environment or the `nm-applet` running, NetworkManager retrieves the password from these services. In other cases, NetworkManager prompts for the password.

3. If the client is required to verify the certificate of the authenticator, set the `802-1x.ca-cert` parameter in the connection profile to the path of the CA certificate:

   ```bash
   # nmcli connection modify wpl1s0 802-1x.ca-cert /etc/pki/ca-trust/source/anchors/ca.crt
   ```

   **NOTE**

   For security reasons, Red Hat recommends using the certificate of the authenticator to enable clients to validate the identity of the authenticator.

4. Activate the connection profile:

   ```bash
   # nmcli connection up wpl1s0
   ```

**Verification steps**

- Access resources on the network that require network authentication.

**Additional resources**

- Managing Wi-Fi connections
- The `802-1x settings` section in the `nm-settings(5)` man page
- `nmcli(1)` man page
CHAPTER 8. CONFIGURING VLAN TAGGING

This section describes how to configure Virtual Local Area Network (VLAN). A VLAN is a logical network within a physical network. The VLAN interface tags packets with the VLAN ID as they pass through the interface, and removes tags of returning packets.

You create a VLAN interface on top of another interface, such as an Ethernet, bond, team, or bridge device. This interface is called the parent interface.

8.1. CONFIGURING VLAN TAGGING USING NMCLI COMMANDS

This section describes how to configure Virtual Local Area Network (VLAN) tagging using the nmcli utility.

Prerequisites

- The interface you plan to use as a parent to the virtual VLAN interface supports VLAN tags.
- If you configure the VLAN on top of a bond interface:
  - The ports of the bond are up.
  - The bond is not configured with the fail_over_mac=follow option. A VLAN virtual device cannot change its MAC address to match the parent’s new MAC address. In such a case, the traffic would still be sent with the then incorrect source MAC address.
  - The bond is usually not expected to get IP addresses via DHCP or IPv6 autoconfiguration. Ensure it by setting ipv4.method=disable and ipv6.method=ignore options while creating a bond; otherwise if DHCP/IPv6-autoconf fails after some time, the interface might be brought down.
  - The switch the host is connected to is configured to support VLAN tags. For details, see the documentation of your switch.

Procedure

1. Display the network interfaces:

   ```
   # nmcli device status
   DEVICE   TYPE      STATE         CONNECTION
   enp1s0   ethernet  disconnected  enp1s0
   bridge0  bridge    connected     bridge0
   bond0    bond      connected     bond0
   ...
   ```

2. Create the VLAN interface. For example, to create a VLAN interface named vlan10 that uses enp1s0 as its parent interface and that tags packets with VLAN ID 10, enter:

   ```
   # nmcli connection add type vlan con-name vlan10 ifname vlan10 vlan.parent enp1s0 vlan.id 10
   ```

   Note that the VLAN must be within the range from 0 to 4094.

3. By default, the VLAN connection inherits the maximum transmission unit (MTU) from the parent interface. Optionally, set a different MTU value:
4. Configure the IP settings of the VLAN device. Skip this step if you want to use this VLAN device as a port of other devices.
   a. Configure the IPv4 settings. For example, to set a static IPv4 address, network mask, default gateway, and DNS server to the `vlan10` connection, enter:

   ```
   # nmcli connection modify vlan10 ipv4.addresses '192.0.2.1/24'
   # nmcli connection modify vlan10 ipv4.gateway '192.0.2.254'
   # nmcli connection modify vlan10 ipv4.dns '192.0.2.253'
   # nmcli connection modify vlan10 ipv4.method manual
   ```

   b. Configure the IPv6 settings. For example, to set a static IPv6 address, network mask, default gateway, and DNS server to the `vlan10` connection, enter:

   ```
   # nmcli connection modify vlan10 ipv6.addresses '2001:db8:1::1/32'
   # nmcli connection modify vlan10 ipv6.gateway '2001:db8:1::fffe'
   # nmcli connection modify vlan10 ipv6.dns '2001:db8:1::fffd'
   # nmcli connection modify vlan10 ipv6.method manual
   ```

5. Activate the connection:

   ```
   # nmcli connection up vlan10
   ```

### Verification steps

1. Verify the settings:

   ```
   # ip -d addr show vlan10
   4: vlan10@enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue
   state UP group default qlen 1000
   link/ether 52:54:00:72:2f:6e brd ff:ff:ff:ff:ff:ff promiscuity 0
   vlan protocol 802.1Q id 10 <REORDER_HDR> numtxqueues 1 numrxqueues 1
   gso_max_size 65536 gso_max_segs 65535
   inet 192.0.2.1/24 brd 192.0.2.255 scope global noprefixroute vlan10
      valid_lft forever preferred_lft forever
   inet6 2001:db8:1::1/32 scope global noprefixroute
      valid_lft forever preferred_lft forever
   inet6 fe80::8dd7:9030:6f8e:89e6/64 scope link noprefixroute
      valid_lft forever preferred_lft forever
   ```

### Additional resources

- Testing basic network settings.
- Configuring NetworkManager to avoid using a specific profile to provide a default gateway .
- `nmcli-examples(7)` man page
- The `vlan setting` section in the `nm-settings(5)` man page
8.2. CONFIGURING VLAN TAGGING USING NM-CONNECTION-EDITOR

This section describes how to configure Virtual Local Area Network (VLAN) tagging using the `nm-connection-editor` application.

Prerequisites

- The interface you plan to use as a parent to the virtual VLAN interface supports VLAN tags.
- If you configure the VLAN on top of a bond interface:
  - The ports of the bond are up.
  - The bond is not configured with the `fail_over_mac=follow` option. A VLAN virtual device cannot change its MAC address to match the parent’s new MAC address. In such a case, the traffic would still be sent with the then incorrect source MAC address.
- The switch the host is connected to is configured to support VLAN tags. For details, see the documentation of your switch.

Procedure

1. Open a terminal, and enter `nm-connection-editor`:

   ```
   $ nm-connection-editor
   ```

2. Click the + button to add a new connection.

3. Select the VLAN connection type, and click Create.

4. On the VLAN tab:
   a. Select the parent interface.
   b. Select the VLAN id. Note that the VLAN must be within the range from 0 to 4094.
   c. By default, the VLAN connection inherits the maximum transmission unit (MTU) from the parent interface. Optionally, set a different MTU value.
   d. Optionally, set the name of the VLAN interface and further VLAN-specific options.
5. Configure the IP settings of the VLAN device. Skip this step if you want to use this VLAN device as a port of other devices.

a. On the IPv4 Settings tab, configure the IPv4 settings. For example, set a static IPv4 address, network mask, default gateway, and DNS server:
b. On the IPv6 Settings tab, configure the IPv6 settings. For example, set a static IPv6 address, network mask, default gateway, and DNS server.

6. Click Save to save the VLAN connection.

Verification steps

1. Verify the settings:

```
# ip -d addr show vlan10
4: vlan10@enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue
    state UP group default qlen 1000
    link/ether 52:54:00:d5:e0:fb brd ff:ff:ff:ff:ff:ff promiscuity 0
    vlan protocol 802.1Q id 10 <REORDER_HDR> numtxqueues 1 numrxqueues 1
    gso_max_size 65536 gso_max_segs 65535
    inet 192.0.2.1/24 brd 192.0.2.255 scope global noprefixroute vlan10
      valid_lft forever preferred_lft forever
    inet6 2001:db8:1::1/32 scope global noprefixroute
      valid_lft forever preferred_lft forever
    inet6 fe80::8dd7:9030:6f8e:89e6/64 scope link noprefixroute
      valid_lft forever preferred_lft forever
```

Additional resources

- Testing basic network settings.
- Configuring NetworkManager to avoid using a specific profile to provide a default gateway.

8.3. CONFIGURING VLAN TAGGING USING NMSTATECTL

This section describes how to use the nmstatectl utility to configure a VLAN with ID 10 that uses an Ethernet connection. As the child device, the VLAN connection contains the IP, default gateway, and DNS configurations.
Depending on your environment, adjust the YAML file accordingly. For example, to use a bridge, or bond device in the VLAN, adapt the `base-iface` attribute and `type` attributes of the ports you use in the VLAN.

**Prerequisites**

- To use Ethernet devices as ports in the VLAN, the physical or virtual Ethernet devices must be installed on the server.
- The `nmstate` package is installed.

**Procedure**

1. Create a YAML file, for example `~/create-vlan.yml`, with the following contents:

```yaml
---
interfaces:
- name: vlan10
  type: vlan
  state: up
  ipv4:
    enabled: true
    address:
      - ip: 192.0.2.1
        prefix-length: 24
        dhcp: false
  ipv6:
    enabled: true
    address:
      - ip: 2001:db8:1::1
        prefix-length: 64
        autoconf: false
        dhcp: false
  vlan:
    base-iface: enp1s0
    id: 10
- name: enp1s0
  type: ethernet
  state: up
routes:
  config:
    - destination: 0.0.0.0/0
      next-hop-address: 192.0.2.254
      next-hop-interface: vlan10
    - destination: ::/0
      next-hop-address: 2001:db8:1::fffe
      next-hop-interface: vlan10
dns-resolver:
  config:
    search:
      - example.com
    server:
      - 192.0.2.200
      - 2001:db8:1::ffbb
```
2. Apply the settings to the system:

```
# nmstatectl apply ~/create-vlan.yml
```

Verification steps

1. Display the status of the devices and connections:

```
# nmcli device status
DEVICE      TYPE      STATE      CONNECTION
vlan10      vlan      connected  vlan10
```

2. Display all settings of the connection profile:

```
# nmcli connection show vlan10
connection.id:     vlan10
connection.uuid:   1722970f-788e-4f81-bd7d-a86bf21c9df5
connection.stable-id:  --
connection.type:    vlan
connection.interface-name:  vlan10
...
```

3. Display the connection settings in YAML format:

```
# nmstatectl show vlan0
```

Additional resources

- `nmstatectl(8)` man page
- `/usr/share/doc/nmstate/examples/`

### 8.4. CONFIGURING VLAN TAGGING USING RHEL SYSTEM ROLE

You can use the Networking RHEL System Role to configure VLAN tagging. This procedure describes how to add an Ethernet connection and a VLAN with ID 10 on top of this Ethernet connection. As the child device, the VLAN connection contains the IP, default gateway, and DNS configurations.

Depending on your environment, adjust the play accordingly. For example:

- To use the VLAN as a port in other connections, such as a bond, omit the `ip` attribute, and set the IP configuration in the child configuration.

- To use team, bridge, or bond devices in the VLAN, adapt the `interface_name` and `type` attributes of the ports you use in the VLAN.

**Prerequisites**

- The `ansible-core` and `rhel-system-roles` packages are installed on the control node.

- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.
Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/.vlan-ethernet.yml` playbook with the following content:

   ```
   ---
   - name: Configure a VLAN that uses an Ethernet connection
     hosts: node.example.com
     become: true
     tasks:
       - include_role:
           name: rhel-system-roles.network
     vars:
       network_connections:
         # Add an Ethernet profile for the underlying device of the VLAN
         - name: enp1s0
           type: ethernet
           interface_name: enp1s0
           autoconnect: yes
           state: up
           ip:
             dhcp4: no
             auto6: no
         # Define the VLAN profile
         - name: enp1s0.10
           type: vlan
           ip:
             address:
               - "192.0.2.1/24"
               - "2001:db8:1::1/64"
           gateway4: 192.0.2.254
           gateway6: 2001:db8:1::ffe
           dns:
             - 192.0.2.200
             - 2001:db8:1::ffbb
           dns_search:
             - example.com
           vlan_id: 10
           parent: enp1s0
           state: up
   ```

   The `parent` attribute in the VLAN profile configures the VLAN to operate on top of the `enp1s0` device.

3. Run the playbook:

   - To connect as `root` user to the managed host, enter:

     ```
     # ansible-playbook -u root ~/.vlan-ethernet.yml
     ```
To connect as a user to the managed host, enter:

```bash
# ansible-playbook -u user_name --ask-become-pass ~/vlan-ethernet.yml
```

The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file
- `ansible-playbook(1)` man page
CHAPTER 9. USING A VXLAN TO CREATE A VIRTUAL LAYER-2 DOMAIN FOR VMS

A virtual extensible LAN (VXLAN) is a networking protocol that tunnels layer-2 traffic over an IP network using the UDP protocol. For example, certain virtual machines (VMs), that are running on different hosts can communicate over a VXLAN tunnel. The hosts can be in different subnets or even in different data centers around the world. From the perspective of the VMs, other VMs in the same VXLAN are within the same layer-2 domain.

This documentation describes how to configure a VXLAN on RHEL hosts, which is invisible to the VMs:

In this example, RHEL-host-A and RHEL-host-B use a bridge, br0, to connect the virtual network of a VM on each host with a VXLAN named vxlan10. Due to this configuration, the VXLAN is invisible to the VMs, and the VMs do not require any special configuration. If you later connect more VMs to the same virtual network, the VMs are automatically members of the same virtual layer-2 domain.

**IMPORTANT**

Just as normal layer-2 traffic, data in a VXLAN is not encrypted. For security reasons, use a VXLAN over a VPN or other types of encrypted connections.

### 9.1. BENEFITS OF VXLANS

A virtual extensible LAN (VXLAN) provides the following major benefits:

- VXLANs use a 24-bit ID. Therefore, you can create up to 16,777,216 isolated networks. For example, a virtual LAN (VLAN), supports only 4,096 isolated networks.

- VXLANs use the IP protocol. This enables you to route the traffic and virtually run systems in different networks and locations within the same layer-2 domain.

- Unlike most tunnel protocols, a VXLAN is not only a point-to-point network. A VXLAN can learn the IP addresses of the other endpoints either dynamically or use statically-configured forwarding entries.
• Certain network cards support UDP tunnel-related offload features.

Additional resources

• /usr/share/doc/kernel-doc-<kernel_version>/Documentation/networking/vxlan.rst provided by the kernel-doc package

9.2. CONFIGURING THE ETHERNET INTERFACE ON THE HOSTS

To connect a RHEL VM host to the Ethernet, create a network connection profile, configure the IP settings, and activate the profile.

Run this procedure on both RHEL hosts, and adjust the IP address configuration accordingly.

Prerequisites

• The host is connected to the Ethernet hosts.

Procedure

1. Add a new Ethernet connection profile to NetworkManager:

```
# nmcli connection add con-name Example ifname enp1s0 type ethernet
```

2. Configure the IPv4 settings:

```
# nmcli connection modify Example ipv4.addresses 198.51.100.2/24 ipv4.method manual ipv4.gateway 198.51.100.254 ipv4.dns 198.51.100.200 ipv4.dns-search example.com
```

Skip this step if the network uses DHCP.

3. Activate the Example connection:

```
# nmcli connection up Example
```

Verification

1. Display the status of the devices and connections:

```
# nmcli device status
DEVICE      TYPE      STATE      CONNECTION
enp1s0      ethernet  connected  Example
```

2. Ping a host in a remote network to verify the IP settings:

```
# ping RHEL-host-B.example.com
```

Note that you cannot ping the other VM host before you have configured the network on that host as well.

Additional resources
9.3. CREATING A NETWORK BRIDGE WITH A VXLAN ATTACHED

To make a virtual extensible LAN (VXLAN) invisible to virtual machines (VMs), create a bridge on a host, and attach the VXLAN to the bridge. Use NetworkManager to create both the bridge and the VXLAN. You do not add any traffic access point (TAP) devices of the VMs, typically named `vnet*` on the host, to the bridge. The `libvirtd` service adds them dynamically when the VMs start.

Run this procedure on both RHEL hosts, and adjust the IP addresses accordingly.

**Procedure**

1. Create the bridge `br0`:

   ```
   # nmcli connection add type bridge con-name br0 ifname br0 ipv4.method disabled ipv6.method disabled
   ```

   This command sets no IPv4 and IPv6 addresses on the bridge device, because this bridge works on layer 2.

2. Create the VXLAN interface and attach it to `br0`:

   ```
   # nmcli connection add type vxlan slave-type bridge con-name br0-vxlan10 ifname vxlan10 id 10 local 198.51.100.2 remote 203.0.113.1 master br0
   ```

   This command uses the following settings:
   - **id 10**: Sets the VXLAN identifier.
   - **local 198.51.100.2**: Sets the source IP address of outgoing packets.
   - **remote 203.0.113.1**: Sets the unicast or multicast IP address to use in outgoing packets when the destination link layer address is not known in the VXLAN device forwarding database.
   - **master br0**: Sets this VXLAN connection to be created as a port in the `br0` connection.

   By default, NetworkManager uses 8472 as the destination port. If the destination port is different, additionally, pass the `destination-port <port_number>` option to the command.

3. Activate the `br0` connection profile:

   ```
   # nmcli connection up br0
   ```

4. Open port 8472 for incoming UDP connections in the local firewall:

   ```
   # firewall-cmd --permanent --add-port=8472/udp
   # firewall-cmd --reload
   ```

**Verification**
Display the forwarding table:

```
# bridge fdb show dev vxlan10
2a:53:bd:d5:b3:0a master br0 permanent
00:00:00:00:00:00 dst 203.0.113.1 self permanent
...
```

Additional resources

- nm-settings(5)

9.4. CREATING A VIRTUAL NETWORK IN LIBVIRT WITH AN EXISTING BRIDGE

To enable virtual machines (VM) to use the br0 bridge with the attached virtual extensible LAN (VXLAN), first add a virtual network to the libvirtd service that uses this bridge.

Prerequisites

- You installed the libvirt package.
- You started and enabled the libvirtd service.
- You configured the br0 device with the VXLAN on RHEL.

Procedure

1. Create the `~/vxlan10-bridge.xml` file with the following content:

   ```xml
   <network>
   <name>vxlan10-bridge</name>
   <forward mode="bridge" />
   <bridge name="br0" />
   </network>
   ```

2. Use the `~/vxlan10-bridge.xml` file to create a new virtual network in libvirt:

   ```
   # virsh net-define ~/vxlan10-bridge.xml
   ```

3. Remove the `~/vxlan10-bridge.xml` file:

   ```
   # rm ~/vxlan10-bridge.xml
   ```

4. Start the vxlan10-bridge virtual network:

   ```
   # virsh net-start vxlan10-bridge
   ```

5. Configure the vxlan10-bridge virtual network to start automatically when the libvirtd service starts:

   ```
   # virsh net-autostart vxlan10-bridge
   ```
9.5. CONFIGURING VIRTUAL MACHINES TO USE VXLAN

To configure a VM to use a bridge device with an attached virtual extensible LAN (VXLAN) on the host, create a new VM that uses the `vxlan10-bridge` virtual network or update the settings of existing VMs to use this network.

Perform this procedure on the RHEL hosts.

Prerequisites

- You configured the `vxlan10-bridge` virtual network in `libvirtd`.

Procedure

- To create a new VM and configure it to use the `vxlan10-bridge` network, pass the `--network network:vxlan10-bridge` option to the `virt-install` command when you create the VM:

  ```
  # virt-install ... --network network:vxlan10-bridge
  ```

- To change the network settings of an existing VM:
  a. Connect the VM’s network interface to the `vxlan10-bridge` virtual network:

  ```
  # virt-xml VM_name --edit --network network=vxlan10-bridge
  ```

  b. Shut down the VM, and start it again:

  ```
  # virsh shutdown VM_name
  # virsh start VM_name
  ```

Verification

1. Display the virtual network interfaces of the VM on the host:

  ```
  # virsh domiflist VM_name
  Interface Type Source    Model   MAC
  -------------------------
  vnet1 bridge vxlan10-bridge virtio 52:54:00:c5:98:1c
  ```
2. Use the `brctl` utility, provided by the `bridge-utils` package, to display the bridges configured on the host and their attached interfaces:

```bash
# brctl show
bridge name bridge id  STP enabled interfaces
br0  8000.9270aef5b21e yes vnet1
     vxlan10
```

Note that the `libvirtd` service dynamically updates the bridge’s configuration. When you start a VM which uses the `vxlan10-bridge` network, the corresponding `vnet*` device on the host appears as a port of the bridge.

3. Use address resolution protocol (ARP) requests to verify whether VMs are in the same VXLAN:
   a. Start two or more VMs in the same VXLAN.
   b. Send an ARP request from one VM to the other one:

```bash
# arping -c 1 192.0.2.2
ARPING 192.0.2.2 from 192.0.2.1 enp1s0
Unicast reply from 192.0.2.2 [52:54:00:c5:98:1c] 1.450ms
Sent 1 probe(s) (0 broadcast(s))
Received 1 response(s) (0 request(s), 0 broadcast(s))
```

If the command shows a reply, the VM is in the same layer-2 domain and, in this case in the same VXLAN.

Install the `iputils` package to use the `arping` utility.

CHAPTER 10. CONFIGURING A NETWORK BRIDGE

A network bridge is a link-layer device which forwards traffic between networks based on a table of MAC addresses. The bridge builds the MAC addresses table by listening to network traffic and thereby learning what hosts are connected to each network. For example, you can use a software bridge on a Red Hat Enterprise Linux host to emulate a hardware bridge or in virtualization environments, to integrate virtual machines (VM) to the same network as the host.

A bridge requires a network device in each network the bridge should connect. When you configure a bridge, the bridge is called `controller` and the devices it uses `ports`.

You can create bridges on different types of devices, such as:

- Physical and virtual Ethernet devices
- Network bonds
- Network teams
- VLAN devices

Due to the IEEE 802.11 standard which specifies the use of 3-address frames in Wi-Fi for the efficient use of airtime, you cannot configure a bridge over Wi-Fi networks operating in Ad-Hoc or Infrastructure modes.

10.1. CONFIGURING A NETWORK BRIDGE USING NMCLI COMMANDS

This section explains how to configure a network bridge using the `nmcli` utility.

**Prerequisites**

- Two or more physical or virtual network devices are installed on the server.
- To use Ethernet devices as ports of the bridge, the physical or virtual Ethernet devices must be installed on the server.
- To use team, bond, or VLAN devices as ports of the bridge, you can either create these devices while you create the bridge or you can create them in advance as described in:
  - Configuring a network team using nmcli commands
  - Configuring a network bridge using nmcli commands
  - Configuring VLAN tagging using nmcli commands

**Procedure**

1. Create a bridge interface:

   ```
   # nmcli connection add type bridge con-name bridge0 ifname bridge0
   ```

   This command creates a bridge named `bridge0`, enter:

2. Display the network interfaces, and note the names of the interfaces you want to add to the bridge:
In this example:

- **enp7s0** and **enp8s0** are not configured. To use these devices as ports, add connection profiles in the next step.

- **bond0** and **bond1** have existing connection profiles. To use these devices as ports, modify their profiles in the next step.

3. Assign the interfaces to the bridge.

   a. If the interfaces you want to assign to the bridge are not configured, create new connection profiles for them:

   ```
   # nmcli connection add type ethernet slave-type bridge con-name bridge0-port1
   ifname enp7s0 master bridge0
   # nmcli connection add type ethernet slave-type bridge con-name bridge0-port2
   ifname enp8s0 master bridge0
   ```

   These commands create profiles for **enp7s0** and **enp8s0**, and add them to the **bridge0** connection.

   b. If you want to assign an existing connection profile to the bridge, set the **master** parameter of these connections to **bridge0**:

   ```
   # nmcli connection modify bond0 master bridge0
   # nmcli connection modify bond1 master bridge0
   ```

   These commands assign the existing connection profiles named **bond0** and **bond1** to the **bridge0** connection.

4. Configure the IP settings of the bridge. Skip this step if you want to use this bridge as a ports of other devices.

   a. Configure the IPv4 settings. For example, to set a static IPv4 address, network mask, default gateway, DNS server, and DNS search domain of the **bridge0** connection, enter:

   ```
   # nmcli connection modify bridge0 ipv4.addresses '192.0.2.1/24'
   # nmcli connection modify bridge0 ipv4.gateway '192.0.2.254'
   # nmcli connection modify bridge0 ipv4.dns '192.0.2.253'
   # nmcli connection modify bridge0 ipv4.dns-search 'example.com'
   # nmcli connection modify bridge0 ipv4.method manual
   ```

   b. Configure the IPv6 settings. For example, to set a static IPv6 address, network mask, default gateway, DNS server, and DNS search domain of the **bridge0** connection, enter:

   ```
   # nmcli connection modify bridge0 ipv6.addresses '2001:db8:1::1/64'
   # nmcli connection modify bridge0 ipv6.gateway '2001:db8:1::fffe'
   # nmcli connection modify bridge0 ipv6.dns '2001:db8:1::fffd'
   ```
# nmcli connection modify bridge0 ipv6.dns-search 'example.com'
# nmcli connection modify bridge0 ipv6.method manual

5. Optional: Configure further properties of the bridge. For example, to set the Spanning Tree Protocol (STP) priority of bridge0 to 16384, enter:

```bash
# nmcli connection modify bridge0 bridge.priority '16384'
```

By default, STP is enabled.

6. Activate the connection:

```bash
# nmcli connection up bridge0
```

7. Verify that the ports are connected, and the CONNECTION column displays the port’s connection name:

```bash
# nmcli device
DEVICE TYPE STATE CONNECTION
... enp7s0 ethernet connected bridge0-port1
enp8s0 ethernet connected bridge0-port2
```

When you activate any port of the connection, NetworkManager also activates the bridge, but not the other ports of it. You can configure that Red Hat Enterprise Linux enables all ports automatically when the bridge is enabled:

a. Enable the `connection.autoconnect-slaves` parameter of the bridge connection:

```bash
# nmcli connection modify bridge0 connection.autoconnect-slaves 1
```

b. Reactivate the bridge:

```bash
# nmcli connection up bridge0
```

Verification steps

- Use the `ip` utility to display the link status of Ethernet devices that are ports of a specific bridge:

```bash
# ip link show master bridge0
3: enp7s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel master bridge0 state UP mode DEFAULT group default qlen 1000
   link/ether 52:54:00:62:61:0e brd ff:ff:ff:ff:ff:ff
4: enp8s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel master bridge0 state UP mode DEFAULT group default qlen 1000
   link/ether 52:54:00:9e:f1:ce brd ff:ff:ff:ff:ff:ff
```

- Use the `bridge` utility to display the status of Ethernet devices that are ports of any bridge device:

```bash
# bridge link show
3: enp7s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master bridge0 state forwarding priority 32 cost 100
```
4: enp8s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master bridge0 state listening priority 32 cost 100
5: enp9s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master bridge1 state forwarding priority 32 cost 100
6: enp11s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master bridge1 state blocking priority 32 cost 100

To display the status for a specific Ethernet device, use the bridge link show dev ethernet_device_name command.

Additional resources

- Testing basic network settings
- Configuring NetworkManager to avoid using a specific profile to provide a default gateway
- nmcli-examples(7) man page
- The bridge settings section in the nm-settings(5) man page
- The bridge-port settings section in the nm-settings(5) man page
- bridge(8) man page
- NetworkManager duplicates a connection after restart of NetworkManager service

10.2. CONFIGURING A NETWORK BRIDGE USING NM-CONNECTION-EDITOR

This section explains how to configure a network bridge using the nm-connection-editor application.

Note that nm-connection-editor can add only new ports to a bridge. To use an existing connection profile as a port, create the bridge using the nmcli utility as described in Configuring a network bridge using nmcli commands.

Prerequisites

- Two or more physical or virtual network devices are installed on the server.
- To use Ethernet devices as ports of the bridge, the physical or virtual Ethernet devices must be installed on the server.
- To use team, bond, or VLAN devices as ports of the bridge, ensure that these devices are not already configured.

Procedure

1. Open a terminal, and enter nm-connection-editor:

   $ nm-connection-editor

2. Click the + button to add a new connection.

3. Select the Bridge connection type, and click Create.
4. In the **Bridge** tab:
   
a. Optional: Set the name of the bridge interface in the **Interface name** field.
   
b. Click the **Add** button to create a new connection profile for a network interface and adding the profile as a port to the bridge.
      
i. Select the connection type of the interface. For example, select **Ethernet** for a wired connection.
   
ii. Optionally, set a connection name for the port device.

iii. If you create a connection profile for an Ethernet device, open the **Ethernet** tab, and select in the **Device** field the network interface you want to add as a port to the bridge. If you selected a different device type, configure it accordingly.

iv. Click **Save**.

c. Repeat the previous step for each interface you want to add to the bridge.

![Editing Bridge connection 1](image)

---

5. Optional: Configure further bridge settings, such as Spanning Tree Protocol (STP) options.

6. Configure the IP settings of the bridge. Skip this step if you want to use this bridge as a port of other devices.

   a. In the **IPv4 Settings** tab, configure the IPv4 settings. For example, set a static IPv4 address, network mask, default gateway, DNS server, and DNS search domain:
b. In the **IPv6 Settings** tab, configure the IPv6 settings. For example, set a static IPv6 address, network mask, default gateway, DNS server, and DNS search domain:

7. Save the bridge connection.

**Verification steps**
Use the `ip` utility to display the link status of Ethernet devices that are ports of a specific bridge:

```bash
# ip link show master bridge0
3: enp7s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel master bridge0 state UP mode DEFAULT group default qlen 1000
   link/ether 52:54:00:62:61:0e brd ff:ff:ff:ff:ff:ff
4: enp8s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel master bridge0 state UP mode DEFAULT group default qlen 1000
   link/ether 52:54:00:9e:f1:ce brd ff:ff:ff:ff:ff:ff
```

Use the `bridge` utility to display the status of Ethernet devices that are ports in any bridge device:

```bash
# bridge link show
3: enp7s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master bridge0 state forwarding priority 32 cost 100
4: enp8s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master bridge0 state listening priority 32 cost 100
5: enp9s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master bridge1 state forwarding priority 32 cost 100
6: enp11s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master bridge1 state blocking priority 32 cost 100
...
```

To display the status for a specific Ethernet device, use the `bridge link show dev ethernet_device_name` command.

Additional resources

- Configuring a network bond using `nm-connection-editor`
- Configuring a network team using `nm-connection-editor`
- Configuring VLAN tagging using `nm-connection-editor`
- Testing basic network settings
- Configuring NetworkManager to avoid using a specific profile to provide a default gateway

### 10.3. CONFIGURING A NETWORK BRIDGE USING NMSTATECTL

This section describes how to use the `nmstatectl` utility to configure a Linux network bridge `bridge0` with following settings:

- Network interfaces in the bridge: `enp1s0` and `enp7s0`
- Spanning Tree Protocol (STP): Enabled
- Static IPv4 address: `192.0.2.1` with the `/24` subnet mask
- Static IPv6 address: `2001:db8:1::1` with the `/64` subnet mask
- IPv4 default gateway: `192.0.2.254`
- IPv6 default gateway: `2001:db8:1::ffe`
- IPv4 DNS server: 192.0.2.200
- IPv6 DNS server: 2001:db8:1::ffbb
- DNS search domain: example.com

Prerequisites

- Two or more physical or virtual network devices are installed on the server.
- To use Ethernet devices as ports in the bridge, the physical or virtual Ethernet devices must be installed on the server.
- To use team, bond, or VLAN devices as ports in the bridge, set the interface name in the `port` list, and define the corresponding interfaces.
- The `nmstate` package is installed.

Procedure

1. Create a YAML file, for example `~/create-bridge.yml`, with the following contents:

```yaml
---
interfaces:
- name: bridge0
  type: linux-bridge
  state: up
  ipv4:
    enabled: true
    address:
    - ip: 192.0.2.1
      prefix-length: 24
      dhcp: false
  ipv6:
    enabled: true
    address:
    - ip: 2001:db8:1::1
      prefix-length: 64
      autoconf: false
      dhcp: false
  bridge:
    options:
      stp:
        enabled: true
    port:
    - name: enp1s0
      type: ethernet
      state: up
    - name: enp7s0
      type: ethernet
      state: up
  routes:
    config:
```
- destination: 0.0.0.0/0
  next-hop-address: 192.0.2.254
  next-hop-interface: bridge0
- destination: ::/0
  next-hop-address: 2001:db8:1::fffe
  next-hop-interface: bridge0
dns-resolver:
  config:
    search:
    - example.com
  server:
    - 192.0.2.200
    - 2001:db8:1::ffbb

2. Apply the settings to the system:

```bash
# nmstatectl apply ~/create-bridge.yml
```

Verification steps

1. Display the status of the devices and connections:

```bash
# nmcli device status
DEVICE        TYPE      STATE      CONNECTION
bridge0        bridge    connected   bridge0
```

2. Display all settings of the connection profile:

```bash
# nmcli connection show bridge0
connection.id:    bridge0
connection.uuid:  e2cc9206-75a2-4622-89cf-1252926060a9
connection.stable-id: --
connection.type:  bridge
connection.interface-name: bridge0
...
```

3. Display the connection settings in YAML format:

```bash
# nmstatectl show bridge0
```

- [nmstatectl(8) man page](/usr/share/doc/nmstate/examples/)
CHAPTER 11. CONFIGURING NETWORK TEAMING

This section describes the basics of network teaming, the differences between bonding and teaming, and how to configure a network team on Red Hat Enterprise Linux.

IMPORTANT

Network teaming is deprecated in Red Hat Enterprise Linux 9. Consider using the network bonding driver as an alternative. For details, see Configuring network bonding.

You can create network teams on different types of devices, such as:

- Physical and virtual Ethernet devices
- Network bonds
- Network bridges
- VLAN devices

11.1. MIGRATING A NETWORK TEAM CONFIGURATION TO NETWORK BOND

Network teaming is deprecated in Red Hat Enterprise Linux 9. If you already have a working network team configured, for example because you upgraded from an earlier RHEL version, you can migrate the configuration to a network bond that is managed by NetworkManager.

IMPORTANT

The team2bond utility only converts the network team configuration to a bond. Afterwards, you must manually configure further settings of the bond, such as IP addresses and DNS configuration.

Prerequisites

- The team-team0 NetworkManager connection profile is configured and manages the team0 device.
- The teamd package is installed.

Procedure

1. Optional: Display the IP configuration of the team-team0 NetworkManager connection:

```bash
# nmcli connection show team-team0 | grep "^ip"
...  
ipv4.method: manual
ipv4.dns: 192.0.2.253
ipv4.dns-search: example.com
ipv4.addresses: 192.0.2.1/24
ipv4.gateway: 192.0.2.254
...  
ipv6.method: manual
```
2. Export the configuration of the team0 device to a JSON file:

```
# teamdctl team0 config dump actual > /tmp/team0.json
```

3. Remove the network team. For example, if you configured the team in NetworkManager, remove the team-team0 connection profile and the profiles of associated ports:

```
# nmcli connection delete team-team0
# nmcli connection delete team-team0-port1
# nmcli connection delete team-team0-port2
```

4. Run the team2bond utility in dry-run mode to display nmcli commands that set up a network bond with similar settings as the team device:

```
# team2bond --config=/tmp/team0.json --rename=bond0
```

```
nmcli con add type bond ifname bond0 bond.options "mode=active-backup,num_grat_arp=1,num_unsol_na=1,resend_igmp=1,miimon=100,miimon=100"
nmcli con add type ethernet ifname enp7s0 master bond0
nmcli con add type ethernet ifname enp8s0 master bond0
```

The first command contains two miimon options because the team configuration file contained two link_watch entries. Note that this does not affect the creation of the bond.

If you bound services to the device name of the team and want to avoid updating or breaking these services, omit the --rename=bond0 option. In this case, team2bond uses the same interface name for the bond as for the team.

5. Verify that the options for the bond the team2bond utility suggested are correct.

6. Create the bond. You can execute the suggested nmcli commands or re-run the team2bond command with the --exec-cmd option:

```
# team2bond --config=/tmp/team0.json --rename=bond0 --exec-cmd
```

Connection 'bond-bond0' (0241a531-0c72-4202-80df-73eadfc126b5) successfully added.
Connection 'bond-slave-enp7s0' (38489729-b624-4606-a784-1cf01e2f6d6) successfully added.
Connection 'bond-slave-enp8s0' (de97ec06-7daa-4298-9a71-9d4c7909daa1) successfully added.

You require the name of the bond connection profile (bond-bond0) in the next steps.

7. Set the IPv4 settings that were previously configured on team-team0 to the bond-bond0 connection:

```
# nmcli connection modify bond-bond0 ipv4.addresses '192.0.2.1/24'
# nmcli connection modify bond-bond0 ipv4.gateway '192.0.2.254'
# nmcli connection modify bond-bond0 ipv4.dns '192.0.2.253'
# nmcli connection modify bond-bond0 ipv4.dns-search 'example.com'
# nmcli connection modify bond-bond0 ipv4.method manual
```
8. Set the IPv6 settings that were previously configured on **team-team0** to the **bond-bond0** connection:

```bash
# nmcli connection modify bond-bond0 ipv6.addresses '2001:db8:1::1/64'
# nmcli connection modify bond-bond0 ipv6.gateway '2001:db8:1::fffe'
# nmcli connection modify bond-bond0 ipv6.dns '2001:db8:1::fffd'
# nmcli connection modify bond-bond0 ipv6.dns-search 'example.com'
# nmcli connection modify bond-bond0 ipv6.method manual
```

9. Activate the connection:

```bash
# nmcli connection up bond-bond0
```

**Verification**

1. Display the IP configuration of the **bond-bond0** NetworkManager connection:

```bash
# nmcli connection show bond-bond0 | egrep "^ip"
```

```bash
... 
ip4.method: manual
ip4.dns: 192.0.2.253
ip4.dns-search: example.com
ip4.addresses: 192.0.2.1/24
ip4.gateway: 192.0.2.254
... 
ip6.method: manual
ip6.dns: 2001:db8:1::fffd
ip6.dns-search: example.com
ip6.addresses: 2001:db8:1::1/64
ip6.gateway: 2001:db8:1::fffe
... 
```

2. Display the status of the bond:

```bash
# cat /proc/net/bonding/bond0
```

```
Ethernet Channel Bonding Driver: v5.13.0-0.rc7.51.el9.x86_64

Bonding Mode: fault-tolerance (active-backup)
Primary Slave: None
Currently Active Slave: enp7s0
MII Status: up
MII Polling Interval (ms): 100
Up Delay (ms): 0
Down Delay (ms): 0
Peer Notification Delay (ms): 0

Slave Interface: enp7s0
MII Status: up
Speed: Unknown
Duplex: Unknown
Link Failure Count: 0
Permanent HW addr: 52:54:00:bf:b1:a9
Slave queue ID: 0
```
Slave Interface: enp8s0
MII Status: up
Speed: Unknown
Duplex: Unknown
Link Failure Count: 0
Permanent HW addr: 52:54:00:04:36:0f
Slave queue ID: 0

In this example, both ports are up.

3. To verify that bonding failover works:
   a. Temporarily remove the network cable from the host. Note that there is no method to properly test link failure events using the command line.
   b. Display the status of the bond:

```
# cat /proc/net/bonding/bond0
```

11.2. UNDERSTANDING NETWORK TEAMING

Network teaming is a feature that combines or aggregates network interfaces to provide a logical interface with higher throughput or redundancy.

Network teaming uses a kernel driver to implement fast handling of packet flows, as well as user-space libraries and services for other tasks. This way, network teaming is an easily extensible and scalable solution for load-balancing and redundancy requirements.

**IMPORTANT**

Certain network teaming features, such as the fail-over mechanism, do not support direct cable connections without a network switch. For further details, see Is bonding supported with direct connection using crossover cables?

11.3. UNDERSTANDING THE DEFAULT BEHAVIOR OF CONTROLLER AND PORT INTERFACES

Consider the following default behavior of, when managing or troubleshooting team or bond port interfaces using the **NetworkManager** service:

- Starting the controller interface does not automatically start the port interfaces.
- Starting a port interface always starts the controller interface.
- Stopping the controller interface also stops the port interface.
- A controller without ports can start static IP connections.
- A controller without ports waits for ports when starting DHCP connections.
- A controller with a DHCP connection waiting for ports completes when you add a port with a carrier.
A controller with a DHCP connection waiting for ports continues waiting when you add a port without carrier.

11.4. UNDERSTANDING THE TEAMD SERVICE, RUNNERS, AND LINK-WATCHERS

The team service, teamd, controls one instance of the team driver. This instance of the driver adds instances of a hardware device driver to form a team of network interfaces. The team driver presents a network interface, for example team0, to the kernel.

The teamd service implements the common logic to all methods of teaming. Those functions are unique to the different load sharing and backup methods, such as round-robin, and implemented by separate units of code referred to as runners. Administrators specify runners in JavaScript Object Notation (JSON) format, and the JSON code is compiled into an instance of teamd when the instance is created. Alternatively, when using NetworkManager, you can set the runner in the team.runner parameter, and NetworkManager auto-creates the corresponding JSON code.

The following runners are available:

- **broadcast**: Transmits data over all ports.
- **roundrobin**: Transmits data over all ports in turn.
- **activebackup**: Transmits data over one port while the others are kept as a backup.
- **loadbalance**: Transmits data over all ports with active Tx load balancing and Berkeley Packet Filter (BPF)-based Tx port selectors.
- **random**: Transmits data on a randomly selected port.
- **lacp**: Implements the 802.3ad Link Aggregation Control Protocol (LACP).

The teamd services uses a link watcher to monitor the state of subordinate devices. The following link-watchers are available:

- **ethtool**: The libteam library uses the ethtool utility to watch for link state changes. This is the default link-watcher.
- **arp_ping**: The libteam library uses the arp_ping utility to monitor the presence of a far-end hardware address using Address Resolution Protocol (ARP).
- **nsna_ping**: On IPv6 connections, the libteam library uses the Neighbor Advertisement and Neighbor Solicitation features from the IPv6 Neighbor Discovery protocol to monitor the presence of a neighbor’s interface.

Each runner can use any link watcher, with the exception of lacp. This runner can only use the ethtool link watcher.

11.5. INSTALLING THE TEAMD SERVICE

To configure a network team in NetworkManager, you require the teamd service and the team plug-in for NetworkManager. Both are installed on Red Hat Enterprise Linux by default. This section describes how you install the required packages in case that you remove them.

**Prerequisites**
An active Red Hat subscription is assigned to the host.

### Procedure

- Install the **teamd** and **NetworkManager-team** packages:

  ```
  # dnf install teamd NetworkManager-team
  ```

### 11.6. CONFIGURING A NETWORK TEAM USING NMCLI COMMANDS

This section describes how to configure a network team using **nmcli** utility.

**IMPORTANT**

Network teaming is deprecated in Red Hat Enterprise Linux 9. Consider using the network bonding driver as an alternative. For details, see Configuring network bonding.

#### Prerequisites

- Two or more physical or virtual network devices are installed on the server.
- To use Ethernet devices as ports of the team, the physical or virtual Ethernet devices must be installed on the server and connected to a switch.
- To use bond, bridge, or VLAN devices as ports of the team, you can either create these devices while you create the team or you can create them in advance as described in:

  - Configuring a network bond using nmcli commands
  - Configuring a network bridge using nmcli commands
  - Configuring VLAN tagging using nmcli commands

#### Procedure

1. Create a team interface:

   ```
   # nmcli connection add type team con-name team0 ifname team0 team.runner activebackup
   ```

   This command creates a network team named **team0** that uses the **activebackup** runner.

2. Optionally, set a link watcher. For example, to set the **ethtool** link watcher in the **team0** connection profile:

   ```
   # nmcli connection modify team0 team.link-watchers "name=ethtool"
   ```

   Link watchers support different parameters. To set parameters for a link watcher, specify them space-separated in the **name** property. Note that the name property must be surrounded by quotes. For example, to use the **ethtool** link watcher and set its **delay-up** parameter to 2500 milliseconds (2.5 seconds):

   ```
   # nmcli connection modify team0 team.link-watchers "name=ethtool delay-up=2500"
   ```
To set multiple link watchers and each of them with specific parameters, the link watchers must be separated by a comma. The following example sets the `ethtool` link watcher with the `delay-up` parameter and the `arp_ping` link watcher with the `source-host` and `target-host` parameter:

```
# nmcli connection modify team0 team.link-watchers "name=ethtool delay-up=2, name=arp_ping source-host=192.0.2.1 target-host=192.0.2.2"
```

3. Display the network interfaces, and note the names of the interfaces you want to add to the team:

```
# nmcli device status
DEVICE  TYPE      STATE         CONNECTION
enp7s0  ethernet  disconnected  --
enp8s0  ethernet  disconnected  --
bond0   bond      connected  bond0
bond1   bond      connected  bond1
...
```

In this example:

- `enp7s0` and `enp8s0` are not configured. To use these devices as ports, add connection profiles in the next step. Note that you can only use Ethernet interfaces in a team that are not assigned to any connection.

- `bond0` and `bond1` have existing connection profiles. To use these devices as ports, modify their profiles in the next step.

4. Assign the port interfaces to the team:

a. If the interfaces you want to assign to the team are not configured, create new connection profiles for them:

```
# nmcli connection add type ethernet slave-type team con-name team0-port1
ifname enp7s0 master team0
# nmcli connection add type ethernet slave-type team con-name team0-port2
ifname enp8s0 master team0
```

These commands create profiles for `enp7s0` and `enp8s0`, and add them to the `team0` connection.

b. To assign an existing connection profile to the team, set the `master` parameter of these connections to `team0`:

```
# nmcli connection modify bond0 master team0
# nmcli connection modify bond1 master team0
```

These commands assign the existing connection profiles named `bond0` and `bond1` to the `team0` connection.

5. Configure the IP settings of the team. Skip this step if you want to use this team as a ports of other devices.

a. Configure the IPv4 settings. For example, to set a static IPv4 address, network mask, default gateway, DNS server, and DNS search domain the `team0` connection, enter:
b. Configure the IPv6 settings. For example, to set a static IPv6 address, network mask, default gateway, DNS server, and DNS search domain of the `team0` connection, enter:

```bash
# nmcli connection modify team0 ipv6.addresses '2001:db8:1::1/64'
# nmcli connection modify team0 ipv6.gateway '2001:db8:1::fffe'
# nmcli connection modify team0 ipv6.dns '2001:db8:1::fffd'
# nmcli connection modify team0 ipv6.dns-search 'example.com'
# nmcli connection modify team0 ipv6.method manual
```

6. Activate the connection:

```bash
# nmcli connection up team0
```

Verification steps

- Display the status of the team:

```bash
# teamdctl team0 state
setup:
  runner: activebackup
ports:
enp7s0
  link watches:
    link summary: up
    instance[link_watch_0]:
      name: ethtool
      link: up
down count: 0
enp8s0
  link watches:
    link summary: up
    instance[link_watch_0]:
      name: ethtool
      link: up
down count: 0
runner:
  active port: enp7s0
```

In this example, both ports are up.

Additional resources

- Testing basic network settings
- Configuring NetworkManager to avoid using a specific profile to provide a default gateway
- Understanding the teamd service, runners, and link-watchers
11.7. CONFIGURING A NETWORK TEAM USING NM-CONNECTION-EDITOR

This section describes how you configure a network team using the `nm-connection-editor` application.

Note that `nm-connection-editor` can add only new ports to a team. To use an existing connection profile as a port, create the team using the `nmcli` utility as described in Configuring a network team using `nmcli` commands.

**IMPORTANT**

Network teaming is deprecated in Red Hat Enterprise Linux 9. Consider using the network bonding driver as an alternative. For details, see Configuring network bonding.

Prerequisites

- Two or more physical or virtual network devices are installed on the server.
- To use Ethernet devices as ports of the team, the physical or virtual Ethernet devices must be installed on the server.
- To use team, bond, or VLAN devices as ports of the team, ensure that these devices are not already configured.

Procedure

1. Open a terminal, and enter `nm-connection-editor`:

   ```
   $ nm-connection-editor
   ```

2. Click the + button to add a new connection.

3. Select the Team connection type, and click Create.

4. In the Team tab:
   
   a. Optional: Set the name of the team interface in the Interface name field.

   b. Click the Add button to add a new connection profile for a network interface and adding the profile as a port to the team.

      i. Select the connection type of the interface. For example, select Ethernet for a wired connection.

      ii. Optional: Set a connection name for the port.

      iii. If you create a connection profile for an Ethernet device, open the Ethernet tab, and select in the Device field the network interface you want to add as a port to the team. If you selected a different device type, configure it accordingly. Note that you can only
use Ethernet interfaces in a team that are not assigned to any connection.

iv. Click **Save**.

c. Repeat the previous step for each interface you want to add to the team.

![Editing Team connection 1](image)

<table>
<thead>
<tr>
<th>Connection name</th>
<th>Team connection 1</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>General</strong></td>
<td><strong>Team</strong></td>
</tr>
<tr>
<td>Interface name</td>
<td>team0</td>
</tr>
<tr>
<td>MTU</td>
<td>automatic - + bytes</td>
</tr>
<tr>
<td>Teamed connections</td>
<td>team0-port1, team0-port2</td>
</tr>
</tbody>
</table>

| **Add** | **Edit** |

| **IPv4 Settings** | **IPv6 Settings** |

- **d.** Click the **Advanced** button to set advanced options to the team connection.
  
  i. In the **Runner** tab, select the runner.

  ii. In the **Link Watcher** tab, set the link watcher and its optional settings.

  iii. Click **OK**.

5. Configure the IP settings of the team. Skip this step if you want to use this team as a port of other devices.
a. In the **IPv4 Settings** tab, configure the IPv4 settings. For example, set a static IPv4 address, network mask, default gateway, DNS server, and DNS search domain:

<table>
<thead>
<tr>
<th>Address</th>
<th>Netmask</th>
<th>Gateway</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.0.2.1</td>
<td>24</td>
<td>192.0.2.254</td>
</tr>
</tbody>
</table>

b. In the **IPv6 Settings** tab, configure the IPv6 settings. For example, set a static IPv6 address, network mask, default gateway, DNS server, and DNS search domain:

<table>
<thead>
<tr>
<th>Address</th>
<th>Prefix</th>
<th>Gateway</th>
</tr>
</thead>
<tbody>
<tr>
<td>2001:db8:1::1</td>
<td>64</td>
<td>2001:db8:1::ff3</td>
</tr>
</tbody>
</table>

6. Save the team connection.

Verification steps

- Display the status of the team:

```bash
# teamdctl team0 state
setup:
  runner: activebackup
ports:
  enp7s0
    link watches:
      link summary: up
      instance[link_watch_0]:
        name: ethtool
        link: up
        down count: 0
  enp8s0
    link watches:
      link summary: up
      instance[link_watch_0]:
        name: ethtool
        link: up
        down count: 0
runner:
  active port: enp7s0
```

CHAPTER 12. CONFIGURING NETWORK BONDING

This section describes the basics of network bonding, the differences between bonding and teaming, and how to configure a network bond on Red Hat Enterprise Linux.

You can create bonds on different types of devices, such as:

- Physical and virtual Ethernet devices
- Network bridges
- Network teams
- VLAN devices

12.1. UNDERSTANDING NETWORK BONDING

Network bonding is a method to combine or aggregate network interfaces to provide a logical interface with higher throughput or redundancy.

The `active-backup`, `balance-tlb`, and `balance-alb` modes do not require any specific configuration of the network switch. However, other bonding modes require configuring the switch to aggregate the links. For example, Cisco switches requires `EtherChannel` for modes 0, 2, and 3, but for mode 4, the Link Aggregation Control Protocol (LACP) and `EtherChannel` are required.

For further details, see the documentation of your switch and [Linux Ethernet Bonding Driver HOWTO](https://access.redhat.com/documentation/en-US/Red_Hat_Enterprise_Linux/9/html/Configuring_and_maneagning_networking/chap-configuring-network-bonding.html).

**IMPORTANT**

Certain network bonding features, such as the fail-over mechanism, do not support direct cable connections without a network switch. For further details, see the [Is bonding supported with direct connection using crossover cables?](https://access.redhat.com/documentation/en-US/Red_Hat_Enterprise_Linux/9/html/Configuring_and_maneagning_networking/chap-configuring-network-bonding.html) KCS solution.

12.2. UNDERSTANDING THE DEFAULT BEHAVIOR OF CONTROLLER AND PORT INTERFACES

Consider the following default behavior of, when managing or troubleshooting team or bond port interfaces using the `NetworkManager` service:

- Starting the controller interface does not automatically start the port interfaces.
- Starting a port interface always starts the controller interface.
- Stopping the controller interface also stops the port interface.
- A controller without ports can start static IP connections.
- A controller without ports waits for ports when starting DHCP connections.
- A controller with a DHCP connection waiting for ports completes when you add a port with a carrier.
- A controller with a DHCP connection waiting for ports continues waiting when you add a port without carrier.
12.3. UPSTREAM SWITCH CONFIGURATION DEPENDING ON THE BONDING MODES

The following table describes which settings you must apply to the upstream switch depending on the bonding mode:

<table>
<thead>
<tr>
<th>Bonding mode</th>
<th>Configuration on the switch</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - balance-rr</td>
<td>Requires static Etherchannel enabled (not LACP-negotiated)</td>
</tr>
<tr>
<td>1 - active-backup</td>
<td>Requires autonomous ports</td>
</tr>
<tr>
<td>2 - balance-xor</td>
<td>Requires static Etherchannel enabled (not LACP-negotiated)</td>
</tr>
<tr>
<td>3 - broadcast</td>
<td>Requires static Etherchannel enabled (not LACP-negotiated)</td>
</tr>
<tr>
<td>4 - 802.3ad</td>
<td>Requires LACP-negotiated Etherchannel enabled</td>
</tr>
<tr>
<td>5 - balance-tlb</td>
<td>Requires autonomous ports</td>
</tr>
<tr>
<td>6 - balance-alb</td>
<td>Requires autonomous ports</td>
</tr>
</tbody>
</table>

For configuring these settings on your switch, see the switch documentation.

12.4. CONFIGURING A NETWORK BOND USING NMCLI COMMANDS

This section describes how to configure a network bond using `nmcli` commands.

Prerequisites

- Two or more physical or virtual network devices are installed on the server.
- To use Ethernet devices as ports of the bond, the physical or virtual Ethernet devices must be installed on the server.
- To use team, bridge, or VLAN devices as ports of the bond, you can either create these devices while you create the bond or you can create them in advance as described in:
  - Configuring a network team using nmcli commands
  - Configuring a network bridge using nmcli commands
  - Configuring VLAN tagging using nmcli commands

Procedure

1. Create a bond interface:

   ```bash
   # nmcli connection add type bond con-name bond0 ifname bond0 bond.options "mode=active-backup"
   ```
This command creates a bond named **bond0** that uses the **active-backup** mode.

To additionally set a Media Independent Interface (MII) monitoring interval, add the `miimon=interval` option to the `bond.options` property. For example, to use the same command but, additionally, set the MII monitoring interval to **1000** milliseconds (1 second), enter:

```
# nmcli connection add type bond con-name bond0 ifname bond0 bond.options "mode=active-backup,miimon=1000"
```

2. Display the network interfaces, and note names of interfaces you plan to add to the bond:

```
# nmcli device status
DEVICE   TYPE      STATE         CONNECTION
enp7s0   ethernet  disconnected  --
enp8s0   ethernet  disconnected  --
bridge0  bridge    connected     bridge0
bridge1  bridge    connected     bridge1
... 
```

In this example:

- **enp7s0** and **enp8s0** are not configured. To use these devices as ports, add connection profiles in the next step.
- **bridge0** and **bridge1** have existing connection profiles. To use these devices as ports, modify their profiles in the next step.

3. Assign interfaces to the bond:

a. If the interfaces you want to assign to the bond are not configured, create new connection profiles for them:

```
# nmcli connection add type ethernet slave-type bond con-name bond0-port1 ifname enp7s0 master bond0
# nmcli connection add type ethernet slave-type bond con-name bond0-port2 ifname enp8s0 master bond0
```

These commands create profiles for **enp7s0** and **enp8s0**, and add them to the **bond0** connection.

b. To assign an existing connection profile to the bond, set the **master** parameter of these connections to **bond0**:

```
# nmcli connection modify bridge0 master bond0
# nmcli connection modify bridge1 master bond0
```

These commands assign the existing connection profiles named **bridge0** and **bridge1** to the **bond0** connection.

4. Configure the IP settings of the bond. Skip this step if you want to use this bond as a port of other devices.

a. Configure the IPv4 settings. For example, to set a static IPv4 address, network mask, default gateway, DNS server, and DNS search domain to the **bond0** connection, enter:
b. Configure the IPv6 settings. For example, to set a static IPv6 address, network mask, default gateway, DNS server, and DNS search domain to the bond0 connection, enter:

```
# nmcli connection modify bond0 ipv6.addresses '2001:db8:1::1/64'
# nmcli connection modify bond0 ipv6.gateway '2001:db8:1::fffe'
# nmcli connection modify bond0 ipv6.dns '2001:db8:1::fffd'
# nmcli connection modify bond0 ipv6.dns-search 'example.com'
# nmcli connection modify bond0 ipv6.method manual
```

5. Activate the connection:

```
# nmcli connection up bond0
```

6. Verify that the ports are connected, and the CONNECTION column displays the port’s connection name:

```
# nmcli device
DEVICE   TYPE      STATE      CONNECTION
...     enp7s0   ethernet  connected  bond0-port1
...     enp8s0   ethernet  connected  bond0-port2
```

When you activate any port of the connection, NetworkManager also activates the bond, but not the other ports of it. You can configure that Red Hat Enterprise Linux enables all ports automatically when when the bond is enabled:

a. Enable the connection.autoconnect-slaves parameter of the bond’s connection:

```
# nmcli connection modify bond0 connection.autoconnect-slaves 1
```

b. Reactivate the bridge:

```
# nmcli connection up bond0
```

Verification steps

1. Temporarily remove the network cable from the host. Note that there is no method to properly test link failure events using software utilities. Tools that deactivate connections, such as nmcli, show only the bonding driver’s ability to handle port configuration changes and not actual link failure events.

2. Display the status of the bond:

```
# cat /proc/net/bonding/bond0
```

Additional resources
12.5. CONFIGURING A NETWORK BOND USING NM-CONNECTION-EDITOR

This section describes how to configure a network bond using the `nm-connection-editor` application.

Note that `nm-connection-editor` can add only new ports to a bond. To use an existing connection profile as a port, create the bond using the `nmcli` utility as described in Configuring a network bond using nmcli commands.

Prerequisites

- Two or more physical or virtual network devices are installed on the server.
- To use Ethernet devices as ports of the bond, the physical or virtual Ethernet devices must be installed on the server.
- To use team, bond, or VLAN devices as ports of the bond, ensure that these devices are not already configured.

Procedure

1. Open a terminal, and enter `nm-connection-editor`:

   ```
   $ nm-connection-editor
   ```

2. Click the + button to add a new connection.

3. Select the Bond connection type, and click Create.

4. In the Bond tab:
   a. Optional: Set the name of the bond interface in the Interface name field.
   b. Click the Add button to add a network interface as a port to the bond.
      i. Select the connection type of the interface. For example, select Ethernet for a wired connection.
      ii. Optional: Set a connection name for the port.
      iii. If you create a connection profile for an Ethernet device, open the Ethernet tab, and select in the Device field the network interface you want to add as a port to the bond. If you selected a different device type, configure it accordingly. Note that you can only use Ethernet interfaces in a bond that are not configured.
      iv. Click Save.
   c. Repeat the previous step for each interface you want to add to the bond:
d. Optional: Set other options, such as the Media Independent Interface (MII) monitoring interval.

5. Configure the IP settings of the bond. Skip this step if you want to use this bond as a port of other devices.

   a. In the IPv4 Settings tab, configure the IPv4 settings. For example, set a static IPv4 address, network mask, default gateway, DNS server, and DNS search domain:

   b. In the IPv6 Settings tab, configure the IPv6 settings. For example, set a static IPv6 address, network mask, default gateway, DNS server, and DNS search domain:
6. Click **Save** to save the bond connection.

7. Close **nm-connection-editor**.

**Verification steps**

1. Temporarily remove the network cable from the host.
   
   Note that there is no method to properly test link failure events using software utilities. Tools that deactivate connections, such as **nmcli**, show only the bonding driver’s ability to handle port configuration changes and not actual link failure events.

2. Display the status of the bond:

   ```bash
   # cat /proc/net/bonding/bond0
   ```

**Additional resources**

- Testing basic network settings.
- Configuring NetworkManager to avoid using a specific profile to provide a default gateway.
- Configuring a network team using **nm-connection-editor**
- Configuring a network bridge using **nm-connection-editor**
- Configuring VLAN tagging using **nm-connection-editor**

### 12.6. Configuring a Network Bond Using **nmstatectl**
This section describes how to use the `nmstatectl` utility to configure a network bond, `bond0`, with the following settings:

- Network interfaces in the bond: `enp1s0` and `enp7s0`
- Mode: `active-backup`
- Static IPv4 address: `192.0.2.1` with a `/24` subnet mask
- Static IPv6 address: `2001:db8:1::1` with a `/64` subnet mask
- IPv4 default gateway: `192.0.2.254`
- IPv6 default gateway: `2001:db8:1::fffe`
- IPv4 DNS server: `192.0.2.200`
- IPv6 DNS server: `2001:db8:1::ffbb`
- DNS search domain: `example.com`

**Prerequisites**

- Two or more physical or virtual network devices are installed on the server.
- To use Ethernet devices as ports in the bond, the physical or virtual Ethernet devices must be installed on the server.
- To use team, bridge, or VLAN devices as ports in the bond, set the interface name in the `port` list, and define the corresponding interfaces.
- The `nmstate` package is installed.

**Procedure**

1. Create a YAML file, for example, `~/create-bond.yml`, with the following contents:

```yaml
---
interfaces:
- name: bond0
type: bond
state: up
ipv4:
  enabled: true
  address:
    - ip: 192.0.2.1
      prefix-length: 24
dhcp: false
ipv6:
  enabled: true
  address:
    - ip: 2001:db8:1::1
      prefix-length: 64
  autoconf: false
dhcp: false
  link-aggregation:
    mode: active-backup
```
port:
- enp1s0
- enp7s0
- name: enp1s0
type: ethernet
state: up
- name: enp7s0
type: ethernet
state: up

routes:
config:
- destination: 0.0.0.0/0
  next-hop-address: 192.0.2.254
  next-hop-interface: bond0
- destination: ::/0
  next-hop-address: 2001:db8:1::fffe
  next-hop-interface: bond0

dns-resolver:
config:
  search:
  - example.com
  server:
  - 192.0.2.200
  - 2001:db8:1::ffbb

2. Apply the settings to the system:

```
# nmstatectl apply ~/create-bond.yml
```

Verification steps

1. Display the status of the devices and connections:

```
# nmcli device status
DEVICE      TYPE      STATE      CONNECTION
bond0        bond      connected  bond0
```

2. Display all settings of the connection profile:

```
# nmcli connection show bond0
connection.id:   bond0
connection.uuid: 79cbc3bd-302e-4b1f-ad89-f12533b818ee
connection.stable-id: --
connection.type:   bond
connection.interface-name: bond0
... 
```

3. Display the connection settings in YAML format:

```
# nmstatectl show bond0
```
12.7. CONFIGURING A NETWORK BOND USING RHEL SYSTEM ROLES

You can use the Networking RHEL System Role to configure a network bond. This procedure describes how to configure a bond in active-backup mode that uses two Ethernet devices, and sets an IPv4 and IPv6 addresses, default gateways, and DNS configuration.

**NOTE**

Set the IP configuration on the bond and not on the ports of the Linux bond.

**Prerequisites**

- The `ansible-core` package and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.
- Two or more physical or virtual network devices are installed on the server.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/.bond-ethernet.yml` playbook with the following content:

   ```yaml
   ---
   - name: Configure a network bond that uses two Ethernet ports
     hosts: node.example.com
     become: true
     tasks:
     - include_role:
         name: rhel-system-roles.network

     vars:
     network_connections:
         # Define the bond profile
         - name: bond0
           type: bond
           interface_name: bond0
           ip:
             address:
             - "192.0.2.1/24"
             - "2001:db8:1::1/64"
           gateway4: 192.0.2.254
           gateway6: 2001:db8:1::ffe
dns:
   ```

Additional resources

- `nmstatectl(8)` man page
- `/usr/share/doc/nmstate/examples/`
# Add an Ethernet profile to the bond
- name: bond0-port1
  interface_name: enp7s0
  type: ethernet
  controller: bond0
  state: up

# Add a second Ethernet profile to the bond
- name: bond0-port2
  interface_name: enp8s0
  type: ethernet
  controller: bond0
  state: up

3. Run the playbook:
   
   - To connect as root user to the managed host, enter:
     
     ```bash
     # ansible-playbook -u root ~/bond-ethernet.yml
     ```
     
   - To connect as a user to the managed host, enter:
     
     ```bash
     # ansible-playbook -u user_name --ask-become-pass ~/bond-ethernet.yml
     ```

     The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

     If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Additional resources

   - /usr/share/ansible/roles/rhel-system-roles.network/README.md file
   - ansible-playbook(1) man page

12.8. CREATING A NETWORK BOND TO ENABLE SWITCHING BETWEEN AN ETHERNET AND WIRELESS CONNECTION WITHOUT INTERRUPTING THE VPN

RHEL users who connect their workstation to their company’s network typically use a VPN to access remote resources. However, if the workstation switches between an Ethernet and Wi-Fi connection, for example, if you release a laptop from a docking station with an Ethernet connection, the VPN connection is interrupted. To avoid this problem, you can create a network bond that uses the Ethernet and Wi-Fi connection in active-backup mode.
Prerequisites

- The host contains an Ethernet and a Wi-Fi device.
- An Ethernet and Wi-Fi NetworkManager connection profile has been created and both connections work independently.

This procedure uses the following connection profiles to create a network bond named **bond0**:

- **Docking_station** associated with the **enp11s0u1** Ethernet device
- **Wi-Fi** associated with the **wlp61s0** Wi-Fi device

Procedure

1. Create a bond interface in **active-backup** mode:

   ```bash
   # nmcli connection add type bond con-name bond0 ifname bond0 bond.options "mode=active-backup"
   ``

   This command names both the interface and connection profile **bond0**.

2. Configure the IPv4 settings of the bond:

   - If a DHCP server in your network assigns IPv4 addresses to hosts, no action is required.
   - If your local network requires static IPv4 addresses, set the address, network mask, default gateway, DNS server, and DNS search domain to the **bond0** connection:

     ```bash
     # nmcli connection modify bond0 ipv4.addresses '192.0.2.1/24'
     # nmcli connection modify bond0 ipv4.gateway '192.0.2.254'
     # nmcli connection modify bond0 ipv4.dns '192.0.2.253'
     # nmcli connection modify bond0 ipv4.dns-search 'example.com'
     # nmcli connection modify bond0 ipv4.method manual
     ```

3. Configure the IPv6 settings of the bond:

   - If your router or a DHCP server in your network assigns IPv6 addresses to hosts, no action is required.
   - If your local network requires static IPv6 addresses, set the address, network mask, default gateway, DNS server, and DNS search domain to the **bond0** connection:

     ```bash
     # nmcli connection modify bond0 ipv6.addresses '2001:db8:1::1/64'
     # nmcli connection modify bond0 ipv6.gateway '2001:db8:1::ffe'
     # nmcli connection modify bond0 ipv6.dns '2001:db8:1::fffd'
     # nmcli connection modify bond0 ipv6.dns-search 'example.com'
     # nmcli connection modify bond0 ipv6.method manual
     ```

4. Display the connection profiles:

   ```bash
   # nmcli connection show
   NAME       UUID                                  TYPE      DEVICE
   Docking_station  256dd073-fecc-339d-91ae-9834a00407f9  ethernet  enp11s0u1
   Wi-Fi        1f1531c7-8737-4c60-91af-2d21164417e8  wifi      wlp61s0
   ```
You require the names of the connection profiles and the Ethernet device name in the next steps.

5. Assign the connection profile of the Ethernet connection to the bond:
   
   ```
   # nmcli connection modify Docking_station master bond0
   ```

6. Assign the connection profile of the Wi-Fi connection to the bond:
   
   ```
   # nmcli connection modify Wi-Fi master bond0
   ```

7. If your Wi-Fi network uses MAC filtering to allow only MAC addresses on a allow list to access the network, configure that NetworkManager dynamically assigns the MAC address of the active port to the bond:
   
   ```
   # nmcli connection modify bond0 +bond.options fail_over_mac=1
   ```

   With this setting, you must set only the MAC address of the Wi-Fi device to the allow list instead of the MAC address of both the Ethernet and Wi-Fi device.

8. Set the device associated with the Ethernet connection as primary device of the bond:
   
   ```
   # nmcli con modify bond0 +bond.options "primary=enp11s0u1"
   ```

   With this setting, the bond always uses the Ethernet connection if it is available.

9. Configure that NetworkManager automatically activates ports when the `bond0` device is activated:
   
   ```
   # nmcli connection modify bond0 connection.autoconnect-slaves 1
   ```

10. Activate the `bond0` connection:
    
    ```
    # nmcli connection up bond0
    ```

**Verification steps**

- Display the currently active device, the status of the bond and its ports:

  ```
  # cat /proc/net/bonding/bond0
  Ethernet Channel Bonding Driver: v3.7.1 (April 27, 2011)

  Bonding Mode: fault-tolerance (active-backup) (fail_over_mac active)
  Primary Slave: enp11s0u1 (primary_reselect always)
  Currently Active Slave: enp11s0u1
  MII Status: up
  MII Polling Interval (ms): 1
  Up Delay (ms): 0
  Down Delay (ms): 0
  Peer Notification Delay (ms): 0

  Slave Interface: enp11s0u1
  MII Status: up
  Speed: 1000 Mbps
  ```
Duplex: full  
Link Failure Count: 0  
Permanent HW addr: 00:53:00:59:da:b7  
Slave queue ID: 0

Slave Interface: wlp61s0

**MII Status: up**

Speed: Unknown  
Duplex: Unknown  
Link Failure Count: 2  
Permanent HW addr: 00:53:00:b3:22:ba  
Slave queue ID: 0

Additional resources

CHAPTER 13. SETTING UP A WIREGUARD VPN

WireGuard is a high-performance VPN solution that runs in the Linux kernel. It uses modern cryptography and is easier to configure than many other VPN solutions. Additionally, WireGuard’s small codebase reduces the surface for attacks and, therefore, improves security. For authentication and encryption, WireGuard uses keys similar to SSH.

IMPORTANT

WireGuard is provided as a Technology Preview only. Technology Preview features are not supported with Red Hat production Service Level Agreements (SLAs), might not be functionally complete, and Red Hat does not recommend using them for production. These previews provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

See Technology Preview Features Support Scope on the Red Hat Customer Portal for information about the support scope for Technology Preview features.

To set up a WireGuard VPN, you must complete the following steps. You can perform each step by using different options:

1. Create public and private keys for every host in the VPN.

2. Configure the WireGuard server by using nmcli, nmtui, nm-connection-editor, or the wg-quick service.

3. Configure firewalld on the WireGuard server by using the command line or graphical interface.

4. Configure the WireGuard client by using nmcli, nm-connection-editor, or the wg-quick service.

Note that WireGuard operates only on the network layer (layer 3). Therefore, you cannot use DHCP and must assign static IP addresses or IPv6 link-local addresses to the tunnel devices on both the server and clients.

IMPORTANT

You can use WireGuard only if the Federal Information Processing Standard (FIPS) mode in RHEL is disabled.

Note that all hosts that participate in a WireGuard VPN are peers. This documentation uses the terms client to describe hosts that establish a connection and server to describe the host with the fixed hostname or IP address that the clients connect to and optionally route all traffic through this server.

13.1. PROTOCOLS AND PRIMITIVES USED BY WIREGUARD

WireGuard uses the following protocols and primitives:

- ChaCha20 for symmetric encryption, authenticated with Poly1305, using Authenticated Encryption with Associated Data (AEAD) construction as described in RFC7539
- Curve25519 for Elliptic-curve Diffie–Hellman (ECDH) key exchange
- BLAKE2s for hashing and keyed hashing, as described in RFC7693
- SipHash24 for hash table keys
13.2. HOW WIREGUARD USES TUNNEL IP ADDRESSES, PUBLIC KEYS, AND REMOTE ENDPOINTS

When WireGuard sends a network packet to a peer:

1. WireGuard reads the destination IP from the packet and compares it to the list of allowed IP addresses in the local configuration. If the peer is not found, WireGuard drops the packet.

2. If the peer is valid, WireGuard encrypts the packet using the peer’s public key.

3. The sending host looks up the most recent Internet IP address of the host and sends the encrypted packet to it.

When WireGuard receives a packet:

1. WireGuard decrypts the packet using private key of the remote host.

2. WireGuard reads the internal source address from the packet and looks up whether the IP is configured in the list of allowed IP addresses in the settings for the peer on the local host. If the source IP is on the allowlist, WireGuard accepts the packet. If the IP address is not on the list, WireGuard drops the packet.

The association of public keys and allowed IP addresses is called Cryptokey Routing Table. This means that the list of IP addresses behaves similar to a routing table when sending packets, and as a kind of access control list when receiving packets.

13.3. USING A WIREGUARD CLIENT BEHIND NAT AND FIREWALLS

WireGuard uses the UDP protocol and transmits data only when a peer sends packets. Stateful firewalls and network address translation (NAT) on routers track connections to enable a peer behind NAT or a firewall to receive packets.

To keep the connection active, WireGuard supports persistent keepalives. This means you can set an interval at which WireGuard sends keepalive packets. By default, the persistent keep-alive feature is disabled to reduce network traffic. Enable this feature on the client if you use the client in a network with NAT or if a firewall closes the connection after some time of inactivity.

13.4. CREATING PRIVATE AND PUBLIC KEYS TO BE USED IN WIREGUARD CONNECTIONS

WireGuard uses base64-encoded private and public keys to authenticate hosts to each other. Therefore, you must create the keys on each host that participates in the WireGuard VPN.

**IMPORTANT**

For secure connections, create different keys for each host, and ensure that you only share the public key with the remote WireGuard host. Do not use the example keys used in this documentation.

**Procedure**

1. Install the wireguard-tools package:
# dnf install wireguard-tools

2. Create a private key and a corresponding public key for the host:

```
# wg genkey | tee /etc/wireguard/$HOSTNAME.private.key | wg pubkey >
/etc/wireguard/$HOSTNAME.public.key
```

You will need the content of the key files, but not the files themselves. However, Red Hat recommends keeping the files in case that you need to remember the keys in future.

3. Set secure permissions on the key files:

```
# chmod 600 /etc/wireguard/$HOSTNAME.private.key
/etc/wireguard/$HOSTNAME.public.key
```

4. Display the private key:

```
# cat /etc/wireguard/$HOSTNAME.private.key
YFAnE0psgIdiAF7XR4abxiwVRnlMfelttxu10s/c4JXg=
```

You will need the private key to configure the WireGuard connection on the local host. Do not share the private key.

5. Display the public key:

```
# cat /etc/wireguard/$HOSTNAME.public.key
UtjqCJ57DeAscYKRfp7cFGiQqdONRn69u249Fa4O6BE=
```

You will need the public key to configure the WireGuard connection on the remote host.

Additional resources

- The `wg(8)` man page

**13.5. CONFIGURING A WIREGUARD SERVER USING NMCLI**

You can configure the WireGuard server by creating a connection profile in NetworkManager. Use this method to let NetworkManager manage the WireGuard connection.

This procedure assumes the following settings:

- **Server:**
  - Private key: `YFAnE0psgIdiAF7XR4abxiwVRnlMfelttxu10s/c4JXg=`
  - Tunnel IPv4 address: `192.0.2.1/24`
  - Tunnel IPv6 address: `2001:db8:1::1/32`

- **Client:**
  - Public key: `bnwfQcC8/g2l4vvEqcRUM2e6Hi3Nskk6G9t4r26nFVM=`
  - Tunnel IPv4 address: `192.0.2.2/24`
Tunnel IPv6 address: 2001:db8:1::2/32

Prerequisites

- You have generated the public and private key for both the server and client.
- You know the following information:
  - The private key of the server
  - The static tunnel IP addresses and subnet masks of the client
  - The public key of the client
  - The static tunnel IP addresses and subnet masks of the server

Procedure

1. Add a NetworkManager WireGuard connection profile:

```
# nmcli connection add type wireguard con-name server-wg0 ifname wg0 autoconnect no
```

This command creates a profile named `server-wg0` and assigns the virtual interface `wg0` to it. To prevent the connection from starting automatically after you add it without finalizing the configuration, disable the `autoconnect` parameter.

2. Set the tunnel IPv4 address and subnet mask of the server:

```
# nmcli connection modify server-wg0 ipv4.method manual ipv4.addresses 192.0.2.1/24
```

3. Set the tunnel IPv6 address and subnet mask of the server:

```
# nmcli connection modify server-wg0 ipv6.method manual ipv6.addresses 2001:db8:1::1/32
```

4. Add the server’s private key to the connection profile:

```
# nmcli connection modify server-wg0 wireguard.private-key "YFAnE0psgIdiAF7XR4abxiwVRnlMfeltxu10s/c4JXg="
```

5. Set the port for incoming WireGuard connections:

```
# nmcli connection modify server-wg0 wireguard.listen-port 51820
```

Always set a fixed port number on hosts that receive incoming WireGuard connections. If you do not set a port, WireGuard uses a random free port each time you activate the `wg0` interface.

6. Add peer configurations for each client that you want to allow to communicate with this server. You must add these settings manually, because the `nmcli` utility does not support setting the corresponding connection properties.

   a. Edit the `/etc/NetworkManager/system-connections/server-wg0.nmconnection` file, and append:
The `[wireguard-peer.<public_key_of_the_client>]` entry defines the peer section of the client, and the section name contains the public key of the client.

- The `allowed-ips` parameter sets the tunnel IP addresses of the client that are allowed to send data to this server.

Add a section for each client.

b. Reload the `server-wg0` connection profile:

```
#nmcli connection load /etc/NetworkManager/system-connections/server-wg0.nmconnection
```

7. Optional: Configure the connection to start automatically, enter:

```
#nmcli connection modify server-wg0 autoconnect yes
```

8. Reactivate the `server-wg0` connection:

```
#nmcli connection up server-wg0
```

Next steps

- Configure the firewalld service on the WireGuard server.

Verification

1. Display the interface configuration of the `wg0` device:

```
#wg show wg0
interface: wg0
public key: UtjqCJ57DeAsyKRFp7cFGiQqdONRn69u249Fa4O6BE=
private key: (hidden)
listening port: 51820
peer: bnfQcC8/g2/rvEycRUM2e6Hi3Nskk6G9r4r26nFVM=
allowed ips: 192.0.2.2/32, 2001:db8:1::2/128
```

To display the private key in the output, use the `WG_HIDE_KEYS=never wg show wg0` command.

2. Display the IP configuration of the `wg0` device:

```
#ip address show wg0
20: wg0: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1420 qdisc noqueue state UNKNOWN group default qlen 1000
 link/none
inet 192.0.2.1/24 brd 192.0.2.255 scope global noprefixroute wg0
   valid_lft forever preferred_lft forever
inet6 2001:db8:1::1/32 scope global noprefixroute
```
valid_lft forever preferred_lft forever
inet6 fe80::3ef:8863:1ce2:844/64 scope link noprefixroute
valid_lft forever preferred_lft forever

Additional resources

- The `wg(8)` man page
- The `WireGuard setting` section in the `nm-settings(5)` man page

### 13.6. CONFIGURING A WIREGUARD SERVER USING NMTUI

You can configure the WireGuard server by creating a connection profile in NetworkManager. Use this method to let NetworkManager manage the WireGuard connection.

This procedure assumes the following settings:

- **Server:**
  - Private key: `YFAnE0psgIdiAF7XR4abxiwVRnlMfeltxu10s/c4JXg=
  - Tunnel IPv4 address: `192.0.2.1/24`
  - Tunnel IPv6 address: `2001:db8:1::1/32`

- **Client:**
  - Public key: `bnwfQcC8/g2i4vvEqcRUM2e6Hi3Nskk6G9t4r26nFVM=
  - Tunnel IPv4 address: `192.0.2.2/24`
  - Tunnel IPv6 address: `2001:db8:1::2/32`

Prerequisites

- You have generated the public and private key for both the server and client.
- You know the following information:
  - The private key of the server
  - The static tunnel IP addresses and subnet masks of the client
  - The public key of the client
  - The static tunnel IP addresses and subnet masks of the server
- You installed the `NetworkManager-tui` package.

Procedure

1. Start the `nmtui` application:

   ```bash
   # nmtui
   ```

2. Select **Edit a connection**, and press **Enter**.
3. Select Add, and press Enter.

4. Select the WireGuard connection type in the list, and press Enter.

5. In the Edit connection window:
   a. Enter the name of the connection and the virtual interface, such as wg0, that NetworkManager should assign to the connection.
   b. Enter the private key of the server.
   c. Set the listen port number, such as 51820, for incoming WireGuard connections. Always set a fixed port number on hosts that receive incoming WireGuard connections. If you do not set a port, WireGuard uses a random free port each time you activate the interface.
   d. Click Add next to the Peers pane:
      i. Enter the public key of the client.
      ii. Set the Allowed IPs field to the tunnel IP addresses of the client that are allowed to send data to this server.
      iii. Select OK, and press Enter.
   e. Select Show next to IPv4 Configuration, and press Enter.
      i. Select the IPv4 configuration method Manual.
      ii. Enter the tunnel IPv4 address and the subnet mask. Leave the Gateway field empty.
   f. Select Show next to IPv6 Configuration, and press Enter.
      i. Select the IPv6 configuration method Manual.
      ii. Enter the tunnel IPv6 address and the subnet mask. Leave the Gateway field empty.
g. Select **OK**, and press **Enter**.

![WireGuard Configuration Interface](image)

6. In the window with the list of connections, select **Back**, and press **Enter**.

7. In the **NetworkManager TUI** main window, select **Quit**, and press **Enter**.

**Next steps**

- Configure the firewalld service on the WireGuard server.

**Verification**

1. Display the interface configuration of the **wg0** device:

```bash
# wg show wg0
interface: wg0
  public key: UtjqCJ57DeAscYKRfp7cFGiQqdONRn69u249Fa4O6BE=
  private key: (hidden)
  listening port: 51820

peer: bnwfQcC8/g24vvEqcRUM2e6Hi3Nskk6G9t4r26nFVM=
  allowed ips: 192.0.2.2/32, 2001:db8:1::2/128
```

To display the private key in the output, use the **WG_HIDE_KEYS=never wg show wg0** command.

2. Display the IP configuration of the **wg0** device:
Additional resources

- The `wg(8)` man page

### 13.7. CONFIGURING A WIREGUARD SERVER USING NM-CONNECTION-EDITOR

You can configure the WireGuard server by creating a connection profile in NetworkManager. Use this method to let NetworkManager manage the WireGuard connection.

#### Prerequisites

- You have generated the public and private key for both the server and client.
- You know the following information:
  - The private key of the server
  - The static tunnel IP addresses and subnet masks of the client
  - The public key of the client
  - The static tunnel IP addresses and subnet masks of the server

#### Procedure

1. Open a terminal, and enter:
   ```bash
   # nm-connection-editor
   ```

2. Add a new connection by clicking the ✪ button.

3. Select the **WireGuard** connection type, and click **Create**.

4. Optional: Update the connection name.

5. On the **General** tab, select **Connect automatically with priority**. Optionally, set a priority value.

6. On the **WireGuard** tab:
   a. Enter the name of the virtual interface, such as `wg0`, that NetworkManager should assign to the connection.
   b. Enter the private key of the server.
c. Set the listen port number, such as 51820, for incoming WireGuard connections. Always set a fixed port number on hosts that receive incoming WireGuard connections. If you do not set a port, WireGuard uses a random free port each time you activate the interface.

d. Click **Add** to add peers:
   i. Enter the public key of the client.
   ii. Set the **Allowed IPs** field to the tunnel IP addresses of the client that are allowed to send data to this server.
   iii. Click **Apply**.

7. On the **IPv4 Settings** tab:
   a. Select **Manual** in the **Method** list.
   b. Click **Add** to enter the tunnel IPv4 address and the subnet mask. Leave the **Gateway** field empty.

8. On the **IPv6 Settings** tab:
   a. Select **Manual** in the **Method** list.
   b. Click **Add** to enter the tunnel IPv6 address and the subnet mask. Leave the **Gateway** field empty.

9. Click **Save** to store the connection profile.

**Next steps**

- Configure the `firewalld` service on the WireGuard server.

**Verification**

1. Display the interface configuration of the **wg0** device:

   ```bash
   # wg show wg0
   interface: wg0
   public key: UtjqCJ57DeAscYKRIp7cFGiQqdONRn69u249Fa4O6BE=
   private key: (hidden)
   listening port: 51820
   peer: bnwfQcC8/g2i4vvEqcRUM2e6Hi3Nskk6G9t4r26nFVM=
   allowed ips: 192.0.2.2/32, 2001:db8:1::2/128
   
   To display the private key in the output, use the `WG_HIDE_KEYS=never wg show wg0` command.
   ```

2. Display the IP configuration of the **wg0** device:

   ```bash
   # ip address show wg0
   20: wg0: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1420 qdisc noqueue state
   UNKNOWN group default qlen 1000
   link/none
   ```
inet 192.0.2.1/24 brd 192.0.2.255 scope global noprefixroute wg0 valid_lft forever preferred_lft forever

- The `wg(8)` man page

13.8. CONFIGURING A WIREGUARD SERVER USING THE WG-QUICK SERVICE

You can configure the WireGuard server by creating a configuration file in the `/etc/wireguard/` directory. Use this method to configure the service independently from NetworkManager.

This procedure assumes the following settings:

- **Server:**
  - Private key: `YFAnE0psgliAF7XR4abxiwVRnlMfeltxu10s/c4JXg=
  - Tunnel IPv4 address: `192.0.2.1/24`
  - Tunnel IPv6 address: `2001:db8:1::1/32`

- **Client:**
  - Public key: `bnwfQcC8/g2i4vvEqcRUM2e6Hi3Nskk6G9t4r26nFVM=
  - Tunnel IPv4 address: `192.0.2.2/24`
  - Tunnel IPv6 address: `2001:db8:1::2/32`

Prerequisites

- You have generated the public and private key for both the server and client.
- You know the following information:
  - The private key of the server
  - The static tunnel IP addresses and subnet masks of the client
  - The public key of the client
  - The static tunnel IP addresses and subnet masks of the server

Procedure

1. Install the `wireguard-tools` package:

   ```
   # dnf install wireguard-tools
   ```
2. Create the `/etc/wireguard/wg0.conf` file with the following content:

```
[Interface]
Address = 192.0.2.1/24, 2001:db8:1::1/32
ListenPort = 51820
PrivateKey = YFAnE0psgIIdiAF7XR4abxiwVRnlMfeltxu10s/c4JXg=

[Peer]
PublicKey = bnwfQcC8/g2i4vvEqcRUM2e6Hi3Nsik6G9t4r26nFVM=
AllowedIPs = 192.0.2.2, 2001:db8:1::2
```

- The `[Interface]` section describes the WireGuard settings of the interface on the server:
  - **Address**: A comma-separated list of the server’s tunnel IP addresses.
  - **PrivateKey**: The private key of the server.
  - **ListenPort**: The port on which WireGuard listens for incoming UDP connections. Always set a fixed port number on hosts that receive incoming WireGuard connections. If you do not set a port, WireGuard uses a random free port each time you activate the `wg0` interface.

- Each `[Peer]` section describes the settings of one client:
  - **PublicKey**: The public key of the client.
  - **AllowedIPs**: The tunnel IP addresses of the client that are allowed to send data to this server.

3. Enable and start the WireGuard connection:

```
# systemctl enable --now wg-quick@wg0
```

The systemd instance name must match the name of the configuration file in the `/etc/wireguard/` directory without the `.conf` suffix. The service also uses this name for the virtual network interface.

Next steps

- **Configure the firewall service on the WireGuard server.**

Verification

1. Display the interface configuration of the `wg0` device:

```
# wg show wg0
interface: wg0
  public key: UtjqCJ57DeAscYKRlfp7cFGiQqdONRn69u249Fa4O6BE=
  private key: (hidden)
  listening port: 51820

peer: bnwfQcC8/g2i4vvEqcRUM2e6Hi3Nsik6G9t4r26nFVM=
  allowed ips: 192.0.2.2/32, 2001:db8:1::2/128
```

To display the private key in the output, use the `WG_HIDE_KEY=never wg show wg0` command.
2. Display the IP configuration of the `wg0` device:

```
# ip address show wg0
20: wg0: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1420 qdisc noqueue state UNKNOWN group default qlen 1000
    link/none
    inet 192.0.2.1/24 scope global wg0
        valid_lft forever preferred_lft forever
    inet6 2001:db8:1::1/32 scope global
        valid_lft forever preferred_lft forever
```

Additional resources

- The `wg(8)` man page
- The `wg-quick(8)` man page

### 13.9. CONFIGURING FIREWALLD ON A WIREGUARD SERVER USING THE COMMAND LINE

You must configure the `firewalld` service on the WireGuard server to allow incoming connections from clients. Additionally, if clients should be able to use the WireGuard server as the default gateway and route all traffic through the tunnel, you must enable masquerading.

**Procedure**

1. Open the WireGuard port for incoming connections in the `firewalld` service:

   ```
   # firewall-cmd --permanent --add-port=51820/udp --zone=public
   ```

2. If clients should route all traffic through the tunnel and use the WireGuard server as the default gateway, enable masquerading for the `public` zone:

   ```
   # firewall-cmd --permanent --zone=public --add-masquerade
   ```

3. Reload the `firewalld` rules.

   ```
   # firewall-cmd --reload
   ```

**Verification**

- Display the configuration of the `public` zone:

  ```
  # firewall-cmd --list-all
  public (active)
  ... ports: 51820/udp
  masquerade: yes
  ...
  ```

**Additional resources**
13.10. CONFIGURING FIREWALLD ON A WIREGUARD SERVER USING THE GRAPHICAL INTERFACE

You must configure the firewalld service on the WireGuard server to allow incoming connections from clients. Additionally, if clients should be able to use the WireGuard server as the default gateway and route all traffic through the tunnel, you must enable masquerading.

Procedure

1. Press the Super key, enter firewall, and select the Firewall application from the results.
2. Select Permanent in the Configuration list.
3. Select the public zone.
4. Allow incoming connections to the WireGuard port:
   a. On the Ports tab, click Add.
   b. Enter the port number you set for incoming WireGuard connections:
   c. Select udp from the Protocol list.
   d. Click OK.
5. If clients should route all traffic through the tunnel and use the WireGuard server as the default gateway:
   a. Navigate to the Masquerading tab of the public zone.
   b. Select Masquerade zone.
6. Select Options → Reload Firewalld.

Verification

- Display the configuration of the public zone:

```bash
# firewall-cmd --list-all
public (active)
...  
ports: 51820/udp
masquerade: yes
...
```

13.11. CONFIGURING A WIREGUARD CLIENT USING NMCLI

You can configure a WireGuard client by creating a connection profile in NetworkManager. Use this method to let NetworkManager manage the WireGuard connection.

This procedure assumes the following settings:

- Client:
Private key: aPUcp5vHz8yMLrzk8SsDyYnV33IhE/k20e52iKJFV0A=

Tunnel IPv4 address: 192.0.2.2/24

Tunnel IPv6 address: 2001:db8:1::2/32

Server:

Public key: UtjqCJ57DeAscYKRfp7cFGiQqdONRn69u249Fa4O6BE=

Tunnel IPv4 address: 192.0.2.1/24

Tunnel IPv6 address: 2001:db8:1::1/32

Prerequisites

- You have generated the public and private key for both the server and client.
- You know the following information:
  - The private key of the client
  - The static tunnel IP addresses and subnet masks of the client
  - The public key of the server
  - The static tunnel IP addresses and subnet masks of the server

Procedure

1. Add a NetworkManager WireGuard connection profile:

```
# nmcli connection add type wireguard con-name client-wg0 ifname wg0 autoconnect no
```

This command creates a profile named client-wg0 and assigns the virtual interface wg0 to it. To prevent the connection from starting automatically after you add it without finalizing the configuration, disable the autoconnect parameter.

2. Optional: Configure NetworkManager so that it does not automatically start the client-wg connection:

```
# nmcli connection modify client-wg0 autoconnect no
```

3. Set the tunnel IPv4 address and subnet mask of the client:

```
# nmcli connection modify client-wg0 ipv4.method manual ipv4.addresses 192.0.2.2/24
```

4. Set the tunnel IPv6 address and subnet mask of the client:

```
# nmcli connection modify client-wg0 ipv6.method manual ipv6.addresses 2001:db8:1::2/32
```

5. If you want to route all traffic through the tunnel, set the tunnel IP addresses of the server as the default gateway:
6. Add the server’s private key to the connection profile:

```bash
# nmcli connection modify client-wg0 wireguard.private-key "aPUcp5vHz2yMLrzk8SsDyYnV33lhE/k20e52iKJFV0A="
```

a. Edit the `/etc/NetworkManager/system-connections/client-wg0.nmconnection` file, and append:

```
[wireguard-peer.UtjqCJ57DeAscYKRfp7cFGiQqdONRn69u249Fa4O6BE=]
endpoint=server.example.com:51820
allowed-ips=192.0.2.1;2001:db8:1::1;
persistent-keepalive=20
```

- The `[wireguard-peer.<public_key_of_the_server>]` entry defines the peer section of the server, and the section name contains the public key of the server.
- The `endpoint` parameter sets the hostname or IP address and the port of the server. The client uses this information to establish the connection.
- The `allowed-ips` parameter sets a list of IP addresses that are allowed to send data to this client. For example, set the parameter to:
  - The tunnel IP addresses of the server to allow only the server to communicate with this client. The value in the example above configures this scenario.
  - `0.0.0.0/0;::/0;` to allow any remote IPv4 and IPv6 address to communicate with this client. Use this setting to route all traffic through the tunnel and use the WireGuard server as default gateway.
- The optional `persistent-keepalive` parameter defines an interval in seconds in which WireGuard sends a keepalive packet to the server. Set this parameter if you use the client in a network with network address translation (NAT) or if a firewall closes the UDP connection after some time of inactivity.

b. Reload the `client-wg0` connection profile:

```bash
# nmcli connection load /etc/NetworkManager/system-connections/client-wg0.nmconnection
```

7. Reactivate the `client-wg0` connection:

```bash
# nmcli connection up client-wg0
```

**Verification**

1. Ping the IP addresses of the server:

```bash
# ping 192.0.2.1
# ping6 2001:db8:1::1
```

2. Display the interface configuration of the `wg0` device:
To display the private key in the output, use the `WG_HIDE_KEYS=never wg show wg0` command.

Note that the output contains only the latest handshake and transfer entries if you have already sent traffic through the VPN tunnel.

3. Display the IP configuration of the `wg0` device:

```
# ip address show wg0
10: wg0: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1420 qdisc noqueue state UNKNOWN group default qlen 1000
    link/none
    inet 192.0.2.2/24 brd 192.0.2.255 scope global noprefixroute wg0
        valid_lft forever preferred_lft forever
    inet6 fe80::73d9:6f51:ea6f:863e/64 scope link noprefixroute
        valid_lft forever preferred_lft forever
```

### 13.12. Configuring a WireGuard Client Using NMTUI

You can configure a WireGuard client by creating a connection profile in NetworkManager. Use this method to let NetworkManager manage the WireGuard connection.

This procedure assumes the following settings:

- Client:
  - Private key: `aPUcp5vHz8yMLrzk8SsDyYnV33IhE/k20e52iKJFV0A=`
  - Tunnel IPv4 address: `192.0.2.2/24`
  - Tunnel IPv6 address: `2001:db8:1::2/32`

- Server:
- Public key: \texttt{UtjqCJ57DeAscYKRfp7cFGiQqdONRn69u249Fa4O6BE=}
- Tunnel IPv4 address: \texttt{192.0.2.1/24}
- Tunnel IPv6 address: \texttt{2001:db8:1::1/32}

Prerequisites

- You have generated the public and private key for both the server and client.
- You know the following information:
  - The private key of the client
  - The static tunnel IP addresses and subnet masks of the client
  - The public key of the server
  - The static tunnel IP addresses and subnet masks of the server
- You installed the \texttt{NetworkManager-tui} package

Procedure

1. Start the \texttt{nmtui} application:
   ```bash
   # nmtui
   ```

2. Select \texttt{Edit a connection}, and press \texttt{Enter}.

3. Select \texttt{Add}, and press \texttt{Enter}.

4. Select the \texttt{WireGuard} connection type in the list, and press \texttt{Enter}.

5. In the \texttt{Edit connection} window:
   a. Enter the name of the connection and the virtual interface, such as \texttt{wg0}, that NetworkManager should assign to the connection.
   
   b. Enter the private key of the client.

   ![Edit Connection](CHAPTER_13. SETTING_UP_A_WIREGUARD_VPN.png)

   c. Click \texttt{Add} next to the \texttt{Peers} pane:
      i. Enter the public key of the server.
      
      ii. Set the \texttt{Allowed IPs} field. For example, set it to:
- The tunnel IP addresses of the server to allow only the server to communicate with this client.

- `0.0.0.0/0,::/0` to allow any remote IPv4 and IPv6 address to communicate with this client. Use this setting to route all traffic through the tunnel and use the WireGuard server as default gateway.

iii. Enter the host name or IP address and port of the WireGuard server into the **Endpoint** field. Use the following format: `hostname_or_IP:port_number`

iv. Optional: If you use the client in a network with network address translation (NAT) or if a firewall closes the UDP connection after some time of inactivity, set a persistent keep alive interval in seconds. In this interval, the client sends a keepalive packet to the server.

v. Select **OK**, and press **Enter**.

![WireGuard Configuration](image)

d. Select **Show** next to **IPv4 Configuration**, and press **Enter**.

i. Select the IPv4 configuration method **Manual**.

ii. Enter the tunnel IPv4 address and the subnet mask. Leave the **Gateway** field empty.

e. Select **Show** next to **IPv6 Configuration**, and press **Enter**.

i. Select the IPv6 configuration method **Manual**.

ii. Enter the tunnel IPv6 address and the subnet mask. Leave the **Gateway** field empty.

f. Optional: Select **Automatically connect**.

g. Select **OK**, and press **Enter**
6. In the window with the list of connections, select **Back**, and press **Enter**.

7. In the **NetworkManager TUI** main window, select **Quit**, and press **Enter**.

**Verification**

1. Ping the IP addresses of the server:

   ```
   # ping 192.0.2.1
   # ping6 2001:db8:1::1
   ```

2. Display the interface configuration of the **wg0** device:

   ```
   # wg show wg0
   interface: wg0
   public key: bnwfQcC8/g2i4vvEqcRUM2e6Hi3Nskk6G9t4r26nFVM=
   private key: (hidden)
   listening port: 51820
   peer: UtjqCJ57DeAscYKRfp7cFGiQqdONRn69u249Fa4O6BE=
   endpoint: server.example.com:51820
   allowed ips: 192.0.2.1/32, 2001:db8:1::1/128
   latest handshake: 1 minute, 41 seconds ago
   transfer: 824 B received, 1.01 KiB sent
   persistent keepalive: every 20 seconds
   ```
To display the private key in the output, use the `WG_HIDE_KEYS=never wg show wg0` command.

Note that the output contains only the latest handshake and transfer entries if you have already sent traffic through the VPN tunnel.

3. Display the IP configuration of the `wg0` device:

```bash
# ip address show wg0
10: wg0: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1420 qdisc noqueue state UNKNOWN group default qlen 1000
    link/none
    inet 192.0.2.2/24 brd 192.0.2.255 scope global noprefixroute wg0
        valid_lft forever preferred_lft forever
    inet6 2001:db8:1::/32 scope global noprefixroute
        valid_lft forever preferred_lft forever
    inet6 fe80::73d9:6f51:ea6f:863e/64 scope link noprefixroute
        valid_lft forever preferred_lft forever
```

Additional resources

- The `wg(8)` man page

13.13. CONFIGURING A WIREGUARD CLIENT USING NM-CONNECTION-EDITOR

You can configure a WireGuard client by creating a connection profile in NetworkManager. Use this method to let NetworkManager manage the WireGuard connection.

Prerequisites

- You have generated the public and private key for both the server and client.
- You know the following information:
  - The private key of the client
  - The static tunnel IP addresses and subnet masks of the client
  - The public key of the server
  - The static tunnel IP addresses and subnet masks of the server

Procedure

1. Open a terminal, and enter:

   ```bash
   # nm-connection-editor
   ```

2. Add a new connection by clicking the + button.

3. Select the WireGuard connection type, and click Create.

4. Optional: Update the connection name.
5. Optional: On the General tab, select Connect automatically with priority.

6. On the WireGuard tab:
   a. Enter the name of the virtual interface, such as wg0, that NetworkManager should assign to the connection.
   b. Enter client’s private key.
   c. Click Add to add peers:
      i. Enter the public key of the server.
      ii. Set the Allowed IPs field. For example, set it to:
         - The tunnel IP addresses of the server to allow only the server to communicate with this client.
         - 0.0.0.0/0::$ffff:0/0; to allow any remote IPv4 and IPv6 address to communicate with this client. Use this setting to route all traffic through the tunnel and use the WireGuard server as default gateway.
      iii. Enter the hostname or IP address and port of the WireGuard server into the Endpoint field. Use the following format: hostname_or_IP:port_number
      iv. Optional: If you use the client in a network with network address translation (NAT) or if a firewall closes the UDP connection after some time of inactivity, set a persistent keep alive interval in seconds. In this interval, the client sends a keepalive packet to the server.
      v. Click Apply.

7. On the IPv4 Settings tab:
   b. Click Add to enter the tunnel IPv4 address and the subnet mask.
   c. If you want to route all traffic through the tunnel, set the tunnel IPv4 address of the server in the Gateway field. Otherwise, leave the field empty.

8. On the IPv6 Settings tab:
   b. Click Add to enter the tunnel IPv6 address and the subnet mask.
   c. If you want to route all traffic through the tunnel, set the tunnel IPv6 address of the server in the Gateway field. Otherwise, leave the field empty.

9. Click Save to store the connection profile.

Verification

1. Ping the IP addresses of the server:

   `# ping 192.0.2.1
   # ping6 2001:db8:1::1`
2. Display the interface configuration of the **wg0** device:

```bash
# wg show wg0
interface: wg0
  public key: bnfwQcC8/g2i4vvEqcRUM2e6Hi3Nskk6G9t4r26FVM=
  private key: (hidden)
  listening port: 51820
  peer: UtjqCJ57DeAsycG8y7cFGiQqdORn69u249FA4O6BE=
  endpoint: server.example.com:51820
  allowed ips: 192.0.2.1/32, 2001:db8:1::1/128
  latest handshake: 1 minute, 41 seconds ago
  transfer: 824 B received, 1.01 KiB sent
  persistent keepalive: every 20 seconds
```

To display the private key in the output, use the `WG_HIDE_KEYS=never wg show wg0` command.

Note that the output only contains the latest handshake and transfer entries if you have already sent traffic through the VPN tunnel.

3. Display the IP configuration of the **wg0** device:

```bash
# ip address show wg0
10: wg0: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1420 qdisc noqueue state UNKNOWN group default qlen 1000
  link/none
  inet 192.0.2.2/24 brd 192.0.2.255 scope global noprefixroute wg0
    valid_lft forever preferred_lft forever
  inet6 fe80::73d9:6f51:ea6f:863e/64 scope link noprefixroute
    valid_lft forever preferred_lft forever
  inet6 2001:db8:1::2/32 scope global noprefixroute
    valid_lft forever preferred_lft forever
```

- The **wg(8)** man page

### 13.14. CONFIGURING A WIREGUARD CLIENT USING THE WG-QUICK SERVICE

You can configure a WireGuard client by creating a configuration file in the `/etc/wireguard/` directory. Use this method to configure the service independently from NetworkManager.

This procedure assumes the following settings:

- **Client:**
  - Private key: `aPUcp5vHz8yMLrzk8SsDYnV33lhe/k20e52iKjFV0A=`
  - Tunnel IPv4 address: `192.0.2.2/24`
  - Tunnel IPv6 address: `2001:db8:1::2/32`

- **Server:**
Prerequisites

- You have generated the public and private key for both the server and client.
- You know the following information:
  - The private key of the client
  - The static tunnel IP addresses and subnet masks of the client
  - The public key of the server
  - The static tunnel IP addresses and subnet masks of the server

Procedure

1. Install the `wireguard-tools` package:

   ```
   # dnf install wireguard-tools
   ```

2. Create the `/etc/wireguard/wg0.conf` file with the following content:

   ```
   [Interface]
   Address = 192.0.2.2/24, 2001:db8:1::2/32
   PrivateKey = aPUcp5vHz8yMLrz8SsDyYnV33lhE/k20e52iKJFV0A=

   [Peer]
   PublicKey = UtjqCJ57DeAscYKRfp7cFGiQqdONRn69u249Fa4O6BE=
   AllowedIPs = 192.0.2.1, 2001:db8:1::1
   Endpoint = server.example.com:51820
   PersistentKeepalive = 20
   ```

- The [Interface] section describes the WireGuard settings of the interface on the client:
  - **Address**: A comma-separated list of the client’s tunnel IP addresses.
  - **PrivateKey**: The private key of the client.

- The [Peer] section describes the settings of the server:
  - **PublicKey**: The public key of the server.
  - **AllowedIPs**: The IP addresses that are allowed to send data to this client. For example, set the parameter to:
    - The tunnel IP addresses of the server to allow only the server to communicate with this client. The value in the example above configures this scenario.
- **0.0.0.0/0, ::/0** to allow any remote IPv4 and IPv6 address to communicate with this client. Use this setting to route all traffic through the tunnel and use the WireGuard server as default gateway.

  - **Endpoint**: Sets the hostname or IP address and the port of the server. The client uses this information to establish the connection.

  - The optional **persistent-keepalive** parameter defines an interval in seconds in which WireGuard sends a keepalive packet to the server. Set this parameter if you use the client in a network with network address translation (NAT) or if a firewall closes the UDP connection after some time of inactivity.

3. Enable and start the WireGuard connection:

   ```
   # systemctl enable --now wg-quick@wg0
   ```

   The systemd instance name must match the name of the configuration file in the `/etc/wireguard/` directory without the `.conf` suffix. The service also uses this name for the virtual network interface.

**Verification**

1. Ping the IP addresses of the server:

   ```
   # ping 192.0.2.1
   # ping6 2001:db8:1::1
   ```

2. Display the interface configuration of the **wg0** device:

   ```
   # wg show wg0
   interface: wg0
   public key: bnwfQcC8/g2i4vvEqcRUM2e6IyiJNskk6G9t4r26nFVM=
   private key: (hidden)
   listening port: 51820
   peer: UtjqCJ57DeAscYKRfp7cFGiQqdONRn69u249Fa406BE=
   endpoint: server.example.com:51820
   allowed ips: 192.0.2.1/32, 2001:db8:1::1/128
   latest handshake: 1 minute, 41 seconds ago
   transfer: 824 B received, 1.01 KiB sent
   persistent keepalive: every 20 seconds
   ```

   To display the private key in the output, use the `WG_HIDE_KEYS=never wg show wg0` command.

   Note that the output contains only the latest handshake and transfer entries if you have already sent traffic through the VPN tunnel.

3. Display the IP configuration of the **wg0** device:

   ```
   # ip address show wg0
   10: wg0: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1420 qdisc noqueue state
   UNKNOWN group default qlen 1000
   link/none
   inet 192.0.2.2/24 scope global wg0
   ```
valid_lft forever preferred_lft forever
inet6 2001:db8:1::2/32 scope global
valid_lft forever preferred_lft forever

- The `wg(8)` man page
- The `wg-quick(8)` man page
CHAPTER 14. CONFIGURING A VPN CONNECTION

This section explains how to configure a virtual private network (VPN) connection.

A VPN is a way of connecting to a local network over the Internet. IPsec provided by Libreswan is the preferred method for creating a VPN. Libreswan is an user-space IPsec implementation for VPN. A VPN enables the communication between your LAN, and another, remote LAN by setting up a tunnel across an intermediate network such as the Internet. For security reasons, a VPN tunnel always uses authentication and encryption. For cryptographic operations, Libreswan uses the NSS library.

14.1. CONFIGURING A VPN CONNECTION WITH CONTROL-CENTER

This procedure describes how to configure a VPN connection using control-center.

Prerequisites

- The NetworkManager-libreswan-gnome package is installed.

Procedure

1. Press the Super key, type Settings, and press Enter to open the control-center application.
2. Select the Network entry on the left.
3. Click the + icon.
4. Select VPN.
5. Select the Identity menu entry to see the basic configuration options:
   - General
     - Gateway – The name or IP address of the remote VPN gateway.
   - Authentication
   - Type
     - IKEv2 (Certificate) - client is authenticated by certificate. It is more secure (default).
     - IKEv1 (XAUTH) - client is authenticated by user name and password, or a pre-shared key (PSK).

   The following configuration settings are available under the Advanced section:
Figure 14.1. Advanced options of a VPN connection

![IPsec Advanced Options](image)

**Identification**
- Domain: [field]

**Security**
- Phase1 Algorithms: [field]
- Phase2 Algorithms: [field]
- [ ] Disable PFS
- Phase1 Lifetime: [field]
- Phase2 Lifetime: [field]
- [ ] Disable rekeying

**Connectivity**
- Remote Network: [field]
- [ ] narrowing
- Enable fragmentation: yes
- Enable MOBIKE: no

[Apply button]
WARNING  
When configuring an IPsec-based VPN connection using the `gnome-control-center` application, the **Advanced** dialog displays the configuration, but it does not allow any changes. As a consequence, users cannot change any advanced IPsec options. Use the `nm-connection-editor` or `nmcli` tools instead to perform configuration of the advanced properties.

Identification

- **Domain** – If required, enter the Domain Name.

Security

- **Phase1 Algorithms** – corresponds to the `ike` Libreswan parameter – enter the algorithms to be used to authenticate and set up an encrypted channel.

- **Phase2 Algorithms** – corresponds to the `esp` Libreswan parameter – enter the algorithms to be used for the IPsec negotiations.
  Check the **Disable PFS** field to turn off Perfect Forward Secrecy (PFS) to ensure compatibility with old servers that do not support PFS.

- **Phase1 Lifetime** – corresponds to the `ikelifetime` Libreswan parameter – how long the key used to encrypt the traffic will be valid.

- **Phase2 Lifetime** – corresponds to the `salifetime` Libreswan parameter – how long a particular instance of a connection should last before expiring.
  Note that the encryption key should be changed from time to time for security reasons.

- **Remote network** – corresponds to the `rightsubnet` Libreswan parameter – the destination private remote network that should be reached through the VPN.
  Check the **narrowing** field to enable narrowing. Note that it is only effective in IKEv2 negotiation.

- **Enable fragmentation** – corresponds to the `fragmentation` Libreswan parameter – whether or not to allow IKE fragmentation. Valid values are **yes** (default) or **no**.

- **Enable Mobike** – corresponds to the `mobike` Libreswan parameter – whether to allow Mobility and Multihoming Protocol (MOBIKE, RFC 4555) to enable a connection to migrate its endpoint without needing to restart the connection from scratch. This is used on mobile devices that switch between wired, wireless, or mobile data connections. The values are **no** (default) or **yes**.

6. Select the **IPv4** menu entry:

   **IPv4 Method**

   - **Automatic (DHCP)** – Choose this option if the network you are connecting to uses a DHCP server to assign dynamic IP addresses.

   - **Link-Local Only** – Choose this option if the network you are connecting to does not have a DHCP server and you do not want to assign IP addresses manually. Random addresses will be assigned as per RFC 3927 with prefix 169.254/16.
- **Manual** – Choose this option if you want to assign IP addresses manually.

- **Disable** – IPv4 is disabled for this connection.

**DNS**

In the DNS section, when Automatic is ON, switch it to OFF to enter the IP address of a DNS server you want to use separating the IPs by comma.

**Routes**

Note that in the Routes section, when Automatic is ON, routes from DHCP are used, but you can also add additional static routes. When OFF, only static routes are used.

- **Address** – Enter the IP address of a remote network or host.

- **Netmask** – The netmask or prefix length of the IP address entered above.

- **Gateway** – The IP address of the gateway leading to the remote network or host entered above.

- **Metric** – A network cost, a preference value to give to this route. Lower values will be preferred over higher values.

**Use this connection only for resources on its network**

Select this check box to prevent the connection from becoming the default route. Selecting this option means that only traffic specifically destined for routes learned automatically over the connection or entered here manually is routed over the connection.

7. To configure IPv6 settings in a VPN connection, select the IPv6 menu entry:

**IPv6 Method**

- **Automatic** – Choose this option to use IPv6 Stateless Address AutoConfiguration (SLAAC) to create an automatic, stateless configuration based on the hardware address and Router Advertisements (RA).

- **Automatic, DHCP only** – Choose this option to not use RA, but request information from DHCPv6 directly to create a stateful configuration.

- **Link-Local Only** – Choose this option if the network you are connecting to does not have a DHCP server and you do not want to assign IP addresses manually. Random addresses will be assigned as per RFC 4862 with prefix FE80::0.

- **Manual** – Choose this option if you want to assign IP addresses manually.

- **Disable** – IPv6 is disabled for this connection.

Note that DNS, Routes, Use this connection only for resources on its network are common to IPv4 settings.

8. Once you have finished editing the VPN connection, click the Add button to customize the configuration or the Apply button to save it for the existing one.

9. Switch the profile to ON to activate the VPN connection.

- nm-settings-libreswan(5)
14.2. CONFIGURING A VPN CONNECTION USING NM-CONNECTION-EDITOR

This procedure describes how to configure a VPN connection using `nm-connection-editor`.

Prerequisites

- The `NetworkManager-libreswan-gnome` package is installed.
- If you configure an Internet Key Exchange version 2 (IKEv2) connection:
  - The certificate is imported into the IPsec network security services (NSS) database.
  - The nickname of the certificate in the NSS database is known.

Procedure

1. Open a terminal, and enter:
   
   ```
   $ nm-connection-editor
   ```

2. Click the + button to add a new connection.

3. Select the **IPsec based VPN** connection type, and click Create.

4. On the **VPN** tab:
   
   a. Enter the host name or IP address of the VPN gateway into the **Gateway** field, and select an authentication type. Based on the authentication type, you must enter different additional information:
      
      - **IKEv2 (Certificate)** authenticates the client by using a certificate, which is more secure. This setting requires the nickname of the certificate in the IPsec NSS database
      - **IKEv1 (XAUTH)** authenticates the user by using a user name and password (pre-shared key). This setting requires that you enter the following values:
        
        - User name
        - Password
        - Group name
        - Secret
      
   b. If the remote server specifies a local identifier for the IKE exchange, enter the exact string in the **Remote ID** field. In the remote server runs Libreswan, this value is set in the server’s `leftid` parameter.
c. Optionally, configure additional settings by clicking the Advanced button. You can configure the following settings:

- **Identification**
  - **Domain** – If required, enter the domain name.

- **Security**
  - **Phase1 Algorithms** corresponds to the *ike* Libreswan parameter. Enter the algorithms to be used to authenticate and set up an encrypted channel.

  - **Phase2 Algorithms** corresponds to the *esp* Libreswan parameter. Enter the algorithms to be used for the IPsec negotiations. Check the **Disable PFS** field to turn off Perfect Forward Secrecy (PFS) to ensure compatibility with old servers that do not support PFS.

  - **Phase1 Lifetime** corresponds to the *ikelifetime* Libreswan parameter. This parameter defines how long the key used to encrypt the traffic is valid.

  - **Phase2 Lifetime** corresponds to the *salifetime* Libreswan parameter. This parameter defines how long a security association is valid.

- **Connectivity**
Remote network corresponds to the `rightsubnet` Libreswan parameter and defines the destination private remote network that should be reached through the VPN. Check the narrowing field to enable narrowing. Note that it is only effective in the IKEv2 negotiation.

Enable fragmentation corresponds to the `fragmentation` Libreswan parameter and defines whether or not to allow IKE fragmentation. Valid values are yes (default) or no.

Enable Mobike corresponds to the `mobike` Libreswan parameter. The parameter defines whether to allow Mobility and Multihoming Protocol (MOBIKE) (RFC 4555) to enable a connection to migrate its endpoint without needing to restart the connection from scratch. This is used on mobile devices that switch between wired, wireless or mobile data connections. The values are no (default) or yes.

5. On the IPv4 Settings tab, select the IP assignment method and, optionally, set additional static addresses, DNS servers, search domains, and routes.

![IPv4 Settings](image)

6. Save the connection.

**NOTE**

When you add a new connection by clicking the + button, NetworkManager creates a new configuration file for that connection and then opens the same dialog that is used for editing an existing connection. The difference between these dialogs is that an existing connection profile has a Details menu entry.

### 14.3. CONFIGURING AUTOMATIC DETECTION AND USAGE OF ESP HARDWARE OFFLOAD TO ACCELERATE AN IPSEC CONNECTION

Offloading Encapsulating Security Payload (ESP) to the hardware accelerates IPsec connections over Ethernet. By default, Libreswan detects if hardware supports this feature and, as a result, enables ESP hardware offload. This procedure describes how to enable the automatic detection in case that the feature was disabled or explicitly enabled.

#### Prerequisites
- The network card supports ESP hardware offload.
- The network driver supports ESP hardware offload.
- The IPsec connection is configured and works.

#### Procedure
1. Edit the Libreswan configuration file in the `/etc/ipsec.d/` directory of the connection that should use automatic detection of ESP hardware offload support.
2. Ensure the `nic-offload` parameter is not set in the connection’s settings.
3. If you removed `nic-offload`, restart the `ipsec` service:
   ```bash
   # systemctl restart ipsec
   ```

#### Verification
If the network card supports ESP hardware offload support, following these steps to verify the result:

1. Display the `tx_ipsec` and `rx_ipsec` counters of the Ethernet device the IPsec connection uses:
   ```bash
   # ethtool -S enp1s0 | grep "_ipsec"
   tx_ipsec: 10
   rx_ipsec: 10
   ```

2. Send traffic through the IPsec tunnel. For example, ping a remote IP address:
   ```bash
   # ping -c 5 remote_ip_address
   ```

3. Display the `tx_ipsec` and `rx_ipsec` counters of the Ethernet device again:
   ```bash
   # ethtool -S enp1s0 | grep "_ipsec"
   tx_ipsec: 15
   rx_ipsec: 15
   ```
   If the counter values have increased, ESP hardware offload works.

#### Additional resources
- [Configuring a VPN with IPsec](#)
14.4. CONFIGURING ESP HARDWARE OFFLOAD ON A BOND TO ACCELERATE AN IPSEC CONNECTION

Offloading Encapsulating Security Payload (ESP) to the hardware accelerates IPsec connections. If you use a network bond for fail-over reasons, the requirements and the procedure to configure ESP hardware offload are different from those using a regular Ethernet device. For example, in this scenario, you enable the offload support on the bond, and the kernel applies the settings to the ports of the bond.

Prerequisites

- All network cards in the bond support ESP hardware offload.
- The network driver supports ESP hardware offload on a bond device. In RHEL, only the `ixgbe` driver supports this feature.
- The bond is configured and works.
- The bond uses the `active-backup` mode. The bonding driver does not support any other modes for this feature.
- The IPsec connection is configured and works.

Procedure

1. Enable ESP hardware offload support on the network bond:

   ```
   # nmcli connection modify bond0 ethtool.feature-esp-hw-offload on
   ```

   This command enables ESP hardware offload support on the `bond0` connection.

2. Reactivate the `bond0` connection:

   ```
   # nmcli connection up bond0
   ```

3. Edit the Libreswan configuration file in the `/etc/ipsec.d/` directory of the connection that should use ESP hardware offload, and append the `nic-offload=yes` statement to the connection entry:

   ```
   conn example
   ...
   nic-offload=yes
   ```

4. Restart the `ipsec` service:

   ```
   # systemctl restart ipsec
   ```

Verification

1. Display the active port of the bond:

   ```
   # grep "Currently Active Slave" /proc/net/bonding/bond0
   ```

   Currently Active Slave: `enp1s0`

2. Display the `tx_ipsec` and `rx_ipsec` counters of the active port:

   ```
   #
   ```
3. Send traffic through the IPsec tunnel. For example, ping a remote IP address:

```
# ping -c 5 remote_ip_address
```

4. Display the `tx_ipsec` and `rx_ipsec` counters of the active port again:

```
# ethtool -S enp1s0 | egrep "_ipsec"
  tx_ipsec: 15
  rx_ipsec: 15
```

If the counter values have increased, ESP hardware offload works.

CHAPTER 15. CONFIGURING IP TUNNELS

Similar to a VPN, an IP tunnel directly connects two networks over a third network, such as the Internet. However, not all tunnel protocols support encryption.

The routers in both networks that establish the tunnel requires at least two interfaces:

- One interface that is connected to the local network
- One interface that is connected to the network through which the tunnel is established.

To establish the tunnel, you create a virtual interface on both routers with an IP address from the remote subnet.

NetworkManager supports the following IP tunnels:

- Generic Routing Encapsulation (GRE)
- Generic Routing Encapsulation over IPv6 (IP6GRE)
- Generic Routing Encapsulation Terminal Access Point (GRETAP)
- Generic Routing Encapsulation Terminal Access Point over IPv6 (IP6GRETAP)
- IPv4 over IPv4 (IPIP)
- IPv4 over IPv6 (IPIP6)
- IPv6 over IPv6 (IP6IP6)
- Simple Internet Transition (SIT)

Depending on the type, these tunnels act either on layer 2 or 3 of the Open Systems Interconnection (OSI) model.

15.1. CONFIGURING AN IPIP TUNNEL USING NMCLI TO ENCAPSULATE IPV4 TRAFFIC IN IPV4 PACKETS

An IP over IP (IPIP) tunnel operates on OSI layer 3 and encapsulates IPv4 traffic in IPv4 packets as described in RFC 2003.

**IMPORTANT**

Data sent through an IPIP tunnel is not encrypted. For security reasons, use the tunnel only for data that is already encrypted, for example, by other protocols, such as HTTPS.

Note that IPIP tunnels support only unicast packets. If you require an IPv4 tunnel that supports multicast, see Configuring a GRE tunnel using nmcli to encapsulate layer-3 traffic in IPv4 packets.

This procedure describes how to create an IPIP tunnel between two RHEL routers to connect two internal subnets over the Internet as shown in the following diagram:
Prerequisites

- Each RHEL router has a network interface that is connected to its local subnet.
- Each RHEL router has a network interface that is connected to the Internet.
- The traffic you want to send through the tunnel is IPv4 unicast.

Procedure

1. On the RHEL router in network A:
   a. Create an IPIP tunnel interface named `tun0`:
      ```shell
      # nmcli connection add type ip-tunnel ip-tunnel.mode ipip con-name tun0 ifname tun0 remote 198.51.100.5 local 203.0.113.10
      ```
      The `remote` and `local` parameters set the public IP addresses of the remote and the local routers.
   b. Set the IPv4 address to the `tun0` device:
      ```shell
      # nmcli connection modify tun0 ipv4.addresses '10.0.1.1/30'
      ```
      Note that a /30 subnet with two usable IP addresses is sufficient for the tunnel.
   c. Configure the `tun0` connection to use a manual IPv4 configuration:
      ```shell
      # nmcli connection modify tun0 ipv4.method manual
      ```
   d. Add a static route that routes traffic to the `172.16.0.0/24` network to the tunnel IP on router B:
      ```shell
      # nmcli connection modify tun0 +ipv4.routes "172.16.0.0/24 10.0.1.2"
      ```
   e. Enable the `tun0` connection.
# nmcli connection up tun0

f. Enable packet forwarding:

```bash
# echo "net.ipv4.ip_forward=1" > /etc/sysctl.d/95-IPv4-forwarding.conf
# sysctl -p /etc/sysctl.d/95-IPv4-forwarding.conf
```

2. On the RHEL router in network B:

a. Create an IPIP tunnel interface named tun0:

```bash
# nmcli connection add type ip-tunnel ip-tunnel.mode ipip con-name tun0 ifname tun0 remote 203.0.113.10 local 198.51.100.5
```

The `remote` and `local` parameters set the public IP addresses of the remote and local routers.

b. Set the IPv4 address to the tun0 device:

```bash
# nmcli connection modify tun0 ipv4.addresses '10.0.1.2/30'
```

c. Configure the tun0 connection to use a manual IPv4 configuration:

```bash
# nmcli connection modify tun0 ipv4.method manual
```

d. Add a static route that routes traffic to the 192.0.2.0/24 network to the tunnel IP on router A:

```bash
# nmcli connection modify tun0 +ipv4.routes "192.0.2.0/24 10.0.1.1"
```

e. Enable the tun0 connection.

```bash
# nmcli connection up tun0
```

f. Enable packet forwarding:

```bash
# echo "net.ipv4.ip_forward=1" > /etc/sysctl.d/95-IPv4-forwarding.conf
# sysctl -p /etc/sysctl.d/95-IPv4-forwarding.conf
```

**Verification steps**

- From each RHEL router, ping the IP address of the internal interface of the other router:
  
  a. On Router A, ping 172.16.0.1:

  ```bash
  # ping 172.16.0.1
  ```
  
  b. On Router B, ping 192.0.2.1:

  ```bash
  # ping 192.0.2.1
  ```

**Additional resources**
15.2. CONFIGURING A GRE TUNNEL USING NMCLI TO ENCAPSULATE LAYER-3 TRAFFIC IN IPV4 PACKETS

A Generic Routing Encapsulation (GRE) tunnel encapsulates layer-3 traffic in IPv4 packets as described in RFC 2784. A GRE tunnel can encapsulate any layer 3 protocol with a valid Ethernet type.

IMPORTANT

Data sent through a GRE tunnel is not encrypted. For security reasons, use the tunnel only for data that is already encrypted, for example, by other protocols, such as HTTPS.

This procedure describes how to create a GRE tunnel between two RHEL routers to connect two internal subnets over the Internet as shown in the following diagram:

NOTE

The gre0 device name is reserved. Use gre1 or a different name for the device.

Prerequisites

- Each RHEL router has a network interface that is connected to its local subnet.
- Each RHEL router has a network interface that is connected to the Internet.

Procedure

1. On the RHEL router in network A:
   a. Create a GRE tunnel interface named gre1:

      ```
      # nmcli connection add type ip-tunnel ip-tunnel.mode gre con-name gre1 ifname gre1 remote 198.51.100.5 local 203.0.113.10
      ```
The **remote** and **local** parameters set the public IP addresses of the remote and the local routers.

b. Set the IPv4 address to the **gre1** device:

```bash
# nmcli connection modify gre1 ipv4.addresses '10.0.1.2/30'
```

Note that a /30 subnet with two usable IP addresses is sufficient for the tunnel.

c. Configure the **gre1** connection to use a manual IPv4 configuration:

```bash
# nmcli connection modify gre1 ipv4.method manual
```

d. Add a static route that routes traffic to the **172.16.0.0/24** network to the tunnel IP on router B:

```bash
# nmcli connection modify gre1 +ipv4.routes "172.16.0.0/24 10.0.1.2"
```

e. Enable the **gre1** connection.

```bash
# nmcli connection up gre1
```

f. Enable packet forwarding:

```bash
# echo "net.ipv4.ip_forward=1" > /etc/sysctl.d/95-IPv4-forwarding.conf
# sysctl -p /etc/sysctl.d/95-IPv4-forwarding.conf
```

2. On the RHEL router in network B:

a. Create a GRE tunnel interface named **gre1**:

```bash
# nmcli connection add type ip-tunnel ip-tunnel.mode gre con-name gre1 ifname gre1 remote 203.0.113.10 local 198.51.100.5
```

The **remote** and **local** parameters set the public IP addresses of the remote and the local routers.

b. Set the IPv4 address to the **gre1** device:

```bash
# nmcli connection modify gre1 ipv4.addresses '10.0.1.2/30'
```

c. Configure the **gre1** connection to use a manual IPv4 configuration:

```bash
# nmcli connection modify gre1 ipv4.method manual
```

d. Add a static route that routes traffic to the **192.0.2.0/24** network to the tunnel IP on router A:

```bash
# nmcli connection modify gre1 +ipv4.routes "192.0.2.0/24 10.0.1.1"
```

e. Enable the **gre1** connection.

```bash
# nmcli connection up gre1
```
f. Enable packet forwarding:

```bash
# echo "net.ipv4.ip_forward=1" > /etc/sysctl.d/95-IPv4-forwarding.conf
# sysctl -p /etc/sysctl.d/95-IPv4-forwarding.conf
```

Verification steps

1. From each RHEL router, ping the IP address of the internal interface of the other router:
   a. On Router A, ping 172.16.0.1:
      ```bash
      # ping 172.16.0.1
      ```
   b. On Router B, ping 192.0.2.1:
      ```bash
      # ping 192.0.2.1
      ```

Additional resources

- `nmcli` man page
- The `ip-tunnel settings` section in the `nm-settings(5)` man page

15.3. CONFIGURING A GRETAP TUNNEL TO TRANSFER ETHERNET FRAMES OVER IPV4

A Generic Routing Encapsulation Terminal Access Point (GRETAP) tunnel operates on OSI level 2 and encapsulates Ethernet traffic in IPv4 packets as described in RFC 2784.

**IMPORTANT**

Data sent through a GRETAP tunnel is not encrypted. For security reasons, establish the tunnel over a VPN or a different encrypted connection.

This procedure describes how to create a GRETAP tunnel between two RHEL routers to connect two networks using a bridge as shown in the following diagram:
NOTE

The gretap0 device name is reserved. Use gretap1 or a different name for the device.

Prerequisites

- Each RHEL router has a network interface that is connected to its local network, and the interface has no IP configuration assigned.
- Each RHEL router has a network interface that is connected to the Internet.

Procedure

1. On the RHEL router in network A:
   a. Create a bridge interface named bridge0:

   ```bash
   # nmcli connection add type bridge con-name bridge0 ifname bridge0
   ```

   b. Configure the IP settings of the bridge:

   ```bash
   # nmcli connection modify bridge0 ipv4.addresses '192.0.2.1/24'
   # nmcli connection modify bridge0 ipv4.method manual
   ```

   c. Add a new connection profile for the interface that is connected to local network to the bridge:

   ```bash
   # nmcli connection add type ethernet slave-type bridge con-name bridge0-port1 ifname enp1s0 master bridge0
   ```

   d. Add a new connection profile for the GRETAP tunnel interface to the bridge:
# nmcli connection add type ip-tunnel ip-tunnel.mode gretap slave-type bridge con-name bridge0-port2 ifname gretap1 remote 198.51.100.5 local 203.0.113.10 master bridge0

The `remote` and `local` parameters set the public IP addresses of the remote and the local routers.

e. Optional: Disable the Spanning Tree Protocol (STP) if you do not need it:

```
# nmcli connection modify bridge0 bridge.stp no
```

By default, STP is enabled and causes a delay before you can use the connection.

f. Configure that activating the `bridge0` connection automatically activates the ports of the bridge:

```
# nmcli connection modify bridge0 connection.autoconnect-slaves 1
```

g. Active the `bridge0` connection:

```
# nmcli connection up bridge0
```

2. On the RHEL router in network B:

a. Create a bridge interface named `bridge0`:

```
# nmcli connection add type bridge con-name bridge0 ifname bridge0
```

b. Configure the IP settings of the bridge:

```
# nmcli connection modify bridge0 ipv4.addresses '192.0.2.2/24'
# nmcli connection modify bridge0 ipv4.method manual
```

c. Add a new connection profile for the interface that is connected to local network to the bridge:

```
# nmcli connection add type ethernet slave-type bridge con-name bridge0-port1 ifname enp1s0 master bridge0
```

d. Add a new connection profile for the GRETAP tunnel interface to the bridge:

```
# nmcli connection add type ip-tunnel ip-tunnel.mode gretap slave-type bridge con-name bridge0-port2 ifname gretap1 remote 203.0.113.10 local 198.51.100.5 master bridge0
```

The `remote` and `local` parameters set the public IP addresses of the remote and the local routers.

e. Optional: Disable the Spanning Tree Protocol (STP) if you do not need it:

```
# nmcli connection modify bridge0 bridge.stp no
```
f. Configure that activating the `bridge0` connection automatically activates the ports of the bridge:

```
# nmcli connection modify bridge0 connection.autoconnect-slaves 1
```

g. Active the `bridge0` connection:

```
# nmcli connection up bridge0
```

**Verification steps**

1. On both routers, verify that the `enp1s0` and `gretap1` connections are connected and that the `CONNECTION` column displays the connection name of the port:

```
# nmcli device
DEVICE   TYPE      STATE      CONNECTION
... 
bridge0  bridge    connected  bridge0
enp1s0   ethernet  connected  bridge0-port1
gretap1  iptunnel  connected  bridge0-port2
```

2. From each RHEL router, ping the IP address of the internal interface of the other router:
   a. On Router A, ping `192.0.2.2`:

```
# ping 192.0.2.2
```
   b. On Router B, ping `192.0.2.1`:

```
# ping 192.0.2.1
```

**15.4. ADDITIONAL RESOURCES**

- `ip-link(8)` man page
CHAPTER 16. PORT MIRRORING

Network administrators can use port mirroring to replicate inbound and outbound network traffic being communicated from one network device to another. Administrators use port mirroring to monitor network traffic and collect network data to:

- Debug networking issues and tune the network flow
- Inspect and analyze the network traffic to troubleshoot networking problems
- Detect an intrusion

16.1. MIRRORING A NETWORK INTERFACE USING NMCLI

You can configure port mirroring using NetworkManager. The following procedure mirrors the network traffic from enp1s0 to enp7s0 by adding Traffic Control (tc) rules and filters to the enp1s0 network interface.

Prerequisites

- A network interface to mirror the network traffic to.

Procedure

1. Add a network connection profile you want to mirror the network traffic from:

   ```bash
   # nmcli connection add type ethernet ifname enp1s0 con-name enp1s0 autoconnect no
   ```

2. Attach `prio` qdisc to enp1s0 for the egress (outgoing) traffic with handle '10:'. The `prio` qdisc attached without children allows attaching filters.

   ```bash
   # nmcli connection modify enp1s0 +tc.qdisc "root prio handle 10:"
   ```

3. Add a qdisc for the ingress traffic, with handle 'ffff:'.

   ```bash
   # nmcli connection modify enp1s0 +tc.qdisc "ingress handle ffff:"
   ```

4. To match packets on the ingress and egress qdiscs and to mirror them to another interface, add the following filters.

   ```bash
   # nmcli connection modify enp1s0 +tc.tfilter "parent ffff: matchall action mirred egress mirror dev mirror-of-enp1s0"
   # nmcli connection modify enp1s0 +tc.tfilter "parent 10: matchall action mirred egress mirror dev mirror-of-enp1s0"
   ```

   The `matchall` filter matches all packets and the `mirred` action redirects packets to destination.

5. Activate the connection:

   ```bash
   # nmcli connection up enp1s0
   ```
Verification steps

1. Install the `tcpdump` utility:

   ```
   # dnf install tcpdump
   ```

2. View the traffic mirrored on the target device (`mirror-of-enp1s0`):

   ```
   # tcpdump -i enp7s0
   ```

16.2. ADDITIONAL RESOURCES

- For more information about using `tcpdump` utility, refer to the How to capture network packets using `tcpdump` knowledge base solution.
CHAPTER 17. CONFIGURING NETWORK DEVICES TO ACCEPT TRAFFIC FROM ALL MAC ADDRESSES

Network devices usually intercept and read packets that their controller is programmed to receive. You can configure the network devices to accept traffic from all MAC addresses in a virtual switch or at the port group level.

You can use this network mode to:

- diagnose network connectivity issues,
- monitor network activity for security reasons,
- intercept private data-in-transit or intrusion in the network.

This section describes how to configure a network device to accept traffic from all the MAC addresses using `iproute2`, `nmcli`, or `nmstatectl` utilities. You can enable this mode for any kind of network device except InfiniBand.

17.1. TEMPORARILY CONFIGURING A NETWORK DEVICE TO ACCEPT ALL TRAFFIC USING IPROUTE2

This procedure describes how to configure a network device to accept all traffic regardless of the MAC addresses. Any change made using the `iproute2` utility is temporary and lost after the machine reboots.

Procedure

1. Optional: Display the network interfaces to identify the one for which you want to receive all traffic:

   ```
   # ip a
   1: enp1s0: <NO-CARRIER,BROADCAST,MULTICAST,UP> mtu 1500 qdisc fq_codel state DOWN group default qlen 1000
      link/ether 98:fa:9b:a4:34:09 brd ff:ff:ff:ff:ff:ff
   2: bond0: <NO-CARRIER,BROADCAST,MULTICAST,MASTER,UP> mtu 1500 qdisc noqueue state DOWN group default qlen 1000
      link/ether 6a:fd:16:b0:83:5c brd ff:ff:ff:ff:ff:ff
   3: wlp61s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP group default qlen 1000
   ...
   ```

2. Modify the device to enable or disable this property.

   - To enable the `accept-all-mac-addresses` mode for `enp1s0`:
     ```
     # ip link set enp1s0 promisc on
     ```
   - To disable the `accept-all-mac-addresses` mode for `enp1s0`:
     ```
     # ip link set enp1s0 promisc off
     ```

Verification steps
To verify that the accept-all-mac-addresses mode is enabled:

```
# ip link show enp1s0
1: enp1s0: <NO-CARRIER,BROADCAST,MULTICAST,PROMISC,UP> mtu 1500 qdisc fq_codel state DOWN group default qlen 1000
   link/ether 98:fa:9b:a4:34:09 brd ff:ff:ff:ff:ff:ff
```

The PROMISC flag in the device description indicates that the mode is enabled.

17.2. PERMANENTLY CONFIGURING A NETWORK DEVICE TO ACCEPT ALL TRAFFIC USING NMCLI

This procedure describes how to configure a network device to accept traffic regardless of MAC addresses using the nmcli commands.

Procedure

1. Optional: Display the network interfaces to identify the one for which you want to receive all traffic:

```
# ip a
1: enp1s0: <NO-CARRIER,BROADCAST,MULTICAST,UP> mtu 1500 qdisc fq_codel state DOWN group default qlen 1000
   link/ether 98:fa:9b:a4:34:09 brd ff:ff:ff:ff:ff:ff
2: bond0: <NO-CARRIER,BROADCAST,MULTICAST,MASTER,UP> mtu 1500 qdisc noqueue state DOWN group default qlen 1000
   link/ether 6a:fd:16:b0:83:5c brd ff:ff:ff:ff:ff:ff
3: wlp61s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP group default qlen 1000
   ...)
```

You can create a new connection, if you do not have any.

2. Modify the network device to enable or disable this property.

   - To enable the ethernet.accept-all-mac-addresses mode for enp1s0:
     
     ```
     # nmcli connection modify enp1s0 ethernet.accept-all-mac-addresses yes
     ```

   - To disable the accept-all-mac-addresses mode for enp1s0:
     
     ```
     # nmcli connection modify enp1s0 ethernet.accept-all-mac-addresses no
     ```

3. To apply the changes, reactivate the connection:

   ```
   # nmcli connection up enp1s0
   ```

Verification steps

   - To verify that the ethernet.accept-all-mac-addresses mode is enabled:
The `802-3-ethernet.accept-all-mac-addresses: true` indicates that the mode is enabled.

17.3. PERMANENTLY CONFIGURING A NETWORK NETWORK DEVICE TO ACCEPT ALL TRAFFIC USING NMSTATECTL

This procedure describes how to configure a network device to accept all traffic regardless of MAC addresses using the `nmstatectl` utility.

**Prerequisites**

- The `nmstate` package is installed.
- The `.yml` file that you used to configure the device is available.

**Procedure**

1. Edit the existing `enp1s0.yml` file for the `enp1s0` connection and add the following content to it.

   ```yaml
   ---
   interfaces:
   - name: enp1s0
     type: ethernet
     state: up
     accept-all-mac-address: true
   ```

2. Apply the network settings.

   ```bash
   # nmstatectl apply ~/enp1s0.yml
   ```

**Verification steps**

- To verify that the `802-3-ethernet.accept-all-mac-addresses` mode is enabled:

  ```bash
  # nmstatectl show enp1s0
  interfaces:
  - name: enp1s0
    type: ethernet
    state: up
    accept-all-mac-addresses: true
  ```

  The `802-3-ethernet.accept-all-mac-addresses: true` indicates that the mode is enabled.

**Additional resources**

- For further details about `nmstatectl`, see the `nmstatectl(8)` man page.
- For more configuration examples, see the `/usr/share/doc/nmstate/examples/` directory.
CHAPTER 18. SETTING UP AN 802.1X NETWORK AUTHENTICATION SERVICE FOR LAN CLIENTS USING HOSTAPD WITH FREERADIUS BACKEND

The IEEE 802.1X standard defines secure authentication and authorization methods to protect networks from unauthorized clients. Using the hostapd service and FreeRADIUS, you can provide network access control (NAC) in your network.

In this documentation, the RHEL host acts as a bridge to connect different clients with an existing network. However, the RHEL host grants only authenticated clients access to the network.

18.1. PREREQUISITES

- A clean installation of FreeRADIUS.
  - If the freeradius package is already installed, remove the /etc/raddb/ directory, uninstall and then install the package again. Do not reinstall the package using the dnf reinstall command, because the permissions and symbolic links in the /etc/raddb/ directory are then different.

18.2. SETTING UP THE BRIDGE ON THE AUTHENTICATOR

A network bridge is a link-layer device which forwards traffic between hosts and networks based on a table of MAC addresses. If you set up RHEL as an 802.1X authenticator, add both the interfaces on which to perform authentication and the LAN interface to the bridge.

Prerequisites

- The server has multiple Ethernet interfaces.

Procedure

1. Create the bridge interface:

```
# nmcli connection add type bridge con-name br0 ifname br0
```

2. Assign the Ethernet interfaces to the bridge:

```
# nmcli connection add type ethernet slave-type bridge con-name br0-port1 ifname enp1s0 master br0
# nmcli connection add type ethernet slave-type bridge con-name br0-port2 ifname enp9s0 master br0
```
3. Enable the bridge to forward extensible authentication protocol over LAN (EAPOL) packets:

   ```
   # nmcli connection modify br0 group-forward-mask 8
   ```

4. Configure the connection to automatically activate the ports:

   ```
   # nmcli connection modify br0 connection.autoconnect-slaves 1
   ```

5. Activate the connection:

   ```
   # nmcli connection up br0
   ```

Verification

1. Display the link status of Ethernet devices that are ports of a specific bridge:

   ```
   # ip link show master br0
   3: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel master
   br0 state UP mode DEFAULT group default qlen 1000
   link/ether 52:54:00:62:61:0e brd ff:ff:ff:ff:ff:ff
   ...
   ```

2. Verify if forwarding of EAPOL packets is enabled on the `br0` device:

   ```
   # cat /sys/class/net/br0/bridge/group_fwd_mask
   0x8
   ```

   If the command returns `0x8`, forwarding is enabled.

Additional resources

- `nm-settings(5)` man page

18.3. CERTIFICATE REQUIREMENTS BY FREERADIUS

For a secure FreeRADIUS service, you require TLS certificates for different purposes:

- A TLS server certificate for encrypted connections to the server. Use a trusted certificate authority (CA) to issue the certificate. The server certificate requires the extended key usage (EKU) field set to **TLS Web Server Authentication.**

- Client certificates issued by the same CA for extended authentication protocol transport layer security (EAP-TLS). EAP-TLS provides certificate-based authentication and is enabled by default. The client certificates require their EKU field set to **TLS Web Client Authentication.**
WARNING

To secure connection, use your company’s CA or create your own CA to issue
certificates for FreeRADIUS. If you use a public CA, you allow it to authenticate
users and issue client certificates for EAP-TLS.

18.4. CREATING A SET OF CERTIFICATES ON A FREERADIUS SERVER
FOR TESTING PURPOSES

For testing purposes, the freeradius package installs scripts and configuration files in the
/etc/raddb/certs/ directory to create your own certificate authority (CA) and issue certificates.

IMPORTANT

If you use the default configuration, certificates generated by these scripts expire after
60 days and keys use an insecure password ("whatever"). However, you can customize
the CA, server, and client configuration.

After you perform the procedure, the following files, which you require later in this documentation, are
created:

- /etc/raddb/certs/ca.pem: CA certificate
- /etc/raddb/certs/server.key: Private key of the server certificate
- /etc/raddb/certs/server.pem: Server certificate
- /etc/raddb/certs/client.key: Private key of the client certificate
- /etc/raddb/certs/client.pem: Client certificate

Prerequisites

- You installed the freeradius package.

Procedure

1. Change into the /etc/raddb/certs/ directory:

# cd /etc/raddb/certs/

2. Optional: Customize the CA configuration:

[ req ]
default_bits = 2048
input_password = ca_password
output_password = ca_password
...
[certificate_authority]
countryName    = US
stateOrProvinceName  = North Carolina
localityName     = Raleigh
organizationName = Example Inc.
emailAddress     = admin@example.org
commonName       = "Example Certificate Authority"
...

3. Optional: Customize the server configuration:

...  
[ CA_default ]
default_days  = 730
...
[ req ]
distinguished_name = server
default_bits   = 2048
input_password  = key_password
output_password  = key_password
...
[server]
countryName    = US
stateOrProvinceName  = North Carolina
localityName     = Raleigh
organizationName = Example Inc.
emailAddress     = admin@example.org
commonName       = "Example Server Certificate"
...

4. Optional: Customize the client configuration:

...  
[ CA_default ]
default_days  = 365
...
[ req ]
distinguished_name = client
default_bits   = 2048
input_password  = password_on_private_key
output_password  = password_on_private_key
...
[client]
countryName    = US
stateOrProvinceName  = North Carolina
localityName     = Raleigh
organizationName = Example Inc.
emailAddress     = user@example.org
commonName       = user@example.org
...

5. Create the certificates:

# make all
6. Change the group on the `/etc/raddb/certs/server.pem` file to `radiusd`:

```
# chgrp radiusd /etc/raddb/certs/server.pem
```

Additional resources

- `/etc/raddb/certs/README.md`

### 18.5. CONFIGURING FREERADIUS TO AUTHENTICATE NETWORK CLIENTS SECURELY USING EAP

FreeRADIUS supports different methods of the Extensible authentication protocol (EAP). However, for a secure network, this documentation describes how to configure FreeRADIUS to support only the following secure EAP authentication methods:

- **EAP-TLS** (transport layer security) uses a secure TLS connection to authenticate clients using certificates. To use EAP-TLS, you need TLS client certificates for each network client and a server certificate for the server. Note that the same certificate authority (CA) must have issued the certificates. Always use your own CA to create certificates, because all client certificates issued by the CA you use can authenticate to your FreeRADIUS server.

- **EAP-TTLS** (tunneled transport layer security) uses a secure TLS connection and authenticates clients using mechanisms, such as password authentication protocol (PAP) or challenge handshake authentication protocol (CHAP). To use EAP-TTLS, you need a TLS server certificate.

- **EAP-PEAP** (protected extensible authentication protocol) uses a secure TLS connection as the outer authentication protocol to set up the tunnel. The authenticator authenticates the certificate of the RADIUS server. Afterwards, the supplicant authenticates through the encrypted tunnel using Microsoft challenge handshake authentication protocol version 2 (MS-CHAPv2) or other methods.

**NOTE**

The default FreeRADIUS configuration files serve as documentation and describe all parameters and directives. If you want to disable certain features, comment them out instead of removing the corresponding parts in the configuration files. This enables you to preserve the structure of the configuration files and the included documentation.

**Prerequisites**

- You installed the `freeradius` package.

- The configuration files in the `/etc/raddb/` directory are unchanged and as provided by the `freeradius` package.

- The following files exist on the server:
  - TLS private key of the FreeRADIUS host: `/etc/raddb/certs/server.key`
  - TLS server certificate of the FreeRADIUS host: `/etc/raddb/certs/server.pem`
  - TLS CA certificate: `/etc/raddb/certs/ca.pem`
If you store the files in a different location or if they have different names, set the `private_key_file`, `certificate_file`, and `ca_file` parameters in the `/etc/raddb/mods-available/eap` file accordingly.

**Procedure**

1. If the `/etc/raddb/certs/dh` with Diffie–Hellman (DH) parameters does not exist, create one. For example, to create a DH file with a 2048 bits prime, enter:

   ```
   # openssl dhparam -out /etc/raddb/certs/dh 2048
   ```

   For security reasons, do not use a DH file with less than a 2048 bits prime. Depending on the number of bits, the creation of the file can take several minutes.

2. Set secure permissions on the TLS private key, server certificate, CA certificate, and the file with DH parameters:

   ```
   # chmod 640 /etc/raddb/certs/server.key /etc/raddb/certs/server.pem
   /etc/raddb/certs/ca.pem /etc/raddb/certs/dh
   # chown root:radiusd /etc/raddb/certs/server.key /etc/raddb/certs/server.pem
   /etc/raddb/certs/ca.pem /etc/raddb/certs/dh
   ```

3. Edit the `/etc/raddb/mods-available/eap` file:

   a. Set the password of the private key in the `private_key_password` parameter:

   ```
   eap {
       ...
       tls-config tls-common {
           ...
           private_key_password = key_password
           ...
       }
   }
   ```

   b. Depending on your environment, set the `default_eap_type` parameter in the `eap` directive to your primary EAP type you use:

   ```
   eap {
       ...
       default_eap_type = ttls
       ...
   }
   ```

   For a secure environment, use only `ttls`, `tls`, or `peap`.

   c. Comment out the `md5` directives to disable the insecure EAP-MD5 authentication method:

   ```
   eap {
       ...
       # md5 {
       # }
       ...
   }
   ```

---

**CHAPTER 18. SETTING UP AN 802.1X NETWORK AUTHENTICATION SERVICE FOR LAN CLIENTS USING HOSTAPD WITH FREERADIUS BACKEND**

175
Note that, in the default configuration file, other insecure EAP authentication methods are commented out by default.

4. Edit the `/etc/raddb/sites-available/default` file, and comment out all authentication methods other than `eap`:

```plaintext
authenticate {
    ...
    # Auth-Type PAP {
    #     pap
    # }
    # Auth-Type CHAP {
    #     chap
    # }
    # Auth-Type MS-CHAP {
    #     mschap
    # }
    # mschap
    # digest
    ...
}
```

This leaves only EAP enabled and disables plain-text authentication methods.

5. Edit the `/etc/raddb/clients.conf` file:
   a. Set a secure password in the `localhost` and `localhost_ipv6` client directives:

```plaintext
client localhost {
    ipaddr = 127.0.0.1
    ...
    secret = client_password
    ...
}

client localhost_ipv6 {
    ipv6addr = ::1
    secret = client_password
}
```

   b. If RADIUS clients, such as network authenticators, on remote hosts should be able to access the FreeRADIUS service, add corresponding client directives for them:

```plaintext
client hostapd.example.org {
    ipaddr = 192.0.2.2/32
    secret = client_password
}
```

The `ipaddr` parameter accepts IPv4 and IPv6 addresses, and you can use the optional classless inter-domain routing (CIDR) notation to specify ranges. However, you can set only one value in this parameter. For example, to grant access to an IPv4 and IPv6 address, add two client directives.
Use a descriptive name for the client directive, such as a hostname or a word that describes where the IP range is used.

6. If you want to use EAP-TTLS or EAP-PEAP, add the users to the /etc/raddb/users file:

   ```
   example_user  Cleartext-Password := "user_password"
   ```

   For users who should use certificate-based authentication (EAP-TLS), do not add any entry.

7. Verify the configuration files:

   ```
   # radiusd -XC
   ...
   Configuration appears to be OK
   ```

8. Enable and start the `radiusd` service:

   ```
   # systemctl enable --now radiusd
   ```

**Verification**

- Testing EAP-TTLS authentication against a FreeRADIUS server or authenticator
- Testing EAP-TLS authentication against a FreeRADIUS server or authenticator

**Troubleshooting**

1. Stop the `radiusd` service:

   ```
   # systemctl stop radiusd
   ```

2. Start the service in debug mode:

   ```
   # radiusd -X
   ...
   Ready to process requests
   ```

3. Perform authentication tests on the FreeRADIUS host, as referenced in the Verification section.

**Next steps**

- Disable unrequired authentication methods and other features you do not use.

**18.6. CONFIGURING HOSTAPD AS AN AUTHENTICATOR IN A WIRED NETWORK**

The host access point daemon (hostapd) service can act as an authenticator in a wired network to provide 802.1X authentication. For this, the `hostapd` service requires a RADIUS server that authenticates the clients.
The **hostapd** service provides an integrated RADIUS server. However, use the integrated RADIUS server only for testing purposes. For production environments, use FreeRADIUS server, which supports additional features, such as different authentication methods and access control.

**IMPORTANT**

The **hostapd** service does not interact with the traffic plane. The service acts only as an authenticator. For example, use a script or service that uses the **hostapd** control interface to allow or deny traffic based on the result of authentication events.

**Prerequisites**

- You installed the **hostapd** package.
- The FreeRADIUS server has been configured, and it is ready to authenticate clients.

**Procedure**

1. Create the `/etc/hostapd/hostapd.conf` file with the following content:

```
# General settings of hostapd
# ===========================

# Control interface settings
ctrl_interface=/var/run/hostapd
ctrl_interface_group=wheel

# Enable logging for all modules
logger_syslog=-1
logger_stdout=-1

# Log level
logger_syslog_level=2
logger_stdout_level=2

# Wired 802.1X authentication
# ===========================

# Driver interface type
driver=wired

# Enable IEEE 802.1X authorization
ieee8021x=1

# Use port access entry (PAE) group address
# (01:80:c2:00:00:03) when sending EAPOL frames
use_pae_group_addr=1

# Network interface for authentication requests
interface=br0

# RADIUS client configuration
```
For further details about the parameters used in this configuration, see their descriptions in the
/usr/share/doc/hostapd/hostapd.conf example configuration file.

2. Enable and start the hostapd service:

```
# systemctl enable --now hostapd
```

Verification

- See:
  - Testing EAP-TTLS authentication against a FreeRADIUS server or authenticator
  - Testing EAP-TLS authentication against a FreeRADIUS server or authenticator

Troubleshooting

1. Stop the hostapd service:

```
# systemctl stop hostapd
```

2. Start the service in debug mode:

```
# hostapd -d /etc/hostapd/hostapd.conf
```

3. Perform authentication tests on the FreeRADIUS host, as referenced in the Verification section.

Additional resources

- hostapd.conf(5) man page
- /usr/share/doc/hostapd/hostapd.conf
18.7. TESTING EAP-TTLS AUTHENTICATION AGAINST A FREERADIUS SERVER OR AUTHENTICATOR

To test if authentication using extensible authentication protocol (EAP) over tunneled transport layer security (EAP-TTLS) works as expected, run this procedure:

- After you set up the FreeRADIUS server
- After you set up the hostapd service as an authenticator for 802.1X network authentication.

The output of the test utilities used in this procedure provide additional information about the EAP communication and help you to debug problems.

Prerequisites

- When you want to authenticate to:
  - A FreeRADIUS server:
    - The eapol_test utility, provided by the hostapd package, is installed.
    - The client, on which you run this procedure, has been authorized in the FreeRADIUS server’s client databases.
  - An authenticator, the wpa_supplicant utility, provided by the same-named package, is installed.
  - You stored the certificate authority (CA) certificate in the /etc/pki/tls/certs/ca.pem file.

Procedure

1. Create the /etc/wpa_supplicant/wpa_supplicant-TTLS.conf file with the following content:

```
ap_scan=0

network={
    eap=TTLS
    eapol_flags=0
    key_mgmt=IEEE8021X

    # Anonymous identity (sent in unencrypted phase 1)
    # Can be any string
    anonymous_identity="anonymous"

    # Inner authentication (sent in TLS-encrypted phase 2)
    phase2="auth=PAP"
    identity="example_user"
    password="user_password"

    # CA certificate to validate the RADIUS server’s identity
    ca_cert="/etc/pki/tls/certs/ca.pem"
}
```

2. To authenticate to:

- A FreeRADIUS server, enter:
The `-a` option defines the IP address of the FreeRADIUS server, and the `-s` option specifies the password for the host on which you run the command in the FreeRADIUS server’s client configuration.

- An authenticator, enter:

```
# wpa_supplicant -c /etc/wpa_supplicant/wpa_supplicant-TTLS.conf -D wired -i enp0s31f6
```

```
enp0s31f6: CTRL-EVENT-EAP-SUCCESS EAP authentication completed successfully
```

The `-i` option specifies the network interface name on which `wpa_supplicant` sends out extended authentication protocol over LAN (EAPOL) packets.

For more debugging information, pass the `-d` option to the command.

Additional resources

- `/usr/share/doc/wpa_supplicant/wpa_supplicant.conf`

### 18.8. TESTING EAP-TLS AUTHENTICATION AGAINST A FREERADIUS SERVER OR AUTHENTICATOR

To test if authentication using extensible authentication protocol (EAP) transport layer security (EAP-TLS) works as expected, run this procedure:

- After you set up the FreeRADIUS server

- After you set up the `hostapd` service as an authenticator for 802.1X network authentication.

The output of the test utilities used in this procedure provide additional information about the EAP communication and help you to debug problems.

**Prerequisites**

- When you want to authenticate to:

  - A FreeRADIUS server:

    - The `eapol_test` utility, provided by the `hostapd` package, is installed.
    - The client, on which you run this procedure, has been authorized in the FreeRADIUS server’s client databases.
An authenticator, the `wpa_supplicant` utility, provided by the same-named package, is installed.

- You stored the certificate authority (CA) certificate in the `/etc/pki/tls/certs/ca.pem` file.
- The CA that issued the client certificate is the same that issued the server certificate of the FreeRADIUS server.
- You stored the client certificate in the `/etc/pki/tls/certs/client.pem` file.
- You stored the private key of the client in the `/etc/pki/tls/private/client.key`

**Procedure**

1. Create the `/etc/wpa_supplicant/wpa_supplicant-TLS.conf` file with the following content:

   ```
   ap_scan=0

   network={
     eap=TLS
     eapol_flags=0
     key_mgmt=IEEE8021X

     identity="user@example.org"
     client_cert="/etc/pki/tls/certs/client.pem"
     private_key="/etc/pki/tls/private/client.key"
     private_key_passwd="password_on_private_key"

     # CA certificate to validate the RADIUS server’s identity
     ca_cert="/etc/pki/tls/certs/ca.pem"
   }
   ```

2. To authenticate to:

   - A FreeRADIUS server, enter:
     ```
     # eapol_test -c /etc/wpa_supplicant/wpa_supplicant-TLS.conf -a 192.0.2.1 -s client_password
     ...
     EAP: Status notification: remote certificate verification (param=success)
     ...
     CTRL-EVENT-EAP-SUCCESS EAP authentication completed successfully
     ...
     SUCCESS
     ```

     The `-a` option defines the IP address of the FreeRADIUS server, and the `-s` option specifies the password for the host on which you run the command in the FreeRADIUS server’s client configuration.

   - An authenticator, enter:
     ```
     # wpa_supplicant -c /etc/wpa_supplicant/wpa_supplicant-TLS.conf -D wired -i enp0s31f6
     ...
     enp0s31f6: CTRL-EVENT-EAP-SUCCESS EAP authentication completed successfully
     ...
     ```
The `-i` option specifies the network interface name on which `wpa_supplicant` sends out extended authentication protocol over LAN (EAPOL) packets.

For more debugging information, pass the `-d` option to the command.

Additional resources

- `/usr/share/doc/wpa_supplicant/wpa_supplicant.conf`

### 18.9. BLOCKING AND ALLOWING TRAFFIC BASED ON HOSTAPD AUTHENTICATION EVENTS

The `hostapd` service does not interact with the traffic plane. The service acts only as an authenticator. However, you can write a script to allow and deny traffic based on the result of authentication events.

**IMPORTANT**

This procedure is not supported and is no enterprise-ready solution. It only demonstrates how to block or allow traffic by evaluating events retrieved by `hostapd_cli`.

When the `802-1x-tr-mgmt` systemd service starts, RHEL blocks all traffic on the listen port of `hostapd` except extensible authentication protocol over LAN (EAPOL) packets and uses the `hostapd_cli` utility to connect to the `hostapd` control interface. The `/usr/local/bin/802-1x-tr-mgmt` script then evaluates events. Depending on the different events received by `hostapd_cli`, the script allows or blocks traffic for MAC addresses. Note that, when the `802-1x-tr-mgmt` service stops, all traffic is automatically allowed again.

Perform this procedure on the `hostapd` server.

**Prerequisites**

- The `hostapd` service has been configured, and the service is ready to authenticate clients.

**Procedure**

1. Create the `/usr/local/bin/802-1x-tr-mgmt` file with the following content:

```bash
#!/bin/sh
if [ "x$1" == "xblock_all" ]
then
    nft delete table bridge tr-mgmt-br0 2>/dev/null || true
    nft -f - << EOF
        table bridge tr-mgmt-br0 {
            set allowed_macs {
                type ether_addr
            }
            chain accesscontrol {
                ether saddr @allowed_macs accept
                ether daddr @allowed_macs accept
                drop
            }
        }
    EOF
```
chain forward {
    type filter hook forward priority 0; policy accept;
    meta ibrname "br0" jump accesscontrol
}
EOF
    echo "802-1x-tr-mgmt Blocking all traffic through br0. Traffic for given host will be allowed after 802.1x authentication"

elif [ "x$1" == "xallow_all" ]
then
    nft delete table bridge tr-mgmt-br0
    echo "802-1x-tr-mgmt Allowed all forwarding again"
fi

case ${2:-NOTANEVENT} in
    AP-STA-CONNECTED | CTRL-EVENT-EAP-SUCCESS | CTRL-EVENT-EAP-SUCCESS2)
        nft add element bridge tr-mgmt-br0 allowed_macs { $3 }
        echo "$1: Allowed traffic from $3"
        ;;
    AP-STA-DISCONNECTED | CTRL-EVENT-EAP-FAILURE)
        nft delete element bridge tr-mgmt-br0 allowed_macs { $3 }
        echo "802-1x-tr-mgmt $1: Denied traffic from $3"
        ;;
esac

2. Create the `/etc/systemd/system/802-1x-tr-mgmt@.service` systemd service file with the following content:

```
[Unit]
Description=Example 802.1x traffic management for hostapd
After=hostapd.service
After=sys-devices-virtual-net-%i.device

[Service]
Type=simple
ExecStartPre=/bin/sh -c '/usr/sbin/tc qdisc del dev %i ingress > /dev/null 2>&1'
ExecStartPre=/bin/sh -c '/usr/sbin/tc qdisc del dev %i clsact > /dev/null 2>&1'
ExecStartPre=/usr/sbin/tc qdisc add dev %i clsact
ExecStartPre=/usr/sbin/tc filter add dev %i ingress pref 10000 protocol 0x888e matchall action ok index 100
ExecStartPre=/usr/sbin/tc filter add dev %i ingress pref 10001 protocol all matchall action drop index 101
ExecStart=/usr/sbin/hostapd_cli -i %i -a /usr/local/bin/802-1x-tr-mgmt
ExecStopPost=/usr/sbin/tc qdisc del dev %i clsact

[Install]
WantedBy=multi-user.target
```
3. Reload systemd:

   ```bash
   # systemctl daemon-reload
   ```

4. Enable and start the `802-1x-tr-mgmt` service with the interface name `hostapd` is listening on:

   ```bash
   # systemctl enable --now 802-1x-tr-mgmt@br0.service
   ```

**Verification**

- Authenticate with a client to the network. See:
  - Testing EAP-TTLS authentication against a FreeRADIUS server or authenticator
  - Testing EAP-TLS authentication against a FreeRADIUS server or authenticator

**Additional resources**

- `systemd.service(5)` man page
CHAPTER 19. AUTHENTICATING A RHEL CLIENT TO THE NETWORK USING THE 802.1X STANDARD WITH A CERTIFICATE STORED ON THE FILE SYSTEM

Administrators frequently use port-based Network Access Control (NAC) based on the IEEE 802.1X standard to protect a network from unauthorized LAN and Wi-Fi clients. The procedures in this section describe different options to configure network authentication.

19.1. CONFIGURING 802.1X NETWORK AUTHENTICATION ON AN EXISTING ETHERNET CONNECTION USING NMCLI

Using the `nmcli` utility, you can configure the client to authenticate itself to the network. This procedure describes how to configure TLS authentication in an existing NetworkManager Ethernet connection profile named `enp1s0` to authenticate to the network.

Prerequisites

- The network supports 802.1X network authentication.
- The Ethernet connection profile exists in NetworkManager and has a valid IP configuration.
- The following files required for TLS authentication exist on the client:
  - The client key stored is in the `/etc/pki/tls/private/client.key` file, and the file is owned and only readable by the `root` user.
  - The client certificate is stored in the `/etc/pki/tls/certs/client.crt` file.
  - The Certificate Authority (CA) certificate is stored in the `/etc/pki/tls/certs/ca.crt` file.
- The `wpa_supplicant` package is installed.

Procedure

1. Set the Extensible Authentication Protocol (EAP) to `tls` and the paths to the client certificate and key file:

   ```bash
   # nmcli connection modify enp1s0 802-1x.eap tls 802-1x.client-cert /etc/pki/tls/certs/client.crt 802-1x.private-key /etc/pki/tls/certs/certs/client.key
   ```

   Note that you must set the `802-1x.eap`, `802-1x.client-cert`, and `802-1x.private-key` parameters in a single command.

2. Set the path to the CA certificate:

   ```bash
   # nmcli connection modify enp1s0 802-1x.ca-cert /etc/pki/tls/certs/ca.crt
   ```

3. Set the identity of the user used in the certificate:

   ```bash
   # nmcli connection modify enp1s0 802-1x.identity user@example.com
   ```

4. Optionally, store the password in the configuration:
# nmcli connection modify enp1s0 802-1x.private-key-password password

**IMPORTANT**

By default, NetworkManager stores the password in clear text in the /etc/sysconfig/network-scripts/keys-connection_name file, that is readable only by the root user. However, clear text passwords in a configuration file can be a security risk.

To increase the security, set the **802-1x.password-flags** parameter to **0x1**. With this setting, on servers with the GNOME desktop environment or the **nm-applet** running, NetworkManager retrieves the password from these services. In other cases, NetworkManager prompts for the password.

5. Activate the connection profile:

   ```
   # nmcli connection up enp1s0
   ```

**Verification steps**

- Access resources on the network that require network authentication.

**Additional resources**

- Configuring an Ethernet connection
- The **802-1x settings** section in the **nm-settings(5)** man page
- **nmcli(1)** man page

### 19.2. CONFIGURING A STATIC ETHERNET CONNECTION WITH 802.1X NETWORK AUTHENTICATION USING NMSTATECTL

Using the **nmstate** utility, you can create an Ethernet connection that uses the 802.1X standard to authenticate the client. This procedure describes how to add an Ethernet connection for the **enp1s0** interface with the following settings:

- A static IPv4 address - **192.0.2.1** with a /24 subnet mask
- A static IPv6 address - **2001:db8:1::1** with a /64 subnet mask
- An IPv4 default gateway - **192.0.2.254**
- An IPv6 default gateway - **2001:db8:1::ffe**
- An IPv4 DNS server - **192.0.2.200**
- An IPv6 DNS server - **2001:db8:1::ffbb**
- A DNS search domain - **example.com**
- 802.1X network authentication using the **TLS** Extensible Authentication Protocol (EAP)
NOTE

The **nmstate** library only supports the **TLS** EAP method.

**Prerequisites**

- The network supports 802.1X network authentication.
- The managed node uses NetworkManager.
- The following files required for TLS authentication exist on the client:
  - The client key stored is in the `/etc/pki/tls/private/client.key` file, and the file is owned and only readable by the **root** user.
  - The client certificate is stored in the `/etc/pki/tls/certs/client.crt` file.
  - The Certificate Authority (CA) certificate is stored in the `/etc/pki/tls/certs/ca.crt` file.

**Procedure**

1. Create a YAML file, for example `~/create-ethernet-profile.yml`, with the following contents:

```yaml
---
interfaces:
- name: enp1s0
type: ethernet
state: up
ipv4:
  enabled: true
  address:
    - ip: 192.0.2.1
      prefix-length: 24
dhcp: false
ipv6:
  enabled: true
  address:
    - ip: 2001:db8:1::1
      prefix-length: 64
      autoconf: false
dhcp: false
802.1x:
  ca-cert: /etc/pki/tls/certs/ca.crt
  client-cert: /etc/pki/tls/certs/client.crt
eap-methods:
  - tls
    identity: client.example.org
    private-key: /etc/pki/tls/private/client.key
    private-key-password: password
routes:
cfg:
  - destination: 0.0.0.0/0
    next-hop-address: 192.0.2.254
    next-hop-interface: enp1s0
  - destination: ::/0
    next-hop-address: 2001:db8:1::ffe
```
The networking RHEL System Role, you can automate the creation of an Ethernet connection that
uses the 802.1X standard to authenticate the client. This procedure describes how to remotely add an
Ethernet connection for the `enp1s0` interface with the following settings by running an Ansible
playbook:

- A static IPv4 address - `192.0.2.1` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `192.0.2.254`
- An IPv6 default gateway - `2001:db8:1::fffe`
- An IPv4 DNS server - `192.0.2.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`
- 802.1X network authentication using the TLS Extensible Authentication Protocol (EAP)

Run this procedure on the Ansible control node.

Prerequisites

- The `ansible-core` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, you must have
  appropriate `sudo` permissions on the managed node.
- The network supports 802.1X network authentication.
- The managed node uses NetworkManager.
- The following files required for TLS authentication exist on the control node:
The client key is stored in the `/srv/data/client.key` file.

The client certificate is stored in the `/srv/data/client.crt` file.

The Certificate Authority (CA) certificate is stored in the `/srv/data/ca.crt` file.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

```
node.example.com
```

2. Create the `~/enable-802.1x.yml` playbook with the following content:

```yaml
---
- name: Configure an Ethernet connection with 802.1X authentication
  hosts: node.example.com
  become: true
  tasks:
  - name: Copy client key for 802.1X authentication
    copy:
      src: "/srv/data/client.key"
      dest: "/etc/pki/tls/private/client.key"
      mode: 0600

  - name: Copy client certificate for 802.1X authentication
    copy:
      src: "/srv/data/client.crt"
      dest: "/etc/pki/tls/certs/client.crt"

  - name: Copy CA certificate for 802.1X authentication
    copy:
      src: "/srv/data/ca.crt"
      dest: "/etc/pki/ca-trust/source/anchors/ca.crt"

  - include_role:
    name: rhel-system-roles.network
  vars:
    network_connections:
    - name: enp1s0
      type: ethernet
      autoconnect: yes
    ip:
      address:
        - 192.0.2.1/24
        - 2001:db8:1::1/64
      gateway4: 192.0.2.254
      gateway6: 2001:db8:1::ffee
    dns:
      - 192.0.2.200
      - 2001:db8:1::ffbb
    dns_search:
      - example.com
    ieee802_1x:
      identity: user_name
```

Red Hat Enterprise Linux 9 Configuring and managing networking

190
3. Run the playbook:

- To connect as root user to the managed host, enter:

  # ansible-playbook -u root ~/enable-802.1x.yml

- To connect as a user to the managed host, enter:

  # ansible-playbook -u user_name --ask-become-pass ~/ethernet-static-IP.yml

  The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

  If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file
- /usr/share/ansible/roles/rhel-system-roles.network/README.md file
- ansible-playbook(1) man page

19.4. CONFIGURING A WI-FI CONNECTION WITH 802.1X NETWORK AUTHENTICATION USING THE RHEL SYSTEM ROLES

Using RHEL System Roles, you can automate the creation of a Wi-Fi connection. This procedure describes how to remotely add a wireless connection profile for the wlp0s29u1u2 interface using an Ansible playbook. The created profile uses the 802.1X standard to authenticate the client to a Wi-Fi network. The playbook configures the connection profile to use DHCP. To configure static IP settings, adapt the parameters in the ip dictionary accordingly.

Prerequisites

- You installed the ansible and rhel-system-roles packages on the control node.
- The network supports 802.1X network authentication.
- If you use a different remote user than root when you run the playbook, you must have appropriate sudo permissions on the managed node.
- You installed the wpa_supplicant package on the managed node.
- DHCP is available in the network of the managed node.
- The following files required for TLS authentication exist on the control node:
- The client key is stored in the /srv/data/client.key file.
- The client certificate is stored in the /srv/data/client.crt file.
- The CA certificate is stored in the /srv/data/ca.crt file.

Perform the following procedure on the Ansible control node.

Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the /etc/ansible/hosts Ansible inventory file:

   node.example.com

2. Create the ~/enable-802.1x.yml playbook with the following content:

```yaml
---
- name: Configure a Wi-Fi connection with 802.1X authentication
  hosts: "node.example.com"
  become: true
  tasks:
    - name: Copy client key for 802.1X authentication
      copy:
        src: "/srv/data/client.key"
        dest: "/etc/pki/tls/private/client.key"
        mode: 0400

    - name: Copy client certificate for 802.1X authentication
      copy:
        src: "/srv/data/client.crt"
        dest: "/etc/pki/tls/certs/client.crt"

    - name: Copy CA certificate for 802.1X authentication
      copy:
        src: "/srv/data/ca.crt"
        dest: "/etc/pki/ca-trust/source/anchors/ca.crt"

    - block:
        - import_role:
            name: linux-system-roles.network
            vars:
              network_connections:
                - name: Configure the Example-Wi-Fi profile
                  interface_name: wlp0s29u1u2
                  state: up
                  type: wireless
                  autoconnect: yes
                  ip:
                    dhcp4: true
                    auto6: true
                  wireless:
                    ssid: "Example-Wi-Fi"
                    key_mgmt: "wpa-eap"
                  ieee802_1x:
                    identity: "user_name"
```

3. Run the playbook:

- To connect as a root user to the managed host, enter:
  
  ```
  # ansible-playbook -u root ~/enable-802.1x.yml
  ```

- To connect as a user to the managed host, enter:
  
  ```
  # ansible-playbook -u user_name --ask-become-pass ~/ethernet-static-IP.yml
  ```

  The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

  If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

- `ansible-playbook(1)` man page
CHAPTER 20. MANAGING THE DEFAULT GATEWAY SETTING

The default gateway is a router that forwards network packets when no other route matches the destination of a packet. In a local network, the default gateway is typically the host that is one hop closer to the internet.

20.1. SETTING THE DEFAULT GATEWAY ON AN EXISTING CONNECTION USING NMCLI

In most situations, administrators set the default gateway when they create a connection as explained in, for example, Configuring a static Ethernet connection using nmcli.

This section describes how to set or update the default gateway on a previously created connection using the nmcli utility.

Prerequisites

- At least one static IP address must be configured on the connection on which the default gateway will be set.
- If the user is logged in on a physical console, user permissions are sufficient. Otherwise, user must have root permissions.

Procedure

1. Set the IP address of the default gateway.
   For example, to set the IPv4 address of the default gateway on the example connection to 192.0.2.1:

   ```shell
   $ sudo nmcli connection modify example ipv4.gateway "192.0.2.1"
   ```

   For example, to set the IPv6 address of the default gateway on the example connection to 2001:db8:1::1:

   ```shell
   $ sudo nmcli connection modify example ipv6.gateway "2001:db8:1::1"
   ```

2. Restart the network connection for changes to take effect. For example, to restart the example connection using the command line:

   ```shell
   $ sudo nmcli connection up example
   ```

   **WARNING**
   All connections currently using this network connection are temporarily interrupted during the restart.

3. Optionally, verify that the route is active.
   To display the IPv4 default gateway:
$ ip -4 route
default via 192.0.2.1 dev example proto static metric 100

To display the IPv6 default gateway:

$ ip -6 route
default via 2001:db8:1::1 dev example proto static metric 100 pref medium

Additional resources

- Configuring a static Ethernet connection using nmcli

20.2. SETTING THE DEFAULT GATEWAY ON AN EXISTING CONNECTION USING THE NMCLI INTERACTIVE MODE

In most situations, administrators set the default gateway when they create a connection as explained in, for example, Configuring a dynamic Ethernet connection using the nmcli interactive editor.

This section describes how to set or update the default gateway on a previously created connection using the interactive mode of the nmcli utility.

Prerequisites

- At least one static IP address must be configured on the connection on which the default gateway will be set.
- If the user is logged in on a physical console, user permissions are sufficient. Otherwise, the user must have root permissions.

Procedure

1. Open the nmcli interactive mode for the required connection. For example, to open the nmcli interactive mode for the example connection:

   ```bash
   $ sudo nmcli connection edit example
   ```

2. Set the default gateway.
   For example, to set the IPv4 address of the default gateway on the example connection to 192.0.2.1:

   ```bash
   nmcli> set ipv4.gateway 192.0.2.1
   ```
   
   For example, to set the IPv6 address of the default gateway on the example connection to 2001:db8:1::1:

   ```bash
   nmcli> set ipv6.gateway 2001:db8:1::1
   ```

3. Optionally, verify that the default gateway was set correctly:

   ```bash
   nmcli> print
   ...
   ipv4.gateway: 192.0.2.1
   ```
... ipv6.gateway: 2001:db8:1::1 ...

4. Save the configuration:

   nmcli> save persistent

5. Restart the network connection for changes to take effect:

   nmcli> activate example

   ![WARNING]
   All connections currently using this network connection are temporarily interrupted during the restart.

6. Leave the `nmcli` interactive mode:

   nmcli> quit

7. Optionally, verify that the route is active.
   To display the IPv4 default gateway:

   $ ip -4 route
default via 192.0.2.1 dev example proto static metric 100

   To display the IPv6 default gateway:

   $ ip -6 route
default via 2001:db8:1::1 dev example proto static metric 100 pref medium

**Additional resources**

- Configuring a static Ethernet connection using the nmcli interactive editor

**20.3. SETTING THE DEFAULT GATEWAY ON AN EXISTING CONNECTION USING NM-CONNECTION-EDITOR**

In most situations, administrators set the default gateway when they create a connection. This section describes how to set or update the default gateway on a previously created connection using the `nm-connection-editor` application.

**Prerequisites**

- At least one static IP address must be configured on the connection on which the default gateway will be set.
Procedure

1. Open a terminal, and enter `nm-connection-editor`:

   $ nm-connection-editor

2. Select the connection to modify, and click the gear wheel icon to edit the existing connection.

3. Set the IPv4 default gateway. For example, to set the IPv4 address of the default gateway on the connection to 192.0.2.1:
   
   a. Open the IPv4 Settings tab.
   
   b. Enter the address in the gateway field next to the IP range the gateway’s address is within:

<table>
<thead>
<tr>
<th>Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address</td>
</tr>
<tr>
<td>------------</td>
</tr>
<tr>
<td>192.0.2.123</td>
</tr>
</tbody>
</table>

4. Set the IPv6 default gateway. For example, to set the IPv6 address of the default gateway on the connection to 2001:db8:1::1:

   a. Open the IPv6 tab.
   
   b. Enter the address in the gateway field next to the IP range the gateway’s address is within:

<table>
<thead>
<tr>
<th>Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address</td>
</tr>
<tr>
<td>------------</td>
</tr>
<tr>
<td>2001:db8:1::5</td>
</tr>
</tbody>
</table>

5. Click OK.

6. Click Save.

7. Restart the network connection for changes to take effect. For example, to restart the example connection using the command line:

   $ sudo nmcli connection up example

   **WARNING**
   All connections currently using this network connection are temporarily interrupted during the restart.

8. Optionally, verify that the route is active.
   To display the IPv4 default gateway:
To display the IPv6 default gateway:

```
$ ip -6 route
default via 2001:db8:1::1 dev example proto static metric 100 pref medium
```

Additional resources

- Configuring an Ethernet connection using nm-connection-editor

## 20.4. SETTING THE DEFAULT GATEWAY ON AN EXISTING CONNECTION USING CONTROL-CENTER

In most situations, administrators set the default gateway when they create a connection. This section describes how to set or update the default gateway on a previously created connection using the `control-center` application.

**Prerequisites**

- At least one static IP address must be configured on the connection on which the default gateway will be set.
- The network configuration of the connection is open in the `control-center` application.

**Procedure**

1. Set the IPv4 default gateway. For example, to set the IPv4 address of the default gateway on the connection to `192.0.2.1`:
   a. Open the IPv4 tab.
   b. Enter the address in the **gateway** field next to the IP range the gateway’s address is within:

   ![IPv4 Gateway](image)

2. Set the IPv6 default gateway. For example, to set the IPv6 address of the default gateway on the connection to `2001:db8:1::1`:
   a. Open the IPv6 tab.
   b. Enter the address in the **gateway** field next to the IP range the gateway’s address is within:

   ![IPv6 Gateway](image)

3. Click **Apply**.
4. Back in the **Network** window, disable and re-enable the connection by switching the button for the connection to **Off** and back to **On** for changes to take effect.

![WARNING]

**WARNING**

All connections currently using this network connection are temporarily interrupted during the restart.

5. Optionally, verify that the route is active.
   To display the IPv4 default gateway:

   ```
   $ ip -4 route
default via 192.0.2.1 dev example proto static metric 100
   ```
   
   To display the IPv6 default gateway:

   ```
   $ ip -6 route
default via 2001:db8:1::1 dev example proto static metric 100 pref medium
   ```

**Additional resources**

### 20.5. Setting the Default Gateway on an Existing Connection Using `nmstatectl`

You can set the default gateway of a network connection using the `nmstatectl` utility. This procedure describes how to set the default gateway of the existing `enp1s0` connection to **192.0.2.1**.

**Prerequisites**

- At least one static IP address must be configured on the connection on which the default gateway will be set.

- The `enp1s0` interface is configured, and the IP address of the default gateway is within the subnet of the IP configuration of this interface.

- The `nmstate` package is installed.

**Procedure**

1. Create a YAML file, for example `~/set-default-gateway.yml`, with the following contents:

   ```yaml
   ---
   routes:
   config:
   ```
2. Apply the settings to the system:

```
# nmstatectl apply ~/set-default-gateway.yml
```

Additional resources

- For further details about `nmstatectl`, see the `nmstatectl(8)` man page.
- For more configuration examples, see the `/usr/share/doc/nmstate/examples/` directory.

## 20.6. SETTING THE DEFAULT GATEWAY ON AN EXISTING CONNECTION USING SYSTEM ROLES

You can use the Networking RHEL System Role to set the default gateway.

**IMPORTANT**

When you run a play that uses the Networking RHEL System Role, the system role overrides an existing connection profile with the same name if the value of settings does not match the ones specified in the play. Therefore, always specify the whole configuration of the network connection profile in the play, even if, for example, the IP configuration already exists. Otherwise, the role resets these values to their defaults.

Depending on whether it already exists, the procedure creates or updates the `enp1s0` connection profile with the following settings:

- A static IPv4 address - `198.51.100.20` with a /24 subnet mask
- A static IPv6 address - `2001:db8:1::1` with a /64 subnet mask
- An IPv4 default gateway - `198.51.100.254`
- An IPv6 default gateway - `2001:db8:1::fffe`
- An IPv4 DNS server - `198.51.100.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`

**Prerequisites**

- The `ansible-core` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than `root` when you run the playbook, this user has appropriate `sudo` permissions on the managed node.

**Procedure**
1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/ethernet-connection.yml` playbook with the following content:

   ```yaml
   ---
   - name: Configure an Ethernet connection with static IP and default gateway
     hosts: node.example.com
     become: true
     tasks:
     - include_role:
       name: rhel-system-roles.network

     vars:
     network_connections:
     - name: enp1s0
       type: ethernet
       autoconnect: yes
       ip:
       address:
       - 198.51.100.20/24
       - 2001:db8:1::1/64
       gateway4: 198.51.100.254
       gateway6: 2001:db8:1::fffe
       dns:
       - 198.51.100.200
       - 2001:db8:1::ffbb
       dns_search:
       - example.com
     state: up
   ```

3. Run the playbook:

   - To connect as root user to the managed host, enter:
     ```
     # ansible-playbook -u root ~/ethernet-connection.yml
     ```

   - To connect as a user to the managed host, enter:
     ```
     # ansible-playbook -u user_name --ask-become-pass ~/ethernet-connection.yml
     ```

     The `--ask-become-pass` option makes sure that the `ansible-playbook` command prompts for the `sudo` password of the user defined in the `-u user_name` option.

     If you do not specify the `-u user_name` option, `ansible-playbook` connects to the managed host as the user that is currently logged in to the control node.

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md`
- `ansible-playbook(1)` man page
20.7. HOW NETWORKMANAGER MANAGES MULTIPLE DEFAULT GATEWAYS

In certain situations, for example for fallback reasons, you set multiple default gateways on a host. However, to avoid asynchronous routing issues, each default gateway of the same protocol requires a separate metric value. Note that RHEL only uses the connection to the default gateway that has the lowest metric set.

You can set the metric for both the IPv4 and IPv6 gateway of a connection using the following command:

```
# nmcli connection modify connection-name ipv4.route-metric value ipv6.route-metric value
```

**IMPORTANT**

Do not set the same metric value for the same protocol in multiple connection profiles to avoid routing issues.

If you set a default gateway without a metric value, NetworkManager automatically sets the metric value based on the interface type. For that, NetworkManager assigns the default value of this network type to the first connection that is activated, and sets an incremented value to each other connection of the same type in the order they are activated. For example, if two Ethernet connections with a default gateway exist, NetworkManager sets a metric of 100 on the route to the default gateway of the connection that you activate first. For the second connection, NetworkManager sets 101.

The following is an overview of frequently-used network types and their default metrics:

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Default metric value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPN</td>
<td>50</td>
</tr>
<tr>
<td>Ethernet</td>
<td>100</td>
</tr>
<tr>
<td>MACsec</td>
<td>125</td>
</tr>
<tr>
<td>InfiniBand</td>
<td>150</td>
</tr>
<tr>
<td>Bond</td>
<td>300</td>
</tr>
<tr>
<td>Team</td>
<td>350</td>
</tr>
<tr>
<td>VLAN</td>
<td>400</td>
</tr>
<tr>
<td>Bridge</td>
<td>425</td>
</tr>
<tr>
<td>TUN</td>
<td>450</td>
</tr>
<tr>
<td>Wi-Fi</td>
<td>600</td>
</tr>
</tbody>
</table>

---

## 20.8. CONFIGURING NETWORKMANAGER TO AVOID USING A SPECIFIC PROFILE TO PROVIDE A DEFAULT GATEWAY

You can configure that NetworkManager never uses a specific profile to provide the default gateway. Follow this procedure for connection profiles that are not connected to the default gateway.

### Prerequisites

- The NetworkManager connection profile for the connection that is not connected to the default gateway exists.

### Procedure

1. If the connection uses a dynamic IP configuration, configure that NetworkManager does not use the connection as the default route for IPv4 and IPv6 connections:

   ```
   # nmcli connection modify connection_name ipv4.never-default yes ipv6.never-default yes
   ```

   Note that setting `ipv4.never-default` and `ipv6.never-default` to `yes`, automatically removes the default gateway’s IP address for the corresponding protocol from the connection profile.

2. Activate the connection:

   ```
   # nmcli connection up connection_name
   ```

### Verification steps

- Use the `ip -4 route` and `ip -6 route` commands to verify that RHEL does not use the network interface for the default route for the IPv4 and IPv6 protocol.

---

## 20.9. FIXING UNEXPECTED ROUTING BEHAVIOR DUE TO MULTIPLE DEFAULT GATEWAYS

There are only a few scenarios, such as when using multipath TCP, in which you require multiple default gateways on a host. In most cases, you configure only a single default gateway to avoid unexpected routing behavior or asynchronous routing issues.
NOTE

To route traffic to different internet providers, use policy-based routing instead of multiple default gateways.

Prerequisites

- The host uses NetworkManager to manage network connections, which is the default.
- The host has multiple network interfaces.
- The host has multiple default gateways configured.

Procedure

1. Display the routing table:
   - For IPv4, enter:
     ```
     # ip -4 route
     default via 192.0.2.1 dev enp1s0 proto static metric 101
     default via 198.51.100.1 dev enp7s0 proto static metric 102
     ...
     ```
   - For IPv6, enter:
     ```
     # ip -6 route
     default via 2001:db8:1::1 dev enp1s0 proto static metric 101 pref medium
     default via 2001:db8:2::1 dev enp7s0 proto static metric 102 pref medium
     ...
     ```
   Entries starting with **default** indicate a default route. Note the interface names of these entries displayed next to dev.

2. Use the following commands to display the NetworkManager connections that use the interfaces you identified in the previous step:

   ```
   # nmcli -f GENERAL.CONNECTION,IP4.GATEWAY,IP6.GATEWAY device show enp1s0
   GENERAL.CONNECTION: Corporate-LAN
   IP4.GATEWAY: 192.168.122.1
   IP6.GATEWAY: 2001:db8:1::1
   
   # nmcli -f GENERAL.CONNECTION,IP4.GATEWAY,IP6.GATEWAY device show enp7s0
   GENERAL.CONNECTION: Internet-Provider
   IP4.GATEWAY: 198.51.100.1
   IP6.GATEWAY: 2001:db8:2::1
   ```
   In these examples, the profiles named **Corporate-LAN** and **Internet-Provider** have the default gateways set. Because, in a local network, the default gateway is typically the host that is one hop closer to the internet, the rest of this procedure assumes that the default gateways in the **Corporate-LAN** are incorrect.

3. Configure that NetworkManager does not use the **Corporate-LAN** connection as the default route for IPv4 and IPv6 connections:
# nmcli connection modify Corporate-LAN ipv4.never-default yes ipv6.never-default yes

Note that setting `ipv4.never-default` and `ipv6.never-default` to `yes`, automatically removes the default gateway’s IP address for the corresponding protocol from the connection profile.

4. Activate the **Corporate-LAN** connection:

```
# nmcli connection up Corporate-LAN
```

**Verification steps**

- Display the IPv4 and IPv6 routing tables and verify that only one default gateway is available for each protocol:
  - For IPv4, enter:
    ```
    # ip -4 route
default via 192.0.2.1 dev enp1s0 proto static metric 101 ...
    ```
  - For IPv6, enter:
    ```
    # ip -6 route
default via 2001:db8:1::1 dev enp1s0 proto static metric 101 pref medium ...
    ```

**Additional resources**

- Configuring policy-based routing to define alternative routes
- Getting started with Multipath TCP
CHAPTER 21. CONFIGURING STATIC ROUTES

By default, and if a default gateway is configured, Red Hat Enterprise Linux forwards traffic for networks that are not directly connected to the host to the default gateway. Using a static route, you can configure that Red Hat Enterprise Linux forwards the traffic for a specific host or network to a different router than the default gateway. This section describes different options how to configure static routes.

21.1. HOW TO USE THE NMCLI COMMAND TO CONFIGURE A STATIC ROUTE

To configure a static route, use the nmcli utility with the following syntax:

```
$ nmcli connection modify connection_name ipv4.routes "ip[/<prefix>] [next_hop] [metric] [attribute=value] [attribute=value] ...
```

The command supports the following route attributes:

- **cwnd=n**: Sets the congestion window (CWND) size, defined in number of packets.
- **lock-cwnd=true|false**: Defines whether or not the kernel can update the CWND value.
- **lock-mtu=true|false**: Defines whether or not the kernel can update the MTU to path MTU discovery.
- **lock-window=true|false**: Defines whether or not the kernel can update the maximum window size for TCP packets.
- **mtu=n**: Sets the maximum transfer unit (MTU) to use along the path to the destination.
- **onlink=true|false**: Defines whether the next hop is directly attached to this link even if it does not match any interface prefix.
- **scope=n**: For IPv4 routes, this attribute sets the scope of the destinations covered by the route prefix. Set the value as an integer (0-255).
- **src=address**: Sets the source address to prefer when sending traffic to the destinations covered by the route prefix.
- **table=table_id**: Sets the ID of the table the route should be added to. If you omit this parameter, NetworkManager uses the main table.
- **tos=n**: Sets the type of service (TOS) key. Set the value as an integer (0-255).
- **type=value**: Sets the route type. NetworkManager supports the unicast, local, blackhole, unreachable, and prohibit route types. The default is unicast.
- **window=n**: Sets the maximal window size for TCP to advertise to these destinations, measured in bytes.

If you use the ipv4.routes sub-command, nmcli overrides all current settings of this parameter. To add an additional route, use the nmcli connection modify connection_name +ipv4.routes "..." command. In a similar way, you can use nmcli connection modify connection_name -ipv4.routes "..." to remove a specific route.
21.2. CONFIGURING A STATIC ROUTE USING AN NMCLI COMMAND

You can add a static route to the configuration of a network connection using the `nmcli connection modify` command.

The procedure in this section describes how to add a route to the `192.0.2.0/24` network that uses the gateway running on `198.51.100.1`, which is reachable through the `example` connection.

Prerequisites

- The network is configured
- The gateway for the static route must be directly reachable on the interface.
- If the user is logged in on a physical console, user permissions are sufficient. Otherwise, the command requires `root` permissions.

Procedure

1. Add the static route to the `example` connection:

   ```bash
   $ sudo nmcli connection modify example +ipv4.routes "192.0.2.0/24 198.51.100.1"
   ```

   To set multiple routes in one step, pass the individual routes comma-separated to the command. For example, to add a route to the `192.0.2.0/24` and `203.0.113.0/24` networks, both routed through the `198.51.100.1` gateway, enter:

   ```bash
   $ sudo nmcli connection modify example +ipv4.routes "192.0.2.0/24 198.51.100.1, 203.0.113.0/24 198.51.100.1"
   ```

2. Optionally, verify that the routes were added correctly to the configuration:

   ```bash
   $ nmcli connection show example
   ...
   ipv4.routes:   { ip = 192.0.2.1/24, nh = 198.51.100.1 }
   ...
   ```

3. Restart the network connection:

   ```bash
   $ sudo nmcli connection up example
   ```

   **WARNING**

   Restarting the connection briefly disrupts connectivity on that interface.

4. Optionally, verify that the route is active:
$ ip route
... 192.0.2.0/24 via 198.51.100.1 dev example proto static metric 100

Additional resources

- nmcli(1) man page

21.3. CONFIGURING A STATIC ROUTE USING CONTROL-CENTER

You can use `control-center` in GNOME to add a static route to the configuration of a network connection.

The procedure in this section describes how to add a route to the 192.0.2.0/24 network that uses the gateway running on 198.51.100.1.

Prerequisites

- The network is configured.
- The gateway for the static route must be directly reachable on the interface.
- The network configuration of the connection is opened in the `control-center` application. See Configuring an Ethernet connection using `nm-connection-editor`.

Procedure

1. Open the IPv4 tab.

2. Optionally, disable automatic routes by clicking the On button in the Routes section of the IPv4 tab to use only static routes. If automatic routes are enabled, Red Hat Enterprise Linux uses static routes and routes received from a DHCP server.

3. Enter the address, netmask, gateway, and optionally a metric value:

```
<table>
<thead>
<tr>
<th>Routes</th>
<th>Automatic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address</td>
<td>Netmask</td>
</tr>
<tr>
<td>192.0.2.0</td>
<td>24</td>
</tr>
</tbody>
</table>
```

4. Click Apply.

5. Back in the Network window, disable and re-enable the connection by switching the button for the connection to Off and back to On for changes to take effect.

**WARNING**

Restarting the connection briefly disrupts connectivity on that interface.
6. Optionally, verify that the route is active:

```
$ ip route
...
192.0.2.0/24 via 198.51.100.1 dev example proto static metric 100
```

### 21.4. CONFIGURING A STATIC ROUTE USING NM-CONNECTION-EDITOR

You can use the `nm-connection-editor` application to add a static route to the configuration of a network connection.

The procedure in this section describes how to add a route to the `192.0.2.0/24` network that uses the gateway running on `198.51.100.1`, which is reachable through the `example` connection.

#### Prerequisites
- The network is configured.
- The gateway for the static route must be directly reachable on the interface.

#### Procedure

1. Open a terminal and enter `nm-connection-editor`:

   ```
   $ nm-connection-editor
   ```

2. Select the `example` connection and click the gear wheel icon to edit the existing connection.

3. Open the `IPv4` tab.

4. Click the `Routes` button.

5. Click the `Add` button and enter the address, netmask, gateway, and optionally a metric value.

   ![Editing IPv4 routes for example](image)

6. Click `OK`.

7. Click `Save`.

8. Restart the network connection for changes to take effect. For example, to restart the `example` connection using the command line:

   ```
   $ sudo nmcli connection up example
   ```

9. Optionally, verify that the route is active:
$ ip route
... 192.0.2.0/24 via 198.51.100.1 dev example proto static metric 100

21.5. CONFIGURING A STATIC ROUTE USING THE NMCLI INTERACTIVE MODE

You can use the interactive mode of the **nmcli** utility to add a static route to the configuration of a network connection.

The procedure in this section describes how to add a route to the **192.0.2.0/24** network that uses the gateway running on **198.51.100.1**, which is reachable through the **example** connection.

**Prerequisites**

- The network is configured.
- The gateway for the static route must be directly reachable on the interface.
- If the user is logged in on a physical console, user permissions are sufficient. Otherwise, the command requires **root** permissions.

**Procedure**

1. Open the **nmcli** interactive mode for the **example** connection:

   ```bash
   $ sudo nmcli connection edit example
   ```

2. Add the static route:

   ```bash
   nmcli> set ipv4.routes 192.0.2.0/24 198.51.100.1
   ```

3. Optionally, verify that the routes were added correctly to the configuration:

   ```bash
   nmcli> print
   ...
   ipv4.routes:  { ip = 192.0.2.1/24, nh = 198.51.100.1 }
   ...
   ```

   The **ip** attribute displays the network to route and the **nh** attribute the gateway (next hop).

4. Save the configuration:

   ```bash
   nmcli> save persistent
   ```

5. Restart the network connection:

   ```bash
   nmcli> activate example
   ```
WARNING

When you restart the connection, all connections currently using this connection will be temporarily interrupted.

6. Leave the `nmcli` interactive mode:

```
nmcli> quit
```

7. Optionally, verify that the route is active:

```
$ ip route
...
192.0.2.0/24 via 198.51.100.1 dev example proto static metric 100
```

### 21.6. CONFIGURING A STATIC ROUTE USING NMSTATECTL

You can add a static route to the configuration of a network connection using the `nmstatectl` utility.

The procedure in this section describes how to add a route to the `192.0.2.0/24` network that uses the gateway running on `198.51.100.1`, which is reachable through the `enp1s0` interface.

**Prerequisites**

- The `enp1s0` network interface is configured.
- The gateway for the static route must be directly reachable on the interface.
- The `nmstate` package is installed.

**Procedure**

1. Create a YAML file, for example `~/add-static-route-to-enp1s0.yml`, with the following contents:

```yaml
---
routes:
  config:
    - destination: 192.0.2.0/24
      next-hop-address: 198.51.100.1
      next-hop-interface: enp1s0
```

2. Apply the settings to the system:

```
# nmstatectl apply ~/add-static-route-to-enp1s0.yml
```

**Additional resources**

- `nmstatectl(8)` man page
21.7. CONFIGURING A STATIC ROUTE USING RHEL SYSTEM ROLES

You can use the Networking RHEL System Role to configure static routes.

**IMPORTANT**

When you run a play that uses the Networking RHEL System Role, the system role overrides an existing connection profile with the same name if the value of settings does not match the ones specified in the play. Therefore, always specify the whole configuration of the network connection profile in the play, even if, for example, the IP configuration already exists. Otherwise, the role resets these values to their defaults.

Depending on whether it already exists, the procedure creates or updates the `enp7s0` connection profile with the following settings:

- A static IPv4 address - `198.51.100.20` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - `198.51.100.254`
- An IPv6 default gateway - `2001:db8:1::fffe`
- An IPv4 DNS server - `198.51.100.200`
- An IPv6 DNS server - `2001:db8:1::ffbb`
- A DNS search domain - `example.com`
- Static routes:
  - `192.0.2.0/24` with gateway `198.51.100.1`
  - `203.0.113.0/24` with gateway `198.51.100.2`

**Prerequisites**

- The `ansible-core` and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than root when you run the playbook, this user has appropriate `sudo` permissions on the managed node.

**Procedure**

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/add-static-routes.yml` playbook with the following content:

   ```
   ---
   - name: Configure an Ethernet connection with static IP and additional routes
   ```
hosts: node.example.com
become: true
tasks:
  - include_role:
      name: rhel-system-roles.network

vars:
  network_connections:
    - name: enp7s0
      type: ethernet
      autoconnect: yes
      ip:
        address:
          - 198.51.100.20/24
          - 2001:db8:1::1/64
      gateway4: 198.51.100.254
      gateway6: 2001:db8:1::fffe
  dns:
    - 198.51.100.200
    - 2001:db8:1::ffbb
  dns_search:
    - example.com
  route:
    - network: 192.0.2.0
      prefix: 24
      gateway: 198.51.100.1
    - network: 203.0.113.0
      prefix: 24
      gateway: 198.51.100.2
  state: up

3. Run the playbook:

   - To connect as root user to the managed host, enter:

     ```
     # ansible-playbook -u root ~/add-static-routes.yml
     ```

   - To connect as a user to the managed host, enter:

     ```
     # ansible-playbook -u user_name --ask-become-pass ~/add-static-routes.yml
     ```

     The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Verification steps

   - Display the routing table:

     ```
     # ip -4 route
default via 198.51.100.254 dev enp7s0 proto static metric 100
192.0.2.0/24 via 198.51.100.1 dev enp7s0 proto static metric 100
     ```
203.0.113.0/24 via 198.51.100.2 dev enp7s0 proto static metric 100

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.network/README.md` file
- `ansible-playbook(1)` man page
CHAPTER 22. CONFIGURING POLICY-BASED ROUTING TO DEFINE ALTERNATIVE ROUTES

By default, the kernel in RHEL decides where to forward network packets based on the destination address using a routing table. Policy-based routing enables you to configure complex routing scenarios. For example, you can route packets based on various criteria, such as the source address, packet metadata, or protocol.

This section describes how to configure policy-based routing using NetworkManager.

NOTE

On systems that use NetworkManager, only the `nmcli` utility supports setting routing rules and assigning routes to specific tables.

22.1. ROUTING TRAFFIC FROM A SPECIFIC SUBNET TO A DIFFERENT DEFAULT GATEWAY USING NETWORKMANAGER

This section describes how to configure RHEL as a router that, by default, routes all traffic to Internet provider A using the default route. Using policy-based routing, RHEL routes traffic received from the internal workstations subnet to provider B.

The procedure assumes the following network topology:

Prerequisites

- The system uses NetworkManager to configure the network, which is the default.
- The RHEL router you want to set up in the procedure has four network interfaces:
  - The `enp7s0` interface is connected to the network of provider A. The gateway IP in the provider’s network is 198.51.100.2, and the network uses a /30 network mask.
  - The `enp1s0` interface is connected to the network of provider B. The gateway IP in the provider’s network is 192.0.2.2, and the network uses a /30 network mask.
The `enp8s0` interface is connected to the `10.0.0.0/24` subnet with internal workstations.

- The `enp9s0` interface is connected to the `203.0.113.0/24` subnet with the company’s servers.

- Hosts in the internal workstations subnet use `10.0.0.1` as the default gateway. In the procedure, you assign this IP address to the `enp8s0` network interface of the router.

- Hosts in the server subnet use `203.0.113.1` as the default gateway. In the procedure, you assign this IP address to the `enp9s0` network interface of the router.

- The `firewalld` service is enabled and active.

**Procedure**

1. Configure the network interface to provider A:

```
# nmcli connection add type ethernet con-name Provider-A ifname enp7s0
ipv4.method manual ipv4.addresses 198.51.100.1/30 ipv4.gateway 198.51.100.2
ipv4.dns 198.51.100.200 connection.zone external
```

The `nmcli connection add` command creates a NetworkManager connection profile. The following list describes the options of the command:

- **type ethernet**: Defines that the connection type is Ethernet.

- **con-name** `connection_name`: Sets the name of the profile. Use a meaningful name to avoid confusion.

- **ifname** `network_device`: Sets the network interface.

- **ipv4.method manual**: Enables to configure a static IP address.

- **ipv4.addresses** `IP_address/subnet_mask`: Sets the IPv4 addresses and subnet mask.

- **ipv4.gateway** `IP_address`: Sets the default gateway address.

- **ipv4.dns** `IP_of_DNS_server`: Sets the IPv4 address of the DNS server.

- **connection.zone** `firewalld_zone`: Assigns the network interface to the defined `firewalld` zone. Note that `firewalld` automatically enables masquerading for interfaces assigned to the `external` zone.

2. Configure the network interface to provider B:

```
# nmcli connection add type ethernet con-name Provider-B ifname enp1s0
ipv4.method manual ipv4.addresses 192.0.2.1/30 ipv4.routes "0.0.0.0/0 192.0.2.2 table=5000" connection.zone external
```

This command uses the `ipv4.routes` parameter instead of `ipv4.gateway` to set the default gateway. This is required to assign the default gateway for this connection to a different routing table (5000) than the default. NetworkManager automatically creates this new routing table when the connection is activated.

3. Configure the network interface to the internal workstations subnet:
This command uses the `ipv4.routes` parameter to add a static route to the routing table with ID 5000. This static route for the 10.0.0.0/24 subnet uses the IP of the local network interface to provider B (192.0.2.1) as next hop.

Additionally, the command uses the `ipv4.routing-rules` parameter to add a routing rule with priority 5 that routes traffic from the 10.0.0.0/24 subnet to table 5000. Low values have a high priority.

Note that the syntax in the `ipv4.routing-rules` parameter is the same as in an `ip rule add` command, except that `ipv4.routing-rules` always requires specifying a priority.

4. Configure the network interface to the server subnet:

```bash
# nmcli connection add type ethernet con-name Servers ifname enp9s0 ipv4.method manual ipv4.addresses 203.0.113.1/24 connection.zone trusted
```

Verification steps

1. On a RHEL host in the internal workstation subnet:
   a. Install the `traceroute` package:
      ```bash
      # dnf install traceroute
      ```
   
   b. Use the `traceroute` utility to display the route to a host on the Internet:
      ```bash
      # traceroute redhat.com
      traceroute to redhat.com (209.132.183.105), 30 hops max, 60 byte packets
      1  10.0.0.1 (10.0.0.1)     0.337 ms  0.260 ms  0.223 ms
      2  192.0.2.1 (192.0.2.1)   0.884 ms  1.066 ms  1.248 ms
      ...
      ```
      The output of the command displays that the router sends packets over 192.0.2.1, which is the network of provider B.

2. On a RHEL host in the server subnet:
   a. Install the `traceroute` package:
      ```bash
      # dnf install traceroute
      ```
   
   b. Use the `traceroute` utility to display the route to a host on the Internet:
      ```bash
      # traceroute redhat.com
      traceroute to redhat.com (209.132.183.105), 30 hops max, 60 byte packets
      1  203.0.113.1 (203.0.113.1)    2.179 ms  2.073 ms  1.944 ms
      2  198.51.100.2 (198.51.100.2)  1.868 ms  1.798 ms  1.549 ms
      ...
      ```
The output of the command displays that the router sends packets over 198.51.100.2, which is the network of provider A.

**Troubleshooting steps**

**On the RHEL router:**

1. Display the rule list:
   
   ```
   # ip rule list
   0: from all lookup local
   5: from 10.0.0.0/24 lookup 5000
   32766: from all lookup main
   32767: from all lookup default
   ```

   By default, RHEL contains rules for the tables **local**, **main**, and **default**.

2. Display the routes in table **5000**:
   
   ```
   # ip route list table 5000
   0.0.0.0/0 via 192.0.2.2 dev enp1s0 proto static metric 100
   10.0.0.0/24 dev enp8s0 proto static scope link src 192.0.2.1 metric 102
   ```

3. Display the interfaces and firewall zones:
   
   ```
   # firewall-cmd --get-active-zones
   external interfaces: enp1s0 enp7s0
   trusted interfaces: enp8s0 enp9s0
   ```

4. Verify that the **external** zone has masquerading enabled:
   
   ```
   # firewall-cmd --info-zone=external
   external (active)
   target: default
   icmp-block-inversion: no
   interfaces: enp1s0 enp7s0
   sources:
   services: ssh
   ports:
   protocols: 
   masquerade: yes
   ... 
   ```

CHAPTER 23. CREATING A DUMMY INTERFACE

As a Red Hat Enterprise Linux user, you can create and use dummy network interfaces for debugging and testing purposes. A dummy interface provides a device to route packets without actually transmitting them. It enables you to create additional loopback-like devices managed by NetworkManager and makes an inactive SLIP (Serial Line Internet Protocol) address look like a real address for local programs.

23.1. CREATING A DUMMY INTERFACE WITH BOTH AN IPV4 AND IPV6 ADDRESS USING NMCLI

You can create a dummy interface with various settings. This procedure describes how to create a dummy interface with both an IPv4 and IPv6 address. After creating the dummy interface, NetworkManager automatically assigns it to the default public firewall zone.

NOTE

To configure a dummy interface without IPv4 or IPv6 address, set the ipv4.method and ipv6.method parameters to disabled. Otherwise, IP auto-configuration fails, and NetworkManager deactivates the connection and removes the dummy device.

Procedure

1. To create a dummy interface named dummy0 with static IPv4 and IPv6 addresses, enter:

   ```
   # nmcli connection add type dummy ifname dummy0 ipv4.method manual
   ipv4.addresses 192.0.2.1/24 ipv6.method manual ipv6.addresses 2001:db8:2::1/64
   ```

2. Optional: To view the dummy interface, enter:

   ```
   # nmcli connection show
   NAME            UUID                                  TYPE      DEVICE
   enp1s0          db1060e9-c164-476f-b2b5-caec62dc1b05  ethernet    ens3
   dummy-dummy0    aaf6eb56-73e5-4746-9037-eed42ca8a65  dummy    dummy0
   ```

CHAPTER 24. USING NMSTATE-AUTOCONF TO AUTOMATICALLY CONFIGURE THE NETWORK STATE USING LLDP

Network devices can use the Link Layer Discovery Protocol (LLDP) to advertise their identity, capabilities, and neighbors in a LAN. The `nmstate-autoconf` utility can use this information to automatically configure local network interfaces.

**IMPORTANT**

The `nmstate-autoconf` utility is provided as a Technology Preview only. Technology Preview features are not supported with Red Hat production Service Level Agreements (SLAs), might not be functionally complete, and Red Hat does not recommend using them for production. These previews provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

See [Technology Preview Features Support Scope](https://www.redhat.com) on the Red Hat Customer Portal for information about the support scope for Technology Preview features.

### 24.1. USING NMSTATE-AUTOCONF TO AUTOMATICALLY CONFIGURE NETWORK INTERFACES

The `nmstate-autoconf` utility uses LLDP to identify the VLAN settings of interfaces connected to a switch to configure local devices.

This procedure assumes the following scenario and that the switch broadcasts the VLAN settings using LLDP:

- The `enp1s0` and `enp2s0` interfaces of the RHEL server are connected to switch ports that are configured with VLAN ID 100 and VLAN name `prod-net`.
- The `enp3s0` interface of the RHEL server is connected to a switch port that is configured with VLAN ID 200 and VLAN name `mgmt-net`.

The `nmstate-autoconf` utility then uses this information to create the following interfaces on the server:

- `bond100` - A bond interface with `enp1s0` and `enp2s0` as ports.
- `prod-net` - A VLAN interface on top of `bond100` with VLAN ID 100.
- `mgmt-net` - A VLAN interface on top of `enp3s0` with VLAN ID 200

If you connect multiple network interfaces to different switch ports for which LLDP broadcasts the same VLAN ID, `nmstate-autoconf` creates a bond with these interfaces and, additionally, configures the common VLAN ID on top of it.

**Prerequisites**

- The `nmstate` package is installed.
- LLDP is enabled on the network switch.
- The Ethernet interfaces are up.
Procedure

1. Enable LLDP on the Ethernet interfaces:
   a. Create a YAML file, for example `~/enable-lldp.yml`, with the following contents:

   ```yaml
   interfaces:
   - name: enp1s0
     type: ethernet
     lldp:
       enabled: true
   - name: enp2s0
     type: ethernet
     lldp:
       enabled: true
   - name: enp3s0
     type: ethernet
     lldp:
       enabled: true
   
   b. Apply the settings to the system:
      
      ```
      # nmstatectl apply ~/enable-lldp.yml
      ```

2. Configure the network interfaces using LLDP:
   a. Optional, start a dry-run to display and verify the YAML configuration that `nmstate-autoconf` generates:

   ```
   # nmstate-autoconf -d enp1s0,enp2s0,enp3s0
   ---
   interfaces:
   - name: prod-net
     type: vlan
     state: up
     vlan:
       base-iface: bond100
       id: 100
   - name: mgmt-net
     type: vlan
     state: up
     vlan:
       base-iface: enp3s0
       id: 200
   - name: bond100
     type: bond
     state: up
     link-aggregation:
       mode: balance-rr
       port:
       - enp1s0
       - enp2s0
   ```
   
   b. Use `nmstate-autoconf` to generate the configuration based on information received from LLDP, and apply the settings to the system:
Next steps

- If there is no DHCP server in your network that provides the IP settings to the interfaces, configure them manually. For details, see:
  - Configuring an Ethernet connection
  - Configuring network bonding

Verification

1. Display the settings of the individual interfaces:

   # nmstatectl show <interface_name>

Additional resources

- The nmstate-autoconf(8) man page
CHAPTER 25. USING LLDP TO DEBUG NETWORK CONFIGURATION PROBLEMS

You can use the Link Layer Discovery Protocol (LLDP) to debug network configuration problems in the topology. This means that, LLDP can report configuration inconsistencies with other hosts or routers and switches.

25.1. DEBUGGING AN INCORRECT VLAN CONFIGURATION USING LLDP INFORMATION

If you configured a switch port to use a certain VLAN and a host does not receive these VLAN packets, you can use the Link Layer Discovery Protocol (LLDP) to debug the problem. Perform this procedure on the host that does not receive the packets.

Prerequisites

- The nmstate package is installed.
- The switch supports LLDP.
- LLDP is enabled on neighbor devices.

Procedure

1. Create the ~/enable-LLDP-enp1s0.yml file with the following content:

```yaml
interfaces:
  - name: enp1s0
    type: ethernet
    lldp:
      enabled: true
```

2. Use the ~/enable-LLDP-enp1s0.yml file to enable LLDP on interface enp1s0:

```
# nmstatectl apply ~/enable-LLDP-enp1s0.yml
```

3. Display the LLDP information:

```
# nmstatectl show enp1s0
- name: enp1s0
  type: ethernet
  state: up
  ipv4:
    enabled: false
dhcp: false
  ipv6:
    enabled: false
  autoconf: false
dhcp: false
  lldp:
    enabled: true
  neighbors:
    - - type: 5
```
4. Verify the output to ensure that the settings match your expected configuration. For example, the LLDP information of the interface connected to the switch shows that the switch port this host is connected to uses VLAN ID 448:

- type: 127
  ieee-802-1-vlans:
  - name: v2-0488-03-0505
    vid: 488
    oui: 00:80:c2
    subtype: 3
- type: 127
  ieee-802-3-max-frame-size: 1522
  oui: 00:12:0f
  subtype: 4
  mac-address: 82:75:BE:6F:8C:7A
  mtu: 1500
If the network configuration of the \texttt{enp1s0} interface uses a different VLAN ID, change it accordingly.

Additional resources

Configuring VLAN tagging
CHAPTER 26. MANUALLY CREATING NETWORKMANAGER PROFILES IN KEY FILE FORMAT

By default, NetworkManager stores profiles in the key file format. For example, the `nmcli` utility, the `networking` RHEL System Role, or the `nmstate` API to manage profiles use this format. However, NetworkManager still supports profiles in the deprecated `ifcfg` format.

26.1. THE KEY FILE FORMAT OF NETWORKMANAGER PROFILES

NetworkManager uses the INI-style key file format when it stores connection profiles on disk.

Example of an Ethernet connection profile in key file format

```
[connection]
id=example_connection
uuid=82c6272d-1ff7-4d56-9c7c-0eb27c300029
type=ethernet
autoconnect=true

[ipv4]
method=auto

[ipv6]
method=auto

[ethernet]
mac-address=00:53:00:8f:fa:66
```

Each section corresponds to a NetworkManager setting name as described in the `nm-settings(5)` and `nm-settings-keyfile(5)` man pages. Each key-value-pair in a section is one of the properties listed in the settings specification of the man page.

Most variables in NetworkManager key files have a one-to-one mapping. This means that a NetworkManager property is stored in the key file as a variable of the same name and in the same format. However, there are exceptions, mainly to make the key file syntax easier to read. For a list of these exceptions, see the `nm-settings-keyfile(5)` man page.

IMPORTANT

For security reasons, because connection profiles can contain sensitive information, such as private keys and passphrases, NetworkManager uses only configuration files owned by the `root` and that are only readable and writable by `root`.

Depending on the purpose of the connection profile, save it in one of the following directories:

- `/etc/NetworkManager/system-connections/`: The general location for persistent profiles created by the user that can also be edited. NetworkManager copies them automatically to `/etc/NetworkManager/system-connections/`.

- `/run/NetworkManager/system-connections/`: For temporary profiles that are automatically removed when you reboot the system.
NetworkManager does not automatically reload profiles from disk. When you create or update a
connection profile in key file format, use the `nmcli connection reload` command to inform
NetworkManager about the changes.

26.2. CREATING A NETWORKMANAGER PROFILE IN KEY FILE
FORMAT

This section explains a general procedure on how to manually create a NetworkManager connection
profile in key file format.

**NOTE**

Manually creating or updating the configuration files can result in an unexpected or non-
functional network configuration. Red Hat recommends that you use NetworkManager
utilities, such as `nmcli`, the `network` RHEL System Role, or the `nmstate` API to manage
NetworkManager connections.

**Procedure**

1. If you create a profile for a hardware interface, such as Ethernet, display the MAC address of this
interface:

```bash
# ip address show enp1s0
2: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
group default qlen 1000
    link/ether 00:53:00:8f:fa:66 brd ff:ff:ff:ff:ff:ff
```

2. Create a connection profile. For example, for a connection profile of an Ethernet device that
uses DHCP, create the `/etc/NetworkManager/system-connections/example.nmconnection`
file with the following content:

```plaintext
[connection]
id=example_connection
type=ethernet
autoconnect=true

[ipv4]
method=auto

[ipv6]
method=auto

[ethernet]
mac-address=00:53:00:8f:fa:66
```
NOTE

You can use any file name with a .nmconnection suffix. However, when you later use `nmcli` commands to manage the connection, you must use the connection name set in the id variable when you refer to this connection. When you omit the id variable, use the file name without the .nmconnection to refer to this connection.

3. Set permissions on the configuration file so that only the root user can read and update it:

```
# chown root:root /etc/NetworkManager/system-connections/example.nmconnection
# chmod 600 /etc/NetworkManager/system-connections/example.nmconnection
```

4. Reload the connection profiles:

```
# nmcli connection reload
```

5. Verify that NetworkManager read the profile from the configuration file:

```
# nmcli -f NAME,UUID,FILENAME connection
NAME                UUID                                  FILENAME
example-connection  86da2486-068d-4d05-9ac7-957ec118afba
/etc/NetworkManager/system-connections/example.nmconnection
...
```

If the command does not show the newly added connection, verify that the file permissions and the syntax you used in the file are correct.

6. Optional: If you set the autoconnect variable in the profile to false, activate the connection:

```
# nmcli connection up example_connection
```

Verification

1. Display the connection profile:

```
# nmcli connection show example_connection
```

2. Display the IP settings of the interface:

```
# ip address show enp1s0
```

Additional resources

- `nm-settings-keyfile` (5)
CHAPTER 27. USING NETCONSOLE TO LOG KERNEL MESSAGES OVER A NETWORK

Using the netconsole kernel module and the same-named service, you can log kernel messages over a network to debug the kernel when logging to disk fails or when using a serial console is not possible.

27.1. CONFIGURING THE NETCONSOLE SERVICE TO LOG KERNEL MESSAGES TO A REMOTE HOST

Using the netconsole kernel module, you can log kernel messages to a remote system log service.

Prerequisites

- A system log service, such as rsyslog is installed on the remote host.
- The remote system log service is configured to receive incoming log entries from this host.

Procedure

1. Install the netconsole-service package:
   
   ```
   # dnf install netconsole-service
   ```

2. Edit the /etc/sysconfig/netconsole file and set the SYSLOGADDR parameter to the IP address of the remote host:
   
   ```
   # SYSLOGADDR=192.0.2.1
   ```

3. Enable and start the netconsole service:
   
   ```
   # systemctl enable --now netconsole
   ```

Verification steps

- Display the /var/log/messages file on the remote system log server.

Additional resources

- Configuring a remote logging solution
CHAPTER 28. SYSTEMD NETWORK TARGETS AND SERVICES

NetworkManager configures the network during the system boot process. However, when booting with a remote root (/), such as if the root directory is stored on an iSCSI device, the network settings are applied in the initial RAM disk (initrd) before RHEL is started. For example, if the network configuration is specified on the kernel command line using rd.neednet=1 or a configuration is specified to mount remote file systems, then the network settings are applied on initrd.

This section describes different targets such as network, network-online, and NetworkManager-wait-online service that are used while applying network settings, and how to configure the systemd service to start after the network-online service is started.

28.1. DIFFERENCES BETWEEN THE NETWORK AND NETWORK-ONLINE SYSTEMD TARGET

Systemd maintains the network and network-online target units. The special units such as NetworkManager-wait-online.service, have WantedBy=network-online.target and Before=network-online.target parameters. If enabled, these units get started with network-online.target and delay the target to be reached until some form of network connectivity is established. They delay the network-online target until the network is connected.

The network-online target starts a service, which adds substantial delays to further execution. Systemd automatically adds dependencies with Wants and After parameters for this target unit to all the System V (SysV) init script service units with a Linux Standard Base (LSB) header referring to the $network facility. The LSB header is metadata for init scripts. You can use it to specify dependencies. This is similar to the systemd target.

The network target does not significantly delay the execution of the boot process. Reaching the network target means that the service that is responsible for setting up the network has started. However, it does not mean that a network device was configured. This target is important during the shutdown of the system. For example, if you have a service that was ordered after the network target during bootup, then this dependency is reversed during the shutdown. The network does not get disconnected until your service has been stopped. All mount units for remote network file systems automatically start the network-online target unit and order themselves after it.

NOTE

The network-online target unit is only useful during the system starts. After the system has completed booting up, this target does not track the online state of the network. Therefore, you cannot use network-online to monitor the network connection. This target provides a one-time system startup concept.

28.2. OVERVIEW OF NETWORKMANAGER-WAIT-ONLINE

The NetworkManager-wait-online service waits with a timeout for the network to be configured. This network configuration involves plugging-in an Ethernet device, scanning for a Wi-Fi device, and so forth. NetworkManager automatically activates suitable profiles that are configured to start automatically. The failure of the automatic activation process due to a DHCP timeout or similar event might keep NetworkManager busy for an extended period of time. Depending on the configuration, NetworkManager retries activating the same profile or a different profile.

When the startup completes, either all profiles are in a disconnected state or are successfully activated. You can configure profiles to auto-connect. The following are a few examples of parameters that set timeouts or define when the connection is considered active:
- `connection.wait-device-timeout` - sets the timeout for the driver to detect the device
- `ipv4.may-fail` and `ipv6.may-fail` - sets activation with one IP address family ready, or whether a particular address family must have completed configuration.
- `ipv4.gateway-ping-timeout` - delays activation.

Additional resources
- The `nm-settings(5)` man page

28.3. CONFIGURING A SYSTEMD SERVICE TO START AFTER THE NETWORK HAS BEEN STARTED

Red Hat Enterprise Linux installs `systemd` service files in the `/usr/lib/systemd/system/` directory. This procedure creates a drop-in snippet for a service file in `/etc/systemd/system/service_name.service.d/` that is used together with the service file in `/usr/lib/systemd/system/` to start a particular service after the network is online. It has a higher priority if settings in the drop-in snippet overlap with the ones in the service file in `/usr/lib/systemd/system/`.

Procedure

1. To open the service file in the editor, enter:
   ```bash
   # systemctl edit service_name
   ```
2. Enter the following, and save the changes:
   ```
   [Unit]
   After=network-online.target
   ```
3. Reload the `systemd` service.
   ```bash
   # systemctl daemon-reload
   ```
CHAPTER 29. LINUX TRAFFIC CONTROL

Linux offers tools for managing and manipulating the transmission of packets. The Linux Traffic Control (TC) subsystem helps in policing, classifying, shaping, and scheduling network traffic. TC also mangles the packet content during classification by using filters and actions. The TC subsystem achieves this by using queuing disciplines (qdisc), a fundamental element of the TC architecture.

The scheduling mechanism arranges or rearranges the packets before they enter or exit different queues. The most common scheduler is the First-In-First-Out (FIFO) scheduler. You can do the qdiscs operations temporarily using the tc utility or permanently using NetworkManager.

This section explains queuing disciplines and describes how to update the default qdiscs in RHEL.

29.1. OVERVIEW OF QUEUING DISCIPLINES

Queuing disciplines (qdiscs) help with queuing up and, later, scheduling of traffic transmission by a network interface. A qdisc has two operations;

- enqueue requests so that a packet can be queued up for later transmission and
- dequeue requests so that one of the queued-up packets can be chosen for immediate transmission.

Every qdisc has a 16-bit hexadecimal identification number called a handle, with an attached colon, such as 1: or abcd:. This number is called the qdisc major number. If a qdisc has classes, then the identifiers are formed as a pair of two numbers with the major number before the minor, <major>:<minor>, for example abcd:1. The numbering scheme for the minor numbers depends on the qdisc type. Sometimes the numbering is systematic, where the first-class has the ID <major>:1, the second one <major>:2, and so on. Some qdiscs allow the user to set class minor numbers arbitrarily when creating the class.

Classful qdiscs

Different types of qdiscs exist and help in the transfer of packets to and from a networking interface. You can configure qdiscs with root, parent, or child classes. The point where children can be attached are called classes. Classes in qdisc are flexible and can always contain either multiple children classes or a single child, qdisc. There is no prohibition against a class containing a classful qdisc itself, this facilitates complex traffic control scenarios.

Classful qdiscs do not store any packets themselves. Instead, they enqueue and dequeue requests down to one of their children according to criteria specific to the qdisc. Eventually, this recursive packet passing ends up where the packets are stored (or picked up from in the case of dequeuing).

Classless qdiscs

Some qdiscs contain no child classes and they are called classless qdiscs. Classless qdiscs require less customization compared to classful qdiscs. It is usually enough to attach them to an interface.

Additional resources

- tc(8) man page
- tc-actions.8 man page

29.2. AVAILABLE QDISCS IN RHEL
Each **qdisc** addresses unique networking-related issues. The following is the list of **qdiscs** available in RHEL. You can use any of the following **qdisc** to shape network traffic based on your networking requirements.

**Table 29.1. Available schedulers in RHEL**

### IMPORTANT

The qdisc offload requires hardware and driver support on NIC.

### Additional resources

- The `tc(8), cbq, cbs, choke, CoDel, drr, fq, htb, mqprio, netem, pie, sfb, pfifo, tc-red, sfq, tbf, and prio` man pages.

### 29.3. INSPECTING QDISCS OF A NETWORK INTERFACE USING THE TC UTILITY

By default, Red Hat Enterprise Linux systems use `fq_codel qdisc`. This procedure describes how to inspect qdisc counters.

#### Procedure

1. Optional: View your current qdisc:
   ```bash
   # tc qdisc show dev enp0s1
   ```
2. Inspect the current qdisc counters:
   ```bash
   # tc -s qdisc show dev enp0s1
   qdisc fq_codel 0: root refcnt 2 limit 10240p flows 1024 quantum 1514 target 5.0ms interval 100.0ms memory_limit 32Mb ecn
   Sent 1008193 bytes 5559 pkt (dropped 233, overlimits 55 requeues 77)
   backlog 0b 0p requeues 0
   ```
dropped - the number of times a packet is dropped because all queues are full
overlimits - the number of times the configured link capacity is filled
sent - the number of dequeues

29.4. UPDATING THE DEFAULT QDISC

If you observe networking packet losses with the current qdisc, you can change the qdisc based on your network-requirements. You can select the qdisc, which meets your network requirements. This procedure describes how to change the default qdisc in Red Hat Enterprise Linux.

Procedure

1. View the current default qdisc:
   
   ```
   # sysctl -a | grep qdisc
   net.core.default_qdisc = fq_codel
   ```

2. View the qdisc of current Ethernet connection:
   
   ```
   # tc -s qdisc show dev enp0s1
   qdisc fq_codel 0: root refcnt 2 limit 1024p flows 1024 quantum 1514 target 5.0ms interval 100.0ms memory_limit 32Mb ecn
   Sent 0 bytes 0 pkt (dropped 0, overlimits 0 requeues 0)
   backlog 0b 0p requeues 0
   maxpacket 0 drop_overlimit 0 new_flow_count 0 ecn_mark 0
   new_flows_len 0 old_flows_len 0
   ```

3. Update the existing qdisc:
   
   ```
   # sysctl -w net.core.default_qdisc=pfifo_fast
   ```

4. To apply the changes, reload the network driver:
   
   ```
   # rmmod NETWORKDRIVERNAME
   
   # modprobe NETWORKDRIVERNAME
   ```

5. Start the network interface:
   
   ```
   # ip link set enp0s1 up
   ```

Verification steps

- View the qdisc of the Ethernet connection:
  
  ```
  # tc -s qdisc show dev enp0s1
  qdisc pfifo_fast 0: root refcnt 2 bands 3 priomap 1 2 2 2 1 2 0 0 1 1 1 1 1 1 1 1
  Sent 373186 bytes 5333 pkt (dropped 0, overlimits 0 requeues 0)
  backlog 0b 0p requeues 0
  ....
  ```

Additional resources

- How to set sysctl variables on Red Hat Enterprise Linux
29.5. TEMPORARILY SETTING THE CURRENT QDISK OF A NETWORK INTERFACE USING THE TC UTILITY

You can update the current qdisc without changing the default one. This procedure describes how to change the current qdisc in Red Hat Enterprise Linux.

Procedure

1. Optional: View the current qdisc:
   
   ```
   # tc -s qdisc show dev enp0s1
   ```

2. Update the current qdisc:
   
   ```
   # tc qdisc replace dev enp0s1 root htb
   ```

Verification step

- View the updated current qdisc:

```
# tc -s qdisc show dev enp0s1
qdisc htb 8001: root refcnt 2 r2q 10 default 0 direct_packets_stat 0 direct_qlen 1000
Sent 0 bytes 0 pkt (dropped 0, overlimits 0 requeues 0)
backlog 0b 0p requeues 0
```

29.6. PERMANENTLY SETTING THE CURRENT QDISK OF A NETWORK INTERFACE USING NETWORKMANAGER

You can update the current qdisc value of a NetworkManager connection.

Procedure

1. Optional: View the current qdisc:

```
# tc qdisc show dev enp0s1
qdisc fq_codel 0: root refcnt 2
```

2. Update the current qdisc:

```
# nmcli connection modify enp0s1 tc.qdiscs 'root pfifo_fast'
```

3. Optional: To add another qdisc over the existing qdisc, use the +tc.qdisc option:

```
# nmcli connection modify enp0s1 +tc.qdisc 'ingress handle ffff:'
```

4. Activate the changes:

```
# nmcli connection up enp0s1
```

Verification steps

- View current qdisc the network interface:
# tc qdisc show dev enp0s1
qdisc pfifo_fast 8001: root refcnt 2 bands 3 priomap 1 2 2 1 2 0 0 1 1 1 1 1 1
qdisc ingress ffff: parent ffff:fff1 ---------------

CHAPTER 30. GETTING STARTED WITH MULTIPATH TCP

Multipath TCP (MPTCP) is an extension to the Transmission Control Protocol (TCP). Using Internet Protocol (IP), a host can send packets to a destination. TCP ensures reliable delivery of the data through the Internet and automatically adjusts its bandwidth in response to network load.

This section describes how to:

- Create a new MPTCP connection
- Enable the server to use MPTCP
- Disable MPTCP in the kernel

It also includes the advantages of using MPTCP.

30.1. MPTCP BENEFITS

The Multipath TCP (MPTCP) design improves connection stability. Note, that in MPTCP terminology, links are considered as paths.

The following are the advantages of MPTCP:

- It allows a connection to simultaneously use multiple network interfaces.
- In case a connection is bound to a link speed, the usage of multiple links can increase the connection throughput. Note, that in case of the connection is bound to a CPU, the usage of multiple links causes the connection slowdown.
- It increases the resilience to link failures.

30.2. PREPARING RHEL TO ENABLE MPTCP SUPPORT

By default the MPTCP support is disabled in RHEL. Enable MPTCP so that applications that support this feature can use it. Additionally, you have to configure user space applications to force use MPTCP sockets if those applications have TCP sockets by default.

Prerequisites

The following packages are installed:

- iperf3
- mptcpd

Procedure

1. Enable MPTCP sockets in the kernel:

   ```bash
   # echo "net.mptcp.enabled=1" > /etc/sysctl.d/90-enable-MPTCP.conf
   # sysctl -p /etc/sysctl.d/90-enable-MPTCP.conf
   ```

2. Start the `iperf3` server, and force it to create MPTCP sockets instead of TCP sockets:
3. Connect the client to the server, and force it to create MPTCP sockets instead of TCP sockets:

```bash
# mptcpize iperf3 -c 127.0.0.1 -t 3
```

4. After the connection is established, verify the `ss` output to see the subflow-specific status:

```bash
# ss -nti '( dport :5201 )'
```

5. Verify MPTCP counters by using `nstat MPTcp*` command:

```bash
# nstat MPTcp*
```

```
#kernel
MPTcpExtMPCapableSYNRX 2 0.0
MPTcpExtMPCapableSYNTX 2 0.0
MPTcpExtMPCapableSYNACKRX 2 0.0
MPTcpExtMPCapableACKRX 2 0.0
```

Additional resources

- `tcp(7)` man page
- `mptcpize(8)` man page

### 30.3. USING IPROUTE2 TO CONFIGURE AND ENABLE MULTIPLE PATHS FOR MPTCP APPLICATIONS

Each MPTCP connection uses a single subflow similar to plain TCP. To leverage the MPTCP benefits specify a higher limit for maximum number of subflows for each MPTCP connection and configure additional endpoints to create those subflows.

Note that MPTCP does not yet support mixed IPv6 and IPv4 endpoints for the same socket. Use endpoints belonging to the same address family.

Prerequisites

- The `mptcpd` package is installed
- The `iperf3` package is installed
Server network interface settings:
- enp4s0: 192.0.2.1/24
- enp1s0: 198.51.100.1/24

Client network interface settings:
- enp4s0f0: 192.0.2.2/24
- enp4s0f1: 198.51.100.2/24

Procedure

1. Set the per connection additional subflow limits to 1 on the server:
   
   ```
   # ip mptcp limits set subflow 1
   ```

   Note, that sets a maximum number of additional subflows which each connection can have, excluding the initial one.

2. Set the per connection and additional subflow limits to 1 on the client:
   
   ```
   # ip mptcp limits set subflow 1 add_addr_accepted 1
   ```

3. Add IP address 198.51.100.1 as a new MPTCP endpoint on the server:
   
   ```
   # ip mptcp endpoint add 198.51.100.1 dev enp1s0 signal
   ```

   **IMPORTANT**

   You can set the following values for flags to subflow, backup, signal. Setting the flag to;
   
   - signal, sends an ADD_ADDR packet after the three-way-handshake is completed
   - subflow, sends an MP_JOIN SYN by the client
   - backup, sets the endpoint as a backup address

4. Start the iperf3 server, and force it to create MPTCP sockets instead of TCP sockets:
   
   ```
   # mptcpize run iperf3 -s
   ```

   Server listening on 5201

5. Connect the client to the server, and force it to create MPTCP sockets instead of TCP sockets:
   
   ```
   # mptcpize iperf3 -c 192.0.2.1 -t 3
   ```

Verification steps

1. Verify the connection is established:
# ss -nti '( sport :5201 )'

2. Verify the connection and IP address limit:

   # ip mptcp limit show

3. Verify the newly added endpoint:

   # ip mptcp endpoint show

4. Verify MPTCP counters by using the nstat MPTcp* command on a server:

   # nstat MPTcp*

   #kernel
   MPTcpExtMPCapableSYNRX        2                  0.0
   MPTcpExtMPCapableACKRX        2                  0.0
   MPTcpExtMPJoinSynRx           2                  0.0
   MPTcpExtMPJoinAckRx           2                  0.0
   MPTcpExtEchoAdd               2                  0.0

Additional resources

- ip-mptcp(8) man page
- mptcpize(8) man page

30.4. MONITORING MPTCP SUB-FLOWS

The life cycle of a multipath TCP (MPTCP) socket can be complex: The main MPTCP socket is created, the MPTCP path is validated, one or more sub-flows are created and eventually removed. Finally, the MPTCP socket is terminated.

The MPTCP protocol allows monitoring MPTCP-specific events related to socket and sub-flow creation and deletion, using the ip utility provided by the iproute package. This utility uses the netlink interface to monitor MPTCP events.

This procedure demonstrates how to monitor MPTCP events. For that, it simulates a MPTCP server application, and a client connects to this service. The involved clients in this example use the following interfaces and IP addresses:

- Server: 192.0.2.1
- Client (Ethernet connection): 192.0.2.2
- Client (WiFi connection): 192.0.2.3

To simplify this example, all interfaces are within the same subnet. This is not a requirement. However, it is important that routing has been configured correctly, and the client can reach the server via both interfaces.

Prerequisites

- A RHEL client with two network interfaces, such as a laptop with Ethernet and WiFi
The client can connect to the server via both interfaces

A RHEL server

Both the client and the server run RHEL 9.0 or later

You installed the `mptcpd` package on both the client and the server

Procedure

1. Set the per connection additional subflow limits to 1 on both client and server:

   ```
   # ip mptcp limits set add_addr_accepted 0 subflows 1
   ```

2. On the server, to simulate a MPTCP server application, start `netcat (nc)` in listen mode with enforced MPTCP sockets instead of TCP sockets:

   ```
   # mptcpize run nc -l -k -p 12345
   ```

   The `-k` option causes that `nc` does not close the listener after the first accepted connection. This is required to demonstrate the monitoring of sub-flows.

3. On the client:
   a. Identify the interface with the lowest metric:

      ```
      # ip -4 route
      192.0.2.0/24 dev enp1s0 proto kernel scope link src 192.0.2.2 metric 100
      192.0.2.0/24 dev wlp2s0 proto kernel scope link src 192.0.2.3 metric 600
      ```

      The `enp1s0` interface has a lower metric than `wlp2s0`. Therefore, RHEL uses `enp1s0` by default.

   b. On the first terminal, start the monitoring:

      ```
      # ip mptcp monitor
      ```

   c. On the second terminal, start a MPTCP connection to the server:

      ```
      # mptcpize run nc 192.0.2.1 12345
      ```

      RHEL uses the `enp1s0` interface and its associated IP address as a source for this connection.

      On the monitoring terminal, the `ip mptcp monitor` command now logs:

      ```
      [       CREATED] token=63c070d2 remid=0 locid=0 saddr4=192.0.2.2 daddr4=192.0.2.1
      sport=36444 dport=12345
      ```

      The token identifies the MPTCP socket as an unique ID, and later it enables you to correlate MPTCP events on the same socket.
d. On the terminal with the running `nc` connection to the server, press `Enter`. This first data packet fully establishes the connection. Note that, as long as no data has been sent, the connection is not established.

On the monitoring terminal, `ip mptcp monitor` now logs:

```
[ ESTABLISHED] token=63c070d2 remid=0 locid=0 saddr4=192.0.2.2
daddr4=192.0.2.1 sport=36444 dport=12345
```

e. Optional: Display the connections to port 12345 on the server:

```
# ss -taunp | grep "::12345"
tcp ESTAB 0 0 192.0.2.2:36444 192.0.2.1:12345
```

At this point, only one connection to the server has been established.

f. On a third terminal, create another endpoint:

```
# ip mptcp endpoint add dev wlp2s0 192.0.2.3 subflow
```

This command sets the name and IP address of the WiFi interface of the client in this command.

On the monitoring terminal, `ip mptcp monitor` now logs:

```
[SF_ESTABLISHED] token=63c070d2 remid=0 locid=2 saddr4=192.0.2.3
daddr4=192.0.2.1 sport=53345 dport=12345 backup=0 ifindex=3
```

The `locid` field displays the local address ID of the new sub-flow and identifies this sub-flow even if the connection uses network address translation (NAT). The `saddr4` field matches the endpoint’s IP address from the `ip mptcp endpoint add` command.

g. Optional: Display the connections to port 12345 on the server:

```
# ss -taunp | grep "::12345"
tcp ESTAB 0 0 192.0.2.2:36444 192.0.2.1:12345
tcp ESTAB 0 0 192.0.2.3%wlp2s0:53345 192.0.2.1:12345
```

The command now displays two connections:

- The connection with source address 192.0.2.2 corresponds to the first MPTCP sub-flow that you established previously.
- The connection from the sub-flow over the `wlp2s0` interface with source address 192.0.2.3.

h. On the third terminal, delete the endpoint:

```
# ip mptcp endpoint delete id 2
```

Use the ID from the `locid` field from the `ip mptcp monitor` output, or retrieve the endpoint ID using the `ip mptcp endpoint show` command.

On the monitoring terminal, `ip mptcp monitor` now logs:
On the first terminal with the `nc` client, press `Ctrl+C` to terminate the session. On the monitoring terminal, `ip mptcp monitor` now logs:

```
[ CLOSED] token=63c070d2
```

Additional resources

- `ip-mptcp(1)` man page
- How NetworkManager manages multiple default gateways

### 30.5. DISABLING MULTIPATH TCP IN THE KERNEL

This procedure describes how to disable the MPTCP option in the kernel.

**Procedure**

- Disable the `mptcp.enabled` option.

  ```
  # echo "net.mptcp.enabled=0" > /etc/sysctl.d/90-enable-MPTCP.conf
  # sysctl -p /etc/sysctl.d/90-enable-MPTCP.conf
  ```

**Verification steps**

- Verify whether the `mptcp.enabled` is disabled in the kernel.

  ```
  # sysctl -a | grep mptcp.enabled
  net.mptcp.enabled = 0
  ```
CHAPTER 31. MANAGING THE MPTCPD SERVICE

This section describes the basic management of the mptcpd service. The mptcpd package provides the mptcpize tool, which switches on the mptcp protocol in the TCP environment.

31.1. CONFIGURING MPTCPD

The mptcpd service is a component of the mptcp protocol which provides an instrument to configure mptcp endpoints. The mptcpd service creates a subflow endpoint for each address by default. The endpoint list is updated dynamically according to IP addresses modification on the running host. The mptcpd service creates the list of endpoints automatically. It enables multiple paths as an alternative to using the ip utility.

Prerequisites

- The mptcpd package installed

Procedure

1. Enable mptcp.enabled option in the kernel with the following command:

```bash
# echo "net.mptcp.enabled=1" > /etc/sysctl.d/90-enable-MPTCP.conf
# sysctl -p /etc/sysctl.d/90-enable-MPTCP.conf
```

2. Start the mptcpd service:

```bash
# systemctl start mptcp.service
```

3. Verify endpoint creation:

```bash
# ip mptcp endpoint
```

4. To stop the mptcpd service, use the following command:

```bash
# systemctl stop mptcp.service
```

5. To configure mptcpd service manually, modify the /etc/mptcpd/mptcpd.conf configuration file.

Note, that the endpoint, which mptcpd service creates, lasts till the host shutdown.

Additional resources

- mptcpd(8) man page.

31.2. MANAGING APPLICATIONS WITH MPTCPIZE TOOL

Using the mptcpize tool manage applications and services.

The instruction below shows how to use the mptcpize tool to manage applications in the TCP environment.

Assuming, you need to run the iperf3 utility with the enabled MPTCP socket. You can achieve this goal by following the procedure below.

Prerequisites

- The mptcpd package is installed
• The **iperf3** package is installed

**Procedure**

• Start **iperf3** utility with **MPTCP** sockets enabled:
  
  ```
  # mptcpize run iperf3 -s &
  ```

### 31.3. ENABLING MPTCP SOCKETS FOR A SERVICES USING THE MPTCPIZE UTILITY

The following set of commands instruct you how to manage services using the **mptcpize** tool. You can enable or disable the **mptcp** socket for a service.

Assuming, you need to manage **mptcp** socket for the **nginx** service. You can achieve this goal by following the procedure below.

**Prerequisites**

• The **mptcpd** package is installed

• The **nginx** package is installed

**Procedure**

1. Enable **MPTCP** sockets for a service:

   ```
   # mptcpize enable nginx
   ```

2. Disable the **MPTCP** sockets for a service:

   ```
   # mptcpize disable nginx
   ```

3. Restart the service to make the changes to take effect:

   ```
   # systemctl restart nginx
   ```
CHAPTER 32. CONFIGURING THE ORDER OF DNS SERVERS

Most applications use the `getaddrinfo()` function of the `glibc` library to resolve DNS requests. By default, `glibc` sends all DNS requests to the first DNS server specified in the `etc/resolv.conf` file. If this server does not reply, Red Hat Enterprise Linux uses the next server in this file.

This section describes how to customize the order of DNS servers.

32.1. HOW NETWORKMANAGER ORDERS DNS SERVERS IN /ETC/RESOLV.CONF

NetworkManager orders DNS servers in the `/etc/resolv.conf` file based on the following rules:

- If only one connection profile exists, NetworkManager uses the order of IPv4 and IPv6 DNS server specified in that connection.

- If multiple connection profiles are activated, NetworkManager orders DNS servers based on a DNS priority value. If you set DNS priorities, the behavior of NetworkManager depends on the value set in the `dns` parameter. You can set this parameter in the `[main]` section in the `/etc/NetworkManager/NetworkManager.conf` file:

  - `dns=default` or if the `dns` parameter is not set:
    NetworkManager orders the DNS servers from different connections based on the `ipv4.dns-priority` and `ipv6.dns-priority` parameter in each connection.

    If you set no value or you set `ipv4.dns-priority` and `ipv6.dns-priority` to 0, NetworkManager uses the global default value. See Default values of DNS priority parameters.

  - `dns=dnsmasq` or `dns=systemd-resolved`:
    When you use one of these settings, NetworkManager sets either 127.0.0.1 for `dnsmasq` or 127.0.0.53 as `nameserver` entry in the `/etc/resolv.conf` file.

    Both the `dnsmasq` and `systemd-resolved` services forward queries for the search domain set in a NetworkManager connection to the DNS server specified in that connection, and forwades queries to other domains to the connection with the default route. When multiple connections have the same search domain set, `dnsmasq` and `systemd-resolved` forward queries for this domain to the DNS server set in the connection with the lowest priority value.

Default values of DNS priority parameters

NetworkManager uses the following default values for connections:

- 50 for VPN connections

- 100 for other connections

Valid DNS priority values:

You can set both the global default and connection-specific `ipv4.dns-priority` and `ipv6.dns-priority` parameters to a value between -2147483647 and 2147483647.

- A lower value has a higher priority.

- Negative values have the special effect of excluding other configurations with a greater value. For example, if at least one connection with a negative priority value exists, NetworkManager uses only the DNS servers specified in the connection profile with the lowest priority.
If multiple connections have the same DNS priority, NetworkManager prioritizes the DNS in the following order:

a. VPN connections

b. Connection with an active default route. The active default route is the default route with the lowest metric.

Additional resources

- The `dns-priority` parameter description in the `ipv4` and `ipv6` sections in the `nm-settings(5)` man page
- Using different DNS servers for different domains

### 32.2. Setting a NetworkManager-wide Default DNS Server Priority Value

NetworkManager uses the following DNS priority default values for connections:

- **50** for VPN connections
- **100** for other connections

This section describes how to override these system-wide defaults with a custom default value for IPv4 and IPv6 connections.

**Procedure**

1. Edit the `/etc/NetworkManager/NetworkManager.conf` file:
   
   a. Add the `[connection]` section, if it does not exist:

   ```
   [connection]
   ```

   b. Add the custom default values to the `[connection]` section. For example, to set the new default for both IPv4 and IPv6 to **200**, add:

   ```
   ipv4.dns-priority=200  
   ipv6.dns-priority=200  
   ```

   You can set the parameters to a value between **-2147483647** and **2147483647**. Note that setting the parameters to **0** enables the built-in defaults (**50** for VPN connections and **100** for other connections).

2. Reload the `NetworkManager` service:

   ```
   # systemctl reload NetworkManager
   ```

**Additional resources**

- Connection Section in the `NetworkManager.conf(5)` man page
32.3. SETTING THE DNS PRIORITY OF A NETWORKMANAGER CONNECTION

This section describes how to define the order of DNS servers when NetworkManager creates or updates the /etc/resolv.conf file.

Note that setting DNS priorities makes only sense if you have multiple connections with different DNS servers configured. If you have only one connection with multiple DNS servers configured, manually set the DNS servers in the preferred order in the connection profile.

Prerequisites

- The system has multiple NetworkManager connections configured.

- The system either has no dns parameter set in the /etc/NetworkManager/NetworkManager.conf file or the parameter is set to default.

Procedure

1. Optionally, display the available connections:

   ```
   # nmcli connection show
   NAME        UUID                                  TYPE      DEVICE
   Example_con_1 d17ee488-4665-4de2-b28a-48befab0cd43  ethernet  enp1s0
   Example_con_2 916e4f67-7145-3ffa-9f7b-e7cada8f6bf7  ethernet  enp7s0
   ...
   ```

2. Set the ipv4.dns-priority and ipv6.dns-priority parameters. For example, to set both parameters to 10 for the Example_con_1 connection:

   ```
   # nmcli connection modify Example_con_1 ipv4.dns-priority 10 ipv6.dns-priority 10
   ```

3. Optionally, repeat the previous step for other connections.

4. Re-activate the connection you updated:

   ```
   # nmcli connection up Example_con_1
   ```

Verification steps

- Display the contents of the /etc/resolv.conf file to verify that the DNS server order is correct:

  ```
  # cat /etc/resolv.conf
  ```
CHAPTER 33. USING NETWORKMANAGER TO DISABLE IPV6 FOR A SPECIFIC CONNECTION

This section describes how to disable the *IPv6* protocol on a system that uses NetworkManager to manage network interfaces. If you disable *IPv6*, NetworkManager automatically sets the corresponding *sysctl* values in the Kernel.

**NOTE**

If disabling IPv6 using kernel tunables or kernel boot parameters, additional consideration must be given to system configuration. For more information, see the *How do I disable or enable the IPv6 protocol in RHEL?* article.

Prerequisites

- The system uses NetworkManager to manage network interfaces, which is the default on Red Hat Enterprise Linux.

33.1. DISABLING IPV6 ON A CONNECTION USING NMCLI

This procedure describes how to disable the *IPv6* protocol using the *nmcli* utility.

**Procedure**

1. Optionally, display the list of network connections:

   ```
   # nmcli connection show
   NAME   UUID                                  TYPE      DEVICE
   Example 7a7e0151-9c18-4e6f-89ee-65bb2d64d365  ethernet  enp1s0
   ...
   ```

2. Set the *ipv6.method* parameter of the connection to *disabled*:

   ```
   # nmcli connection modify Example ipv6.method "disabled"
   ```

3. Restart the network connection:

   ```
   # nmcli connection up Example
   ```

**Verification steps**

1. Enter the *ip address show* command to display the IP settings of the device:

   ```
   # ip address show enp1s0
   2: enp1s0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP
      group default qlen 1000
      link/ether 52:54:00:6b:74:be brd ff:ff:ff:ff:ff
      inet 192.0.2.1/24 brd 192.10.2.255 scope global noprefixroute enp1s0
      valid_lft forever preferred_lft forever
   ```

   If no *inet6* entry is displayed, *IPv6* is disabled on the device.
2. Verify that the `/proc/sys/net/ipv6/conf/enp1s0/disable_ipv6` file now contains the value `1`:

```
# cat /proc/sys/net/ipv6/conf/enp1s0/disable_ipv6
1
```

The value `1` means that IPv6 is disabled for the device.
CHAPTER 34. MONITORING AND TUNING THE RX RING BUFFER

Receive (RX) ring buffers are shared buffers between the device driver and network interface card (NIC), and store incoming packets until the device driver can process them.

You can increase the size of the Ethernet device RX ring buffer if the packet drop rate causes applications to report:

- a loss of data,
- cluster fence,
- slow performance,
- timeouts, and
- failed backups.

This section describes how to identify the number of dropped packets and increase the RX ring buffer to reduce a high packet drop rate.

34.1. DISPLAYING THE NUMBER OF DROPPED PACKETS

The `ethtool` utility enables administrators to query, configure, or control network driver settings.

The exhaustion of the RX ring buffer causes an increment in the counters, such as "discard" or "drop" in the output of `ethtool -S interface_name`. The discarded packets indicate that the available buffer is filling up faster than the kernel can process the packets.

This procedure describes how to display drop counters using `ethtool`.

**Procedure**

1. To view drop counters for the `enp1s0` interface, enter:

   ```
   $ ethtool -S enp1s0
   ```

34.2. INCREASING THE RX RING BUFFER TO REDUCE A HIGH PACKET DROP RATE

The `ethtool` utility helps to increase the RX buffer to reduce a high packet drop rate.

**Procedure**

1. To view the maximum RX ring buffer size:

   ```
   # ethtool -g enp1s0
   Ring parameters for enp1s0:
   Pre-set maximums:
   RX: 4080
   RX Mini: 0
   RX Jumbo: 16320
   ```
2. If the values in the **Pre-set maximums** section are higher than in the **Current hardware settings** section, increase RX ring buffer:

- To temporary change the RX ring buffer of the `enp1s0` device to **4080**, enter:

  ```bash
  # ethtool -G enp1s0 rx 4080
  ```

- To permanently change the RX ring buffer create a NetworkManager dispatcher script. For details, see the **How to make NIC ethtool settings persistent (apply automatically at boot)** article and create a dispatcher script.

**IMPORTANT**

Depending on the driver your network interface card uses, changing in the ring buffer can shortly interrupt the network connection.

Additional resources

- `ifconfig` and `ip commands report packet drops in RHEL7`
- `Should I be concerned about a 0.05% packet drop rate?`
- `ethtool(8)` man page
CHAPTER 35. CONFIGURING 802.3 LINK SETTINGS

35.1. UNDERSTANDING AUTO-NEGOTIATION

Auto-negotiation is a feature of the IEEE 802.3u Fast Ethernet protocol. It targets the device ports to provide an optimal performance of speed, duplex mode, and flow control for information exchange over a link. Using the auto-negotiation protocol, you have optimal performance of data transfer over the Ethernet.

NOTE

To utilize maximum performance of auto-negotiation, use the same configuration on both sides of a link.

35.2. CONFIGURING 802.3 LINK SETTINGS USING THE NMCLI UTILITY

To configure the 802.3 link settings of an Ethernet connection, modify the following configuration parameters:

- 802-3-ethernet.auto-negotiate
- 802-3-ethernet.speed
- 802-3-ethernet.duplex

Procedure

1. Display the current settings of the connection:

```
# nmcli connection show Example-connection
...
802-3-ethernet.speed: 0
802-3-ethernet.duplex: --
802-3-ethernet.auto-negotiate: no
...
```

You can use these values if you need to reset the parameters in case of any problems.

2. Set the speed and duplex link settings:

```
# nmcli connection modify Example-connection 802-3-ethernet.auto-negotiate no 802-3-ethernet.speed 10000 802-3-ethernet.duplex full
```

This command disables auto-negotiation and sets the speed of the connection to 10000 Mbit full duplex.

3. Reactivate the connection:

```
# nmcli connection up Example-connection
```

Verification

- Use the `ethtool` utility to verify the values of Ethernet interface `enp1s0`: 

# ethtool enp1s0

Settings for enp1s0:

```
...  
Advertised auto-negotiation: No
...
Speed: 10000Mb/s
Duplex: Full
Auto-negotiation: off
...
Link detected: yes
```

Additional resources

- Network interface speed is 100Mbps and should be 1Gbps
- `nm-settings(5)` man page
CHAPTER 36. CONFIGURING ETHTOOL OFFLOAD FEATURES

Network interface cards can use the TCP offload engine (TOE) to offload processing certain operations to the network controller to improve the network throughput.

This section describes how to set offload features.

36.1. OFFLOAD FEATURES SUPPORTED BY NETWORKMANAGER

You can set the following `ethtool` offload features using NetworkManager:

- `ethtool.feature-esp-hw-offload`
- `ethtool.feature-esp-tx-csum-hw-offload`
- `ethtool.feature-fcoe-mtu`
- `ethtool.feature-gro`
- `ethtool.feature-gso`
- `ethtool.feature-highdma`
- `ethtool.feature-hw-tc-offload`
- `ethtool.feature-l2-fwd-offload`
- `ethtool.feature-loopback`
- `ethtool.feature-lro`
- `ethtool.feature-macsec-hw-offload`
- `ethtool.feature-ntuple`
- `ethtool.feature-rx`
- `ethtool.feature-rx-all`
- `ethtool.feature-rx-fcs`
- `ethtool.feature-rx-gro-hw`
- `ethtool.feature-rx-gro-list`
- `ethtool.feature-rx-udp_tunnel-port-offload`
- `ethtool.feature-rx-udp-gro-forwarding`
- `ethtool.feature-rx-vlan-filter`
- `ethtool.feature-rx-vlan-stag-filter`
- `ethtool.feature-rx-vlan-stag-hw-parse`
- `ethtool.feature-rxhash`
ethtool.feature-rxvlan
ethtool.feature-sg
ethtool.feature-tls-hw-record
ethtool.feature-tls-hw-rx-offload
ethtool.feature-tls-hw-tx-offload
ethtool.feature-tso
ethtool.feature-tx
ethtool.feature-tx-checksum-fcoe-crc
ethtool.feature-tx-checksum-ip-generic
ethtool.feature-tx-checksum-ipv4
ethtool.feature-tx-checksum-ipv6
ethtool.feature-tx-checksum-sctp
ethtool.feature-tx-esp-segmentation
ethtool.feature-tx-fcoe-segmentation
ethtool.feature-tx-gre-csum-segmentation
ethtool.feature-tx-gre-segmentation
ethtool.feature-tx-gso-list
ethtool.feature-tx-gso-partial
ethtool.feature-tx-gso-robust
ethtool.feature-tx-ipxip4-segmentation
ethtool.feature-tx-ipxip6-segmentation
ethtool.feature-tx-nocache-copy
ethtool.feature-tx-scatter-gather
ethtool.feature-tx-scatter-gather-fraglist
ethtool.feature-tx-sctp-segmentation
ethtool.feature-tx-tcp-ecn-segmentation
ethtool.feature-tx-tcp-mangleid-segmentation
ethtool.feature-tx-tcp-segmentation
ethtool.feature-tx-tcp6-segmentation
• ethtool.feature-tx-tunnel-remcsum-segmentation
• ethtool.feature-tx-udp-segmentation
• ethtool.feature-tx-udp_tnl-csum-segmentation
• ethtool.feature-tx-udp_tnl-segmentation
• ethtool.feature-tx-vlan-stag-hw-insert
• ethtool.feature-txvlan

For details about the individual offload features, see the documentation of the ethtool utility and the kernel documentation.

### 36.2. CONFIGURING AN ETHTOOL OFFLOAD FEATURE USING NETWORKMANAGER

This section describes how to enable and disable ethtool offload features using NetworkManager, as well as how to remove the setting for a feature from a NetworkManager connection profile.

**Procedure**

1. For example, to enable the RX offload feature and disable TX offload in the `enp1s0` connection profile, enter:
   ```bash
   # nmcli con modify enp1s0 ethtool.feature-rx on ethtool.feature-tx off
   ```
   This command explicitly enables RX offload and disables TX offload.

2. To remove the setting of an offload feature that you previously enabled or disabled, set the feature’s parameter to `ignore`. For example, to remove the configuration for TX offload, enter:
   ```bash
   # nmcli con modify enp1s0 ethtool.feature-tx ignore
   ```

3. Reactivate the network profile:
   ```bash
   # nmcli connection up enp1s0
   ```

**Verification steps**

- Use the `ethtool -k` command to display the current offload features of a network device:
  ```bash
  # ethtool -k network_device
  ```

**Additional resources**

- Offload features supported by NetworkManager

### 36.3. USING RHEL SYSTEM ROLES TO SET ETHTOOL FEATURES

You can use the Networking RHEL System Role to configure ethtool features of a NetworkManager connection.
IMPORTANT

When you run a play that uses the Networking RHEL System Role, the system role overrides an existing connection profile with the same name if the value of settings does not match the ones specified in the play. Therefore, always specify the whole configuration of the network connection profile in the play, even if, for example the IP configuration, already exists. Otherwise the role resets these values to their defaults.

Depending on whether it already exists, the procedure creates or updates the `enp1s0` connection profile with the following settings:

- A static IPv4 address - 198.51.100.20 with a /24 subnet mask
- A static IPv6 address - 2001:db8:1::1 with a /64 subnet mask
- An IPv4 default gateway - 198.51.100.254
- An IPv6 default gateway - 2001:db8:1::fffe
- An IPv4 DNS server - 198.51.100.200
- An IPv6 DNS server - 2001:db8:1::ffbb
- A DNS search domain - example.com
- `ethtool` features:
  - Generic receive offload (GRO): disabled
  - Generic segmentation offload (GSO): enabled
  - TX stream control transmission protocol (SCTP) segmentation: disabled

Prerequisites

- The `ansible-core` package and `rhel-system-roles` packages are installed on the control node.
- If you use a different remote user than root when you run the playbook, this user has appropriate `sudo` permissions on the managed node.

Procedure

1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the `/etc/ansible/hosts` Ansible inventory file:

   ```
   node.example.com
   ```

2. Create the `~/configure-ethernet-device-with-ethtool-features.yml` playbook with the following content:

   ```
   ---
   - name: Configure an Ethernet connection with ethtool features
     hosts: node.example.com
     become: true
     tasks:
     - include_role:
   ```
name: rhel-system-roles.network

vars:
  network_connections:
  - name: enp1s0
    type: ethernet
    autoconnect: yes
    ip:
      address:
      - 198.51.100.20/24
      - 2001:db8:1::1/64
    gateway4: 198.51.100.254
    gateway6: 2001:db8:1::fffe
    dns:
      - 198.51.100.200
      - 2001:db8:1::ffbb
      dns_search:
      - example.com
    ethtool:
      features:
      gro: "no"
      gso: "yes"
      tx_sctp_segmentation: "no"
    state: up

3. Run the playbook:

   - To connect as root user to the managed host, enter:

     # ansible-playbook -u root ~/configure-ethernet-device-with-ethtool-features.yml

   - To connect as a user to the managed host, enter:

     # ansible-playbook -u user_name --ask-become-pass ~/configure-ethernet-device-with-ethtool-features.yml

The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md file
- ansible-playbook(1) man page
CHAPTER 37. CONFIGURING ETHTOOL COALESCE SETTINGS

Using interrupt coalescing, the system collects network packets and generates a single interrupt for multiple packets. This increases the amount of data sent to the kernel with one hardware interrupt, which reduces the interrupt load, and maximizes the throughput.

This section provides different options to set the `ethtool` coalesce settings.

37.1. COALESCE SETTINGS SUPPORTED BY NETWORKMANAGER

You can set the following `ethtool` coalesce settings using NetworkManager:

- `coalesce-adaptive-rx`
- `coalesce-adaptive-tx`
- `coalesce-pkt-rate-high`
- `coalesce-pkt-rate-low`
- `coalesce-rx-frames`
- `coalesce-rx-frames-high`
- `coalesce-rx-frames-irq`
- `coalesce-rx-frames-low`
- `coalesce-rx-usecs`
- `coalesce-rx-usecs-high`
- `coalesce-rx-usecs-irq`
- `coalesce-rx-usecs-low`
- `coalesce-sample-interval`
- `coalesce-stats-block-usecs`
- `coalesce-tx-frames`
- `coalesce-tx-frames-high`
- `coalesce-tx-frames-irq`
- `coalesce-tx-frames-low`
- `coalesce-tx-usecs`
- `coalesce-tx-usecs-high`
- `coalesce-tx-usecs-irq`
- `coalesce-tx-usecs-low`
37.2. CONFIGURING ETHTOOL COALESCE SETTINGS USING NETWORKMANAGER

This section describes how to set `ethtool` coalesce settings using NetworkManager, as well as how you remove the setting from a NetworkManager connection profile.

Procedure

1. For example, to set the maximum number of received packets to delay to 128 in the `enp1s0` connection profile, enter:

   ```
   # nmcli connection modify enp1s0 ethtool.coalesce-rx-frames 128
   ```

2. To remove a coalesce setting, set the setting to `ignore`. For example, to remove the `ethtool.coalesce-rx-frames` setting, enter:

   ```
   # nmcli connection modify enp1s0 ethtool.coalesce-rx-frames ignore
   ```

3. To reactivate the network profile:

   ```
   # nmcli connection up enp1s0
   ```

Verification steps

1. Use the `ethtool -c` command to display the current offload features of a network device:

   ```
   # ethtool -c network_device
   ```

Additional resources

- Coalesce settings supported by NetworkManager

37.3. USING RHEL SYSTEM ROLES TO CONFIGURE ETHTOOL COALESCE SETTINGS

You can use the Networking RHEL System Role to configure `ethtool` coalesce settings of a NetworkManager connection.

**IMPORTANT**

When you run a play that uses the Networking RHEL System Role, the system role overrides an existing connection profile with the same name if the value of settings does not match the ones specified in the play. Therefore, always specify the whole configuration of the network connection profile in the play, even if, for example the IP configuration, already exists. Otherwise the role resets these values to their defaults.

Depending on whether it already exists, the procedure creates or updates the `enp1s0` connection profile with the following settings:

- A static IPv4 address - `198.51.100.20` with a `/24` subnet mask
- A static IPv6 address - `2001:db8:1::1` with a `/64` subnet mask
- An IPv4 default gateway - 198.51.100.254
- An IPv6 default gateway - 2001:db8:1::fffe
- An IPv4 DNS server - 198.51.100.200
- An IPv6 DNS server - 2001:db8:1::ffbb
- A DNS search domain - example.com
- ethtool coalesce settings:
  - RX frames: 128
  - TX frames: 128

Prerequisites
- The ansible-core and rhel-system-roles packages are installed on the control node.
- If you use a different remote user than root when you run the playbook, this user has appropriate sudo permissions on the managed node.

Procedure
1. If the host on which you want to execute the instructions in the playbook is not yet inventoried, add the IP or name of this host to the /etc/ansible/hosts Ansible inventory file:

   node.example.com

2. Create the ~/configure-ethernet-device-with-ethtool-coalesce-settings.yml playbook with the following content:

```yaml
---
- name: Configure an Ethernet connection with ethtool coalesce settings
  hosts: node.example.com
  become: true
  tasks:
  - include_role:
      name: rhel-system-roles.network

  vars:
    network_connections:
      - name: enp1s0
        type: ethernet
        autoconnect: yes
        ip:
          address:
            - 198.51.100.20/24
            - 2001:db8:1::1/64
        gateway4: 198.51.100.254
        gateway6: 2001:db8:1::fffe
        dns:
          - 198.51.100.200
          - 2001:db8:1::ffbb
        dns_search:
```

CHAPTER 37. CONFIGURING ETHTOOL COALESCE SETTINGS
3. Run the playbook:

- To connect as root user to the managed host, enter:

  ```bash
  # ansible-playbook -u root ~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml
  ```

- To connect as a user to the managed host, enter:

  ```bash
  # ansible-playbook -u user_name --ask-become-pass ~/configure-ethernet-device-with-ethtoolcoalesce-settings.yml
  ```

  The --ask-become-pass option makes sure that the ansible-playbook command prompts for the sudo password of the user defined in the -u user_name option.

  If you do not specify the -u user_name option, ansible-playbook connects to the managed host as the user that is currently logged in to the control node.

Additional resources

- /usr/share/ansible/roles/rhel-system-roles.network/README.md

- ansible-playbook(1) man page
CHAPTER 38. USING MACSEC TO ENCRYPT LAYER-2 TRAFFIC IN THE SAME PHYSICAL NETWORK

You can use MACsec to secure the communication between two devices (point-to-point). For example, your branch office is connected over a Metro-Ethernet connection with the central office, you can configure MACsec on the two hosts that connect the offices to increase the security.

Media Access Control security (MACsec) is a layer 2 protocol that secures different traffic types over the Ethernet links including:

- dynamic host configuration protocol (DHCP)
- address resolution protocol (ARP)
- Internet Protocol version 4 / 6 (IPv4 / IPv6) and
- any traffic over IP such as TCP or UDP

MACsec encrypts and authenticates all traffic in LANs, by default with the GCM-AES-128 algorithm, and uses a pre-shared key to establish the connection between the participant hosts. If you want to change the pre-shared key, you need to update the NM configuration on all hosts in the network that uses MACsec.

A MACsec connection uses an Ethernet device, such as an Ethernet network card, VLAN, or tunnel device, as parent. You can either set an IP configuration only on the MACsec device to communicate with other hosts only using the encrypted connection, or you can also set an IP configuration on the parent device. In the latter case, you can use the parent device to communicate with other hosts using an unencrypted connection and the MACsec device for encrypted connections.

MACsec does not require any special hardware. For example, you can use any switch, except if you want to encrypt traffic only between a host and a switch. In this scenario, the switch must also support MACsec.

In other words, there are 2 common methods to configure MACsec;

- host to host and
- host to switch then switch to other host(s)

IMPORTANT
You can use MACsec only between hosts that are in the same (physical or virtual) LAN.

38.1. CONFIGURING A MACSEC CONNECTION USING NMCLI

You can configure Ethernet interfaces to use MACsec using the nmcli utility. This procedure describes how to create a MACsec connection between two hosts that are connected over Ethernet.

Procedure

1. On the first host on which you configure MACsec:
   - Create the connectivity association key (CAK) and connectivity-association key name (CKN) for the pre-shared key:
a. Create a 16-byte hexadecimal CAK:

```bash
# dd if=/dev/urandom count=16 bs=1 2> /dev/null | hexdump -e '1/2 "%04x"'
50b71a8ef0bd5751ea76de6d6c98c03a
```

b. Create a 32-byte hexadecimal CKN:

```bash
# dd if=/dev/urandom count=32 bs=1 2> /dev/null | hexdump -e '1/2 "%04x"'
f2b4297d39da7330910a74abc0449feb45b5c0b9fc23df1430e1898fcf1c4550
```

2. On both hosts you want to connect over a MACsec connection:

3. Create the MACsec connection:

```bash
# nmcli connection add type macsec con-name macsec0 ifname macsec0
collection.autoconnect yes macsec.parent enp1s0 macsec.mode psk macsec.mka-cak 50b71a8ef0bd5751ea76de6d6c98c03a macsec.mka-ckn f2b4297d39da7330910a74abc0449feb45b5c0b9fc23df1430e1898fcf1c4550
```

Use the CAK and CKN generated in the previous step in the `macsec.mka-cak` and `macsec.mka-ckn` parameters. The values must be the same on every host in the MACsec-protected network.

4. Configure the IP settings on the MACsec connection.

   a. Configure the IPv4 settings. For example, to set a static IPv4 address, network mask, default gateway, and DNS server to the `macsec0` connection, enter:

   ```bash
   # nmcli connection modify macsec0 ipv4.method manual ipv4.addresses '192.0.2.1/24' ipv4.gateway '192.0.2.254' ipv4.dns '192.0.2.253'
   ```

   b. Configure the IPv6 settings. For example, to set a static IPv6 address, network mask, default gateway, and DNS server to the `macsec0` connection, enter:

   ```bash
   ```

5. Activate the connection:

   ```bash
   # nmcli connection up macsec0
   ```

Verification steps

1. Verify that the traffic is encrypted:

   ```bash
   # tcpdump -nn -i enp1s0
   ```

2. Optional: Display the unencrypted traffic:

   ```bash
   # tcpdump -nn -i macsec0
   ```

3. Display MACsec statistics:
# ip macsec show

4. Display individual counters for each type of protection: integrity-only (encrypt off) and encryption (encrypt on)

# ip -s macsec show

38.2. ADDITIONAL RESOURCES

- MACsec: a different solution to encrypt network traffic blog.
CHAPTER 39. USING DIFFERENT DNS SERVERS FOR DIFFERENT DOMAINS

By default, Red Hat Enterprise Linux (RHEL) sends all DNS requests to the first DNS server specified in the `/etc/resolv.conf` file. If this server does not reply, RHEL uses the next server in this file.

In environments where one DNS server cannot resolve all domains, administrators can configure RHEL to send DNS requests for a specific domain to a selected DNS server. For example, you can configure one DNS server to resolve queries for `example.com` and another DNS server to resolve queries for `example.net`. For all other DNS requests, RHEL uses the DNS server configured in the connection with the default gateway.

**IMPORTANT**

The `systemd-resolved` service is provided as a Technology Preview only. Technology Preview features are not supported with Red Hat production Service Level Agreements (SLAs), might not be functionally complete, and Red Hat does not recommend using them for production. These previews provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

See Technology Preview Features Support Scope on the Red Hat Customer Portal for information about the support scope for Technology Preview features.

39.1. SENDING DNS REQUESTS FOR A SPECIFIC DOMAIN TO A SELECTED DNS SERVER

This section configures `systemd-resolved` service and NetworkManager to send DNS queries for a specific domain to a selected DNS server.

If you complete the procedure in this section, RHEL uses the DNS service provided by `systemd-resolved` in the `/etc/resolv.conf` file. The `systemd-resolved` service starts a DNS service that listens on port 53 IP address `127.0.0.53`. The service dynamically routes DNS requests to the corresponding DNS servers specified in NetworkManager.

**NOTE**

The `127.0.0.53` address is only reachable from the local system and not from the network.

Prerequisites

- The system has multiple NetworkManager connections configured.
- A DNS server and search domain are configured in the NetworkManager connections that are responsible for resolving a specific domain

For example, if the DNS server specified in a VPN connection should resolve queries for the `example.com` domain, the VPN connection profile must have:

- Configured a DNS server that can resolve `example.com`
- Configured the search domain to `example.com` in the `ipv4.dns-search` and `ipv6.dns-search` parameters

Procedure
1. Start and enable the `systemd-resolved` service:

   ```
   # systemctl --now enable systemd-resolved
   ```

2. Edit the `/etc/NetworkManager/NetworkManager.conf` file, and set the following entry in the `[main]` section:

   ```
   dns=systemd-resolved
   ```

3. Reload the `NetworkManager` service:

   ```
   # systemctl reload NetworkManager
   ```

Verification steps

1. Verify that the `nameserver` entry in the `/etc/resolv.conf` file refers to `127.0.0.53`:

   ```
   # cat /etc/resolv.conf
   nameserver 127.0.0.53
   ```

2. Verify that the `systemd-resolved` service listens on port `53` on the local IP address `127.0.0.53`:

   ```
   # ss -tulpn | grep "127.0.0.53"
   udp  UNCONN 0  0      127.0.0.53%lo:53   0.0.0.0:*    users:(("systemd-
   resolve",pid=1050,fd=12))
   tcp  LISTEN 0  4096   127.0.0.53%lo:53   0.0.0.0:*    users:(("systemd-
   resolve",pid=1050,fd=13))
   ```

Additional resources

- The `dns` parameter description in the `NetworkManager.conf(5)` man page
CHAPTER 40. GETTING STARTED WITH IPVLAN

This document describes the IPVLAN driver.

40.1. IPVLAN OVERVIEW

IPVLAN is a driver for a virtual network device that can be used in container environment to access the host network. IPVLAN exposes a single MAC address to the external network regardless the number of IPVLAN device created inside the host network. This means that a user can have multiple IPVLAN devices in multiple containers and the corresponding switch reads a single MAC address. IPVLAN driver is useful when the local switch imposes constraints on the total number of MAC addresses that it can manage.

40.2. IPVLAN MODES

The following modes are available for IPVLAN:

- **L2 mode**
  In IPVLAN L2 mode, virtual devices receive and respond to address resolution protocol (ARP) requests. The netfilter framework runs only inside the container that owns the virtual device. No netfilter chains are executed in the default namespace on the containerized traffic. Using L2 mode provides good performance, but less control on the network traffic.

- **L3 mode**
  In L3 mode, virtual devices process only L3 traffic and above. Virtual devices do not respond to ARP request and users must configure the neighbour entries for the IPVLAN IP addresses on the relevant peers manually. The egress traffic of a relevant container is landed on the netfilter POSTROUTING and OUTPUT chains in the default namespace while the ingress traffic is threaded in the same way as L2 mode. Using L3 mode provides good control but decreases the network traffic performance.

- **L3S mode**
  In L3S mode, virtual devices process the same way as in L3 mode, except that both egress and ingress traffics of a relevant container are landed on netfilter chain in the default namespace. L3S mode behaves in a similar way to L3 mode but provides greater control of the network.

**NOTE**

The IPVLAN virtual device does not receive broadcast and multicast traffic in case of L3 and L3S modes.

40.3. OVERVIEW OF MACVLAN

The MACVLAN driver allows to create multiple virtual network devices on top of a single NIC, each of them identified by its own unique MAC address. Packets which land on the physical NIC are demultiplexed towards the relevant MACVLAN device via MAC address of the destination. MACVLAN devices do not add any level of encapsulation.

40.4. COMPARISON OF IPVLAN AND MACVLAN

The following table shows the major differences between MACVLAN and IPVLAN.
MACVLAN | IPVLAN
---|---
Uses MAC address for each MACVLAN device. The overlimit of MAC addresses of MAC table in switch might cause loosing the connectivity. | Uses single MAC address which does not limit the number of IPVLAN devices.

Netfilter rules for global namespace cannot affect traffic to or from MACVLAN device in a child namespace. | It is possible to control traffic to or from IPVLAN device in **L3 mode** and **L3S mode**.

Note that both IPVLAN and MACVLAN do not require any level of encapsulation.

### 40.5. CREATING AND CONFIGURING THE IPVLAN DEVICE USING **iproute2**

This procedure shows how to set up the IPVLAN device using **iproute2**.

**Procedure**

1. To create an IPVLAN device, enter the following command:

   ```
   # ip link add link real_NIC_device name IPVLAN_device type ipvlan mode l2
   ```

   Note that network interface controller (NIC) is a hardware component which connects a computer to a network.

   **Example 40.1. Creating an IPVLAN device**

   ```
   # ip link add link enp0s31f6 name my_ipvlan type ipvlan mode l2
   # ip link
   47: my_ipvlan@enp0s31f6: <BROADCAST,MULTICAST> mtu 1500 qdisc noop state DOWN mode DEFAULT group default qlen 1000 link/ether e8:6a:6e:8a:a2:44 brd ff:ff:ff:ff:ff:ff
   ```

2. To assign an **IPv4** or **IPv6** address to the interface, enter the following command:

   ```
   # ip addr add dev IPVLAN_device IP_address/subnet_mask_prefix
   ```

3. In case of configuring an IPVLAN device in **L3 mode** or **L3S mode**, make the following setups:

   a. Configure the neighbor setup for the remote peer on the remote host:

      ```
      # ip neigh add dev peer_device IPVLAN_device_IP_address lladdr MAC_address
      ```

      where **MAC_address** is the MAC address of the real NIC on which an IPVLAN device is based on.

   b. Configure an IPVLAN device for **L3 mode** with the following command:

      ```
      # ip route add dev <real_NIC_device> <peer_IP_address/32>
      ```
For **L3S** mode:

```bash
# ip route add dev real_NIC_device peer_IP_address/32
```

where IP-address represents the address of the remote peer.

4. To set an IPVLAN device active, enter the following command:

```bash
# ip link set dev IPVLAN_device up
```

5. To check if the IPVLAN device is active, execute the following command on the remote host:

```bash
# ping IP_address
```

where the **IP_address** uses the IP address of the IPVLAN device.
CHAPTER 41. REUSING THE SAME IP ADDRESS ON DIFFERENT INTERFACES

With Virtual routing and forwarding (VRF), administrators can use multiple routing tables simultaneously on the same host. For that, VRF partitions a network at layer 3. This enables the administrator to isolate traffic using separate and independent route tables per VRF domain. This technique is similar to virtual LANs (VLAN), which partitions a network at layer 2, where the operating system uses different VLAN tags to isolate traffic sharing the same physical medium.

One benefit of VRF over partitioning on layer 2 is that routing scales better considering the number of peers involved.

Red Hat Enterprise Linux uses a virtual vrt device for each VRF domain and adds routes to a VRF domain by adding existing network devices to a VRF device. Addresses and routes previously attached to the original device will be moved inside the VRF domain.

Note that each VRF domain is isolated from each other.

41.1. PERMANENTLY REUSING THE SAME IP ADDRESS ON DIFFERENT INTERFACES

This procedure describes how to permanently use the same IP address on different interfaces in one server by using the VRF feature.

IMPORTANT

To enable remote peers to contact both VRF interfaces while reusing the same IP address, the network interfaces must belong to different broadcasting domains. A broadcast domain in a network is a set of nodes, which receive broadcast traffic sent by any of them. In most configurations, all nodes connected to the same switch belong to the same broadcasting domain.

Prerequisites

- You are logged in as the root user.
- The network interfaces are not configured.

Procedure

1. Create and configure the first VRF device:
   a. Create a connection for the VRF device and assign it to a routing table. For example, to create a VRF device named vrf0 that is assigned to the 1001 routing table:

   ```
   # nmcli connection add type vrf ifname vrf0 con-name vrf0 table 1001 ipv4.method disabled ipv6.method disabled
   ```

   b. Enable the vrf0 device:

   ```
   # nmcli connection up vrf0
   ```
c. Assign a network device to the VRF just created. For example, to add the `enp1s0` Ethernet device to the `vrf0` VRF device and assign an IP address and the subnet mask to `enp1s0`, enter:

```
# nmcli connection add type ethernet con-name vrf.enp1s0 ifname enp1s0 master vrf0 ipv4.method manual ipv4.address 192.0.2.1/24
```

d. Activate the `vrf.enp1s0` connection:

```
# nmcli connection up vrf.enp1s0
```

2. Create and configure the next VRF device:

a. Create the VRF device and assign it to a routing table. For example, to create a VRF device named `vrf1` that is assigned to the `1002` routing table, enter:

```
# nmcli connection add type vrf ifname vrf1 con-name vrf1 table 1002 ipv4.method disabled ipv6.method disabled
```

b. Activate the `vrf1` device:

```
# nmcli connection up vrf1
```

c. Assign a network device to the VRF just created. For example, to add the `enp7s0` Ethernet device to the `vrf1` VRF device and assign an IP address and the subnet mask to `enp7s0`, enter:

```
# nmcli connection add type ethernet con-name vrf.enp7s0 ifname enp7s0 master vrf1 ipv4.method manual ipv4.address 192.0.2.1/24
```

d. Activate the `vrf.enp7s0` device:

```
# nmcli connection up vrf.enp7s0
```

### 41.2. TEMPORARILY REUSING THE SAME IP ADDRESS ON DIFFERENT INTERFACES

The procedure in this section describes how to temporarily use the same IP address on different interfaces in one server by using the virtual routing and forwarding (VRF) feature. Use this procedure only for testing purposes, because the configuration is temporary and lost after you reboot the system.

**IMPORTANT**

To enable remote peers to contact both VRF interfaces while reusing the same IP address, the network interfaces must belong to different broadcasting domains. A broadcast domain in a network is a set of nodes which receive broadcast traffic sent by any of them. In most configurations, all nodes connected to the same switch belong to the same broadcasting domain.

**Prerequisites**

- You are logged in as the `root` user.
The network interfaces are not configured.

Procedure

1. Create and configure the first VRF device:
   a. Create the VRF device and assign it to a routing table. For example, to create a VRF device named blue that is assigned to the 1001 routing table:
      
      ```
      # ip link add dev blue type vrf table 1001
      ```
   b. Enable the blue device:
      
      ```
      # ip link set dev blue up
      ```
   c. Assign a network device to the VRF device. For example, to add the enp1s0 Ethernet device to the blue VRF device:
      
      ```
      # ip link set dev enp1s0 master blue
      ```
   d. Enable the enp1s0 device:
      
      ```
      # ip link set dev enp1s0 up
      ```
   e. Assign an IP address and subnet mask to the enp1s0 device. For example, to set it to 192.0.2.1/24:
      
      ```
      # ip addr add dev enp1s0 192.0.2.1/24
      ```

2. Create and configure the next VRF device:
   a. Create the VRF device and assign it to a routing table. For example, to create a VRF device named red that is assigned to the 1002 routing table:
      
      ```
      # ip link add dev red type vrf table 1002
      ```
   b. Enable the red device:
      
      ```
      # ip link set dev red up
      ```
   c. Assign a network device to the VRF device. For example, to add the enp7s0 Ethernet device to the red VRF device:
      
      ```
      # ip link set dev enp7s0 master red
      ```
   d. Enable the enp7s0 device:
      
      ```
      # ip link set dev enp7s0 up
      ```
   e. Assign the same IP address and subnet mask to the enp7s0 device as you used for enp1s0 in the blue VRF domain:
3. Optionally, create further VRF devices as described above.

41.3. ADDITIONAL RESOURCES

- /usr/share/doc/kernel-doc-<kernel_version>/Documentation/networking/vrf.txt from the kernel-doc package
CHAPTER 42. STARTING A SERVICE WITHIN AN ISOLATED VRF NETWORK

With virtual routing and forwarding (VRF), you can create isolated networks with a routing table that is different to the main routing table of the operating system. You can then start services and applications so that they have only access to the network defined in that routing table.

42.1. CONFIGURING A VRF DEVICE

To use virtual routing and forwarding (VRF), you create a VRF device and attach a physical or virtual network interface and routing information to it.

WARNING

To prevent that you lock out yourself out remotely, perform this procedure on the local console or remotely over a network interface that you do not want to assign to the VRF device.

Prerequisites

- You are logged in locally or using a network interface that is different to the one you want to assign to the VRF device.

Procedure

1. Create the vrf0 connection with a same-named virtual device, and attach it to routing table 1000:

   ```
   # nmcli connection add type vrf ifname vrf0 con-name vrf0 table 1000 ipv4.method disabled ipv6.method disabled
   ```

2. Add the enp1s0 device to the vrf0 connection, and configure the IP settings:

   ```
   # nmcli connection add type ethernet con-name enp1s0 ifname enp1s0 master vrf0 ipv4.method manual ipv4.address 192.0.2.1/24 ipv4.gateway 192.0.2.254
   ```

   This command creates the enp1s0 connection as a port of the vrf0 connection. Due to this configuration, the routing information are automatically assigned to the routing table 1000 that is associated with the vrf0 device.

3. If you require static routes in the isolated network:
   a. Add the static routes:

      ```
      # nmcli connection modify enp1s0 +ipv4.routes "198.51.100.0/24 192.0.2.2"
      ```

      This adds a route to the 198.51.100.0/24 network that uses 192.0.2.2 as the router.
   b. Activate the connection:
# nmcli connection up enp1s0

Verification

1. Display the IP settings of the device that is associated with vrf0:

   `# ip -br addr show vrf vrf0
    enp1s0  UP  192.0.2.15/24`

2. Display the VRF devices and their associated routing table:

   `# ip vrf show
    Name    Table
    -----------------------
    vrf0    1000`

3. Display the main routing table:

   `# ip route show
    default via 192.168.0.1 dev enp1s0 proto static metric 100`

4. Display the routing table 1000:

   `# ip route show table 1000
    default via 192.0.2.254 dev enp1s0 proto static metric 101
    broadcast 192.0.2.0 dev enp1s0 proto kernel scope link src 192.0.2.1
    192.0.2.0/24 dev enp1s0 proto kernel scope link src 192.0.2.1 metric 101
    local 192.0.2.1 dev enp1s0 proto kernel scope host src 192.0.2.1
    broadcast 192.0.2.255 dev enp1s0 proto kernel scope link src 192.0.2.1
    198.51.100.0/24 via 192.0.2.2 dev enp1s0 proto static metric 101`

   The default entry indicates that services that use this routing table, use 192.0.2.254 as their default gateway and not the default gateway in the main routing table.

5. Execute the traceroute utility in the network associated with vrf0 to verify that the utility uses the route from table 1000:

   `# ip vrf exec vrf0 traceroute 203.0.113.1
    traceroute to 203.0.113.1 (203.0.113.1), 30 hops max, 60 byte packets
    1  192.0.2.254 (192.0.2.254) 0.516 ms 0.459 ms 0.430 ms ...

   The first hop is the default gateway that is assigned to the routing table 1000 and not the default gateway from the system’s main routing table.`

Additional resources

- `ip-vrf(8)`

### 42.2. STARTING A SERVICE WITHIN AN ISOLATED VRF NETWORK

You can configure a service, such as the Apache HTTP Server, to start within an isolated virtual routing and forwarding (VRF) network.
IMPORTANT

Services can only bind to local IP addresses that are in the same VRF network.

Prerequisites

- You configured the vrf0 device.
- You configured Apache HTTP Server to listen only on the IP address that is assigned to the interface associated with the vrf0 device.

Procedure

1. Display the content of the httpd systemd service:

   ```bash
   # systemctl cat httpd
   ...
   [Service]
   ExecStart=/usr/sbin/httpd $OPTIONS -DFOREGROUND
   ...
   
   You require the content of the ExecStart parameter in a later step to run the same command within the isolated VRF network.
   ```

2. Create the /etc/systemd/system/httpd.service.d/ directory:

   ```bash
   # mkdir /etc/systemd/system/httpd.service.d/
   ```

3. Create the /etc/systemd/system/httpd.service.d/override.conf file with the following content:

   ```ini
   [Service]
   ExecStart=/usr/sbin/ip vrf exec vrf0 /usr/sbin/httpd $OPTIONS -DFOREGROUND
   
   To override the ExecStart parameter, you first need to unset it and then set it to the new value as shown.
   ```

4. Reload systemd.

   ```bash
   # systemctl daemon-reload
   ```

5. Restart the httpd service.

   ```bash
   # systemctl restart httpd
   ```

Verification

1. Display the process IDs (PID) of httpd processes:

   ```bash
   # pidof -c httpd
   1904 ...
   ```

2. Display the VRF association for the PIDs, for example:
# ip vrf identify 1904
  vrf0

3. Display all PIDs associated with the vrf0 device:

   # ip vrf pids vrf0
    1904  httpd
    ...

Additional resources

- ip-vrf(8)
CHAPTER 43. SETTING THE ROUTING PROTOCOLS FOR YOUR SYSTEM

This section describes how to use the Free Range Routing (FRRouting, or FRR) feature to enable and set the required routing protocols for your system.

43.1. INTRODUCTION TO FRROUTING

Free Range Routing (FRRouting, or FRR) is a routing protocol stack, which is provided by the frr package available in the AppStream repository.

FRR replaces Quagga that was used on previous RHEL versions. As such, FRR provides TCP/IP-based routing services with support for multiple IPv4 and IPv6 routing protocols.

The supported protocols are:

- Border Gateway Protocol (BGP)
- Intermediate System to Intermediate System (IS-IS)
- Open Shortest Path First (OSPF)
- Protocol-Independent Multicast (PIM)
- Routing Information Protocol (RIP)
- Routing Information Protocol next generation (RIPng)
- Enhanced Interior Gateway Routing Protocol (EIGRP)
- Next Hop Resolution Protocol (NHRP)
- Bidirectional Forwarding Detection (BFD)
- Policy-based Routing (PBR)

FRR is a collection of the following services:

- zebra
- bgpd
- isisd
- ospfd
- ospf6d
- pimd
- ripd
- ripngd
- eigrpd
If frr is installed, the system can act as a dedicated router, which exchanges routing information with other routers in either internal or external network using the routing protocols.

### 43.2. SETTING UP FRROUTING

This section explains how you set up Free Range Routing (FRRouting, or FRR).

**Prerequisites**

- Make sure that the frr package is installed on your system:

```
# dnf install frr
```

**Procedure**

1. Edit the /etc/frr/daemons configuration file, and enable the required daemons for your system. For example, to enable the ripd daemon, include the following line:

```
ripd=yes
```

**WARNING**

The zebra daemon must always be enabled, so that you must set `zebra=yes` to be able to use FRR.

**IMPORTANT**

By default, /etc/frr/daemons contains `[daemon_name]=no` entries for all daemons. Therefore, all daemons are disabled, and starting FRR after a new installation of the system has no effect.

2. Start the frr service:

```
# systemctl start frr
```

3. Optionally, you can also set FRR to start automatically on boot:

```
# systemctl enable frr
```
43.3. MODIFYING THE CONFIGURATION OF FRR

This section describes:

- How to enable an additional daemon after you set up FRR
- How to disable a daemon after you set up FRR

Prerequisites

- FRR is set up as described in Setting up FRRouting.

Procedure

1. Edit the /etc/frr/daemons configuration file, and modify the line for the required daemons to state yes instead of no.
   For example, to enable the ripd daemon:

   
   ripd=yes

2. Reload the frr service:

   # systemctl reload frr

43.4. MODIFYING A CONFIGURATION OF A PARTICULAR DAEMON

With the default configuration, every routing daemon in FRR can only act as a plain router.

For any additional configuration of a daemon, use the following procedure.

Procedure

1. Within the /etc/frr/ directory, create a configuration file for the required daemon, and name the file as follows:

   [daemon_name].conf

   For example, to further configure the eigrpd daemon, create the eigrpd.conf file in the mentioned directory.

2. Populate the new file with the required content.
   For configuration examples of particular FRR daemons, see the /usr/share/doc/frr/ directory.

3. Reload the frr service:

   # systemctl reload frr
CHAPTER 44. TESTING BASIC NETWORK SETTINGS

This section describes how to perform basic network testing.

44.1. USING THE PING UTILITY TO VERIFY THE IP CONNECTION TO OTHER HOSTS

The ping utility sends ICMP packets to a remote host. You can use this functionality to test if the IP connection to a different host works.

Procedure

- Ping the IP address of a host in the same subnet, such as your default gateway:

  ```
  # ping 192.0.2.3
  ```

  If the command fails, verify the default gateway settings.

- Ping an IP address of a host in a remote subnet:

  ```
  # ping 198.162.3.1
  ```

  If the command fails, verify the default gateway settings, and ensure that the gateway forwards packets between the connected networks.

44.2. USING THE HOST UTILITY TO VERIFY NAME RESOLUTION

This procedure describes how to verify name resolution in Red Hat Enterprise Linux.

Procedure

- Use the host utility to verify that name resolution works. For example, to resolve the client.example.com hostname to an IP address, enter:

  ```
  # host client.example.com
  ```

  If the command returns an error, such as connection timed out or no servers could be reached, verify your DNS settings.
CHAPTER 45. RUNNING DHCLIENT EXIT HOOKS USING NETWORKMANAGER A DISPATCHER SCRIPT

You can use a NetworkManager dispatcher script to execute `dhclient` exit hooks.

45.1. THE CONCEPT OF NETWORKMANAGER DISPATCHER SCRIPTS

The `NetworkManager-dispatcher` service executes user-provided scripts in alphabetical order when network events happen. These scripts are typically shell scripts, but can be any executable script or application. You can use dispatcher scripts, for example, to adjust network-related settings that you cannot manage with NetworkManager.

You can store dispatcher scripts in the following directories:

- `/etc/NetworkManager/dispatcher.d/`: The general location for dispatcher scripts the `root` user can edit.
- `/usr/lib/NetworkManager/dispatcher.d/`: For pre-deployed immutable dispatcher scripts.

For security reasons, the `NetworkManager-dispatcher` service executes scripts only if the following conditions met:

- The script is owned by the `root` user.
- The script is only readable and writable by `root`.
- The `setuid` bit is not set on the script.

The `NetworkManager-dispatcher` service runs each script with two arguments:

1. The interface name of the device the operation happened on.
2. The action, such as `up`, when the interface has been activated.

The `Dispatcher scripts` section in the `NetworkManager(8)` man page provides an overview of actions and environment variables you can use in scripts.

The `NetworkManager-dispatcher` service runs one script at a time, but asynchronously from the main NetworkManager process. Note that, if a script is queued, the service will always run it, even if a later event makes it obsolete. However, the `NetworkManager-dispatcher` service runs scripts that are symbolic links referring to files in `/etc/NetworkManager/dispatcher.d/no-wait.d/` immediately, without waiting for the termination of previous scripts, and in parallel.

Additional resources

- The `Dispatcher scripts` section in the `NetworkManager(8)` man page

45.2. CREATING A NETWORKMANAGER DISPATCHER SCRIPT THAT RUNS DHCLIENT EXIT HOOKS

This section explains how to write a NetworkManager dispatcher script that runs `dhclient` exit hooks stored in the `/etc/dhcp/dhclient-exit-hooks.d/` directory when an IPv4 address is assigned or updated from a DHCP server.
Prerequisites

- The dhclient exit hooks are stored in the /etc/dhcp/dhclient-exit-hooks.d/ directory.

Procedure

1. Create the /etc/NetworkManager/dispatcher.d/12-dhclient-down file with the following content:

```bash
#!/bin/bash
# Run dhclient.exit-hooks.d scripts
if [ -n "$DHCP4_DHCP_LEASE_TIME" ] ; then
  if [ "$2" = "dhcp4-change" ] || [ "$2" = "up" ] ; then
    if [ -d /etc/dhcp/dhclient-exit-hooks.d ] ; then
      for f in /etc/dhcp/dhclient-exit-hooks.d/*.sh ; do
        if [ -x "$f" ] ; then
          "$f"
        fi
      done
    fi
  fi
fi
```

2. Set the root user as owner of the file:

```bash
# chown root:root /etc/NetworkManager/dispatcher.d/12-dhclient-down
```

3. Set the permissions so that only the root user can execute it:

```bash
# chmod 0700 /etc/NetworkManager/dispatcher.d/12-dhclient-down
```

4. Restore the SELinux context:

```bash
# restorecon /etc/NetworkManager/dispatcher.d/12-dhclient-down
```

Additional resources

- The Dispatcher scripts section in the NetworkManager(8) man page.
CHAPTER 46. INTRODUCTION TO NETWORKMANAGER DEBUGGING

Increasing the log levels for all or certain domains helps to log more details of the operations NetworkManager performs. Administrators can use this information to troubleshoot problems. NetworkManager provides different levels and domains to produce logging information. The /etc/NetworkManager/NetworkManager.conf file is the main configuration file for NetworkManager. The logs are stored in the journal.

This section provides information on enabling debug logging for NetworkManager and using different logging levels and domains to configure the amount of logging details.

46.1. DEBUGGING LEVELS AND DOMAINS

You can use the levels and domains parameters to manage the debugging for NetworkManager. The level defines the verbosity level, whereas the domains define the category of the messages to record the logs with given severity (level).

<table>
<thead>
<tr>
<th>Log levels</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Does not log any messages about NetworkManager</td>
</tr>
<tr>
<td>ERR</td>
<td>Logs only critical errors</td>
</tr>
<tr>
<td>WARN</td>
<td>Logs warnings that can reflect the operation</td>
</tr>
<tr>
<td>INFO</td>
<td>Logs various informational messages that are useful for tracking state and operations</td>
</tr>
<tr>
<td>DEBUG</td>
<td>Enables verbose logging for debugging purposes</td>
</tr>
<tr>
<td>TRACE</td>
<td>Enables more verbose logging than the DEBUG level</td>
</tr>
</tbody>
</table>

Note that subsequent levels log all messages from earlier levels. For example, setting the log level to INFO also logs messages contained in the ERR and WARN log level.

Additional resources

- NetworkManager.conf(5) man page

46.2. SETTING THE NETWORKMANAGER LOG LEVEL

By default, all the log domains are set to record the INFO log level. Disable rate-limiting before collecting debug logs. With rate-limiting, systemd-journald drops messages if there are too many of them in a short time. This can occur when the log level is TRACE.

This procedure disables rate-limiting and enables recording debug logs for the all (ALL) domains.

Procedure
1. To disable rate-limiting, edit the `/etc/systemd/journald.conf` file, uncomment the `RateLimitBurst` parameter in the `[Journal]` section, and set its value as `0`:

    RateLimitBurst=0

2. Restart the `systemd-journald` service.

    `# systemctl restart systemd-journald`

3. Create the `/etc/NetworkManager/conf.d/95-nm-debug.conf` file with the following content:

    `[logging]
domains=ALL:DEBUG`

    The `domains` parameter can contain multiple comma-separated `domain:level` pairs.

4. Restart the NetworkManager service.

    `# systemctl restart NetworkManager`

### 46.3. TEMPORARILY SETTING LOG LEVELS AT RUN TIME USING NMCLI

You can change the log level at run time using `nmcli`. However, Red Hat recommends to enable debugging using configuration files and restart NetworkManager. Updating debugging `levels` and `domains` using the `.conf` file helps to debug boot issues and captures all the logs from the initial state.

#### Procedure

1. Optional: Display the current logging settings:

    ```
    # nmcli general logging
    LEVEL  DOMAINS
    INFO
    PLATFORM,RFKILL,ETHER,WIFI,BT,MB,DHCP4,DHCP6,PPP,WIFI_SCAN,IP4,IP6,AUTOIP4,DNS,VPN,SHARING,SUPPLICANT,AGENTS,SETTINGS,SUSPEND,CORE,DEVICE,OLPC,WIMAX,INFINIBAND,FIREDOWNLOAD,ADSL,BOND,VLAN,BRIDGE,DBUS_PROPS,TEAM,CONNECTION
    DC,B,DISPATCH
    ```

2. To modify the logging level and domains, use the following options:

   - To set the log level for all domains to the same `LEVEL`, enter:
     ```
     # nmcli general logging level LEVEL domains ALL
     ```
   - To change the level for specific domains, enter:
     ```
     # nmcli general logging level LEVEL domains DOMAINS
     ```

    Note that updating the logging level using this command disables logging for all the other domains.
To change the level of specific domains and preserve the level of all other domains, enter:

```
# nmcli general logging level KEEP domains DOMAIN:LEVEL,DOMAIN:LEVEL
```

### 46.4. VIEWING NETWORKMANAGER LOGS

You can view the NetworkManager logs for troubleshooting.

**Procedure**

- To view the logs, enter:

  ```
  # journalctl -u NetworkManager -b
  ```

**Additional resources**

- The `NetworkManager.conf(5)` man page.
- The `journalctl` man page.
CHAPTER 47. CAPTURING NETWORK PACKETS

To debug network issues and communications, you can capture network packets. The following sections provide instructions and additional information about capturing network packets.

47.1. USING XDPDUMP TO CAPTURE NETWORK PACKETS INCLUDING PACKETS DROPPED BY XDP PROGRAMS

The `xdpdump` utility captures network packets. Unlike the `tcpdump` utility, `xdpdump` uses an extended Berkeley Packet Filter (eBPF) program for this task. This enables `xdpdump` to also capture packets dropped by Express Data Path (XDP) programs. User-space utilities, such as `tcpdump`, are not able to capture these dropped packages, as well as original packets modified by an XDP program.

You can use `xdpdump` to debug XDP programs that are already attached to an interface. Therefore, the utility can capture packets before an XDP program is started and after it has finished. In the latter case, `xdpdump` also captures the XDP action. By default, `xdpdump` captures incoming packets at the entry of the XDP program.

**IMPORTANT**

On other architectures than AMD and Intel 64-bit, the `xdpdump` utility is provided as a Technology Preview only. Technology Preview features are not supported with Red Hat production Service Level Agreements (SLAs), might not be functionally complete, and Red Hat does not recommend using them for production. These previews provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

See [Technology Preview Features Support Scope](https://www.redhat.com) on the Red Hat Customer Portal for information about the support scope for Technology Preview features.

Note that `xdpdump` has no packet filter or decode capabilities. However, you can use it in combination with `tcpdump` for packet decoding.

The procedure describes how to capture all packets on the `enp1s0` interface and write them to the `/root/capture.pcap` file.

**Prerequisites**

- A network driver that supports XDP programs.
- An XDP program is loaded to the `enp1s0` interface. If no program is loaded, `xdpdump` captures packets in a similar way `tcpdump` does, for backward compatibility.

**Procedure**

1. To capture packets on the `enp1s0` interface and write them to the `/root/capture.pcap` file, enter:

   ```bash
   # xdpdump -i enp1s0 -w /root/capture.pcap
   ```

2. To stop capturing packets, press **Ctrl+C**.

**Additional resources**
• **xdpdump(8)** man page

• If you are a developer and you are interested in the source code of **xdpdump**, download and install the corresponding source RPM (SRPM) from the Red Hat Customer Portal.

## 47.2. ADDITIONAL RESOURCES

• **How to capture network packets with tcpdump?**
CHAPTER 48. PROVIDING DHCP SERVICES

The dynamic host configuration protocol (DHCP) is a network protocol that automatically assigns IP information to clients.

This section explains general information on the `dhcpd` service, as well as how to set up a DHCP server and DHCP relay.

If a procedure requires different steps for providing DHCP in IPv4 and IPv6 networks, the sections in this chapter contain procedures for both protocols.

48.1. THE DIFFERENCE BETWEEN STATIC AND DYNAMIC IP ADDRESSING

Static IP addressing

When you assign a static IP address to a device, the address does not change over time unless you change it manually. Use static IP addressing if you want:

- To ensure network address consistency for servers such as DNS, and authentication servers.
- To use out-of-band management devices that work independently of other network infrastructure.

Dynamic IP addressing

When you configure a device to use a dynamic IP address, the address can change over time. For this reason, dynamic addresses are typically used for devices that connect to the network occasionally because the IP address can be different after rebooting the host.

Dynamic IP addresses are more flexible, easier to set up, and administer. The Dynamic Host Control Protocol (DHCP) is a traditional method of dynamically assigning network configurations to hosts.

NOTE

There is no strict rule defining when to use static or dynamic IP addresses. It depends on user’s needs, preferences, and the network environment.

48.2. DHCP TRANSACTION PHASES

The DHCP works in four phases: Discovery, Offer, Request, Acknowledgement, also called the DORA process. DHCP uses this process to provide IP addresses to clients.

Discovery

The DHCP client sends a message to discover the DHCP server in the network. This message is broadcasted at the network and data link layer.

Offer

The DHCP server receives messages from the client and offers an IP address to the DHCP client. This message is unicast at the data link layer but broadcast at the network layer.

Request

The DHCP client requests the DHCP server for the offered IP address. This message is unicast at the data link layer but broadcast at the network layer.

Acknowledgment
The DHCP server sends an acknowledgment to the DHCP client. This message is unicast at the data link layer but broadcast at the network layer. It is the final message of the DHCP DORA process.

### 48.3. THE DIFFERENCES WHEN USING DHCPD FOR DHCPV4 AND DHCPV6

The `dhcpd` service supports providing both DHCPv4 and DHCPv6 on one server. However, you need a separate instance of `dhcpd` with separate configuration files to provide DHCP for each protocol.

**DHCPv4**

- Configuration file: `/etc/dhcp/dhcpd.conf`
- Systemd service name: `dhcpd`

**DHCPv6**

- Configuration file: `/etc/dhcp/dhcpd6.conf`
- Systemd service name: `dhcpd6`

### 48.4. THE LEASE DATABASE OF THE DHCPD SERVICE

A DHCP lease is the time period for which the `dhcpd` service allocates a network address to a client. The `dhcpd` service stores the DHCP leases in the following databases:

- For DHCPv4: `/var/lib/dhcp/dhcpd.leases`
- For DHCPv6: `/var/lib/dhcp/dhcpd6.leases`

**WARNING**

Manually updating the database files can corrupt the databases.

The lease databases contain information about the allocated leases, such as the IP address assigned to a media access control (MAC) address or the time stamp when the lease expires. Note that all time stamps in the lease databases are in Coordinated Universal Time (UTC).

The `dhcpd` service recreates the databases periodically:

1. The service renames the existing files:
   - `/var/lib/dhcp/dhcpd.leases` to `/var/lib/dhcp/dhcpd.leases~`
   - `/var/lib/dhcp/dhcpd6.leases` to `/var/lib/dhcp/dhcpd6.leases~`

2. The service writes all known leases to the newly created `/var/lib/dhcp/dhcpd.leases` and `/var/lib/dhcp/dhcpd6.leases` files.
48.5. COMPARISON OF DHCPV6 TO RADVD

In an IPv6 network, only router advertisement messages provide information on an IPv6 default gateway. As a consequence, if you want to use DHCPv6 in subnets that require a default gateway setting, you must additionally configure a router advertisement service, such as Router Advertisement Daemon (radvd).

The radvd service uses flags in router advertisement packets to announce the availability of a DHCPv6 server.

This section compares DHCPv6 and radvd, and provides information about configuring radvd.

<table>
<thead>
<tr>
<th></th>
<th>DHCPv6</th>
<th>radvd</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provides information on the default gateway</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td>Guarantees random addresses to protect privacy</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>Sends further network configuration options</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>Maps media access control (MAC) addresses to IPv6 addresses</td>
<td>yes</td>
<td>no</td>
</tr>
</tbody>
</table>

48.6. CONFIGURING THE RADVD SERVICE FOR IPV6 ROUTERS

The router advertisement daemon (radvd) sends router advertisement messages that are required for IPv6 stateless autoconfiguration. This enables users to automatically configure their addresses, settings, routes, and to choose a default router based on these advertisements.

The procedure in this section explains how to configure radvd.

NOTE

You can only set /64 prefixes in the radvd service. To use other prefixes, use DHCPv6.

Prerequisites

- You are logged in as the root user.

Procedure

1. Install the radvd package:

   ```bash
   # dnf install radvd
   ```

2. Edit the /etc/radvd.conf file, and add the following configuration:
interface enp1s0
{
    AdvSendAdvert on;
    AdvManagedFlag on;
    AdvOtherConfigFlag on;

    prefix 2001:db8:0:1::/64 {
    }
}

These settings configures radvd to send router advertisement messages on the enp1s0 device for the 2001:db8:0:1::/64 subnet. The AdvManagedFlag on setting defines that the client should receive the IP address from a DHCP server, and the AdvOtherConfigFlag parameter set to on defines that clients should receive non-address information from the DHCP server as well.

3. Optionally, configure that radvd automatically starts when the system boots:

   # systemctl enable radvd

4. Start the radvd service:

   # systemctl start radvd

5. Optionally, display the content of router advertisement packages and the configured values radvd sends:

   # radvdump

Additional resources

- radvd.conf(5) man page
- /usr/share/doc/radvd/radvd.conf.example
- Can I use a prefix length other than 64 bits in IPv6 Router Advertisements?

48.7. SETTING NETWORK INTERFACES FOR THE DHCP SERVERS

By default, the dhcpd service processes requests only on network interfaces that have an IP address in the subnet defined in the configuration file of the service.

For example, in the following scenario, dhcpd listens only on the enp0s1 network interface:

- You have only a subnet definition for the 192.0.2.0/24 network in the /etc/dhcp/dhcppd.conf file.
- The enp0s1 network interface is connected to the 192.0.2.0/24 subnet.
- The enp7s0 interface is connected to a different subnet.

Only follow the procedure in this section if the DHCP server contains multiple network interfaces connected to the same network but the service should listen only on specific interfaces.
Depending on whether you want to provide DHCP for IPv4, IPv6, or both protocols, see the procedure for:

- **IPv4 networks**
- **IPv6 networks**

**Prerequisites**

- You are logged in as the **root** user.
- The **dhcp-server** package is installed.

**Procedure**

- **For IPv4 networks:**
  1. Copy the `/usr/lib/systemd/system/dhcpd.service` file to the `/etc/systemd/system/` directory:
     ```
     # cp /usr/lib/systemd/system/dhcpd.service /etc/systemd/system/
     ```
     Do not edit the `/usr/lib/systemd/system/dhcpd.service` file. Future updates of the **dhcp-server** package can override the changes.

  2. Edit the `/etc/systemd/system/dhcpd.service` file, and append the names of the interface, that **dhcpp** should listen on to the command in the **ExecStart** parameter:
     ```
     ExecStart=/usr/sbin/dhcpd -f -cf /etc/dhcp/dhcpd.conf -user dhcpd -group dhcpd --no-pid $DHCPDARGS
     enp0s1
     enp7s0
     ```
     This example configures that **dhcpp** listens only on the **enp0s1** and **enp7s0** interfaces.

  3. Reload the **systemd** manager configuration:
     ```
     # systemctl daemon-reload
     ```

  4. Restart the **dhcpp** service:
     ```
     # systemctl restart dhcpp.service
     ```

- **For IPv6 networks:**
  1. Copy the `/usr/lib/systemd/system/dhcpd6.service` file to the `/etc/systemd/system/` directory:
     ```
     # cp /usr/lib/systemd/system/dhcpd6.service /etc/systemd/system/
     ```
     Do not edit the `/usr/lib/systemd/system/dhcpd6.service` file. Future updates of the **dhcp-server** package can override the changes.

  2. Edit the `/etc/systemd/system/dhcpd6.service` file, and append the names of the interface, that **dhcpp** should listen on to the command in the **ExecStart** parameter:
ExecStart=/usr/sbin/dhcpd -f -6 -cf /etc/dhcp/dhcpd6.conf -user dhcpd -group dhcpd --no-pid $DHCPDARGS

This example configures that `dhcpd` listens only on the `enp0s1` and `enp7s0` interfaces.

3. Reload the `systemd` manager configuration:

   ```
   # systemctl daemon-reload
   ```

4. Restart the `dhcpd6` service:

   ```
   # systemctl restart dhcpd6.service
   ```

**48.8. SETTING UP THE DHCP SERVICE FOR SUBNETS DIRECTLY CONNECTED TO THE DHCP SERVER**

Use the following procedure if the DHCP server is directly connected to the subnet for which the server should answer DHCP requests. This is the case if a network interface of the server has an IP address of this subnet assigned.

Depending on whether you want to provide DHCP for IPv4, IPv6, or both protocols, see the procedure for:

- IPv4 networks
- IPv6 networks

**Prerequisites**

- You are logged in as the `root` user.
- The `dhcp-server` package is installed.

**Procedure**

For IPv4 networks:

1. Edit the `/etc/dhcp/dhcpd.conf` file:

   a. Optionally, add global parameters that `dhcpd` uses as default if no other directives contain these settings:

      ```
      option domain-name "example.com";
      default-lease-time 86400;
      ```

      This example sets the default domain name for the connection to `example.com`, and the default lease time to **86400** seconds (1 day).

   b. Add the `authoritative` statement on a new line:

      ```
      authoritative;
      ```
IMPORTANT

Without the authoritative statement, the dhcpd service does not answer DHCPREQUEST messages with DHCPNAK if a client asks for an address that is outside of the pool.

c. For each IPv4 subnet directly connected to an interface of the server, add a subnet declaration:

```plaintext
subnet 192.0.2.0 netmask 255.255.255.0 {
    range 192.0.2.20 192.0.2.100;
    option domain-name-servers 192.0.2.1;
    option routers 192.0.2.1;
    option broadcast-address 192.0.2.255;
    max-lease-time 172800;
}
```

This example adds a subnet declaration for the 192.0.2.0/24 network. With this configuration, the DHCP server assigns the following settings to a client that sends a DHCP request from this subnet:

- A free IPv4 address from the range defined in the range parameter
- IP of the DNS server for this subnet: **192.0.2.1**
- Default gateway for this subnet: **192.0.2.1**
- Broadcast address for this subnet: **192.0.2.255**
- The maximum lease time, after which clients in this subnet release the IP and send a new request to the server: **172800 seconds (2 days)**

2. Optionally, configure that dhcpd starts automatically when the system boots:

```plaintext
# systemctl enable dhcpd
```

3. Start the dhcpd service:

```plaintext
# systemctl start dhcpd
```

- For IPv6 networks:

1. Edit the `/etc/dhcp/dhcpd6.conf` file:

   a. Optionally, add global parameters that dhcpd uses as default if no other directives contain these settings:

   ```plaintext
   option dhcp6.domain-search "example.com";
   default-lease-time 86400;
   ```

   This example sets the default domain name for the connection to **example.com**, and the default lease time to **86400 seconds (1 day)**.

   b. Add the authoritative statement on a new line:
authoritative;

**IMPORTANT**

Without the authoritative statement, the **dhcpd** service does not answer **DHCPREQUEST** messages with **DHCPNAK** if a client asks for an address that is outside of the pool.

c. For each IPv6 subnet directly connected to an interface of the server, add a **subnet** declaration:

```plaintext
subnet6 2001:db8:0:1::/64 {
  range6 2001:db8:0:1::20 2001:db8:0:1::100;
  option dhcp6.name-servers 2001:db8:0:1::1;
  max-lease-time 172800;
}
```

This example adds a subnet declaration for the 2001:db8:0:1::/64 network. With this configuration, the DHCP server assigns the following settings to a client that sends a DHCP request from this subnet:

- A free IPv6 address from the range defined in the **range6** parameter.
- The IP of the DNS server for this subnet is **2001:db8:0:1::1**.
- The maximum lease time, after which clients in this subnet release the IP and send a new request to the server is **172800** seconds (2 days).

Note that IPv6 requires uses router advertisement messages to identify the default gateway.

2. Optionally, configure that **dhcpd6** starts automatically when the system boots:

```
# systemctl enable dhcpd6
```

3. Start the **dhcpd6** service:

```
# systemctl start dhcpd6
```

**Additional resources**

- **dhcp-options(5)** man page
- The authoritative statement section in the **dhcpd.conf(5)** man page
- `/usr/share/doc/dhcp-server/dhcpd.conf.example`
- `/usr/share/doc/dhcp-server/dhcpd6.conf.example`

### 48.9. Setting up the DHCP service for subnets that are not directly connected to the DHCP server

Use the following procedure if the DHCP server is not directly connected to the subnet for which the server should answer DHCP requests. This is the case if a DHCP relay agent forwards requests to the
DHCP server, because none of the DHCP server’s interfaces is directly connected to the subnet the server should serve.

Depending on whether you want to provide DHCP for IPv4, IPv6, or both protocols, see the procedure for:

- IPv4 networks
- IPv6 networks

Prerequisites

- You are logged in as the root user.
- The dhcp-server package is installed.

Procedure

- For IPv4 networks:

  1. Edit the /etc/dhcp/dhcpd.conf file:

     a. Optionally, add global parameters that dhcpd uses as default if no other directives contain these settings:

        ```
        option domain-name "example.com";
        default-lease-time 86400;
        ```

        This example sets the default domain name for the connection to example.com, and the default lease time to 86400 seconds (1 day).

     b. Add the authoritative statement on a new line:

        ```
        authoritative;
        ```

        **IMPORTANT**

        Without the authoritative statement, the dhcpd service does not answer DHCPREQUEST messages with DHCPNAK if a client asks for an address that is outside of the pool.

     c. Add a shared-network declaration, such as the following, for IPv4 subnets that are not directly connected to an interface of the server:

        ```
        shared-network example {
        option domain-name-servers 192.0.2.1;
        ...
        subnet 192.0.2.0 netmask 255.255.255.0 {
        range 192.0.2.20 192.0.2.100;
        option routers 192.0.2.1;
        }
        }
        subnet 198.51.100.0 netmask 255.255.255.0 {
        range 198.51.100.20 198.51.100.100;
        ```
This example adds a shared network declaration, that contains a subnet declaration for both the 192.0.2.0/24 and 198.51.100.0/24 networks. With this configuration, the DHCP server assigns the following settings to a client that sends a DHCP request from one of these subnets:

- The IP of the DNS server for clients from both subnets is: 192.0.2.1.
- A free IPv4 address from the range defined in the range parameter, depending on from which subnet the client sent the request.
- The default gateway is either 192.0.2.1 or 198.51.100.1 depending on from which subnet the client sent the request.

d. Add a subnet declaration for the subnet the server is directly connected to and that is used to reach the remote subnets specified in shared-network above:

```
subnet 203.0.113.0 netmask 255.255.255.0 {
}
```

NOTE

If the server does not provide DHCP service to this subnet, the subnet declaration must be empty as shown in the example. Without a declaration for the directly connected subnet, dhcpd does not start.

2. Optionally, configure that dhcpd starts automatically when the system boots:

```
# systemctl enable dhcpd
```

3. Start the dhcpd service:

```
# systemctl start dhcpd
```

- For IPv6 networks:

1. Edit the /etc/dhcp/dhcpd6.conf file:

   a. Optionally, add global parameters that dhcpd uses as default if no other directives contain these settings:

   ```
   option dhcp6.domain-search "example.com";
default-lease-time 86400;
   ```

   This example sets the default domain name for the connection to example.com, and the default lease time to 86400 seconds (1 day).

   b. Add the authoritative statement on a new line:

   ```
   authoritative;
   ```
IMPORTANT

Without the authoritative statement, the dhcpd service does not answer DHCPREQUEST messages with DHCPNAK if a client asks for an address that is outside of the pool.

c. Add a shared-network declaration, such as the following, for IPv6 subnets that are not directly connected to an interface of the server:

```plaintext
shared-network example {
  option domain-name-servers 2001:db8:0:1::1:1
  ...
  subnet6 2001:db8:0:1::1:0/120 {
    range6 2001:db8:0:1::1:20 2001:db8:0:1::1:100
  }
  subnet6 2001:db8:0:1::2:0/120 {
    range6 2001:db8:0:1::2:20 2001:db8:0:1::2:100
  }
  ...
}
```

This example adds a shared network declaration that contains a subnet6 declaration for both the 2001:db8:0:1::1:0/120 and 2001:db8:0:1::2:0/120 networks. With this configuration, the DHCP server assigns the following settings to a client that sends a DHCP request from one of these subnets:

- The IP of the DNS server for clients from both subnets is 2001:db8:0:1::1:1.
- A free IPv6 address from the range defined in the range6 parameter, depending on from which subnet the client sent the request.

Note that IPv6 requires uses router advertisement messages to identify the default gateway.

d. Add a subnet6 declaration for the subnet the server is directly connected to and that is used to reach the remote subnets specified in shared-network above:

```plaintext
subnet6 2001:db8:0:1::50:0/120 {
  }
```

NOTE

If the server does not provide DHCP service to this subnet, the subnet6 declaration must be empty as shown in the example. Without a declaration for the directly connected subnet, dhcpd does not start.

2. Optionally, configure that dhcpd6 starts automatically when the system boots:

```
# systemctl enable dhcpd6
```

3. Start the dhcpd6 service:

```
# systemctl start dhcpd6
```
48.10. ASSIGNING A STATIC ADDRESS TO A HOST USING DHCP

Using a host declaration, you can configure the DHCP server to assign a fixed IP address to a media access control (MAC) address of a host. For example, use this method to always assign the same IP address to a server or network device.

**IMPORTANT**

If you configure a fixed IP address for a MAC address, the IP address must be outside of the address pool you specified in the fixed-address and fixed-address6 parameters.

Depending on whether you want to configure fixed addresses for IPv4, IPv6, or both protocols, see the procedure for:

- IPv4 networks.
- IPv6 networks.

**Prerequisites**

- The dhcpd service is configured and running.
- You are logged in as the root user.

**Procedure**

- For IPv4 networks:
  1. Edit the /etc/dhcp/dhcpd.conf file:
     a. Add a host declaration:

        ```
        host server.example.com {
          hardware ethernet 52:54:00:72:2f:6e;
          fixed-address 192.0.2.130;
        }
        ```

        This example configures the DHCP server to always assigns the 192.0.2.130 IP address to the host with the 52:54:00:72:2f:6e MAC address.

        The dhcpd service identifies systems by the MAC address specified in the fixed-address parameter, and not by the name in the host declaration. As a consequence,
you can set this name to any string that does not match other host declarations. To configure the same system for multiple networks, use a different name, otherwise, dhcpd fails to start.

b. Optionally, add further settings to the host declaration that are specific for this host.

2. Restart the dhcpd service:

`# systemctl start dhcpd`

- For IPv6 networks:

1. Edit the `/etc/dhcp/dhcpd6.conf` file:

   a. Add a host declaration:

   ```
   host server.example.com {
   hardware ethernet 52:54:00:72:2f:6e;
   fixed-address6 2001:db8:0:1::20;
   }
   ```

   This example configures the DHCP server to always assign the 2001:db8:0:1::20 IP address to the host with the 52:54:00:72:2f:6e MAC address.

   The dhcpd service identifies systems by the MAC address specified in the fixed-address6 parameter, and not by the name in the host declaration. As a consequence, you can set this name to any string, as long as it is unique to other host declarations. To configure the same system for multiple networks, use a different name because, otherwise, dhcpd fails to start.

   b. Optionally, add further settings to the host declaration that are specific for this host.

2. Restart the dhcpd6 service:

`# systemctl start dhcpd6`

Additional resources

- `dhcp-options(5)` man page
- `/usr/share/doc/dhcp-server/dhcpd.conf.example`
- `/usr/share/doc/dhcp-server/dhcpd6.conf.example`

### 48.11. USING A GROUP DECLARATION TO APPLY PARAMETERS TO MULTIPLE HOSTS, SUBNETS, AND SHARED NETWORKS AT THE SAME TIME

Using a group declaration, you can apply the same parameters to multiple hosts, subnets, and shared networks.

Note that the procedure in this section describes using a group declaration for hosts, but the steps are the same for subnets and shared networks.
Depending on whether you want to configure a group for IPv4, IPv6, or both protocols, see the procedure for:

- IPv4 networks
- IPv6 networks

Prerequisites

- The `dhcpd` service is configured and running.
- You are logged in as the `root` user.

Procedure

- For IPv4 networks:
  1. Edit the `/etc/dhcp/dhcpd.conf` file:
     a. Add a `group` declaration:

     ```
     group {
       option domain-name-servers 192.0.2.1;

       host server1.example.com {
         hardware ethernet 52:54:00:72:2f:6e;
         fixed-address 192.0.2.130;
       }

       host server2.example.com {
         hardware ethernet 52:54:00:1b:f3:cf;
         fixed-address 192.0.2.140;
       }
     }
     ```

     This `group` definition groups two `host` entries. The `dhcpd` service applies the value set in the `option domain-name-servers` parameter to both hosts in the group.

     b. Optionally, add further settings to the `group` declaration that are specific for these hosts.

     2. Restart the `dhcpd` service:

     ```
     # systemctl start dhcpd
     ```

- For IPv6 networks:
  1. Edit the `/etc/dhcp/dhcpd6.conf` file:

     a. Add a `group` declaration:

     ```
     group {
       option dhcp6.domain-search "example.com";

       host server1.example.com {
         hardware ethernet 52:54:00:72:2f:6e;
       }
     }
     ```
This **group** definition groups two **host** entries. The **dhcpd** service applies the value set in the **option dhcp6.domain-search** parameter to both hosts in the group.

b. Optionally, add further settings to the **group** declaration that are specific for these hosts.

2. Restart the **dhcpd6** service:

```
# systemctl start dhcpd6
```

#### 48.12. RESTORING A CORRUPT LEASE DATABASE

If the DHCP server logs an error that is related to the lease database, such as **Corrupt lease file - possible data loss!**, you can restore the lease database from the copy the **dhcpd** service created. Note that this copy might not reflect the latest status of the database.

**WARNING**

If you remove the lease database instead of replacing it with a backup, you lose all information about the currently assigned leases. As a consequence, the DHCP server could assign leases to clients that have been previously assigned to other hosts and are not expired yet. This leads to IP conflicts.

Depending on whether you want to restore the DHCPv4, DHCPv6, or both databases, see the procedure for:

- **Restoring the DHCPv4 lease database**
- **Restoring the DHCPv6 lease database**

**Prerequisites**

- You are logged in as the **root** user.
• The lease database is corrupt.

Procedure

• Restoring the DHCPv4 lease database:

  1. Stop the dhcpd service:

     ```
     # systemctl stop dhcpd
     ```

  2. Rename the corrupt lease database:

     ```
     # mv /var/lib/dhcpd/dhcpd.leases /var/lib/dhcpd/dhcpd.leases.corrupt
     ```

  3. Restore the copy of the lease database that the dhcp service created when it refreshed the lease database:

     ```
     # cp -p /var/lib/dhcpd/dhcpd.leases~ /var/lib/dhcpd/dhcpd.leases
     ```

     **IMPORTANT**

     If you have a more recent backup of the lease database, restore this backup instead.

  4. Start the dhcpd service:

     ```
     # systemctl start dhcpd
     ```

• Restoring the DHCPv6 lease database:

  1. Stop the dhcpd6 service:

     ```
     # systemctl stop dhcpd6
     ```

  2. Rename the corrupt lease database:

     ```
     # mv /var/lib/dhcpd/dhcpd6.leases /var/lib/dhcpd/dhcpd6.leases.corrupt
     ```

  3. Restore the copy of the lease database that the dhcp service created when it refreshed the lease database:

     ```
     # cp -p /var/lib/dhcpd/dhcpd6.leases~ /var/lib/dhcpd/dhcpd6.leases
     ```

     **IMPORTANT**

     If you have a more recent backup of the lease database, restore this backup instead.

  4. Start the dhcpd6 service:

     ```
     # systemctl start dhcpd6
     ```
48.13. SETTING UP A DHCP RELAY AGENT

The DHCP Relay Agent (dhcrelay) enables the relay of DHCP and BOOTP requests from a subnet with no DHCP server on it to one or more DHCP servers on other subnets. When a DHCP client requests information, the DHCP Relay Agent forwards the request to the list of DHCP servers specified. When a DHCP server returns a reply, the DHCP Relay Agent forwards this request to the client.

Depending on whether you want to set up a DHCP relay for IPv4, IPv6, or both protocols, see the procedure for:

- IPv4 networks
- IPv6 networks

Prerequisites

- You are logged in as the root user.

Procedure

- For IPv4 networks:
  1. Install the dhcp-relay package:
     
     ```
     # dnf install dhcp-relay
     ```
  2. Copy the /lib/systemd/system/dhcrelay.service file to the /etc/systemd/system/ directory:
     
     ```
     # cp /lib/systemd/system/dhcrelay.service /etc/systemd/system/
     ```
     Do not edit the /usr/lib/systemd/system/dhcrelay.service file. Future updates of the dhcp-relay package can override the changes.
  3. Edit the /etc/systemd/system/dhcrelay.service file, and append the -i interface parameter, together with a list of IP addresses of DHCPv4 servers that are responsible for the subnet:
     
     ```
     ExecStart=/usr/sbin/dhcrelay -d --no-pid -i enp1s0 192.0.2.1
     ```
     With these additional parameters, dhcrelay listens for DHCPv4 requests on the enp1s0 interface and forwards them to the DHCP server with the IP 192.0.2.1.
  4. Reload the systemd manager configuration:
     
     ```
     # systemctl daemon-reload
     ```
  5. Optionally, configure that the dhcrelay service starts when the system boots:
     
     ```
     # systemctl enable dhcrelay.service
     ```
6. Start the **dhcrelay** service:

    # systemctl start dhcrelay.service

• For IPv6 networks:

1. Install the **dhcp-relay** package:

    # dnf install dhcp-relay

2. Copy the `/lib/systemd/system/dhcrelay.service` file to the `/etc/systemd/system/` directory and name the file `dhcrelay6.service`:

    # cp /lib/systemd/system/dhcrelay.service /etc/systemd/system/dhcrelay6.service

   Do not edit the `/usr/lib/systemd/system/dhcrelay.service` file. Future updates of the **dhcp-relay** package can override the changes.

3. Edit the `/etc/systemd/system/dhcrelay6.service` file, and append the `-l receiving_interface` and `-u outgoing_interface` parameters:

    ExecStart=/usr/sbin/dhcrelay -d --no-pid -l enp1s0 -u enp7s0

   With these additional parameters, dhcrelay listens for DHCPv6 requests on the enp1s0 interface and forwards them to the network connected to the enp7s0 interface.

4. Reload the **systemd** manager configuration:

    # systemctl daemon-reload

5. Optionally, configure that the **dhcrelay6** service starts when the system boots:

    # systemctl enable dhcrelay6.service

6. Start the **dhcrelay6** service:

    # systemctl start dhcrelay6.service

Additional resources

• **dhcrelay(8)** man page
CHAPTER 49. CONFIGURING AND MANAGING A BIND DNS SERVER

DNS (Domain Name System) is a distributed database system that associates hostnames with their respective IP addresses. BIND (Berkeley Internet Name Domain) consists of a set of DNS-related programs. It contains a name server called named. The /etc/named.conf is the main configuration file in the BIND configuration. This section focuses on installing, configuring, and managing BIND on the DNS server.

49.1. INSTALLING BIND

The installation of the bind-utils package ensures the BIND utilities are available on the system.

Procedure

1. Install BIND:

   # dnf install bind bind-utils

2. Enable and start the named service:

   # systemctl enable --now named

Verification steps

- Verify the status of the named service:

  # systemctl status named

49.2. CONFIGURING BIND AS A CACHING NAME SERVER

The following procedure demonstrates configuring BIND as a caching name server.

Prerequisites

- The bind package is installed.

Procedure

1. Ensure to take backup of the original configuration file.

   # cp /etc/named.conf /etc/named.conf.orig

2. Edit the /etc/named.conf file with the following changes:

   - In the options section, uncomment the listen-on, listen-on-v6, and directory parameters:

     acl clients {192.0.2.0/24;};

     options {
       listen-on port 53 { any; };
**listen-on-v6** port 53 { any; };

directory       "/var/named";

- Set the **allow-query** parameter to your network address. Only the hosts on your local network can query the DNS server:

  allow-query     { localhost; clients; };
  allow-recursion { localhost; clients; };
  recursion yes;
  allow-update     none;     };
  allow-transfer   { localhost; };

};

logging {
  channel default_debug {
    file "data/named.run";
    severity dynamic;
  };
}

- Use the package shipped file as:

  include "/etc/named.rfc1912.zones";

- Create an extra include for any custom zone configuration:

  include "/etc/named/example.zones";

3. Create the **/etc/named/example.zones** file and add the following zone configuration:

```plaintext
//forward zone
zone "example.com" IN {
  type master;
  file "example.com.zone";
};

//backward zone
zone "2.0.192.in-addr.arpa" IN {
  type master;
  file "example.com.rzone";
};
```

- **type**: It defines the zone’s role of the server.
- **master**: It is an authoritative server and maintains the master copy of the zone data.
- **file**: It specifies the zone’s database file.

4. Go to DNS data directory **/var/named/**.
5. Create the `/var/named/example.com.zone` file with your forward zone parameters:

```
$TTL 86400
@ IN SOA example.com. root (42 ; serial 3H ; refresh 15M ; retry 1W ; expiry 1D) ; minimum

IN NS ns.example.com.

ns   IN A  192.0.2.1
station1  IN A  192.0.2.101
station2  IN A  192.0.2.102
station3  IN A  192.0.2.103
```

6. Create the `/var/named/example.com.rzone` file with your reverse zone parameters:

```
$TTL 86400
@ IN SOA example.com. root.example.com (1997022700 ; serial 28800 ; refresh 14400 ; retry 3600000 ; expire 86400) ; minimum

IN NS ns.example.com.

101 IN PTR station1.example.com.
102 IN PTR station2.example.com.
103 IN PTR station3.example.com.
```

7. Set secure permissions on the zone files:

```
# chown root:named /var/named/example.com.zone /var/named/example.com.rzone
# chmod 640 /var/named/example.com.zone /var/named/example.com.rzone
```

8. Restart BIND:

```
# systemctl restart named
```

Verification steps

- Verify the forward zone file:

```
# named-checkzone example.com /var/named/example.com.zone
```
zone example.com/IN: loaded serial xxxxxxx
OK

- Verify the reverse zone file:

  # named-checkzone 2.0.192.in-addr.arpa /var/named/example.com.rzone

  zone 2.0.192.in-addr.arpa/IN: loaded serial xxxxxxx
  OK

- Verify the configuration:

  # named-checkconf /etc/named.conf

  If the configuration is correct, the command does not return any output.
CHAPTER 50. GETTING STARTED WITH DPDK

The data plane development kit (DPDK) provides libraries and network drivers to accelerate package processing in user space.

Administrators use DPDK, for example, in virtual machines to use Single Root I/O Virtualization (SR-IOV) to reduce latencies and increase I/O throughput.

NOTE
Red Hat does not support experimental DPDK APIs.

50.1. INSTALLING THE DPDK PACKAGE

This section describes how to install the dpdk package.

Prerequisites

- Red Hat Enterprise Linux is installed.
- A valid subscription is assigned to the host.

Procedure

- Use the dnf utility to install the dpdk package:

  # dnf install dpdk

50.2. ADDITIONAL RESOURCES

- Network Adapter Fast Datapath Feature Support Matrix
CHAPTER 51. UNDERSTANDING THE EBPF NETWORKING FEATURES IN RHEL

The extended Berkeley Packet Filter (eBPF) is an in-kernel virtual machine that allows code execution in the kernel space. This code runs in a restricted sandbox environment with access only to a limited set of functions.

In networking, you can use eBPF to complement or replace kernel packet processing. Depending on the hook you use, eBPF programs have, for example:

- Read and write access to packet data and metadata
- Can look up sockets and routes
- Can set socket options
- Can redirect packets

51.1. OVERVIEW OF NETWORKING EBPF FEATURES IN RHEL

You can attach extended Berkeley Packet Filter (eBPF) networking programs to the following hooks in RHEL:

- **eXpress Data Path (XDP)**: Provides early access to received packets before the kernel networking stack processes them.

- **tc eBPF classifier with direct-action flag**: Provides powerful packet processing on ingress and egress.

- **Control Groups version 2 (cgroup v2)**: Enables filtering and overriding socket-based operations performed by programs in a control group.

- **Socket filtering**: Enables filtering of packets received from sockets. This feature was also available in the classic Berkeley Packet Filter (cBPF), but has been extended to support eBPF programs.

- **Stream parser**: Enables splitting up streams to individual messages, filtering, and redirecting them to sockets.

- **SO_REUSEPORT socket selection**: Provides a programmable selection of a receiving socket from a reuseport socket group.

- **Flow dissector**: Enables overriding the way the kernel parses packet headers in certain situations.

- **TCP congestion control callbacks**: Enables implementing a custom TCP congestion control algorithm.

- **Routes with encapsulation**: Enables creating custom tunnel encapsulation.

**XDP**

You can attach programs of the `BPF_PROG_TYPE_XDP` type to a network interface. The kernel then executes the program on received packets before the kernel network stack starts processing them. This allows fast packet forwarding in certain situations, such as fast packet dropping to prevent distributed denial of service (DDoS) attacks and fast packet redirects for load balancing scenarios.
You can also use XDP for different forms of packet monitoring and sampling. The kernel allows XDP programs to modify packets and to pass them for further processing to the kernel network stack.

The following XDP modes are available:

- **Native (driver) XDP**: The kernel executes the program from the earliest possible point during packet reception. At this moment, the kernel did not parse the packet and, therefore, no metadata provided by the kernel is available. This mode requires that the network interface driver supports XDP but not all drivers support this native mode.

- **Generic XDP**: The kernel network stack executes the XDP program early in the processing. At that time, kernel data structures have been allocated, and the packet has been pre-processed. If a packet should be dropped or redirected, it requires a significant overhead compared to the native mode. However, the generic mode does not require network interface driver support and works with all network interfaces.

- **Offloaded XDP**: The kernel executes the XDP program on the network interface instead of on the host CPU. Note that this requires specific hardware, and only certain eBPF features are available in this mode.

On RHEL, load all XDP programs using the libxdp library. This library enables system-controlled usage of XDP.

**NOTE**

Currently, there are some system configuration limitations for XDP programs. For example, you must disable certain hardware offload features on the receiving interface. Additionally, not all features are available with all drivers that support the native mode.

**AF_XDP**

Using an XDP program that filters and redirects packets to a given AF_XDP socket, you can use one or more sockets from the AF_XDP protocol family to fast copy packets from the kernel to the user space.

**Traffic Control**

The Traffic Control (tc) subsystem offers the following types of eBPF programs:

- **BPF_PROG_TYPE_SCHED_CLS**

- **BPF_PROG_TYPE_SCHED_ACT**

These types enable you to write custom tc classifiers and tc actions in eBPF. Together with the parts of the tc ecosystem, this provides the ability for powerful packet processing and is the core part of several container networking orchestration solutions.

In most cases, only the classifier is used, as with the direct-action flag, the eBPF classifier can execute actions directly from the same eBPF program. The clsact Queueing Discipline (qdisc) has been designed to enable this on the ingress side.

Note that using a flow dissector eBPF program can influence operation of some other qdiscs and tc classifiers, such as flower.

**Socket filter**

Several utilities use or have used the classic Berkeley Packet Filter (cBPF) for filtering packets received on a socket. For example, the tcpdump utility enables the user to specify expressions, which tcpdump then translates into cBPF code.
As an alternative to cBPF, the kernel allows eBPF programs of the
**BPF_PROG_TYPE_SOCKET_FILTER** type for the same purpose.

**Control Groups**
In RHEL, you can use multiple types of eBPF programs that you can attach to a cgroup. The kernel executes these programs when a program in the given cgroup performs an operation. Note that you can use only cgroups version 2.

The following networking-related cgroup eBPF programs are available in RHEL:

- **BPF_PROG_TYPE_SOCK_OPS**: The kernel calls this program on various TCP events. The program can adjust the behavior of the kernel TCP stack, including custom TCP header options, and so on.
- **BPF_PROG_TYPE_CGROUP_SOCK_ADDR**: The kernel calls this program during `connect`, `bind`, `sendto`, `recvmsg`, `getpeername`, and `getsockname` operations. This program allows changing IP addresses and ports. This is useful when you implement socket-based network address translation (NAT) in eBPF.
- **BPF_PROG_TYPE_CGROUP_SOCKOPT**: The kernel calls this program during `setsockopt` and `getsockopt` operations and allows changing the options.
- **BPF_PROG_TYPE_CGROUP_SOCK**: The kernel calls this program during socket creation, socket releasing, and binding to addresses. You can use these programs to allow or deny the operation, or only to inspect socket creation for statistics.
- **BPF_PROG_TYPE_CGROUP_SKB**: This program filters individual packets on ingress and egress, and can accept or reject packets.
- **BPF_PROG_TYPE_CGROUP_SYSCTL**: This program allows filtering of access to system controls (`sysctl`).

**Stream Parser**
A stream parser operates on a group of sockets that are added to a special eBPF map. The eBPF program then processes packets that the kernel receives or sends on those sockets.

The following stream parser eBPF programs are available in RHEL:

- **BPF_PROG_TYPE_SK_SKB**: An eBPF program parses packets received from the socket into individual messages, and instructs the kernel to drop those messages or send them to another socket in the group.
- **BPF_PROG_TYPE_SK_MSG**: This program filters egress messages. An eBPF program parses the packets into individual messages and either approves or rejects them.

**SO_REUSEPORT socket selection**
Using this socket option, you can bind multiple sockets to the same IP address and port. Without eBPF, the kernel selects the receiving socket based on a connection hash. With the **BPF_PROG_TYPE_SK_REUSEPORT** program, the selection of the receiving socket is fully programmable.

**Flow dissector**
When the kernel needs to process packet headers without going through the full protocol decode, they are dissected. For example, this happens in the `tc` subsystem, in multipath routing, in bonding, or when calculating a packet hash. In this situation the kernel parses the packet headers and fills internal
structures with the information from the packet headers. You can replace this internal parsing using the `BPF_PROG_TYPE_FLOW_DISSECTOR` program. Note that you can only dissect TCP and UDP over IPv4 and IPv6 in eBPF in RHEL.

TCP Congestion Control
You can write a custom TCP congestion control algorithm using a group of `BPF_PROG_TYPE_STRUCT_OPS` programs that implement `struct tcp_congestion_oops` callbacks. An algorithm that is implemented this way is available to the system alongside the built-in kernel algorithms.

Routes with encapsulation
You can attach one of the following eBPF program types to routes in the routing table as a tunnel encapsulation attribute:

- `BPF_PROG_TYPE_LWT_IN`
- `BPF_PROG_TYPE_LWT_OUT`
- `BPF_PROG_TYPE_LWT_XMIT`

The functionality of such an eBPF program is limited to specific tunnel configurations and does not allow creating a generic encapsulation or decapsulation solution.

Socket lookup
To bypass limitations of the `bind` system call, use an eBPF program of the `BPF_PROG_TYPE_SK_LOOKUP` type. Such programs can select a listening socket for new incoming TCP connections or an unconnected socket for UDP packets.

51.2. OVERVIEW OF XDP FEATURES BY NETWORK CARDS

The following is an overview of XDP-enabled network cards and the XDP features you can use with them:

[a] Only if an XDP program is loaded on the interface.

[b] Requires a number of XDP TX queues allocated that is larger or equal to the largest CPU index.

Legend:
- Basic: Supports basic return codes: **DROP**, **PASS**, **ABORTED**, and **TX**.
- Redirect: Supports the **REDIRECT** return code.
- Target: Can be a target of a **REDIRECT** return code.
- HW offload: Supports XDP hardware offload.
- Zero-copy: Supports the zero-copy mode for the **AF_XDP** protocol family.
CHAPTER 52. NETWORK TRACING USING THE BPF COMPILER COLLECTION

This section explains what the BPF Compiler Collection (BCC) is, how you install the BCC, as well as how to perform different network tracing operations using the pre-created scripts provided by the `bcc-tools` package. All of these scripts support the `-ebpf` parameter to display the eBPF code the utility uploads to the kernel. You can use the code to learn more about writing eBPF scripts.

52.1. AN INTRODUCTION TO BCC

BPF Compiler Collection (BCC) is a library, which facilitates the creation of the extended Berkeley Packet Filter (eBPF) programs. The main utility of eBPF programs is analyzing OS performance and network performance without experiencing overhead or security issues.

BCC removes the need for users to know deep technical details of eBPF, and provides many out-of-the-box starting points, such as the `bcc-tools` package with pre-created eBPF programs.

**NOTE**

The eBPF programs are triggered on events, such as disk I/O, TCP connections, and process creations. It is unlikely that the programs should cause the kernel to crash, loop or become unresponsive because they run in a safe virtual machine in the kernel.

52.2. INSTALLING THE BCC-TOOLS PACKAGE

This section describes how to install the `bcc-tools` package, which also installs the BPF Compiler Collection (BCC) library as a dependency.

**Procedure**

1. Install `bcc-tools`:

   ```bash
   # dnf install bcc-tools
   ```

   The BCC tools are installed in the `/usr/share/bcc/tools/` directory.

2. Optionally, inspect the tools:

   ```bash
   # ll /usr/share/bcc/tools/
   ...
   -rwxr-xr-x. 1 root root  4198 Dec 14 17:53 dcsnoop
   -rwxr-xr-x. 1 root root  3931 Dec 14 17:53 dcstat
   -rwxr-xr-x. 1 root root 20040 Dec 14 17:53 deadlock_detector
   -rw-r--r--. 1 root root  7105 Dec 14 17:53 deadlock_detector.c
   drwxr-xr-x. 3 root root  8192 Mar 11 10:28 doc
   -rwxr-xr-x. 1 root root  7588 Dec 14 17:53 execsnoop
   -rwxr-xr-x. 1 root root  6373 Dec 14 17:53 ext4dist
   -rwxr-xr-x. 1 root root 10401 Dec 14 17:53 ext4slower
   ...
   ``

   The `doc` directory in the listing above contains documentation for each tool.
52.3. DISPLAYING TCP CONNECTIONS ADDED TO THE KERNEL’S ACCEPT QUEUE

After the kernel receives the ACK packet in a TCP 3-way handshake, the kernel moves the connection from the SYN queue to the accept queue after the connection’s state changes to ESTABLISHED. Therefore, only successful TCP connections are visible in this queue.

The tcpaccept utility uses eBPF features to display all connections the kernel adds to the accept queue. The utility is lightweight because it traces the accept() function of the kernel instead of capturing packets and filtering them. For example, use tcpaccept for general troubleshooting to display new connections the server has accepted.

Procedure

1. Enter the following command to start the tracing the kernel accept queue:

```
# /usr/share/bcc/tools/tcpaccept
```

```
PID COMM IP RADDR RPORT LADDR LPORT
843 sshd 4 192.0.2.17 50598 192.0.2.1 22
1107 ns-slapd 4 198.51.100.6 38772 192.0.2.1 389
1107 ns-slapd 4 203.0.113.85 38774 192.0.2.1 389
... 
```

Each time the kernel accepts a connection, tcpaccept displays the details of the connections.

2. Press Ctrl+C to stop the tracing process.

Additional resources

- tcpaccept(8) man page
- /usr/share/bcc/tools/doc/tcpaccept_example.txt

52.4. TRACING OUTGOING TCP CONNECTION ATTEMPTS

The tcpconnect utility uses eBPF features to trace outgoing TCP connection attempts. The output of the utility also includes connections that failed.

The tcpconnect utility is lightweight because it traces, for example, the connect() function of the kernel instead of capturing packets and filtering them.

Procedure

1. Enter the following command to start the tracing process that displays all outgoing connections:

```
# /usr/share/bcc/tools/tcpconnect
```

```
PID COMM IP SADDR DADDR DPORT
31346 curl 4 192.0.2.1 198.51.100.16 80
31348 telnet 4 192.0.2.1 203.0.113.231 23
31361 isc-worker00 4 192.0.2.1 192.0.2.254 53
... 
```

Each time the kernel processes an outgoing connection, tcpconnect displays the details of the connections.
2. Press Ctrl+C to stop the tracing process.

Additional resources
- tcpconnect(8) man page
- /usr/share/bcc/tools/doc/tcpconnect_example.txt

52.5. MEASURING THE LATENCY OF OUTGOING TCP CONNECTIONS

The TCP connection latency is the time taken to establish a connection. This typically involves the kernel TCP/IP processing and network round trip time, and not the application runtime.

The tcpconnlat utility uses eBPF features to measure the time between a sent SYN packet and the received response packet.

Procedure

1. Start measuring the latency of outgoing connections:

```
# /usr/share/bcc/tools/tcpconnlat
PID    COMM         IP SADDR      DADDR          DPORT LAT(ms)
32151  isc-worker00 4  192.0.2.1  192.0.2.254    53    0.60
32155  ssh          4  192.0.2.1  203.0.113.190  22    26.34
32319  curl         4  192.0.2.1  198.51.100.59  443   188.96
...  
```

Each time the kernel processes an outgoing connection, tcpconnlat displays the details of the connection after the kernel receives the response packet.

2. Press Ctrl+C to stop the tracing process.

Additional resources
- tcpconnlat(8) man page
- /usr/share/bcc/tools/doc/tcpconnlat_example.txt

52.6. DISPLAYING DETAILS ABOUT TCP PACKETS AND SEGMENTS THAT WERE DROPPED BY THE KERNEL

The tcpdrop utility enables administrators to display details about TCP packets and segments that were dropped by the kernel. Use this utility to debug high rates of dropped packets that can cause the remote system to send timer-based retransmits. High rates of dropped packets and segments can impact the performance of a server.

Instead of capturing and filtering packets, which is resource-intensive, the tcpdrop utility uses eBPF features to retrieve the information directly from the kernel.

Procedure

1. Enter the following command to start displaying details about dropped TCP packets and segments:

```
```
Each time the kernel drops TCP packets and segments, `tcpdrop` displays the details of the connection, including the kernel stack trace that led to the dropped package.

2. Press **Ctrl+C** to stop the tracing process.

Additional resources

- `tcpdrop(8)` man page
- `/usr/share/bcc/tools/doc/tcpdrop_example.txt`

### 52.7. TRACING TCP SESSIONS

The `tcplife` utility uses eBPF to trace TCP sessions that open and close, and prints a line of output to summarize each one. Administrators can use `tcplife` to identify connections and the amount of transferred traffic.

The example in this section describes how to display connections to port **22** (SSH) to retrieve the following information:

- The local process ID (PID)
- The local process name
- The local IP address and port number
- The remote IP address and port number
- The amount of received and transmitted traffic in KB.
- The time in milliseconds the connection was active

**Procedure**

1. Enter the following command to start the tracing of connections to the local port **22**:  

```
/usr/share/bcc/tools/tcplife -L 22
```
Each time a connection is closed, `tcplife` displays the details of the connections.

2. Press \texttt{Ctrl+C} to stop the tracing process.

Additional resources

- `tcplife(8)` man page
- `/usr/share/bcc/tools/doc/tcplife_example.txt`

### 52.8. TRACING TCP RETRANSMISSIONS

The `tcpretrans` utility displays details about TCP retransmissions, such as the local and remote IP address and port number, as well as the TCP state at the time of the retransmissions.

The utility uses eBPF features and, therefore, has a very low overhead.

Procedure

1. Use the following command to start displaying TCP retransmission details:

   ```
   # /usr/share/bcc/tools/tcpretrans
   TIME   PID  IP   LADDR:LPORT   T> RADDR:RPORT         STATE
   00:23:02 0   4  192.0.2.1:22  R> 198.51.100.0:26788  ESTABLISHED
   00:23:02 0   4  192.0.2.1:22  R> 198.51.100.0:26788  ESTABLISHED
   00:45:43 0   4  192.0.2.1:22  R> 198.51.100.0:17634  ESTABLISHED
   ...
   ```

   Each time the kernel calls the TCP retransmit function, `tcpretrans` displays the details of the connection.

2. Press \texttt{Ctrl+C} to stop the tracing process.

Additional resources

- `tcpretrans(8)` man page
- `/usr/share/bcc/tools/doc/tcpretrans_example.txt`

### 52.9. DISPLAYING TCP STATE CHANGE INFORMATION

During a TCP session, the TCP state changes. The `tcpstates` utility uses eBPF functions to trace these state changes, and prints details including the duration in each state. For example, use `tcpstates` to identify if connections spend too much time in the initialization state.

Procedure

1. Use the following command to start tracing TCP state changes:

   ```
   # /usr/share/bcc/tools/tcpstates
   SKADDR       C-PID C-COMM    LADDR     LPORT RADDR       RPORT OLDSTATE    ->
   NEWSTATE     MS
   ffff9cd377b3af80 0    swapper/1  0.0.0.0   22    0.0.0.0     0     LISTEN      -> SYN_RECV
   0.000
   ```
Each time a connection changes its state, tcpstates displays a new line with updated connection details.

If multiple connections change their state at the same time, use the socket address in the first column (SKADDR) to determine which entries belong to the same connection.

2. Press Ctrl+C to stop the tracing process.

Additional resources

- tcpstates(8) man page
- /usr/share/bcc/tools/doc/tcpstates_example.txt

52.10. SUMMARIZING AND AGGREGATING TCP TRAFFIC SENT TO SPECIFIC SUBNETS

The tcpsubnet utility summarizes and aggregates IPv4 TCP traffic that the local host sends to subnets and displays the output on a fixed interval. The utility uses eBPF features to collect and summarize the data to reduce the overhead.

By default, tcpsubnet summarizes traffic for the following subnets:

- 127.0.0.1/32
- 10.0.0.0/8
- 172.16.0.0/12
- 192.0.2.0/24/16
- 0.0.0.0/0

Note that the last subnet (0.0.0.0/0) is a catch-all option. The tcpsubnet utility counts all traffic for subnets different than the first four in this catch-all entry.

Follow the procedure to count the traffic for the 192.0.2.0/24 and 198.51.100.0/24 subnets. Traffic to other subnets will be tracked in the 0.0.0.0/0 catch-all subnet entry.

Procedure

1. Start monitoring the amount of traffic send to the 192.0.2.0/24, 198.51.100.0/24, and other subnets:

   # /usr/share/bcc/tools/tcpsubnet 192.0.2.0/24,198.51.100.0/24,0.0.0.0/0
This command displays the traffic in bytes for the specified subnets once per second.

2. Press **Ctrl+C** to stop the tracing process.

Additional resources

- **tcpsubnet(8)** man page
- **/usr/share/bcc/tools/doc/tcpsubnet.txt**

### 52.11. DISPLAYING THE NETWORK THROUGHPUT BY IP ADDRESS AND PORT

The **tcptop** utility displays TCP traffic the host sends and receives in kilobytes. The report automatically refreshes and contains only active TCP connections. The utility uses eBPF features and, therefore, has only a very low overhead.

**Procedure**

1. To monitor the sent and received traffic, enter:

```
# /usr/share/bcc/tools/tcptop
13:46:29 loadavg: 0.10 0.03 0.01 1/215 3875
```

<table>
<thead>
<tr>
<th>PID</th>
<th>COMM</th>
<th>LADDR</th>
<th>RADDR</th>
<th>RX_KB</th>
<th>TX_KB</th>
</tr>
</thead>
<tbody>
<tr>
<td>3853</td>
<td>3853</td>
<td>192.0.2.1:22</td>
<td>192.0.2.165:41838</td>
<td>32</td>
<td>102626</td>
</tr>
<tr>
<td>1285</td>
<td>sshd</td>
<td>192.0.2.1:22</td>
<td>192.0.2.45:39240</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The output of the command includes only active TCP connections. If the local or remote system closes a connection, the connection is no longer visible in the output.

2. Press **Ctrl+C** to stop the tracing process.

Additional resources

- **tcptop(8)** man page
- **/usr/share/bcc/tools/doc/tcptop.txt**

### 52.12. TRACING ESTABLISHED TCP CONNECTIONS

The **tcptracer** utility traces the kernel functions that connect, accept, and close TCP connections. The utility uses eBPF features and, therefore, has a very low overhead.
Procedure

1. Use the following command to start the tracing process:

```
# /usr/share/bcc/tools/tcptracer
Tracing TCP established connections. Ctrl-C to end.
T  PID    COMM        IP SADDR        DADDR       SPORT  DPORT
A  1088   ns-slapd    4  192.0.2.153  192.0.2.1   0      65535
A  845    sshd        4  192.0.2.1    192.0.2.67  22     42302
X  4502   sshd        4  192.0.2.1    192.0.2.67  22     42302
...
```

Each time the kernel connects, accepts, or closes a connection, `tcptracer` displays the details of the connections.

2. Press Ctrl+C to stop the tracing process.

Additional resources

- `tcptracer(8)` man page
- `/usr/share/bcc/tools/doc/tcptracer_example.txt` file

52.13. TRACING IPV4 AND IPV6 LISTEN ATTEMPTS

The `solisten` utility traces all IPv4 and IPv6 listen attempts. It traces the listen attempts including that ultimately fail or the listening program that does not accept the connection. The utility traces function that the kernel calls when a program wants to listen for TCP connections.

Procedure

1. Enter the following command to start the tracing process that displays all listen TCP attempts:

```
# /usr/share/bcc/tools/solisten
PID    COMM           PROTO         BACKLOG     PORT     ADDR
3643   nc             TCPv4         1           4242     0.0.0.0
3659   nc             TCPv6         1           4242     2001:db8:1::1
4221   redis-server   TCPv6         128         6379     ::
4221   redis-server   TCPv4         128         6379     0.0.0.0
....
```

2. Press Ctrl+C to stop the tracing process.

Additional resources

- `solisten` man page
- `/usr/share/bcc/tools/doc/solisten_example.txt` file

52.14. SUMMARIZING THE SERVICE TIME OF SOFT INTERRUPTS

The `softirqs` utility summarizes the time spent servicing soft interrupts (soft IRQs) and shows this time as either totals or histogram distributions. This utility uses the `irq:softirq_enter` and `irq:softirq_exit` kernel tracepoints, which is a stable tracing mechanism.
Procedure

1. Enter the following command to start the tracing **soft irq** event time:

   ```bash
   # /usr/share/bcc/tools/softirqs
   Tracing soft irq event time... Hit Ctrl-C to end.
   ^C
   SOFTIRQ       TOTAL_usecs
   tasklet         166
   block           9152
   net_rx          12829
   rcu             53140
   sched          182360
   timer          306256
   ```

2. Press **Ctrl+C** to stop the tracing process.

Additional resources

- **softirqs** man page
- `/usr/share/bcc/tools/doc/softirqs_example.txt`
- **mpstat(1)** man page

52.15. ADDITIONAL RESOURCES

- `/usr/share/doc/bcc/README.md` file
CHAPTER 53. GETTING STARTED WITH TIPC

Transparent Inter-process Communication (TIPC), which is also known as Cluster Domain Sockets, is an Inter-process Communication (IPC) service for cluster-wide operation.

Applications that are running in a high-available and dynamic cluster environment have special needs. The number of nodes in a cluster can vary, routers can fail, and, due to load balancing considerations, functionality can be moved to different nodes in the cluster. TIPC minimizes the effort by application developers to deal with such situations, and maximizes the chance that they are handled in a correct and optimal way. Additionally, TIPC provides a more efficient and fault-tolerant communication than general protocols, such as TCP.

53.1. THE ARCHITECTURE OF TIPC

TIPC is a layer between applications using TIPC and a packet transport service (bearer), and spans the level of transport, network, and signaling link layers. However, TIPC can use a different transport protocol as bearer, so that, for example, a TCP connection can serve as a bearer for a TIPC signaling link.

TIPC supports the following bearers:

- Ethernet
- InfiniBand
- UDP protocol

TIPC provides a reliable transfer of messages between TIPC ports, that are the endpoints of all TIPC communication.

The following is a diagram of the TIPC architecture:

53.2. LOADING THE TIPC MODULE WHEN THE SYSTEM BOOTS

Before you can use the TIPC protocol, load the tipc kernel module. This section explains how to configure that RHEL loads this module automatically when the system boots.

Procedure

1. Create the /etc/modules-load.d/tipc.conf file with the following content:

   tipc

2. Restart the systemd-modules-load service to load the module without rebooting the system:
# systemctl start systemd-modules-load

### Verification steps

1. Use the following command to verify that RHEL loaded the `tipc` module:

   ```bash
   # lsmod | grep tipc
   tipc 311296 0
   ```

   If the command shows no entry for the `tipc` module, RHEL failed to load it.

### Additional resources

- `modules-load.d(5)` man page

## 53.3. CREATING A TIPC NETWORK

This section describes how to create a TIPC network.

**IMPORTANT**

The commands configure the TIPC network only temporarily. To permanently configure TIPC on a node, use the commands of this procedure in a script, and configure RHEL to execute that script when the system boots.

### Prerequisites

- The `tipc` module has been loaded. For details, see [Loading the tipc module when the system boots](#).

### Procedure

1. Optional: Set a unique node identity, such as a UUID or the node’s host name:

   ```bash
   # tipc node set identity host_name
   ```

   The identity can be any unique string consisting of a maximum 16 letters and numbers.

   You cannot set or change an identity after this step.

2. Add a bearer. For example, to use Ethernet as media and `enp0s1` device as physical bearer device, enter:

   ```bash
   # tipc bearer enable media eth device enp0s1
   ```

3. Optional: For redundancy and better performance, attach further bearers using the command from the previous step. You can configure up to three bearers, but not more than two on the same media.

4. Repeat all previous steps on each node that should join the TIPC network.

### Verification steps
1. Display the link status for cluster members:

```
# tipc link list
broadcast-link: up
5254006b74be:enp1s0-525400df55d1:enp1s0: up
```

This output indicates that the link between bearer `enp1s0` on node `5254006b74be` and bearer `enp1s0` on node `525400df55d1` is up.

2. Display the TIPC publishing table:

```
# tipc nametable show

<table>
<thead>
<tr>
<th>Type</th>
<th>Lower</th>
<th>Upper</th>
<th>Scope</th>
<th>Port</th>
<th>Node</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1795222054</td>
<td>1795222054</td>
<td>cluster</td>
<td>0</td>
<td>5254006b74be</td>
</tr>
<tr>
<td>0</td>
<td>3741353223</td>
<td>3741353223</td>
<td>cluster</td>
<td>0</td>
<td>525400df55d1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>node</td>
<td>2399405586</td>
<td>5254006b74be</td>
</tr>
<tr>
<td>2</td>
<td>3741353223</td>
<td>3741353223</td>
<td>node</td>
<td>0</td>
<td>5254006b74be</td>
</tr>
</tbody>
</table>
```

- The two entries with service type 0 indicate that two nodes are members of this cluster.
- The entry with service type 1 represents the built-in topology service tracking service.
- The entry with service type 2 displays the link as seen from the issuing node. The range limit 3741353223 represents peer endpoint’s address (a unique 32-bit hash value based on the node identity) in decimal format.

Additional resources

- `tipc-bearer(8)` man page
- `tipc-namespace(8)` man page

53.4. ADDITIONAL RESOURCES

- Red Hat recommends to use other bearer level protocols to encrypt the communication between nodes based on the transport media. For example:
  - MACSec: See Using MACsec to encrypt layer 2 traffic
  - IPsec: See Configuring a VPN with IPsec

- For examples of how to use TIPC, clone the upstream GIT repository using the `git clone` command. This repository contains the source code of demos and test programs that use TIPC features. Note that this repository is not provided by Red Hat.

CHAPTER 54. AUTOMATICALLY CONFIGURING NETWORK INTERFACES IN PUBLIC CLOUDS USING NM-CLOUD-SETUP

Normally, a virtual machine (VM) has only one interface that is configurable by DHCP. However, some VMs might have multiple network interfaces, IP addresses, and IP subnets on one interface that is not configurable by DHCP. Also, administrators can reconfigure the network while the machine is running. The `nm-cloud-setup` utility automatically retrieves configuration information from the metadata server of the cloud service provider and updates the network configurations of VM in public clouds.

54.1. CONFIGURING AND PRE-DEPLOYING NM-CLOUD-SETUP

To enable and configure network interfaces in public clouds, run `nm-cloud-setup` as a timer and service. The following procedure describes how to use `nm-cloud-setup` for Amazon EC2.

NOTE

On Red Hat Enterprise Linux On Demand and AWS golden images, `nm-cloud-setup` is already enabled and no action is required.

Prerequisite

- A network connection exists.
- The connection uses DHCP.
  By default, NetworkManager creates a connection profile which uses DHCP. If no profile was created because you set the `no-auto-default` parameter in `/etc/NetworkManager/NetworkManager.conf`, create this initial connection manually.

Procedure

1. Install the `nm-cloud-setup` package:
   ```bash
   # dnf install NetworkManager-cloud-setup
   ```

2. Create and run the snap-in file for the `nm-cloud-setup` service:
   a. Use the following command to start editing the snap-in file:
      ```bash
      # systemctl edit nm-cloud-setup.service
      ```
      It is important to either start the service explicitly or reboot the system to make configuration settings effective.
   b. Use the `systemd` snap-in file to configure the cloud provider in `nm-cloud-setup`. For example, to use Amazon EC2, enter:
      ```ini
      [Service]
      Environment=NM_CLOUD_SETUP_EC2=yes
      ```

You can set the following environment variables to enable the cloud provide you use:

- `NM_CLOUD_SETUP_AZURE` for Microsoft Azure
- **NM_CLOUD_SETUP_EC2** for Amazon EC2 (AWS)
- **NM_CLOUD_SETUP_GCP** for Google Cloud Platform (GCP)
- **NM_CLOUD_SETUP_ALIYUN** for Alibaba Cloud (Aliyun)

c. Save the file and quit the editor.

3. Reload the **systemd** configuration:

   ```
   # systemctl daemon-reload
   ```

4. Enable and start the **nm-cloud-setup** service:

   ```
   # systemctl enable --now nm-cloud-setup.service
   ```

5. Enable and start the **nm-cloud-setup** timer:

   ```
   # systemctl enable --now nm-cloud-setup.timer
   ```

Additional resources

- **nm-cloud-setup(8)** man page
- Configuring an Ethernet connection
