Red Hat Enterprise Linux 9.0

Monitoring and managing system status and performance

Optimizing system throughput, latency, and power consumption
Red Hat Enterprise Linux 9.0 Monitoring and managing system status and performance

Optimizing system throughput, latency, and power consumption
Abstract

This documentation collection provides instructions on how to monitor and optimize the throughput, latency, and power consumption of Red Hat Enterprise Linux 9 in different scenarios.
# Table of Contents

MAKING OPEN SOURCE MORE INCLUSIVE ................................................................. 9

PROVIDING FEEDBACK ON RED HAT DOCUMENTATION ........................................ 10

CHAPTER 1. GETTING STARTED WITH TUNED ......................................................... 11
  1.1. THE PURPOSE OF TUNED 11
  1.2. TUNED PROFILES 11
    Syntax of profile configuration 11
  1.3. THE DEFAULT TUNED PROFILE 12
  1.4. MERGED TUNED PROFILES 12
  1.5. THE LOCATION OF TUNED PROFILES 13
  1.6. TUNED PROFILES DISTRIBUTED WITH RHEL 13
  1.7. TUNED CPU-PARTITIONING PROFILE 15
  1.8. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING 16
  1.9. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE 17
  1.10. REAL-TIME TUNED PROFILES DISTRIBUTED WITH RHEL 18
  1.11. STATIC AND DYNAMIC TUNING IN TUNED 18
  1.12. TUNED NO-DAEMON MODE 19
  1.13. INSTALLING AND ENABLING TUNED 19
  1.14. LISTING AVAILABLE TUNED PROFILES 20
  1.15. SETTING A TUNED PROFILE 21
  1.16. DISABLING TUNED 22

CHAPTER 2. CUSTOMIZING TUNED PROFILES ....................................................... 23
  2.1. TUNED PROFILES 23
    Syntax of profile configuration 23
  2.2. THE DEFAULT TUNED PROFILE 23
  2.3. MERGED TUNED PROFILES 24
  2.4. THE LOCATION OF TUNED PROFILES 24
  2.5. INHERITANCE BETWEEN TUNED PROFILES 25
  2.6. STATIC AND DYNAMIC TUNING IN TUNED 25
  2.7. TUNED PLUG-INS 26
    Syntax for plug-ins in TuneD profiles 27
    Short plug-in syntax 27
    Conflicting plug-in definitions in a profile 28
  2.8. AVAILABLE TUNED PLUG-INS 28
    Monitoring plug-ins 28
    Tuning plug-ins 28
  2.9. VARIABLES IN TUNED PROFILES 32
  2.10. BUILT-IN FUNCTIONS IN TUNED PROFILES 33
  2.11. BUILT-IN FUNCTIONS AVAILABLE IN TUNED PROFILES 33
  2.12. CREATING NEW TUNED PROFILES 34
  2.13. MODIFYING EXISTING TUNED PROFILES 35
  2.14. SETTING THE DISK SCHEDULER USING TUNED 36

CHAPTER 3. REVIEWING A SYSTEM USING TUNA INTERFACE .................................. 39
  3.1. INSTALLING TUNA TOOL 39
  3.2. VIEWING THE SYSTEM STATUS USING TUNA TOOL 39
  3.3. TUNING CPUs USING TUNA TOOL 40
  3.4. TUNING IRQS USING TUNA TOOL 42

CHAPTER 4. MONITORING PERFORMANCE USING RHEL SYSTEM ROLES ........................ 44
## 4.1. INTRODUCTION TO RHEL SYSTEM ROLES

## 4.2. RHEL SYSTEM ROLES TERMINOLOGY

## 4.3. INSTALLING RHEL SYSTEM ROLES IN YOUR SYSTEM

## 4.4. APPLYING A ROLE

## 4.5. INTRODUCTION TO THE METRICS SYSTEM ROLE

## 4.6. USING THE METRICS SYSTEM ROLE TO MONITOR YOUR LOCAL SYSTEM WITH VISUALIZATION

## 4.7. USING THE METRICS SYSTEM ROLE TO SETUP A FLEET OF INDIVIDUAL SYSTEMS TO MONITOR THEMSELVES

## 4.8. USING THE METRICS SYSTEM ROLE TO MONITOR A FLEET OF MACHINES CENTRALLY VIA YOUR LOCAL MACHINE

## 4.9. SETTING UP AUTHENTICATION WHILE MONITORING A SYSTEM USING THE METRICS SYSTEM ROLE

## 4.10. USING THE METRICS SYSTEM ROLE TO CONFIGURE AND ENABLE METRICS COLLECTION FOR SQL SERVER

## CHAPTER 5. SETTING UP PCP

### 5.1. OVERVIEW OF PCP

### 5.2. INSTALLING AND ENABLING PCP

### 5.3. DEPLOYING A MINIMAL PCP SETUP

### 5.4. SYSTEM SERVICES DISTRIBUTED WITH PCP

### 5.5. TOOLS DISTRIBUTED WITH PCP

### 5.6. PCP DEPLOYMENT ARCHITECTURES

### 5.7. RECOMMENDED DEPLOYMENT ARCHITECTURE

### 5.8. SIZING FACTORS

### 5.9. CONFIGURATION OPTIONS FOR PCP SCALING

### 5.10. EXAMPLE: ANALYZING THE CENTRALIZED LOGGING DEPLOYMENT

### 5.11. EXAMPLE: ANALYZING THE FEDERATED SETUP DEPLOYMENT

### 5.12. TROUBLESHOOTING HIGH MEMORY USAGE

## CHAPTER 6. LOGGING PERFORMANCE DATA WITH PMLOGGER

### 6.1. MODIFYING THE PMLOGGER CONFIGURATION FILE WITH PMLOGCONF

### 6.2. EDITING THE PMLOGGER CONFIGURATION FILE MANUALLY

### 6.3. ENABLING THE PMLOGGER SERVICE

### 6.4. SETTING UP A CLIENT SYSTEM FOR METRICS COLLECTION

### 6.5. SETTING UP A CENTRAL SERVER TO COLLECT DATA

### 6.6. REPLAYING THE PCP LOG ARCHIVES WITH PMREP

## CHAPTER 7. MONITORING PERFORMANCE WITH PERFORMANCE CO-PILOT

### 7.1. MONITORING POSTFIX WITH PMDA-POSTFIX

### 7.2. VISUALLY TRACING PCP LOG ARCHIVES WITH THE PCP CHARTS APPLICATION

### 7.3. COLLECTING DATA FROM SQL SERVER USING PCP

### 7.4. GENERATING PCP ARCHIVES FROM SADC ARCHIVES

## CHAPTER 8. PERFORMANCE ANALYSIS OF XFS WITH PCP

### 8.1. INSTALLING XFS PMDA MANUALLY

### 8.2. EXAMINING XFS PERFORMANCE METRICS WITH PMINFO

### 8.3. Resetsetting XFS PERFORMANCE METRICS WITH PMSTORE

### 8.4. PCP METRIC GROUPS FOR XFS

### 8.5. PER-DEVICE PCP METRIC GROUPS FOR XFS

## CHAPTER 9. SETTING UP GRAPHICAL REPRESENTATION OF PCP METRICS

### 9.1. SETTING UP PCP WITH PCP-ZEROCONF

### 9.2. SETTING UP A GRAFANA-SERVER

### 9.3. ACCESSING THE GRAFANA WEB UI

### 9.4. CONFIGURING PCP REDIS

14.6. OPTIMIZING POWER CONSUMPTION 143
  14.6.1. Optimizing power consumption using the powertop service 143
  14.6.2. The powertop2tuned utility 143
  14.6.3. Optimizing power consumption using the powertop2tuned utility 143
  14.6.4. Comparison of powertop.service and powertop2tuned 144

CHAPTER 15. GETTING STARTED WITH PERF .................................................. 145
15.1. INTRODUCTION TO PERF 145
15.2. INSTALLING PERF 145
15.3. COMMON PERF COMMANDS 145

CHAPTER 16. PROFILING CPU USAGE IN REAL TIME WITH PERF TOP .............. 147
16.1. THE PURPOSE OF PERF TOP 147
16.2. PROFILING CPU USAGE WITH PERF TOP 147
16.3. INTERPRETATION OF PERF TOP OUTPUT 148
16.4. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES 148
16.5. ENABLING DEBUG AND SOURCE REPOSITORIES 148
16.6. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB 149

CHAPTER 17. COUNTING EVENTS DURING PROCESS EXECUTION WITH PERF STAT .................................. 151
17.1. THE PURPOSE OF PERF STAT 151
17.2. COUNTING EVENTS WITH PERF STAT 151
17.3. INTERPRETATION OF PERF STAT OUTPUT 152
17.4. ATTACHING PERF STAT TO A RUNNING PROCESS 153

CHAPTER 18. RECORDING AND ANALYZING PERFORMANCE PROFILES WITH PERF .................................. 154
18.1. THE PURPOSE OF PERF RECORD 154
18.2. RECORDING A PERFORMANCE PROFILE WITHOUT ROOT ACCESS 154
18.3. RECORDING A PERFORMANCE PROFILE WITH ROOT ACCESS 154
18.4. RECORDING A PERFORMANCE PROFILE IN PER-CPU MODE 155
18.5. CAPTURING CALL GRAPH DATA WITH PERF RECORD 155
18.6. ANALYZING PERF.DATA WITH PERF REPORT 156
18.7. INTERPRETATION OF PERF REPORT OUTPUT 157
18.8. GENERATING A PERF.DATA FILE THAT IS READABLE ON A DIFFERENT DEVICE 157
18.9. ANALYZING A PERF.DATA FILE THAT WAS CREATED ON A DIFFERENT DEVICE 158
18.10. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES 159
18.11. ENABLING DEBUG AND SOURCE REPOSITORIES 159
18.12. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB 160
28.4. OVERVIEW OF AN INTERRUPT REQUEST
  28.4.1. Balancing interrupts manually
  28.4.2. Setting the smp_affinity mask

CHAPTER 29. TUNING SCHEDULING POLICY
  29.1. CATEGORIES OF SCHEDULING POLICIES
  29.2. STATIC PRIORITY SCHEDULING WITH SCHED_FIFO
  29.3. ROUND ROBIN PRIORITY SCHEDULING WITH SCHED_RR
  29.4. NORMAL SCHEDULING WITH SCHED_OTHER
  29.5. SETTING SCHEDULER POLICIES
  29.6. POLICY OPTIONS FOR THE CRHT COMMAND
  29.7. CHANGING THE PRIORITY OF SERVICES DURING THE BOOT PROCESS
  29.8. PRIORITY MAP
  29.9. TUNED CPU-PARTITIONING PROFILE
  29.10. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING
  29.11. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE

CHAPTER 30. FACTORS AFFECTING I/O AND FILE SYSTEM PERFORMANCE
  30.1. TOOLS FOR MONITORING AND DIAGNOSING I/O AND FILE SYSTEM ISSUES
  30.2. AVAILABLE TUNING OPTIONS FOR FORMATTING A FILE SYSTEM
  30.3. AVAILABLE TUNING OPTIONS FOR MOUNTING A FILE SYSTEM
  30.4. TYPES OF DISCARDING UNUSED BLOCKS
  30.5. SOLID-STATE DISKS TUNING CONSIDERATIONS
  30.6. GENERIC BLOCK DEVICE TUNING PARAMETERS

CHAPTER 31. USING SYSTEMD TO MANAGE RESOURCES USED BY APPLICATIONS
  31.1. ALLOCATING SYSTEM RESOURCES USING SYSTEMD
  31.2. ROLE OF SYSTEMD IN RESOURCE MANAGEMENT
  31.3. OVERVIEW OF SYSTEMD HIERARCHY FOR CGROUPS
  31.4. LISTING SYSTEMD UNITS
  31.5. VIEWING SYSTEMD CONTROL GROUP HIERARCHY
  31.6. VIEWING CGROUPS OF PROCESSES
  31.7. MONITORING RESOURCE CONSUMPTION
  31.8. USING SYSTEMD UNIT FILES TO SET LIMITS FOR APPLICATIONS
  31.9. USING SYSTEMCTL COMMAND TO SET LIMITS TO APPLICATIONS
  31.10. SETTING GLOBAL DEFAULT CPU AFFINITY THROUGH MANAGER CONFIGURATION
  31.11. CONFIGURING NUMA POLICIES USING SYSTEMD
  31.12. NUMA POLICY CONFIGURATION OPTIONS FOR SYSTEMD
  31.13. CREATING TRANSIENT CGROUPS USING SYSTEMD-RUN COMMAND
  31.14. REMOVING TRANSIENT CONTROL GROUPS

CHAPTER 32. UNDERSTANDING CGROUPS
  32.1. UNDERSTANDING CONTROL GROUPS
  32.2. WHAT ARE KERNEL RESOURCE CONTROLLERS
  32.3. WHAT ARE NAMESPACES

CHAPTER 33. IMPROVING SYSTEM PERFORMANCE WITH ZSWAP
  33.1. WHAT IS ZSWAP
  33.2. ENABLING ZSWAP AT RUNTIME
  33.3. ENABLING ZSWAP PERMANENTLY

CHAPTER 34. USING CGROUPFS TO MANUALLY MANAGE CGROUPS
  34.1. CREATING CGROUPS AND ENABLING CONTROLLERS IN CGROUPS-V2 FILE SYSTEM
  34.2. CONTROLLING DISTRIBUTION OF CPU TIME FOR APPLICATIONS BY ADJUSTING CPU WEIGHT
  34.3. MOUNTING CGROUPS-V1
CHAPTER 35. ANALYZING SYSTEM PERFORMANCE WITH BPF COMPILER COLLECTION

35.1. AN INTRODUCTION TO BCC
35.2. INSTALLING THE BCC-TOOLS PACKAGE
35.3. USING SELECTED BCC-TOOLS FOR PERFORMANCE ANALYSES
   Using execsnoop to examine the system processes
   Using opensnoop to track what files a command opens
   Using biotop to examine the I/O operations on the disk
   Using xfsslower to expose unexpectedly slow file system operations

CHAPTER 36. CONFIGURING HUGE PAGES

36.1. AVAILABLE HUGE PAGE FEATURES
36.2. PARAMETERS FOR RESERVING HUGETLB PAGES AT BOOT TIME
36.3. CONFIGURING HUGETLB AT BOOT TIME
36.4. PARAMETERS FOR RESERVING HUGETLB PAGES AT RUN TIME
36.5. CONFIGURING HUGETLB AT RUN TIME
36.6. ENABLING TRANSPARENT HUGEPAGES
36.7. DISABLING TRANSPARENT HUGEPAGES
36.8. IMPACT OF PAGE SIZE ON TRANSLATION LOOKASIDE BUFFER SIZE

CHAPTER 37. GETTING STARTED WITH SYSTEMTAP

37.1. THE PURPOSE OF SYSTEMTAP
37.2. INSTALLING SYSTEMTAP
37.3. PRIVILEGES TO RUN SYSTEMTAP
37.4. RUNNING SYSTEMTAP SCRIPTS

CHAPTER 38. CROSS-INSTRUMENTATION OF SYSTEMTAP

38.1. SYSTEMTAP CROSS-INSTRUMENTATION
38.2. INITIALIZING CROSS-INSTRUMENTATION OF SYSTEMTAP

CHAPTER 39. MONITORING NETWORK ACTIVITY WITH SYSTEMTAP

39.1. PROFILING NETWORK ACTIVITY WITH SYSTEMTAP
39.2. TRACING FUNCTIONS CALLED IN NETWORK SOCKET CODE WITH SYSTEMTAP
39.3. MONITORING NETWORK PACKET DROPS WITH SYSTEMTAP

CHAPTER 40. PROFILING KERNEL ACTIVITY WITH SYSTEMTAP

40.1. COUNTING FUNCTION CALLS WITH SYSTEMTAP
40.2. TRACING FUNCTION CALLS WITH SYSTEMTAP
40.3. DETERMINING TIME SPENT IN KERNEL AND USER SPACE WITH SYSTEMTAP
40.4. MONITORING POLLING APPLICATIONS WITH SYSTEMTAP
40.5. TRACKING MOST FREQUENTLY USED SYSTEM CALLS WITH SYSTEMTAP
40.6. TRACKING SYSTEM CALL VOLUME PER PROCESS WITH SYSTEMTAP

CHAPTER 41. MONITORING DISK AND I/O ACTIVITY WITH SYSTEMTAP

41.1. SUMMARIZING DISK READ/WRITE TRAFFIC WITH SYSTEMTAP
41.2. TRACKING I/O TIME FOR EACH FILE READ OR WRITE WITH SYSTEMTAP
41.3. TRACKING CUMULATIVE I/O WITH SYSTEMTAP
41.4. MONITORING I/O ACTIVITY ON A SPECIFIC DEVICE WITH SYSTEMTAP
41.5. MONITORING READS AND WRITES TO A FILE WITH SYSTEMTAP
Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your feedback on our documentation. Let us know how we can improve it.

Submitting comments on specific passages

1. View the documentation in the Multi-page HTML format and ensure that you see the Feedback button in the upper right corner after the page fully loads.
2. Use your cursor to highlight the part of the text that you want to comment on.
3. Click the Add Feedback button that appears near the highlighted text.
4. Add your feedback and click Submit.

Submitting feedback through Bugzilla (account required)

1. Log in to the Bugzilla website.
2. Select the correct version from the Version menu.
3. Enter a descriptive title in the Summary field.
4. Enter your suggestion for improvement in the Description field. Include links to the relevant parts of the documentation.
5. Click Submit Bug.
CHAPTER 1. GETTING STARTED WITH TUNED

As a system administrator, you can use the TuneD application to optimize the performance profile of your system for a variety of use cases.

1.1. THE PURPOSE OF TUNED

TuneD is a service that monitors your system and optimizes the performance under certain workloads. The core of TuneD are profiles, which tune your system for different use cases.

TuneD is distributed with a number of predefined profiles for use cases such as:

- High throughput
- Low latency
- Saving power

It is possible to modify the rules defined for each profile and customize how to tune a particular device. When you switch to another profile or deactivate TuneD, all changes made to the system settings by the previous profile revert back to their original state.

You can also configure TuneD to react to changes in device usage and adjusts settings to improve performance of active devices and reduce power consumption of inactive devices.

1.2. TUNED PROFILES

A detailed analysis of a system can be very time-consuming. TuneD provides a number of predefined profiles for typical use cases. You can also create, modify, and delete profiles.

The profiles provided with TuneD are divided into the following categories:

- Power-saving profiles
- Performance-boosting profiles

The performance-boosting profiles include profiles that focus on the following aspects:

- Low latency for storage and network
- High throughput for storage and network
- Virtual machine performance
- Virtualization host performance

Syntax of profile configuration

The tuned.conf file can contain one [main] section and other sections for configuring plug-in instances. However, all sections are optional.

Lines starting with the hash sign (#) are comments.

Additional resources

- tuned.conf(5) man page.
1.3. THE DEFAULT TUNED PROFILE

During the installation, the best profile for your system is selected automatically. Currently, the default profile is selected according to the following customizable rules:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Default profile</th>
<th>Goal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute nodes</td>
<td>throughput-performance</td>
<td>The best throughput performance</td>
</tr>
<tr>
<td>Virtual machines</td>
<td>virtual-guest</td>
<td>The best performance. If you are not interested in the best performance, you can change it to the balanced or powersave profile.</td>
</tr>
<tr>
<td>Other cases</td>
<td>balanced</td>
<td>Balanced performance and power consumption</td>
</tr>
</tbody>
</table>

Additional resources

- tuned.conf(5) man page.

1.4. MERGED TUNED PROFILES

As an experimental feature, it is possible to select more profiles at once. TuneD will try to merge them during the load.

If there are conflicts, the settings from the last specified profile takes precedence.

Example 1.1. Low power consumption in a virtual guest

The following example optimizes the system to run in a virtual machine for the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

```
# tuned-adm profile virtual-guest powersave
```

WARNING

Merging is done automatically without checking whether the resulting combination of parameters makes sense. Consequently, the feature might tune some parameters the opposite way, which might be counterproductive: for example, setting the disk for high throughput by using the throughput-performance profile and concurrently setting the disk spindown to the low value by the spindown-disk profile.

Additional resources
1.5. THE LOCATION OF TUNED PROFILES

Tuned stores profiles in the following directories:

`/usr/lib/tuned/`

Distribution-specific profiles are stored in the directory. Each profile has its own directory. The profile consists of the main configuration file called `tuned.conf`, and optionally other files, for example helper scripts.

`/etc/tuned/`

If you need to customize a profile, copy the profile directory into the directory, which is used for custom profiles. If there are two profiles of the same name, the custom profile located in `/etc/tuned/` is used.

Additional resources

- `tuned.conf(5)` man page.

1.6. TUNED PROFILES DISTRIBUTED WITH RHEL

The following is a list of profiles that are installed with Tuned on Red Hat Enterprise Linux.

**NOTE**

There might be more product-specific or third-party Tuned profiles available. Such profiles are usually provided by separate RPM packages.

**balanced**

The default power-saving profile. It is intended to be a compromise between performance and power consumption. It uses auto-scaling and auto-tuning whenever possible. The only drawback is the increased latency. In the current Tuned release, it enables the CPU, disk, audio, and video plugins, and activates the `conservative` CPU governor. The `raadeon_powersave` option uses the `dpm-balanced` value if it is supported, otherwise it is set to `auto`. It changes the `energy_performance_preference` attribute to the `normal` energy setting. It also changes the `scaling_governor` policy attribute to either the `conservative` or `powersave` CPU governor.

**powersave**

A profile for maximum power saving performance. It can throttle the performance in order to minimize the actual power consumption. In the current Tuned release it enables USB autosuspend, WiFi power saving, and Aggressive Link Power Management (ALPM) power savings for SATA host adapters. It also schedules multi-core power savings for systems with a low wakeup rate and activates the `ondemand` governor. It enables AC97 audio power saving or, depending on your system, HDA-Intel power savings with a 10 seconds timeout. If your system contains a supported Radeon graphics card with enabled KMS, the profile configures it to automatic power saving. On ASUS Eee PCs, a dynamic Super Hybrid Engine is enabled. It changes the `energy_performance_preference` attribute to the `powersave` or `power` energy setting. It also changes the `scaling_governor` policy attribute to either the `ondemand` or `powersave` CPU governor.
NOTE

In certain cases, the **balanced** profile is more efficient compared to the **powersave** profile.

Consider there is a defined amount of work that needs to be done, for example a video file that needs to be transcoded. Your machine might consume less energy if the transcoding is done on the full power, because the task is finished quickly, the machine starts to idle, and it can automatically step-down to very efficient power save modes. On the other hand, if you transcode the file with a throttled machine, the machine consumes less power during the transcoding, but the process takes longer and the overall consumed energy can be higher.

That is why the **balanced** profile can be generally a better option.

**throughput-performance**

A server profile optimized for high throughput. It disables power savings mechanisms and enables **sysctl** settings that improve the throughput performance of the disk and network IO. CPU governor is set to **performance**.

It changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

**accelerator-performance**

The **accelerator-performance** profile contains the same tuning as the **throughput-performance** profile. Additionally, it locks the CPU to low C states so that the latency is less than 100us. This improves the performance of certain accelerators, such as GPUs.

**latency-performance**

A server profile optimized for low latency. It disables power savings mechanisms and enables **sysctl** settings that improve latency. CPU governor is set to **performance** and the CPU is locked to the low C states (by PM QoS).

It changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

**network-latency**

A profile for low latency network tuning. It is based on the **latency-performance** profile. It additionally disables transparent huge pages and NUMA balancing, and tunes several other network-related **sysctl** parameters.

It inherits the **latency-performance** profile which changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

**hpc-compute**

A profile optimized for high-performance computing. It is based on the **latency-performance** profile.

**network-throughput**

A profile for throughput network tuning. It is based on the **throughput-performance** profile. It additionally increases kernel network buffers.

It inherits either the **latency-performance** or **throughput-performance** profile, and changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

**virtual-guest**

A profile designed for Red Hat Enterprise Linux 9 virtual machines and VMWare guests based on the Red Hat Enterprise Linux 9.0 Monitoring and managing system status and performance
A profile designed for Red Hat Enterprise Linux 9 virtual machines and VMWare guests based on the `throughput-performance` profile that, among other tasks, decreases virtual memory swappiness and increases disk readahead values. It does not disable disk barriers.

It inherits the `throughput-performance` profile and changes the `energy_performance_preference` and `scaling_governor` attribute to the `performance` profile.

**virtual-host**

A profile designed for virtual hosts based on the `throughput-performance` profile that, among other tasks, decreases virtual memory swappiness, increases disk readahead values, and enables a more aggressive value of dirty pages writeback.

It inherits the `throughput-performance` profile and changes the `energy_performance_preference` and `scaling_governor` attribute to the `performance` profile.

**oracle**

A profile optimized for Oracle databases loads based on `throughput-performance` profile. It additionally disables transparent huge pages and modifies other performance-related kernel parameters. This profile is provided by the `tuned-profiles-oracle` package.

**desktop**

A profile optimized for desktops, based on the `balanced` profile. It additionally enables scheduler autogroups for better response of interactive applications.

**optimize-serial-console**

A profile that tunes down I/O activity to the serial console by reducing the printk value. This should make the serial console more responsive. This profile is intended to be used as an overlay on other profiles. For example:

```bash
# tuned-adm profile throughput-performance optimize-serial-console
```

**mssql**

A profile provided for Microsoft SQL Server. It is based on the `throughput-performance` profile.

**intel-sst**

A profile optimized for systems with user-defined Intel Speed Select Technology configurations. This profile is intended to be used as an overlay on other profiles. For example:

```bash
# tuned-adm profile cpu-partitioning intel-sst
```

### 1.7. TUNED CPU-PARTITIONING PROFILE

For tuning Red Hat Enterprise Linux 9 for latency-sensitive workloads, Red Hat recommends to use the `cpu-partitioning` TuneD profile.

Prior to Red Hat Enterprise Linux 9, the low-latency Red Hat documentation described the numerous low-level steps needed to achieve low-latency tuning. In Red Hat Enterprise Linux 9, you can perform low-latency tuning more efficiently by using the `cpu-partitioning` TuneD profile. This profile is easily customizable according to the requirements for individual low-latency applications.

The following figure is an example to demonstrate how to use the `cpu-partitioning` profile. This example uses the CPU and node layout.
You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the following configuration options:

**Isolated CPUs with load balancing**

In the cpu-partitioning figure, the blocks numbered from 4 to 23, are the default isolated CPUs. The kernel scheduler’s process load balancing is enabled on these CPUs. It is designed for low-latency processes with multiple threads that need the kernel scheduler load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the `isolated_cores=cpu-list` option, which lists CPUs to isolate that will use the kernel scheduler load balancing.

The list of isolated CPUs is comma-separated or you can specify a range using a dash, such as `3-5`. This option is mandatory. Any CPU missing from this list is automatically considered a housekeeping CPU.

**Isolated CPUs without load balancing**

In the cpu-partitioning figure, the blocks numbered 2 and 3, are the isolated CPUs that do not provide any additional kernel scheduler process load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the `no_balance_cores=cpu-list` option, which lists CPUs to isolate that will not use the kernel scheduler load balancing.

Specifying the `no_balance_cores` option is optional, however any CPUs in this list must be a subset of the CPUs listed in the `isolated_cores` list.

Application threads using these CPUs need to be pinned individually to each CPU.

**Housekeeping CPUs**

Any CPU not isolated in the `cpu-partitioning-variables.conf` file is automatically considered a housekeeping CPU. On the housekeeping CPUs, all services, daemons, user processes, movable kernel threads, interrupt handlers, and kernel timers are permitted to execute.

**Additional resources**

- `tuned-profiles-cpu-partitioning(7)` man page

1.8. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING
This procedure describes how to tune a system for low-latency using the TuneD's `cpu-partitioning` profile. It uses the example of a low-latency application that can use `cpu-partitioning` and the CPU layout as mentioned in the `cpu-partitioning` figure.

The application in this case uses:

- One dedicated reader thread that reads data from the network will be pinned to CPU 2.
- A large number of threads that process this network data will be pinned to CPUs 4-23.
- A dedicated writer thread that writes the processed data to the network will be pinned to CPU 3.

Prerequisites

- You have installed the `cpu-partitioning` TuneD profile by using the `dnf install tuned-profiles-cpu-partitioning` command as root.

Procedure

1. Edit `/etc/tuned/cpu-partitioning-variables.conf` file and add the following information:

```
# Isolated CPUs with the kernel's scheduler load balancing:
isolated_cores=2-23
# Isolated CPUs without the kernel's scheduler load balancing:
no_balance_cores=2,3
```

2. Set the `cpu-partitioning` TuneD profile:

```
# tuned-adm profile cpu-partitioning
```

3. Reboot

After rebooting, the system is tuned for low-latency, according to the isolation in the cpu-partitioning figure. The application can use `taskset` to pin the reader and writer threads to CPUs 2 and 3, and the remaining application threads on CPUs 4-23.

Additional resources

- `tuned-profiles-cpu-partitioning(7)` man page

1.9. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE

You can extend the TuneD profile to make additional tuning changes.

For example, the `cpu-partitioning` profile sets the CPUs to use `cstate=1`. In order to use the `cpu-partitioning` profile but to additionally change the CPU cstate from cstate1 to cstate0, the following procedure describes a new TuneD profile named `my_profile`, which inherits the `cpu-partitioning` profile and then sets C state-0.

Procedure

1. Create the `/etc/tuned/my_profile` directory:

```
# mkdir /etc/tuned/my_profile
```
2. Create a tuned.conf file in this directory, and add the following content:

```
# vi /etc/tuned/my_profile/tuned.conf
[main]
summary=Customized tuning on top of cpu-partitioning
include=cpu-partitioning
[cpu]
force_latency=cstate.id:0|1
```

3. Use the new profile:

```
# tuned-adm profile my_profile
```

NOTE

In the shared example, a reboot is not required. However, if the changes in the my_profile profile require a reboot to take effect, then reboot your machine.

Additional resources

- tuned-profiles-cpu-partitioning(7) man page

1.10. REAL-TIME TUNED PROFILES DISTRIBUTED WITH RHEL

Real-time profiles are intended for systems running the real-time kernel. Without a special kernel build, they do not configure the system to be real-time. On RHEL, the profiles are available from additional repositories.

The following real-time profiles are available:

**realtime**

Use on bare-metal real-time systems.
Provided by the tuned-profiles-realtime package, which is available from the RT or NFV repositories.

**realtime-virtual-host**

Use in a virtualization host configured for real-time.
Provided by the tuned-profiles-nfv-host package, which is available from the NFV repository.

**realtime-virtual-guest**

Use in a virtualization guest configured for real-time.
Provided by the tuned-profiles-nfv-guest package, which is available from the NFV repository.

1.11. STATIC AND DYNAMIC TUNING IN TUNED

This section explains the difference between the two categories of system tuning that TuneD applies: static and dynamic.

**Static tuning**

Mainly consists of the application of predefined `sysctl` and `sysfs` settings and one-shot activation of several configuration tools such as `ethtool`.
Dynamic tuning

Watches how various system components are used throughout the uptime of your system. TuneD adjusts system settings dynamically based on that monitoring information. For example, the hard drive is used heavily during startup and login, but is barely used later when the user might mainly work with applications such as web browsers or email clients. Similarly, the CPU and network devices are used differently at different times. TuneD monitors the activity of these components and reacts to the changes in their use.

By default, dynamic tuning is disabled. To enable it, edit the /etc/tuned/tuned-main.conf file and change the dynamic_tuning option to 1. TuneD then periodically analyzes system statistics and uses them to update your system tuning settings. To configure the time interval in seconds between these updates, use the update_interval option.

Currently implemented dynamic tuning algorithms try to balance the performance and powersave, and are therefore disabled in the performance profiles. Dynamic tuning for individual plug-ins can be enabled or disabled in the TuneD profiles.

Example 1.2. Static and dynamic tuning on a workstation

On a typical office workstation, the Ethernet network interface is inactive most of the time. Only a few emails go in and out or some web pages might be loaded.

For those kinds of loads, the network interface does not have to run at full speed all the time, as it does by default. TuneD has a monitoring and tuning plug-in for network devices that can detect this low activity and then automatically lower the speed of that interface, typically resulting in a lower power usage.

If the activity on the interface increases for a longer period of time, for example because a DVD image is being downloaded or an email with a large attachment is opened, TuneD detects this and sets the interface speed to maximum to offer the best performance while the activity level is high.

This principle is used for other plug-ins for CPU and disks as well.

1.12. TUNED NO-DAEMON MODE

You can run TuneD in no-daemon mode, which does not require any resident memory. In this mode, TuneD applies the settings and exits.

By default, no-daemon mode is disabled because a lot of TuneD functionality is missing in this mode, including:

- D-Bus support
- Hot-plug support
- Rollback support for settings

To enable no-daemon mode, include the following line in the /etc/tuned/tuned-main.conf file:

```
daemon = 0
```

1.13. INSTALLING AND ENABLING TUNED
This procedure installs and enables the TuneD application, installs TuneD profiles, and presets a default TuneD profile for your system.

Procedure

1. Install the TuneD package:
   
   ```
   # dnf install tuned
   ```

2. Enable and start the TuneD service:
   
   ```
   # systemctl enable --now tuned
   ```

3. Optionally, install TuneD profiles for real-time systems:
   
   ```
   # dnf install tuned-profiles-realtime tuned-profiles-nfv
   ```

4. Verify that a TuneD profile is active and applied:
   
   ```
   $ tuned-adm active
   
   Current active profile: balanced
   
   $ tuned-adm verify
   
   Verification succeeded, current system settings match the preset profile. See TuneD log file ('/var/log/tuned/tuned.log') for details.
   ```

1.14. Listing Available Tuned Profiles

This procedure lists all TuneD profiles that are currently available on your system.

Procedure

- To list all available TuneD profiles on your system, use:

  ```
  $ tuned-adm list
  ```

  Available profiles:
  - accelerator-performance - Throughput performance based tuning with disabled higher latency STOP states
  - balanced - General non-specialized TuneD profile
  - desktop - Optimize for the desktop use-case
  - latency-performance - Optimize for deterministic performance at the cost of increased power consumption
  - network-latency - Optimize for deterministic performance at the cost of increased power consumption, focused on low latency network performance
  - network-throughput - Optimize for streaming network throughput, generally only necessary on older CPUs or 40G+ networks
  - powersave - Optimize for low power consumption
  - throughput-performance - Broadly applicable tuning that provides excellent performance across a variety of common server workloads
- virtual-guest - Optimize for running inside a virtual guest
- virtual-host - Optimize for running KVM guests

Current active profile: balanced

- To display only the currently active profile, use:

```
$ tuned-adm active
```

Current active profile: balanced

Additional resources

- tuned-adm(8) man page.

### 1.15. SETTING A TUNED PROFILE

This procedure activates a selected TuneD profile on your system.

**Prerequisites**

- The TuneD service is running. See Installing and Enabling TuneD for details.

**Procedure**

1. Optionally, you can let TuneD recommend the most suitable profile for your system:

```
# tuned-adm recommend
```

*balanced*

2. Activate a profile:

```
# tuned-adm profile selected-profile
```

Alternatively, you can activate a combination of multiple profiles:

```
# tuned-adm profile profile1 profile2
```

**Example 1.3. A virtual machine optimized for low power consumption**

The following example optimizes the system to run in a virtual machine with the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

```
# tuned-adm profile virtual-guest powersave
```

3. View the current active TuneD profile on your system:

```
# tuned-adm active
```

Current active profile: selected-profile
4. Reboot the system:
   # reboot

Verification steps

- Verify that the TuneD profile is active and applied:

   $ tuned-adm verify
   Verifcation succeeded, current system settings match the preset profile. See TuneD log file (’/var/log/tuned/tuned.log’) for details.

Additional resources

- tuned-adm(8) man page

1.16. DISABLING TUNED

This procedure disables TuneD and resets all affected system settings to their original state before TuneD modified them.

Procedure

- To disable all tunings temporarily:

   # tuned-adm off
   The tunings are applied again after the TuneD service restarts.

- Alternatively, to stop and disable the TuneD service permanently:

   # systemctl disable --now tuned

Additional resources

- tuned-adm(8) man page
CHAPTER 2. CUSTOMIZING TUNED PROFILES

You can create or modify TuneD profiles to optimize system performance for your intended use case.

Prerequisites

- Install and enable TuneD as described in Installing and Enabling TuneD for details.

2.1. TUNED PROFILES

A detailed analysis of a system can be very time-consuming. TuneD provides a number of predefined profiles for typical use cases. You can also create, modify, and delete profiles.

The profiles provided with TuneD are divided into the following categories:

- Power-saving profiles
- Performance-boosting profiles

The performance-boosting profiles include profiles that focus on the following aspects:

- Low latency for storage and network
- High throughput for storage and network
- Virtual machine performance
- Virtualization host performance

Syntax of profile configuration

The tuned.conf file can contain one [main] section and other sections for configuring plug-in instances. However, all sections are optional.

Lines starting with the hash sign (#) are comments.

Additional resources

- tuned.conf(5) man page.

2.2. THE DEFAULT TUNED PROFILE

During the installation, the best profile for your system is selected automatically. Currently, the default profile is selected according to the following customizable rules:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Default profile</th>
<th>Goal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute nodes</td>
<td>throughput-performance</td>
<td>The best throughput performance</td>
</tr>
<tr>
<td>Virtual machines</td>
<td>virtual-guest</td>
<td>The best performance. If you are not interested in the best performance, you can change it to the balanced or powersave profile.</td>
</tr>
</tbody>
</table>
2.3. MERGED TUNED PROFILES

As an experimental feature, it is possible to select more profiles at once. TuneD will try to merge them during the load.

If there are conflicts, the settings from the last specified profile takes precedence.

Example 2.1. Low power consumption in a virtual guest

The following example optimizes the system to run in a virtual machine for the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

```
# tuned-adm profile virtual-guest powersave
```

**WARNING**

Merging is done automatically without checking whether the resulting combination of parameters makes sense. Consequently, the feature might tune some parameters the opposite way, which might be counterproductive: for example, setting the disk for high throughput by using the `throughput-performance` profile and concurrently setting the disk spindown to the low value by the `spindown-disk` profile.

Additional resources

- `tuned.conf(5)` man page.

2.4. THE LOCATION OF TUNED PROFILES

TuneD stores profiles in the following directories:

```
/usr/lib/tuned/
```

Distribution-specific profiles are stored in the directory. Each profile has its own directory. The profile consists of the main configuration file called `tuned.conf`, and optionally other files, for example helper scripts.
If you need to customize a profile, copy the profile directory into the directory, which is used for custom profiles. If there are two profiles of the same name, the custom profile located in /etc/tuned/ is used.

Additional resources

- tuned.conf(5) man page.

2.5. INHERITANCE BETWEEN TUNED PROFILES

TuneD profiles can be based on other profiles and modify only certain aspects of their parent profile.

The [main] section of TuneD profiles recognizes the include option:

```
[main]
include=parent
```

All settings from the parent profile are loaded in this child profile. In the following sections, the child profile can override certain settings inherited from the parent profile or add new settings not present in the parent profile.

You can create your own child profile in the /etc/tuned/ directory based on a pre-installed profile in /usr/lib/tuned/ with only some parameters adjusted.

If the parent profile is updated, such as after a TuneD upgrade, the changes are reflected in the child profile.

**Example 2.2. A power-saving profile based on balanced**

The following is an example of a custom profile that extends the balanced profile and sets Aggressive Link Power Management (ALPM) for all devices to the maximum powersaving.

```
[main]
include=balanced

[scsi_host]
alpm=min_power
```

Additional resources

- tuned.conf(5) man page

2.6. STATIC AND DYNAMIC TUNING IN TUNED

This section explains the difference between the two categories of system tuning that TuneD applies: static and dynamic.

**Static tuning**

Mainly consists of the application of predefined sysctl and sysfs settings and one-shot activation of several configuration tools such as ethtool.
Dynamic tuning

Watches how various system components are used throughout the uptime of your system. TuneD adjusts system settings dynamically based on that monitoring information.

For example, the hard drive is used heavily during startup and login, but is barely used later when the user might mainly work with applications such as web browsers or email clients. Similarly, the CPU and network devices are used differently at different times. TuneD monitors the activity of these components and reacts to the changes in their use.

By default, dynamic tuning is disabled. To enable it, edit the /etc/tuned/tuned-main.conf file and change the dynamic_tuning option to 1. TuneD then periodically analyzes system statistics and uses them to update your system tuning settings. To configure the time interval in seconds between these updates, use the update_interval option.

Currently implemented dynamic tuning algorithms try to balance the performance and powersave, and are therefore disabled in the performance profiles. Dynamic tuning for individual plug-ins can be enabled or disabled in the TuneD profiles.

Example 2.3. Static and dynamic tuning on a workstation

On a typical office workstation, the Ethernet network interface is inactive most of the time. Only a few emails go in and out or some web pages might be loaded.

For those kinds of loads, the network interface does not have to run at full speed all the time, as it does by default. TuneD has a monitoring and tuning plug-in for network devices that can detect this low activity and then automatically lower the speed of that interface, typically resulting in a lower power usage.

If the activity on the interface increases for a longer period of time, for example because a DVD image is being downloaded or an email with a large attachment is opened, TuneD detects this and sets the interface speed to maximum to offer the best performance while the activity level is high.

This principle is used for other plug-ins for CPU and disks as well.

2.7. TUNED PLUG-INS

Plug-ins are modules in TuneD profiles that TuneD uses to monitor or optimize different devices on the system.

TuneD uses two types of plug-ins:

Monitoring plug-ins

Monitoring plug-ins are used to get information from a running system. The output of the monitoring plug-ins can be used by tuning plug-ins for dynamic tuning.

Monitoring plug-ins are automatically instantiated whenever their metrics are needed by any of the enabled tuning plug-ins. If two tuning plug-ins require the same data, only one instance of the monitoring plug-in is created and the data is shared.

Tuning plug-ins

Each tuning plug-in tunes an individual subsystem and takes several parameters that are populated from the TuneD profiles. Each subsystem can have multiple devices, such as multiple CPUs or network cards, that are handled by individual instances of the tuning plug-ins. Specific settings for individual devices are also supported.
Syntax for plug-ins in TuneD profiles
Sections describing plug-in instances are formatted in the following way:

```
[NAME]
type=TYPE
devices=DEVICES
```

**NAME**
is the name of the plug-in instance as it is used in the logs. It can be an arbitrary string.

**TYPE**
is the type of the tuning plug-in.

**DEVICES**
is the list of devices that this plug-in instance handles.
The `devices` line can contain a list, a wildcard (`*`), and negation (`!`). If there is no `devices` line, all devices present or later attached on the system of the `TYPE` are handled by the plug-in instance. This is same as using the `devices=*` option.

**Example 2.4. Matching block devices with a plug-in**

The following example matches all block devices starting with `sd`, such as `sda` or `sdb`, and does not disable barriers on them:

```
[data_disk]
type=disk
devices=sd*
disable_barriers=false
```

The following example matches all block devices except `sda1` and `sda2`:

```
[data_disk]
type=disk
devices=!sda1, !sda2
disable_barriers=false
```

If no instance of a plug-in is specified, the plug-in is not enabled.

If the plug-in supports more options, they can be also specified in the plug-in section. If the option is not specified and it was not previously specified in the included plug-in, the default value is used.

**Short plug-in syntax**
If you do not need custom names for the plug-in instance and there is only one definition of the instance in your configuration file, TuneD supports the following short syntax:

```
[TYPE]
devices=DEVICES
```

In this case, it is possible to omit the `type` line. The instance is then referred to with a name, same as the type. The previous example could be then rewritten into:

**Example 2.5. Matching block devices using the short syntax**

```
Conflicting plug-in definitions in a profile
If the same section is specified more than once using the include option, the settings are merged. If they cannot be merged due to a conflict, the last conflicting definition overrides the previous settings. If you do not know what was previously defined, you can use the replace Boolean option and set it to true. This causes all the previous definitions with the same name to be overwritten and the merge does not happen.

You can also disable the plug-in by specifying the enabled=false option. This has the same effect as if the instance was never defined. Disabling the plug-in is useful if you are redefining the previous definition from the include option and do not want the plug-in to be active in your custom profile.

NOTE
Tuned includes the ability to run any shell command as part of enabling or disabling a tuning profile. This enables you to extend Tuned profiles with functionality that has not been integrated into Tuned yet.
You can specify arbitrary shell commands using the script plug-in.

Additional resources
- tuned.conf(5) man page

2.8. AVAILABLE TUNED PLUG-INS
This section lists all monitoring and tuning plug-ins currently available in Tuned.

Monitoring plug-ins
Currently, the following monitoring plug-ins are implemented:

disk
  Gets disk load (number of IO operations) per device and measurement interval.

net
  Gets network load (number of transferred packets) per network card and measurement interval.

load
  Gets CPU load per CPU and measurement interval.

Tuning plug-ins
Currently, the following tuning plug-ins are implemented. Only some of these plug-ins implement dynamic tuning. Options supported by plug-ins are also listed:

cpu
  Sets the CPU governor to the value specified by the governor option and dynamically changes the Power Management Quality of Service (PM QoS) CPU Direct Memory Access (DMA) latency according to the CPU load.
  If the CPU load is lower than the value specified by the load_threshold option, the latency is set to the value specified by the latency_high option, otherwise it is set to the value specified by latency_low.
You can also force the latency to a specific value and prevent it from dynamically changing further. To do so, set the `force_latency` option to the required latency value.

### eeepc_she
Dynamically sets the front-side bus (FSB) speed according to the CPU load. This feature can be found on some netbooks and is also known as the ASUS Super Hybrid Engine (SHE).

If the CPU load is lower or equal to the value specified by the `load_threshold_powersave` option, the plug-in sets the FSB speed to the value specified by the `she_powersave` option. If the CPU load is higher or equal to the value specified by the `load_threshold_normal` option, it sets the FSB speed to the value specified by the `she_normal` option.

Static tuning is not supported and the plug-in is transparently disabled if `TuneD` does not detect the hardware support for this feature.

### net
Configures the Wake-on-LAN functionality to the values specified by the `wake_on_lan` option. It uses the same syntax as the `ethtool` utility. It also dynamically changes the interface speed according to the interface utilization.

### sysctl
Sets various `sysctl` settings specified by the plug-in options. The syntax is `name=value`, where `name` is the same as the name provided by the `sysctl` utility.

Use the `sysctl` plug-in if you need to change system settings that are not covered by other plug-ins available in `TuneD`. If the settings are covered by some specific plug-ins, prefer these plug-ins.

### usb
Sets autosuspend timeout of USB devices to the value specified by the `autosuspend` parameter. The value 0 means that autosuspend is disabled.

### vm
Enables or disables transparent huge pages depending on the value of the `transparent_hugepages` option. Valid values of the `transparent_hugepages` option are:

- "always"
- "never"
- "madvise"

### audio
Sets the autosuspend timeout for audio codecs to the value specified by the `timeout` option. Currently, the `snd_hda_intel` and `snd_ac97_codec` codecs are supported. The value 0 means that the autosuspend is disabled. You can also enforce the controller reset by setting the Boolean option `reset_controller` to `true`.

### disk
Sets the disk elevator to the value specified by the `elevator` option. It also sets:
- APM to the value specified by the `apm` option
- Scheduler quantum to the value specified by the `scheduler_quantum` option
- Disk spindown timeout to the value specified by the `spindown` option
- Disk readahead to the value specified by the `readahead` parameter
- The current disk readahead to a value multiplied by the constant specified by the `readahead_multiply` option

In addition, this plug-in dynamically changes the advanced power management and spindown timeout setting for the drive according to the current drive utilization. The dynamic tuning can be controlled by the Boolean option `dynamic` and is enabled by default.

**scsi_host**

Tunes options for SCSI hosts.
It sets Aggressive Link Power Management (ALPM) to the value specified by the `alpm` option.

**mounts**

Enables or disables barriers for mounts according to the Boolean value of the `disable_barriers` option.

**script**

Executes an external script or binary when the profile is loaded or unloaded. You can choose an arbitrary executable.

---

**IMPORTANT**

The `script` plug-in is provided mainly for compatibility with earlier releases. Prefer other TuneD plug-ins if they cover the required functionality.

TuneD calls the executable with one of the following arguments:

- `start` when loading the profile
- `stop` when unloading the profile

You need to correctly implement the `stop` action in your executable and revert all settings that you changed during the `start` action. Otherwise, the roll-back step after changing your TuneD profile will not work.

Bash scripts can import the `/usr/lib/tuned/functions` Bash library and use the functions defined there. Use these functions only for functionality that is not natively provided by TuneD. If a function name starts with an underscore, such as `_wifi_set_power_level`, consider the function private and do not use it in your scripts, because it might change in the future.

Specify the path to the executable using the `script` parameter in the plug-in configuration.

---

**Example 2.6. Running a Bash script from a profile**

To run a Bash script named `script.sh` that is located in the profile directory, use:

```
[script]
script=${i:PROFILE_DIR}/script.sh
```
sysfs
Sets various sysfs settings specified by the plug-in options.
The syntax is name=value, where name is the sysfs path to use.
Use this plugin in case you need to change some settings that are not covered by other plug-ins.
Prefer specific plug-ins if they cover the required settings.

video
Sets various powersave levels on video cards. Currently, only the Radeon cards are supported.
The powersave level can be specified by using the radeon_powersave option. Supported values are:

- default
- auto
- low
- mid
- high
- dynpm
- dpm-battery
- dpm-balanced
- dpm-performance

For details, see www.x.org. Note that this plug-in is experimental and the option might change in future releases.

bootloader
Adds options to the kernel command line. This plug-in supports only the GRUB 2 boot loader.
Customized non-standard location of the GRUB 2 configuration file can be specified by the grub2_cfg_file option.

The kernel options are added to the current GRUB configuration and its templates. The system needs to be rebooted for the kernel options to take effect.

Switching to another profile or manually stopping the TuneD service removes the additional options.
If you shut down or reboot the system, the kernel options persist in the grub.cfg file.

The kernel options can be specified by the following syntax:

```
cmdline=arg1 arg2 ... argN
```

Example 2.7. Modifying the kernel command line
For example, to add the quiet kernel option to a TuneD profile, include the following lines in the tuned.conf file:
The following is an example of a custom profile that adds the `isolcpus=2` option to the kernel command line:

```
[bootloader]
cmdline=isolcpus=2
```

### 2.9. VARIABLES IN TUNED PROFILES

Variables expand at run time when a Tuned profile is activated.

Using Tuned variables reduces the amount of necessary typing in Tuned profiles.

There are no predefined variables in Tuned profiles. You can define your own variables by creating the `[variables]` section in a profile and using the following syntax:

```
[variables]
variable_name=value
```

To expand the value of a variable in a profile, use the following syntax:

```
${variable_name}
```

**Example 2.8. Isolating CPU cores using variables**

In the following example, the `${isolated_cores}` variable expands to `1,2`, hence the kernel boots with the `isolcpus=1,2` option:

```
[variables]
isolated_cores=1,2

[bootloader]
cmdline=isolcpus=${isolated_cores}
```

The variables can be specified in a separate file. For example, you can add the following lines to `tuned.conf`:

```
[variables]
include=/etc/tuned/my-variables.conf

[bootloader]
cmdline=isolcpus=${isolated_cores}
```

If you add the `isolated_cores=1,2` option to the `/etc/tuned/my-variables.conf` file, the kernel boots with the `isolcpus=1,2` option.
2.10. BUILT-IN FUNCTIONS IN TUNED PROFILES

Built-in functions expand at run time when a TuneD profile is activated.

You can:

- Use various built-in functions together with TuneD variables
- Create custom functions in Python and add them to TuneD in the form of plug-ins

To call a function, use the following syntax:

```bash
${f:function_name:argument_1:argument_2}
```

To expand the directory path where the profile and the tuned.conf file are located, use the `PROFILE_DIR` function, which requires special syntax:

```bash
${i:PROFILE_DIR}
```

Example 2.9. Isolating CPU cores using variables and built-in functions

In the following example, the `non_isolated_cores` variable expands to `0,3-5`, and the `cpulist_invert` built-in function is called with the `0,3-5` argument:

```bash
[variables]
non_isolated_cores=0,3-5

[bootloader]
cmdline=isolcpus=${f:cpulist_invert:${non_isolated_cores}}
```

The `cpulist_invert` function inverts the list of CPUs. For a 6-CPU machine, the inversion is `1,2`, and the kernel boots with the `isolcpus=1,2` command-line option.

2.11. BUILT-IN FUNCTIONS AVAILABLE IN TUNED PROFILES

The following built-in functions are available in all TuneD profiles:

- **PROFILE_DIR**
  - Returns the directory path where the profile and the tuned.conf file are located.
- **exec**
  - Executes a process and returns its output.
- **assertion**
Compares two arguments. If they do not match, the function logs text from the first argument and aborts profile loading.

**assertion_non_equal**

Compares two arguments. If they match, the function logs text from the first argument and aborts profile loading.

**kb2s**

Converts kilobytes to disk sectors.

**s2kb**

Converts disk sectors to kilobytes.

**strip**

Creates a string from all passed arguments and deletes both leading and trailing white space.

**virt_check**

Checks whether **TuneD** is running inside a virtual machine (VM) or on bare metal:

- Inside a VM, the function returns the first argument.
- On bare metal, the function returns the second argument, even in case of an error.

**cpulist_invert**

Inverts a list of CPUs to make its complement. For example, on a system with 4 CPUs, numbered from 0 to 3, the inversion of the list \(0,2,3\) is \(1\).

**cpulist2hex**

Converts a CPU list to a hexadecimal CPU mask.

**cpulist2hex_invert**

Converts a CPU list to a hexadecimal CPU mask and inverts it.

**hex2cpulist**

Converts a hexadecimal CPU mask to a CPU list.

**cpulist_online**

Checks whether the CPUs from the list are online. Returns the list containing only online CPUs.

**cpulist_present**

Checks whether the CPUs from the list are present. Returns the list containing only present CPUs.

**cpulist_unpack**

Unpacks a CPU list in the form of \(1-3,4\) to \(1,2,3,4\).

**cpulist_pack**

Packs a CPU list in the form of \(1,2,3,5\) to \(1-3,5\).

### 2.12. CREATING NEW TUNED PROFILES

This procedure creates a new **TuneD** profile with custom performance rules.

**Prerequisites**

- The **TuneD** service is running. See [Installing and Enabling TuneD](#) for details.
1. In the `/etc/tuned/` directory, create a new directory named the same as the profile that you want to create:

```
# mkdir /etc/tuned/my-profile
```

2. In the new directory, create a file named `tuned.conf`. Add a `[main]` section and plug-in definitions in it, according to your requirements. For example, see the configuration of the `balanced` profile:

```
[main]
summary=General non-specialized TuneD profile

cpu
governor=conservative
energy_perf_bias=normal

[audio]
timeout=10

[video]
radeon_powersave=dpm-balanced, auto

[scsi_host]
alpm=medium_power
```

3. To activate the profile, use:

```
# tuned-adm profile my-profile
```

4. Verify that the TuneD profile is active and the system settings are applied:

```
$ tuned-adm active
Current active profile: my-profile

$ tuned-adm verify
Verification succeeded, current system settings match the preset profile.
See TuneD log file (`/var/log/tuned/tuned.log`) for details.
```

Additional resources
- `tuned.conf(5)` man page

2.13. MODIFYING EXISTING TUNED PROFILES

This procedure creates a modified child profile based on an existing TuneD profile.

Prerequisites
- The TuneD service is running. See Installing and Enabling TuneD for details.
Procedure

1. In the `/etc/tuned/` directory, create a new directory named the same as the profile that you want to create:
   
   ```
   # mkdir /etc/tuned/modified-profile
   ```

2. In the new directory, create a file named `tuned.conf`, and set the `[main]` section as follows:
   
   ```
   [main]
   include=parent-profile
   ```

   Replace `parent-profile` with the name of the profile you are modifying.

3. Include your profile modifications.

   Example 2.10. Lowering swappiness in the throughput-performance profile

   To use the settings from the `throughput-performance` profile and change the value of `vm.swappiness` to 5, instead of the default 10, use:
   
   ```
   [main]
   include=throughput-performance
   ```
   
   ```
   [sysctl]
   vm.swappiness=5
   ```

4. To activate the profile, use:
   
   ```
   # tuned-adm profile modified-profile
   ```

5. Verify that the `TuneD` profile is active and the system settings are applied:
   
   ```
   $ tuned-adm active
   Current active profile: my-profile
   ```
   
   ```
   $ tuned-adm verify
   Verification succeeded, current system settings match the preset profile.
   See TuneD log file (`/var/log/tuned/tuned.log`) for details.
   ```

Additional resources

- `tuned.conf(5)` man page

2.14. SETTING THE DISK SCHEDULER USING TUNED

This procedure creates and enables a `TuneD` profile that sets a given disk scheduler for selected block devices. The setting persists across system reboots.

In the following commands and configuration, replace:
- *device* with the name of the block device, for example `sdf`
- *selected-scheduler* with the disk scheduler that you want to set for the device, for example `bfq`

**Prerequisites**

- The **TuneD** service is installed and enabled. For details, see [Installing and enabling TuneD](#).

**Procedure**

1. Optional: Select an existing **TuneD** profile on which your profile will be based. For a list of available profiles, see [TuneD profiles distributed with RHEL](#).
   To see which profile is currently active, use:
   ```
   $ tuned-adm active
   ```

2. Create a new directory to hold your **TuneD** profile:
   ```
   # mkdir /etc/tuned/my-profile
   ```

3. Find the system unique identifier of the selected block device:
   ```
   $ udevadm info --query=property --name=/dev/device | grep -E '(WWN|SERIAL)'
   ID_WWN=0x5002538d00000000_
   ID_SERIAL= Generic-_SD_MMC_20120501030900000-0:0
   ID_SERIAL_SHORT=20120501030900000
   ```

   **NOTE**
   The command in the this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the *device system unique ID*.

4. Create the `/etc/tuned/my-profile/tuned.conf` configuration file. In the file, set the following options:
   a. Optional: Include an existing profile:
      ```
      [main]
      include=existing-profile
      ```
   b. Set the selected disk scheduler for the device that matches the WWN identifier:
      ```
      [disk]
      devices_udev_regex=IDNAME=device system unique id
      elevator=selected-scheduler
      ```
      Here:
      - Replace *IDNAME* with the name of the identifier being used (for example, `ID_WWN`).
• Replace *device system unique id* with the value of the chosen identifier (for example, 0x5002538d00000000).

To match multiple devices in the *devices_udev_regex* option, enclose the identifiers in parentheses and separate them with vertical bars:

```
devices_udev_regex=(ID_WWN=0x5002538d00000000) | (ID_WWN=0x1234567800000000)
```

5. Enable your profile:

```
# tuned-adm profile my-profile
```

**Verification steps**

1. Verify that the TuneD profile is active and applied:

```
$ tuned-adm active
Current active profile: my-profile
```

```
$ tuned-adm verify
Verification succeeded, current system settings match the preset profile.
See TuneD log file ('/var/log/tuned/tuned.log') for details.
```

2. Read the contents of the /sys/block/device/queue/scheduler file:

```
# cat /sys/block/device/queue/scheduler
[mq-deadline] kyber bfq none
```

In the file name, replace *device* with the block device name, for example *sdc*.

The active scheduler is listed in square brackets ([ ]).

**Additional resources**

• [Customizing TuneD profiles](#)
CHAPTER 3. REVIEWING A SYSTEM USING TUNA INTERFACE

Use the tuna tool to adjust scheduler tunables, tune thread priority, IRQ handlers, and isolate CPU cores and sockets. Tuna reduces the complexity of performing tuning tasks.

The tuna tool performs the following operations:

- Lists the CPUs on a system
- Lists the interrupt requests (IRQs) currently running on a system
- Changes policy and priority information on threads
- Displays the current policies and priorities of a system

3.1. INSTALLING TUNA TOOL

The tuna tool is designed to be used on a running system. This allows application-specific measurement tools to see and analyze system performance immediately after changes have been made.

This procedure describes how to install the tuna tool.

Procedure

- Install the tuna tool:
  
  # dnf install tuna

Verification steps

- View the available tuna CLI options:
  
  # tuna -h

Additional resources

- tuna(8) man page

3.2. VIEWING THE SYSTEM STATUS USING TUNA TOOL

This procedure describes how to view the system status using the tuna command-line interface (CLI) tool.

Prerequisites

- The tuna tool is installed. For more information, see Installing tuna tool.

Procedure

- To view the current policies and priorities:
  
  # tuna --show_threads
thread
<table>
<thead>
<tr>
<th>pid</th>
<th>SCHED_</th>
<th>rtpri</th>
<th>affinity</th>
<th>cmd</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>OTHER</td>
<td>0</td>
<td>0,1</td>
<td>init</td>
</tr>
<tr>
<td>2</td>
<td>FIFO</td>
<td>99</td>
<td>0</td>
<td>migration/0</td>
</tr>
<tr>
<td>3</td>
<td>OTHER</td>
<td>0</td>
<td>0</td>
<td>ksoftirqd/0</td>
</tr>
<tr>
<td>4</td>
<td>FIFO</td>
<td>99</td>
<td>0</td>
<td>watchdog/0</td>
</tr>
</tbody>
</table>

- To view a specific thread corresponding to a PID or matching a command name:
  
  ```
  # tuna --threads=pid_or_cmd_list --show_threads
  ```
  
  The `pid_or_cmd_list` argument is a list of comma-separated PIDs or command-name patterns.

- To tune CPUs using the `tuna` CLI, see Tuning CPUs using tuna tool.
- To tune the IRQs using the `tuna` tool, see Tuning IRQs using tuna tool.
- To save the changed configuration:

  ```
  # tuna --save=filename
  ```

  This command saves only currently running kernel threads. Processes that are not running are not saved.

Additional resources

- `tuna(8)` man page

3.3. TUNING CPUS USING TUNA TOOL

The `tuna` tool commands can target individual CPUs.

Using the tuna tool, you can:

**Isolate CPUs**

All tasks running on the specified CPU move to the next available CPU. Isolating a CPU makes it unavailable by removing it from the affinity mask of all threads.

**Include CPUs**

Allows tasks to run on the specified CPU

**Restore CPUs**

Restores the specified CPU to its previous configuration.

This procedure describes how to tune CPUs using the `tuna` CLI.

**Prerequisites**

- The tuna tool is installed. For more information, see Installing tuna tool.

**Procedure**

- To specify the list of CPUs to be affected by a command:

  ```
  # tuna --cpus=cpu_list [command]
  ```
The `cpu_list` argument is a list of comma-separated CPU numbers. For example, `--cpus=0,2`.

CPU lists can also be specified in a range, for example `--cpus="1-3"`, which would select CPUs 1, 2, and 3.

To add a specific CPU to the current `cpu_list`, for example, use `--cpus=+0`.

Replace `[command]` with, for example, `--isolate`.

- To isolate a CPU:
  
  ```bash
  # tuna --cpus=cpu_list --isolate
  ```

- To include a CPU:
  
  ```bash
  # tuna --cpus=cpu_list --include
  ```

- To use a system with four or more processors, display how to make all the ssh threads run on CPU 0 and 1, and all the http threads on CPU 2 and 3:

  ```bash
  # tuna --cpus=0,1 --threads=ssh* --move --cpus=2,3 --threads=http* --move
  ```

  This command performs the following operations sequentially:

  1. Selects CPUs 0 and 1.
  2. Selects all threads that begin with `ssh`.
  3. Moves the selected threads to the selected CPUs. Tuna sets the affinity mask of threads starting with `ssh` to the appropriate CPUs. The CPUs can be expressed numerically as 0 and 1, in hex mask as 0x3, or in binary as 11.
  4. Resets the CPU list to 2 and 3.
  5. Selects all threads that begin with `http`.
  6. Moves the selected threads to the specified CPUs. Tuna sets the affinity mask of threads starting with `http` to the specified CPUs. The CPUs can be expressed numerically as 2 and 3, in hex mask as 0xC, or in binary as 1100.

**Verification steps**

- Display the current configuration and verify that the changes were performed as expected:

  ```bash
  # tuna --threads=gnome-sc* --show_threads --cpus=0 --move --show_threads --cpus=1 --move --show_threads --cpus=+0 --move --show_threads
  ```

<table>
<thead>
<tr>
<th>thread</th>
<th>_ctxt_switches</th>
<th>pid</th>
<th>SCHED_</th>
<th>rtpri</th>
<th>affinity</th>
<th>voluntary</th>
<th>nonvoluntary</th>
<th>cmd</th>
</tr>
</thead>
<tbody>
<tr>
<td>3861</td>
<td>OTHER</td>
<td>0</td>
<td>0,1</td>
<td>33997</td>
<td>58</td>
<td>gnome-screensav</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>thread</th>
<th>_ctxt_switches</th>
<th>pid</th>
<th>SCHED_</th>
<th>rtpri</th>
<th>affinity</th>
<th>voluntary</th>
<th>nonvoluntary</th>
<th>cmd</th>
</tr>
</thead>
<tbody>
<tr>
<td>3861</td>
<td>OTHER</td>
<td>0</td>
<td>0</td>
<td>33997</td>
<td>58</td>
<td>gnome-screensav</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**CHAPTER 3. REVIEWING A SYSTEM USING TUNA INTERFACE**
This command performs the following operations sequentially:

1. Selects all threads that begin with the `gnome-sc` threads.
2. Displays the selected threads to enable the user to verify their affinity mask and RT priority.
3. Selects CPU 0.
4. Moves the `gnome-sc` threads to the specified CPU, CPU 0.
5. Shows the result of the move.
6. Resets the CPU list to CPU 1.
7. Moves the `gnome-sc` threads to the specified CPU, CPU 1.
8. Displays the result of the move.
9. Adds CPU 0 to the CPU list.
10. Moves the `gnome-sc` threads to the specified CPUs, CPUs 0 and 1.
11. Displays the result of the move.

**Additional resources**

- `/proc/cpuinfo` file
- `tuna(8)` man page

### 3.4. TUNING IRQS USING TUNA TOOL

The `/proc/interrupts` file records the number of interrupts per IRQ, the type of interrupt, and the name of the device that is located at that IRQ.

This procedure describes how to tune the IRQs using the `tuna` tool.

**Prerequisites**

- The tuna tool is installed. For more information, see Installing tuna tool.

**Procedure**

- To view the current IRQs and their affinity:

  ```
  # tuna --show_irqs
  # users    affinity
  0 timer    0
  1 i8042    0
  7 parport0 0
  ```
To specify the list of IRQs to be affected by a command:

```
# tuna --irqs=irq_list [command]
```

The *irq_list* argument is a list of comma-separated IRQ numbers or user-name patterns.

Replace [command] with, for example, `--spread`.

To move an interrupt to a specified CPU:

```
# tuna --irqs=128 --show_irqs
# users  affinity
128 iwlwifi  0,1,2,3
```

```
# tuna --irqs=128 --cpus=3 --move
```

Replace 128 with the irq_list argument and 3 with the cpu_list argument.

The *cpu_list* argument is a list of comma-separated CPU numbers, for example, `--cpus=0,2`. For more information, see Tuning CPUs using tuna tool.

**Verification steps**

- Compare the state of the selected IRQs before and after moving any interrupt to a specified CPU:

```
# tuna --irqs=128 --show_irqs
# users  affinity
128 iwlwifi  3
```

**Additional resources**

- `/proc/interrupts` file
- `tuna(8)` man page
CHAPTER 4. MONITORING PERFORMANCE USING RHEL SYSTEM ROLES

As a system administrator, you can use the Metrics RHEL System Role to monitor the performance of a system.

4.1. INTRODUCTION TO RHEL SYSTEM ROLES

RHEL System Roles is a collection of Ansible roles and modules. RHEL System Roles provide a configuration interface to remotely manage multiple RHEL systems. The interface enables managing system configurations across multiple versions of RHEL, as well as adopting new major releases.

On Red Hat Enterprise Linux 9, the interface currently consists of the following roles:

- Certificate Issuance and Renewal
- Kernel Settings
- Metrics
- Network Bound Disk Encryption client and Network Bound Disk Encryption server
- Networking
- Postfix
- SSH client
- SSH server
- System-wide Cryptographic Policies
- Terminal Session Recording

All these roles are provided by the `rhel-system-roles` package available in the AppStream repository.

Additional resources

- Red Hat Enterprise Linux (RHEL) System Roles
- Documentation in the `/usr/share/doc/rhel-system-roles/` directory [1]

4.2. RHEL SYSTEM ROLES TERMINOLOGY

You can find the following terms across this documentation:

Ansible playbook

Playbooks are Ansible’s configuration, deployment, and orchestration language. They can describe a policy you want your remote systems to enforce, or a set of steps in a general IT process.

Control node

Any machine with Ansible installed. You can run commands and playbooks, invoking `/usr/bin/ansible` or `/usr/bin/ansible-playbook`, from any control node. You can use any computer that has Python installed on it as a control node – laptops, shared desktops, and servers can all run Ansible. However, you cannot use a Windows machine as a control node. You can have multiple control nodes.
Inventory

A list of managed nodes. An inventory file is also sometimes called a “hostfile”. Your inventory can specify information like IP address for each managed node. An inventory can also organize managed nodes, creating and nesting groups for easier scaling. To learn more about inventory, see the Working with Inventory section.

Managed nodes

The network devices, servers, or both that you manage with Ansible. Managed nodes are also sometimes called “hosts”. Ansible is not installed on managed nodes.

4.3. INSTALLING RHEL SYSTEM ROLES IN YOUR SYSTEM

To use the RHEL System Roles, install the required packages in your system.

Prerequisites

- The Ansible Core package is installed on the control machine.
- You have Ansible packages installed in the system you want to use as a control node.

Procedure

1. Install the `rhel-system-roles` package on the system that you want to use as a control node:
   
   `# dnf install rhel-system-roles`

2. Install the Ansible Core package:

   `# dnf install ansible-core`

The Ansible Core package provides the `ansible-playbook` CLI, the Ansible Vault functionality, and the basic modules and filters required by RHEL Ansible content.

As a result, you are able to create an Ansible playbook.

Additional resources

- The Red Hat Enterprise Linux (RHEL) System Roles
- The `ansible-playbook` man page.

4.4. APPLYING A ROLE

The following procedure describes how to apply a particular role.

Prerequisites

- Ensure that the `rhel-system-roles` package is installed on the system that you want to use as a control node:

  `# dnf install rhel-system-roles`

1. Install the Ansible Core package:
# dnf install ansible-core

The Ansible Core package provides the `ansible-playbook` CLI, the Ansible Vault functionality, and the basic modules and filters required by RHEL Ansible content.

- Ensure that you are able to create an Ansible inventory.
  Inventories represent the hosts, host groups, and some of the configuration parameters used by the Ansible playbooks.

  Playbooks are typically human-readable, and are defined in `ini`, `yaml`, `json`, and other file formats.

- Ensure that you are able to create an Ansible playbook.
  Playbooks represent Ansible’s configuration, deployment, and orchestration language. By using playbooks, you can declare and manage configurations of remote machines, deploy multiple remote machines or orchestrate steps of any manual ordered process.

  A playbook is a list of one or more plays. Every play can include Ansible variables, tasks, or roles.

  Playbooks are human-readable, and are defined in the `yaml` format.

### Procedure

1. Create the required Ansible inventory containing the hosts and groups that you want to manage. Here is an example using a file called `inventory.ini` of a group of hosts called `webservers`:

   ```ini
   [webservers]
   host1
   host2
   host3
   ```

2. Create an Ansible playbook including the required role. The following example shows how to use roles through the `roles:` option for a playbook:

   The following example shows how to use roles through the `roles:` option for a given play:

   ```yaml
   ---
   - hosts: webservers
     roles:
     - rhel-system-roles.network
     - rhel-system-roles.postfix
   ```
NOTE

Every role includes a README file, which documents how to use the role and supported parameter values. You can also find an example playbook for a particular role under the documentation directory of the role. Such documentation directory is provided by default with the `rhel-system-roles` package, and can be found in the following location:

```
/usr/share/doc/rhel-system-roles/SUBSYSTEM/
```

Replace `SUBSYSTEM` with the name of the required role, such as `postfix`, `metrics`, `network`, `tlog`, or `ssh`.

3. To execute the playbook on specific hosts, you must perform one of the following:

- Edit the playbook to use `hosts: host1[,host2,...]`, or `hosts: all`, and execute the command:

  ```
  # ansible-playbook name.of.the.playbook
  ```

- Edit the inventory to ensure that the hosts you want to use are defined in a group, and execute the command:

  ```
  # ansible-playbook -i name.of.the.inventory name.of.the.playbook
  ```

- Specify all hosts when executing the `ansible-playbook` command:

  ```
  # ansible-playbook -i host1,host2,... name.of.the.playbook
  ```

IMPORTANT

Be aware that the `-i` flag specifies the inventory of all hosts that are available. If you have multiple targeted hosts, but want to select a host against which you want to run the playbook, you can add a variable in the playbook to be able to select a host. For example:

```
Ansible Playbook | example-playbook.yml:

- hosts: "{{ target_host }}"
  roles:
    - rhel-system-roles.network
    - rhel-system-roles.postfix
```

Playbook execution command:

```
# ansible-playbook -i host1,..hostn -e target_host=host5 example-playbook.yml
```

Additional resources

- Ansible playbooks
- Using roles in Ansible playbook
4.5. INTRODUCTION TO THE METRICS SYSTEM ROLE

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems. The Metrics System Role configures performance analysis services for the local system and, optionally, includes a list of remote systems to be monitored by the local system. The Metrics System Role enables you to use `pcp` to monitor your systems performance without having to configure `pcp` separately, as the set-up and deployment of `pcp` is handled by the playbook.

<table>
<thead>
<tr>
<th>Role variable</th>
<th>Description</th>
<th>Example usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics_monitored_hosts</td>
<td>List of remote hosts to be analyzed by the target host. These hosts will have metrics recorded on the target host, so ensure enough disk space exists below <code>/var/log</code> for each host.</td>
<td>metrics_monitored_hosts: [&quot;webserver.example.com&quot;, &quot;database.example.com&quot;]</td>
</tr>
<tr>
<td>metrics_retention_days</td>
<td>Configures the number of days for performance data retention before deletion.</td>
<td>metrics_retention_days: 14</td>
</tr>
<tr>
<td>metrics_graph_service</td>
<td>A boolean flag that enables the host to be set up with services for performance data visualization via <code>pcp</code> and <code>grafana</code>. Set to false by default.</td>
<td>metrics_graph_service: no</td>
</tr>
<tr>
<td>metrics_query_service</td>
<td>A boolean flag that enables the host to be set up with time series query services for querying recorded <code>pcp</code> metrics via <code>redis</code>. Set to false by default.</td>
<td>metrics_query_service: no</td>
</tr>
<tr>
<td>metrics_provider</td>
<td>Specifies which metrics collector to use to provide metrics. Currently, <code>pcp</code> is the only supported metrics provider.</td>
<td>metrics_provider: &quot;pcp&quot;</td>
</tr>
</tbody>
</table>

NOTE

For details about the parameters used in `metrics_connections` and additional information about the Metrics System Role, see the `/usr/share/ansible/roles/rhel-system-roles.metrics/README.md` file.
4.6. USING THE METRICS SYSTEM ROLE TO MONITOR YOUR LOCAL SYSTEM WITH VISUALIZATION

This procedure describes how to use the Metrics RHEL System Role to monitor your local system while simultaneously provisioning data visualization via Grafana.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to monitor.

**Procedure**

1. Configure `localhost` in the `/etc/ansible/hosts` Ansible inventory by adding the following content to the inventory:
   ```yaml
   localhost ansible_connection=local
   ```
2. Create an Ansible playbook with the following content:
   ```yaml
   ---
   - hosts: localhost
     vars:
       metrics_graph_service: yes
     roles:
       - rhel-system-roles.metrics
   ```
3. Run the Ansible playbook:
   ```bash
   # ansible-playbook name_of_your_playbook.yml
   ```

**NOTE**

Since the `metrics_graph_service` boolean is set to value="yes", Grafana is automatically installed and provisioned with `pcp` added as a data source.

4. To view visualization of the metrics being collected on your machine, access the grafana web interface as described in Accessing the Grafana web UI.

4.7. USING THE METRICS SYSTEM ROLE TO SETUP A FLEET OF INDIVIDUAL SYSTEMS TO MONITOR THEMSELVES

This procedure describes how to use the Metrics System Role to set up a fleet of machines to monitor themselves.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.
1. Add the name or IP of the machines you wish to monitor via the playbook to the `/etc/ansible/hosts` Ansible inventory file under an identifying group name enclosed in brackets:

```
[remotes]
webserver.example.com
database.example.com
```

2. Create an Ansible playbook with the following content:

```yaml
---
- hosts: remotes
  vars:
    metrics_retention_days: 0
  roles:
    - rhel-system-roles.metrics
```

3. Run the Ansible playbook:

```bash
# ansible-playbook name_of_your_playbook.yml -k
```

Where the `-k` prompt for password to connect to remote system.

4.8. USING THE METRICS SYSTEM ROLE TO MONITOR A FLEET OF MACHINES CENTRALLY VIA YOUR LOCAL MACHINE

This procedure describes how to use the Metrics System Role to set up your local machine to centrally monitor a fleet of machines while also provisioning visualization of the data via `grafana` and querying of the data via `redis`.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.

**Procedure**

1. Create an Ansible playbook with the following content:

```yaml
---
- hosts: localhost
  vars:
    metrics_graph_service: yes
    metrics_query_service: yes
    metrics_retention_days: 10
    metrics_monitored_hosts: ["database.example.com", "webserver.example.com"]
  roles:
    - rhel-system-roles.metrics
```
2. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml
```

**NOTE**

Since the `metrics_graph_service` and `metrics_query_service` booleans are set to value="yes", `grafana` is automatically installed and provisioned with `pcp` added as a data source with the `pcp` data recording indexed into `redis`, allowing the `pcp` querying language to be used for complex querying of the data.

3. To view graphical representation of the metrics being collected centrally by your machine and to query the data, access the `grafana` web interface as described in Accessing the Grafana web UI.

### 4.9. SETTING UP AUTHENTICATION WHILE MONITORING A SYSTEM USING THE METRICS SYSTEM ROLE

PCP supports the `scram-sha-256` authentication mechanism through the Simple Authentication Security Layer (SASL) framework. The Metrics RHEL System Role automates the steps to setup authentication using the `scram-sha-256` authentication mechanism. This procedure describes how to setup authentication using the Metrics RHEL System Role.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to use to run the playbook.

**Procedure**

1. Include the following variables in the Ansible playbook you want to setup authentication for:

```yaml
---
vars:
  metrics_username: your_username
  metrics_password: your_password
```

2. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml
```

**Verification steps**

- Verify the `sasl` configuration:

```
# pminfo -f -h "pcp://ip_adress?username=your_username" disk.dev.read
Password: disk.dev.read
inst [0 or "sda"] value 19540

ip_adress should be replaced by the IP address of the host.
```
4.10. USING THE METRICS SYSTEM ROLE TO CONFIGURE AND ENABLE METRICS COLLECTION FOR SQL SERVER

This procedure describes how to use the Metrics RHEL System Role to automate the configuration and enabling of metrics collection for Microsoft SQL Server via `pcp` on your local system.

**Prerequisites**

- The Ansible Core package is installed on the control machine.
- You have the `rhel-system-roles` package installed on the machine you want to monitor.
- You have installed Microsoft SQL Server for Red Hat Enterprise Linux and established a ‘trusted’ connection to an SQL server. See [Install SQL Server and create a database on Red Hat](#).
- You have installed the Microsoft ODBC driver for SQL Server for Red Hat Enterprise Linux. See [Red Hat Enterprise Server and Oracle Linux](#).

**Procedure**

1. Configure `localhost` in the the `/etc/ansible/hosts` Ansible inventory by adding the following content to the inventory:
   ```yaml
   localhost ansible_connection=local
   ```

2. Create an Ansible playbook that contains the following content:
   ```yaml
   ---
   - hosts: localhost
     roles:
       - role: rhel-system-roles.metrics
     vars:
       metrics_from_mssql: yes
   ```

3. Run the Ansible playbook:
   ```bash
   # ansible-playbook name_of_your_playbook.yml
   ```

**Verification steps**

- Use the `pcp` command to verify that SQL Server PMDA agent (mssql) is loaded and running:
  ```bash
  # pcp
  platform: Linux rhel82-2.local 4.18.0-167.el8.x86_64 #1 SMP Sun Dec 15 01:24:23 UTC 2019 x86_64
  hardware: 2 cpus, 1 disk, 1 node, 2770MB RAM
  timezone: PDT+7
  services: pmcd pmproxy
            pmcd: Version 5.0.2-1, 12 agents, 4 clients
            pmda: root pmcd proc pmproxy xfs linux nfsclient mmv kvm mssql
            jbd2 dm
  pmlogger: primary logger: /var/log/pcp/pmlogger/rhel82-2.local/20200326.16.31
  pmie: primary engine: /var/log/pcp/pmie/rhel82-2.local/pmie.log
  ```
Additional resources

- For more information about using Performance Co-Pilot for Microsoft SQL Server, see this Red Hat Developers Blog post.

[1] This documentation is installed automatically with the rhel-system-roles package.
CHAPTER 5. SETTING UP PCP

Performance Co-Pilot (PCP) is a suite of tools, services, and libraries for monitoring, visualizing, storing, and analyzing system-level performance measurements.

This section describes how to install and enable PCP on your system.

5.1. OVERVIEW OF PCP

You can add performance metrics using Python, Perl, C++, and C interfaces. Analysis tools can use the Python, C++, C client APIs directly, and rich web applications can explore all available performance data using a JSON interface.

You can analyze data patterns by comparing live results with archived data.

Features of PCP:

- Light-weight distributed architecture, which is useful during the centralized analysis of complex systems.
- It allows the monitoring and management of real-time data.
- It allows logging and retrieval of historical data.

PCP has the following components:

- The Performance Metric Collector Daemon (pmcd) collects performance data from the installed Performance Metric Domain Agents (pmda). PMDAs can be individually loaded or unloaded on the system and are controlled by the PMCD on the same host.
- Various client tools, such as pminfo or pmstat, can retrieve, display, archive, and process this data on the same host or over the network.
- The pcp package provides the command-line tools and underlying functionality.
- The pcp-gui package provides the graphical application. Install the pcp-gui package by executing the dnf install pcp-gui command. For more information, see Visually tracing PCP log archives with the PCP Charts application.

Additional resources

- pcp(1) man page
- /usr/share/doc/pcp-doc/ directory
- Tools distributed with PCP
- Index of Performance Co-Pilot (PCP) articles, solutions, tutorials, and white papers from Red Hat Customer Portal
- Side-by-side comparison of PCP tools with legacy tools Red Hat Knowledgebase article
- PCP upstream documentation

5.2. INSTALLING AND ENABLING PCP
To begin using PCP, install all the required packages and enable the PCP monitoring services.

This procedure describes how to install PCP using the `pcp` package. If you want to automate the PCP installation, install it using the `pcp-zeroconf` package. For more information on installing PCP by using `pcp-zeroconf`, see Setting up PCP with `pcp-zeroconf`.

**Procedure**

1. Install the `pcp` package:
   ```
   # dnf install pcp
   ```

2. Enable and start the `pmcd` service on the host machine:
   ```
   # systemctl enable pmcd
   # systemctl start pmcd
   ```

**Verification steps**

- Verify if the `pmcd` process is running on the host:
  ```
  # pcp
  ```

Performance Co-Pilot configuration on workstation:

```
platform: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019
x86_64
hardware: 12 cpus, 2 disks, 1 node, 36023MB RAM
timezone: CEST-2
services: pmcd
pmcd: Version 4.3.0-1, 8 agents
pmda: root pmcd proc xfs linux mmv kvm jbd2
```

**Additional resources**

- `pmcd(1)` man page
- Tools distributed with PCP

### 5.3. DEPLOYING A MINIMAL PCP SETUP

The minimal PCP setup collects performance statistics on Red Hat Enterprise Linux. The setup involves adding the minimum number of packages on a production system needed to gather data for further analysis.

You can analyze the resulting `.tar.gz` file and the archive of the `pmlogger` output using various PCP tools and compare them with other sources of performance information.

**Prerequisites**

- PCP is installed. For more information, see Installing and enabling PCP.
### Procedure

1. Update the `pmlogger` configuration:
   ```bash
   # pmlogconf -r /var/lib/pcp/config/pmlogger/config.default
   ```

2. Start the `pmcd` and `pmlogger` services:
   ```bash
   # systemctl start pmcd.service
   # systemctl start pmlogger.service
   ```

3. Execute the required operations to record the performance data.

4. Stop the `pmcd` and `pmlogger` services:
   ```bash
   # systemctl stop pmcd.service
   # systemctl stop pmlogger.service
   ```

5. Save the output and save it to a `tar.gz` file named based on the host name and the current date and time:
   ```bash
   # cd /var/log/pcp/pmlogger/
   # tar -czf $(hostname).$(date +%F-%Hh%M).pcp.tar.gz $(hostname)
   ```

   Extract this file and analyze the data using PCP tools.

- Tools distributed with PCP
- System services distributed with PCP

### 5.4. SYSTEM SERVICES DISTRIBUTED WITH PCP

The following table describes roles of various system services, which are distributed with PCP.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pmcd</code></td>
<td>The Performance Metric Collector Daemon (PMCD).</td>
</tr>
<tr>
<td><code>pmie</code></td>
<td>The Performance Metrics Inference Engine.</td>
</tr>
<tr>
<td><code>pmlogger</code></td>
<td>The performance metrics logger.</td>
</tr>
</tbody>
</table>
5.5. TOOLS DISTRIBUTED WITH PCP

The following table describes usage of various tools, which are distributed with PCP.

Table 5.2. Usage of tools distributed with PCP

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pcp</code></td>
<td>Displays the current status of a Performance Co-Pilot installation.</td>
</tr>
<tr>
<td><code>pcp-atop</code></td>
<td>Shows the system-level occupation of the most critical hardware resources from the performance point of view: CPU, memory, disk, and network.</td>
</tr>
<tr>
<td><code>pcp-atopsar</code></td>
<td>Generates a system-level activity report over a variety of system resource utilization. The report is generated from a raw logfile previously recorded using pmlogger or the <code>-w</code> option of <code>pcp-atop</code>.</td>
</tr>
<tr>
<td><code>pcp-dmcache</code></td>
<td>Displays information about configured Device Mapper Cache targets, such as: device IOPs, cache and metadata device utilization, as well as hit and miss rates and ratios for both reads and writes for each cache device.</td>
</tr>
<tr>
<td><code>pcp-dstat</code></td>
<td>Displays metrics of one system at a time. To display metrics of multiple systems, use <code>-host</code> option.</td>
</tr>
<tr>
<td><code>pcp-free</code></td>
<td>Reports on free and used memory in a system.</td>
</tr>
<tr>
<td><code>pcp-htop</code></td>
<td>Displays all processes running on a system along with their command line arguments in a manner similar to the <code>top</code> command, but allows you to scroll vertically and horizontally as well as interact using a mouse. You can also view processes in a tree format and select and act on multiple processes at once.</td>
</tr>
<tr>
<td><code>pcp-ipcs</code></td>
<td>Displays information on the inter-process communication (IPC) facilities that the calling process has read access for.</td>
</tr>
<tr>
<td><code>pcp-numastat</code></td>
<td>Displays NUMA allocation statistics from the kernel memory allocator.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>pcp-pidstat</code></td>
<td>Displays information about individual tasks or processes running on the system such as: CPU percentage, memory and stack usage, scheduling, and priority. Reports live data for the local host by default.</td>
</tr>
<tr>
<td><code>pcp-ss</code></td>
<td>Displays socket statistics collected by the pmdasockets Performance Metrics Domain Agent (PMDA).</td>
</tr>
<tr>
<td><code>pcp-uptime</code></td>
<td>Displays how long the system has been running, how many users are currently logged on, and the system load averages for the past 1, 5, and 15 minutes.</td>
</tr>
<tr>
<td><code>pcp-vmstat</code></td>
<td>Provides a high-level system performance overview every 5 seconds. Displays information about processes, memory, paging, block IO, traps, and CPU activity.</td>
</tr>
<tr>
<td><code>pmchart</code></td>
<td>Plots performance metrics values available through the facilities of the Performance Co-Pilot.</td>
</tr>
<tr>
<td><code>pmclient</code></td>
<td>Displays high-level system performance metrics by using the Performance Metrics Application Programming Interface (PMAPI).</td>
</tr>
<tr>
<td><code>pmconfig</code></td>
<td>Displays the values of configuration parameters.</td>
</tr>
<tr>
<td><code>pmdbg</code></td>
<td>Displays available Performance Co-Pilot debug control flags and their values.</td>
</tr>
<tr>
<td><code>pmdiff</code></td>
<td>Compares the average values for every metric in either one or two archives, in a given time window, for changes that are likely to be of interest when searching for performance regressions.</td>
</tr>
<tr>
<td><code>pmdumplog</code></td>
<td>Displays control, metadata, index, and state information from a Performance Co-Pilot archive file.</td>
</tr>
<tr>
<td><code>pmdumpext</code></td>
<td>Outputs the values of performance metrics collected live or from a Performance Co-Pilot archive.</td>
</tr>
<tr>
<td><code>pmerr</code></td>
<td>Displays available Performance Co-Pilot error codes and their corresponding error messages.</td>
</tr>
<tr>
<td><code>pmfind</code></td>
<td>Finds PCP services on the network.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>

<tr>
<td>pmprobe</td>
<td>Determines the availability of performance metrics.</td>
</tr>
<tr>
<td>pmrep</td>
<td>Reports on selected, easily customizable, performance metrics values.</td>
</tr>
<tr>
<td>pmsocks</td>
<td>Allows access to a Performance Co-Pilot hosts through a firewall.</td>
</tr>
<tr>
<td>pmstat</td>
<td>Periodically displays a brief summary of system performance.</td>
</tr>
<tr>
<td>pmstore</td>
<td>Modifies the values of performance metrics.</td>
</tr>
<tr>
<td>pmtrace</td>
<td>Provides a command line interface to the trace PMDA.</td>
</tr>
<tr>
<td>pmval</td>
<td>Displays the current value of a performance metric.</td>
</tr>
</tbody>
</table>
5.6. PCP DEPLOYMENT ARCHITECTURES

Performance Co-Pilot (PCP) offers many options to accomplish advanced setups. From the huge variety of possible architectures, this section describes how to scale your PCP deployment based on the recommended deployment set up by Red Hat, sizing factors, and configuration options.

PCP supports multiple deployment architectures, based on the scale of the PCP deployment.

Available scaling deployment setup variants:

### Localhost

Each service runs locally on the monitored machine. When you start a service without any configuration changes, this is the default deployment. Scaling beyond the individual node is not possible in this case.

By default, the deployment setup for Redis is standalone, localhost. However, Redis can optionally perform in a highly-available and highly scalable clustered fashion, where data is shared across multiple hosts. Another viable option is to deploy a Redis cluster in the cloud, or to utilize a managed Redis cluster from a cloud vendor.

### Decentralized

The only difference between localhost and decentralized setup is the centralized Redis service. In this model, the host executes `pmlogger` service on each monitored host and retrieves metrics from a local `pmcd` instance. A local `pmproxy` service then exports the performance metrics to a central Redis instance.

**Figure 5.1. Decentralized logging**

Centralized logging - `pmlogger` farm

When the resource usage on the monitored hosts is constrained, another deployment option is a `pmlogger` farm, which is also known as centralized logging. In this setup, a single logger host executes multiple `pmlogger` processes, and each is configured to retrieve performance metrics from a different remote `pmcd` host. The centralized logger host is also configured to execute the `pmproxy` service, which discovers the resulting PCP archives logs and loads the metric data into a Redis instance.
Figure 5.2. Centralized logging - pmlogger farm

Federated - multiple pmlogger farms

For large scale deployments, Red Hat recommends to deploy multiple pmlogger farms in a federated fashion. For example, one pmlogger farm per rack or data center. Each pmlogger farm loads the metrics into a central Redis instance.
NOTE

By default, the deployment setup for Redis is standalone, localhost. However, Redis can optionally perform in a highly-available and highly scalable clustered fashion, where data is shared across multiple hosts. Another viable option is to deploy a Redis cluster in the cloud, or to utilize a managed Redis cluster from a cloud vendor.

</tr>
</tbody>
</table>

## 5.8. SIZING FACTORS

The following are the sizing factors required for scaling:

**Remote system size**

The number of CPUs, disks, network interfaces, and other hardware resources affects the amount of data collected by each `pmlogger` on the centralized logging host.

**Logged Metrics**

The number and types of logged metrics play an important role. In particular, the `per-process proc.*` metrics require a large amount of disk space, for example, with the standard `pcp-zeroconf` setup, 10s logging interval, 11 MB without proc metrics versus 155 MB with proc metrics - a factor of 10 times more. Additionally, the number of instances for each metric, for example the number of CPUs, block devices, and network interfaces also impacts the required storage capacity.

**Logging Interval**

The interval how often metrics are logged, affects the storage requirements. The expected daily PCP archive file sizes are written to the `pmlogger.log` file for each `pmlogger` instance. These values are uncompressed estimates. Since PCP archives compress very well, approximately 10:1, the actual long term disk space requirements can be determined for a particular site.

pmlogrewrite
After every PCP upgrade, the `pmlogrewrite` tool is executed and rewrites old archives if there were changes in the metric metadata from the previous version and the new version of PCP. This process duration scales linear with the number of archives stored.

Additional resources

- `pmlogrewrite(1)` and `pmlogger(1)` man pages

### 5.9. CONFIGURATION OPTIONS FOR PCP SCALING

The following are the configuration options, which are required for scaling:

**sysctl and rlimit settings**

When archive discovery is enabled, `pmproxy` requires four descriptors for every `pmlogger` that it is monitoring or log-tailing, along with the additional file descriptors for the service logs and `pmproxy` client sockets, if any. Each `pmlogger` process uses about 20 file descriptors for the remote `pmcd` socket, archive files, service logs, and others. In total, this can exceed the default 1024 soft limit on a system running around 200 `pmlogger` processes. The `pmproxy` service in `pcp-5.3.0` and later automatically increases the soft limit to the hard limit. On earlier versions of PCP, tuning is required if a high number of `pmlogger` processes are to be deployed, and this can be accomplished by increasing the soft or hard limits for `pmlogger`. For more information, see [How to set limits (ulimit)](https://manpages.localhost/lib1.0.0/man/man1/policy.conf.8) for services run by systemd.

**Local Archives**

The `pmlogger` service stores metrics of local and remote `pmcds` in the `/var/log/pcp/pmlogger/` directory. To control the logging interval of the local system, update the `/etc/pcp/pmlogger/control.d/config` file and add `-t X` in the arguments, where `X` is the logging interval in seconds. To configure which metrics should be logged, execute `pmlogconf /var/lib/pcp/config/pmlogger/config.clienthostname`. This command deploys a configuration file with a default set of metrics, which can optionally be further customized. To specify retention settings, that is when to purge old PCP archives, update the `/etc/sysconfig/pmlogger_timers` file and specify `PMLOGGER_DAILY_PARAMS="-E -k X"`, where `X` is the amount of days to keep PCP archives.

**Redis**

The `pmproxy` service sends logged metrics from `pmlogger` to a Redis instance. The following are the available two options to specify the retention settings in the `/etc/pcp/pmproxy/pmproxy.conf` configuration file:

- `stream.expire` specifies the duration when stale metrics should be removed, that is metrics which were not updated in a specified amount of time in seconds.

- `stream.maxlen` specifies the maximum number of metric values for one metric per host. This setting should be the retention time divided by the logging interval, for example 20160 for 14 days of retention and 60s logging interval (60*60*24*14/60)

Additional resources

- `pmproxy(1), pmlogger(1), and sysctl(8)` man pages

### 5.10. EXAMPLE: ANALYZING THE CENTRALIZED LOGGING DEPLOYMENT

The following results were gathered on a centralized logging setup, also known as pmlogger farm Red Hat Enterprise Linux 9.0 Monitoring and managing system status and performance
The following results were gathered on a centralized logging setup, also known as pmlogger farm deployment, with a default `pcp-zeroconf 5.3.0` installation, where each remote host is an identical container instance running `pmcd` on a server with 64 CPU cores, 376 GB RAM, and one disk attached.

The logging interval is 10s, proc metrics of remote nodes are not included, and the memory values refer to the Resident Set Size (RSS) value.

**Table 5.4. Detailed utilization statistics for 10s logging interval**

<table>
<thead>
<tr>
<th>Number of Hosts</th>
<th>10</th>
<th>50</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCP Archives Storage per Day</td>
<td>91 MB</td>
<td>522 MB</td>
</tr>
<tr>
<td>pmlogger Memory</td>
<td>160 MB</td>
<td>580 MB</td>
</tr>
<tr>
<td>pmlogger Network per Day (In)</td>
<td>2 MB</td>
<td>9 MB</td>
</tr>
<tr>
<td>pmproxy Memory</td>
<td>1.4 GB</td>
<td>6.3 GB</td>
</tr>
<tr>
<td>Redis Memory per Day</td>
<td>2.6 GB</td>
<td>12 GB</td>
</tr>
</tbody>
</table>

**Table 5.5. Used resources depending on monitored hosts for 60s logging interval**

<table>
<thead>
<tr>
<th>Number of Hosts</th>
<th>10</th>
<th>50</th>
<th>100</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCP Archives Storage per Day</td>
<td>20 MB</td>
<td>120 MB</td>
<td>271 MB</td>
</tr>
<tr>
<td>pmlogger Memory</td>
<td>104 MB</td>
<td>524 MB</td>
<td>1049 MB</td>
</tr>
<tr>
<td>pmlogger Network per Day (In)</td>
<td>0.38 MB</td>
<td>1.75 MB</td>
<td>3.48 MB</td>
</tr>
<tr>
<td>pmproxy Memory</td>
<td>2.67 GB</td>
<td>5.5GB</td>
<td>9 GB</td>
</tr>
<tr>
<td>Redis Memory per Day</td>
<td>0.54 GB</td>
<td>2.65 GB</td>
<td>5.3 GB</td>
</tr>
</tbody>
</table>

**NOTE**

The `pmproxy` queues Redis requests and employs Redis pipelining to speed up Redis queries. This can result in high memory usage. For troubleshooting this issue, see Troubleshooting high memory usage.

### 5.11. EXAMPLE: ANALYZING THE FEDERATED SETUP DEPLOYMENT

The following results were observed on a federated setup, also known as multiple pmlogger farms, consisting of three centralized logging (pmlogger farm) setups, where each pmlogger farm was monitoring 100 remote hosts, that is 300 hosts in total.
This setup of the pmlogger farms is identical to the configuration mentioned in the Example: Analyzing the centralized logging deployment for 60s logging interval, except that the Redis servers were operating in cluster mode.

Table 5.6. Used resources depending on federated hosts for 60s logging interval

<table>
<thead>
<tr>
<th>PCP Archives Storage per Day</th>
<th>pmlogger Memory</th>
<th>Network per Day (In/Out)</th>
<th>pmproxy Memory</th>
<th>Redis Memory per Day</th>
</tr>
</thead>
<tbody>
<tr>
<td>277 MB</td>
<td>1058 MB</td>
<td>15.6 MB / 12.3 MB</td>
<td>6-8 GB</td>
<td>5.5 GB</td>
</tr>
</tbody>
</table>

Here, all values are per host. The network bandwidth is higher due to the inter-node communication of the Redis cluster.

5.12. TROUBLESHOOTING HIGH MEMORY USAGE

The following scenarios can result in high memory usage:

- The pmproxy process is busy processing new PCP archives and does not have spare CPU cycles to process Redis requests and responses.
- The Redis node or cluster is overloaded and cannot process incoming requests on time.

The pmproxy service daemon uses Redis streams and supports the configuration parameters, which are PCP tuning parameters and affects Redis memory usage and key retention. The /etc/pcp/pmproxy/pmproxy.conf file lists the available configuration options for pmproxy and the associated APIs.

This section describes how to troubleshoot high memory usage issue.

Prerequisites

1. Install the pcp-pmda-redis package:

   # dnf install pcp-pmda-redis

2. Install the redis PMDA:

   # cd /var/lib/pcp/pmdas/redis && ./Install

Procedure

- To troubleshoot high memory usage, execute the following command and observe the inflight column:

   $ pmrep :pmproxy
   backlog inflight reqs/s resp/s wait req err resp err changed throttled byte count count/s count/s s/s count/s count/s count/s count/s
   14:59:08 0 0 N/A N/A N/A N/A N/A N/A N/A N/A
   14:59:09 0 0 2268.9 2268.9 28 0 0 2.0 4.0
   14:59:10 0 0 0.0 0.0 0 0 0 0.0 0.0
   14:59:11 0 0 0.0 0.0 0 0 0 0.0 0.0
This column shows how many Redis requests are in-flight, which means they are queued or sent, and no reply was received so far.

A high number indicates one of the following conditions:

- The **pmproxy** process is busy processing new PCP archives and does not have spare CPU cycles to process Redis requests and responses.

- The Redis node or cluster is overloaded and cannot process incoming requests on time.

To troubleshoot the high memory usage issue, reduce the number of **pmlogger** processes for this farm, and add another pmlogger farm. Use the federated - multiple pmlogger farms setup. If the Redis node is using 100% CPU for an extended amount of time, move it to a host with better performance or use a clustered Redis setup instead.

To view the **pmproxy.redis.** metrics, use the following command:

```bash
$pminfo -ftd pmproxy.redis
```

**pmproxy.redis.responses.wait** [wait time for responses]
- Data Type: 64-bit unsigned int  InDom: PM_INDOM_NULL 0xffffffff
- Semantics: counter  Units: microsec
- Value: 546028367374

**pmproxy.redis.responses.error** [number of error responses]
- Data Type: 64-bit unsigned int  InDom: PM_INDOM_NULL 0xffffffff
- Semantics: counter  Units: count
- Value: 1164

**pmproxy.redis.requests.inflight.bytes** [bytes allocated for inflight requests]
- Data Type: 64-bit int  InDom: PM_INDOM_NULL 0xffffffff
- Semantics: discrete  Units: byte
- Value: 0

**pmproxy.redis.requests.inflight.total** [inflight requests]
- Data Type: 64-bit unsigned int  InDom: PM_INDOM_NULL 0xffffffff
- Semantics: discrete  Units: count
- Value: 0

To view how many Redis requests are inflight, see the **pmproxy.redis.requests.inflight.total** metric and **pmproxy.redis.requests.inflight.bytes** metric to view how many bytes are occupied by all current inflight Redis requests.

In general, the redis request queue would be zero but can build up based on the usage of large pmlogger farms, which limits scalability and can cause high latency for pmproxy clients.

- Use the **pminfo** command to view information about performance metrics. For example, to view the **redis.** metrics, use the following command:

```bash
$pminfo -ftd redis
```

**redis.redis_build_id** [Build ID]
- Data Type: string  InDom: 24.0 0x6000000
- Semantics: discrete  Units: count
- Inst [0 or "localhost:6379"] Value: "87e335e57cfa755"

**redis.total_commands_processed** [Total number of commands processed by the server]
- Data Type: 64-bit unsigned int  InDom: 24.0 0x6000000
- Semantics: counter  Units: count
To view the peak memory usage, see the `redis.used_memory_peak` metric.

Additional resources

- `pmdaredis(1)`, `pmproxy(1)`, and `pminfo(1)` man pages
- PCP deployment architectures
CHAPTER 6. LOGGING PERFORMANCE DATA WITH PMLOGGER

With the PCP tool you can log the performance metric values and replay them later. This allows you to perform a retrospective performance analysis.

Using the `pmlogger` tool, you can:

- Create the archived logs of selected metrics on the system
- Specify which metrics are recorded on the system and how often

6.1. MODIFYING THE PMLOGGER CONFIGURATION FILE WITH PMLOGCONF

When the `pmlogger` service is running, PCP logs a default set of metrics on the host.

Use the `pmlogconf` utility to check the default configuration. If the `pmlogger` configuration file does not exist, `pmlogconf` creates it with a default metric values.

Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.

Procedure

1. Create or modify the `pmlogger` configuration file:

   ```
   # pmlogconf -r /var/lib/pcp/config/pmlogger/config.default
   ```

2. Follow `pmlogconf` prompts to enable or disable groups of related performance metrics and to control the logging interval for each enabled group.

Additional resources

- `pmlogconf(1)` and `pmlogger(1)` man pages
- Tools distributed with PCP
- System services distributed with PCP

6.2. EDITING THE PMLOGGER CONFIGURATION FILE MANUALLY

To create a tailored logging configuration with specific metrics and given intervals, edit the `pmlogger` configuration file manually. The default `pmlogger` configuration file is `/var/lib/pcp/config/pmlogger/config.default`. The configuration file specifies which metrics are logged by the primary logging instance.

In manual configuration, you can:

- Record metrics which are not listed in the automatic configuration.
- Choose custom logging frequencies.
• Add PMDA with the application metrics.

Prerequisites

• PCP is installed. For more information, see Installing and enabling PCP.

Procedure

• Open and edit the `/var/lib/pcp/config/pmlogger/config.default` file to add specific metrics:

```
# It is safe to make additions from here on ...
#
log mandatory on every 5 seconds {
  xfs.write
  xfs.write_bytes
  xfs.read
  xfs.read_bytes
}

log mandatory on every 10 seconds {
  xfs.allocs
  xfs.block_map
  xfs.transactions
  xfs.log
}

[access]
disallow * : all;
allow localhost : enquire;
```

Additional resources

• `pmlogger(1)` man page

• Tools distributed with PCP

• System services distributed with PCP

6.3. ENABLING THE PMLOGGER SERVICE

The `pmlogger` service must be started and enabled to log the metric values on the local machine.

This procedure describes how to enable the `pmlogger` service.

Prerequisites

• PCP is installed. For more information, see Installing and enabling PCP.

Procedure

• Start and enable the `pmlogger` service:
# systemctl start pmlogger
# systemctl enable pmlogger

**Verification steps**

- Verify if the **pmlogger** service is enabled:

  ```
  # pcp
  
  Performance Co-Pilot configuration on workstation:
  
  platform: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019 x86_64
  hardware: 12 cpus, 2 disks, 1 node, 36023MB RAM
  timezone: CEST-2
  services: pmcd
  pmcd: Version 4.3.0-1, 8 agents, 1 client
  pmda: root pmcd proc xfs linux mmv kvm jbd2
  pmlogger: primary logger: /var/log/pcp/pmlogger/workstation/20190827.15.54
  ```

**Additional resources**

- [pmlogger](man page)
- Tools distributed with PCP
- System services distributed with PCP
- `/var/lib/pcp/config/pmlogger/config.default` file

## 6.4. SETTING UP A CLIENT SYSTEM FOR METRICS COLLECTION

This procedure describes how to set up a client system so that a central server can collect metrics from clients running PCP.

**Prerequisites**

- PCP is installed. For more information, see [Installing and enabling PCP](#).

**Procedure**

1. Install the **pcp-system-tools** package:

   ```
   # dnf install pcp-system-tools
   ```

2. Configure an IP address for **pmcd**:

   ```
   # echo "-i 192.168.4.62" >>/etc/pcp/pmcd/pmcd.options
   ```

   Replace `192.168.4.62` with the IP address, the client should listen on.

   By default, **pmcd** is listening on the localhost.
3. Configure the firewall to add the public zone permanently:

```
# firewall-cmd --permanent --zone=public --add-port=44321/tcp
success

# firewall-cmd --reload
success
```

4. Set an SELinux boolean:

```
# setsebool -P pcp_bind_all_unreserved_ports on
```

5. Enable the pmcd and pmlogger services:

```
# systemctl enable pmcd pmlogger
# systemctl restart pmcd pmlogger
```

**Verification steps**

- Verify if the pmcd is correctly listening on the configured IP address:

```
# ss -tlp | grep 44321
LISTEN 0 5 127.0.0.1:44321 0.0.0.0:* users:(("pmcd",pid=151595,fd=6))
LISTEN 0 5 192.168.4.62:44321 0.0.0.0:* users:(("pmcd",pid=151595,fd=0))
LISTEN 0 5  [::]:44321  [::]:* users:(("pmcd",pid=151595,fd=7))
```

**Additional resources**

- pmlogger(1), firewall-cmd(1), ss(8), and setsebool(8) man pages
- Tools distributed with PCP
- System services distributed with PCP
- /var/lib/pcp/config/pmlogger/config.default file

### 6.5. SETTING UP A CENTRAL SERVER TO COLLECT DATA

This procedure describes how to create a central server to collect metrics from clients running PCP.

**Prerequisites**

- PCP is installed. For more information, see [Installing and enabling PCP](#).
- Client is configured for metrics collection. For more information, see [Setting up a client system for metrics collection](#).

**Procedure**

1. Install the pcp-system-tools package:

```
# dnf install pcp-system-tools
```
2. Create the `/etc/pcp/pmlogger/control.d/remote` file with the following content:

```sh
# DO NOT REMOVE OR EDIT THE FOLLOWING LINE
$version=1.1

192.168.4.13 n n PCP_ARCHIVE_DIR/rhel7u4a -r -T24h10m -c config.rhel7u4a
192.168.4.14 n n PCP_ARCHIVE_DIR/rhel6u10a -r -T24h10m -c config.rhel6u10a
192.168.4.62 n n PCP_ARCHIVE_DIR/rhel8u1a -r -T24h10m -c config.rhel8u1a
192.168.4.69 n n PCP_ARCHIVE_DIR/rhel9u3a -r -T24h10m -c config.rhel9u3a
```

Replace `192.168.4.13`, `192.168.4.14`, `192.168.4.62` and `192.168.4.69` with the client IP addresses.

3. Enable the `pmcd` and `pmlogger` services:

```sh
# systemctl enable pmcd pmlogger
# systemctl restart pmcd pmlogger
```

Verification steps

- Ensure that you can access the latest archive file from each directory:

```sh
# for i in /var/log/pcp/pmlogger/rhel*/*.0; do pmdumplog -L $i; done
```

Log Label (Log Format Version 2)

Performance metrics from host rhel6u10a.local

ending Mon Nov 25 22:06:04.874 2019

Archive timezone: JST-9

PID for pmlogger: 24002

Log Label (Log Format Version 2)

Performance metrics from host rhel7u4a

commencing Tue Nov 26 06:49:24.954 2019

ending Tue Nov 26 07:06:24.979 2019

Archive timezone: CET-1

PID for pmlogger: 10941

[.]

The archive files from the `/var/log/pcp/pmlogger/` directory can be used for further analysis and graphing.

Additional resources

- `pmlogger(1)` man page
- Tools distributed with PCP
- System services distributed with PCP
- `/var/lib/pcp/config/pmlogger/config.default` file

### 6.6. REPLAYING THE PCP LOG ARCHIVES WITH PMREP

After recording the metric data, you can replay the PCP log archives. To export the logs to text files and import them into spreadsheets, use PCP utilities such as `pcp2csv`, `pcp2xml`, `pmrep` or `pmlogsummary`. 
Using the `pmrep` tool, you can:

- View the log files
- Parse the selected PCP log archive and export the values into an ASCII table
- Extract the entire archive log or only select metric values from the log by specifying individual metrics on the command line

**Prerequisites**

- PCP is installed. For more information, see [Installing and enabling PCP](#).
- The `pmlogger` service is enabled. For more information, see [Enabling the pmlogger service](#).
- Install the `pcp-system-tools` package:

  ```bash
  # dnf install pcp-gui
  ```

**Procedure**

- Display the data on the metric:

  ```bash
  $ pmrep --start @3:00am --archive 20211128 --interval 5seconds --samples 10 --output csv
disk.dev.write
  Time,"disk.dev.write-sda","disk.dev.write-sdb"
  2021-11-28 03:00:00,,
  2021-11-28 03:00:05,4.000,5.200
  2021-11-28 03:00:10,1.600,7.600
  2021-11-28 03:00:15,0.800,7.100
  2021-11-28 03:00:20,16.600,8.400
  2021-11-28 03:00:25,21.400,7.200
  2021-11-28 03:00:30,30,21.200,6.800
  2021-11-28 03:00:35,21.000,27.600
  2021-11-28 03:00:40,12.400,33.800
  2021-11-28 03:00:45,9.800,20.600
  ```

The mentioned example displays the data on the `disk.dev.write` metric collected in an archive at a 5 second interval in comma-separated-value format.

**NOTE**

Replace `20211128` in this example with a filename containing the `pmlogger` archive you want to display data for.

**Additional resources**

- `pmlogger(1), pmrep(1), and pmlogsummary(1)` man pages
- Tools distributed with PCP
- System services distributed with PCP
CHAPTER 7. MONITORING PERFORMANCE WITH PERFORMANCE CO-PILOT

Performance Co-Pilot (PCP) is a suite of tools, services, and libraries for monitoring, visualizing, storing, and analyzing system-level performance measurements.

As a system administrator, you can monitor the system’s performance using the PCP application in Red Hat Enterprise Linux 9.

7.1. MONITORING POSTFIX WITH PMDA-POSTFIX

This procedure describes how to monitor performance metrics of the postfix mail server with pmda-postfix. It helps to check how many emails are received per second.

Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.
- The pmlogger service is enabled. For more information, see Enabling the pmlogger service.

Procedure

1. Install the following packages:
   a. Install the pcp-system-tools:
      
      
      # dnf install pcp-system-tools
   
   b. Install the pmda-postfix package to monitor postfix:
      
      
      # dnf install pcp-pmda-postfix postfix
   
   c. Install the logging daemon:
      
      
      # dnf install rsyslog
   
   d. Install the mail client for testing:
      
      
      # dnf install mutt
2. Enable the postfix and rsyslog services:
   
      
      # systemctl enable postfix rsyslog
      
      # systemctl restart postfix rsyslog
3. Enable the SELinux boolean, so that pmda-postfix can access the required log files:
   
      
      # setsebool -P pcp_read_generic_logs=on
4. Install the PMDA:
   
      
      # cd /var/lib/pcp/pmdas/postfix/
# ./Install

Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Waiting for pmcd to terminate ...
Starting pmcd ...
Check postfix metrics have appeared ... 7 metrics and 58 values

Verification steps

- Verify the `pmda-postfix` operation:
  
  ```
  echo testmail | mutt root
  ```

- Verify the available metrics:
  
  ```
  # pminfo postfix
  postfix.received
  postfix.sent
  postfix.queues.incoming
  postfix.queues.maildrop
  postfix.queues.hold
  postfix.queues.deferred
  postfix.queues.active
  ```

Additional resources

- `rsyslogd(8)`, `postfix(1)`, and `setsebool(8)` man pages
- Tools distributed with PCP
- System services distributed with PCP
- `/var/lib/pcp/config/pmlogger/config.default` file

### 7.2. VISUALLY TRACING PCP LOG ARCHIVES WITH THE PCP CHARTS APPLICATION

After recording metric data, you can replay the PCP log archives as graphs. The metrics are sourced from one or more live hosts with alternative options to use metric data from PCP log archives as a source of historical data. To customize the PCP Charts application interface to display the data from the performance metrics, you can use line plot, bar graphs, or utilization graphs.

Using the PCP Charts application, you can:

- Replay the data in the PCP Charts application application and use graphs to visualize the retrospective data alongside live data of the system.
- Plot performance metric values into graphs.
- Display multiple charts simultaneously.
Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.

- Logged performance data with the pmlogger. For more information, see Logging performance data with pmlogger.

- Install the pcp-gui package:
  
  ```
  # dnf install pcp-gui
  ```

Procedure

1. Launch the PCP Charts application from the command line:

  ```
  # pmchart
  ```

**Figure 7.1. PCP Charts application**

The pmtime server settings are located at the bottom. The start and pause button allows you to control:

- The interval in which PCP polls the metric data
- The date and time for the metrics of historical data

2. Click File and then New Chart to select metric from both the local machine and remote machines by specifying their host name or address. Advanced configuration options include the ability to manually set the axis values for the chart, and to manually choose the color of the plots.

3. Record the views created in the PCP Charts application:

   Following are the options to take images or record the views created in the PCP Charts application:

   - Click File and then Export to save an image of the current view.
Click **Record** and then **Start** to start a recording. Click **Record** and then **Stop** to stop the recording. After stopping the recording, the recorded metrics are archived to be viewed later.

4. Optional: In the **PCP Charts** application, the main configuration file, known as the **view**, allows the metadata associated with one or more charts to be saved. This metadata describes all chart aspects, including the metrics used and the chart columns. Save the custom **view** configuration by clicking **File** and then **Save View**, and load the **view** configuration later.

The following example of the **PCP Charts** application view configuration file describes a stacking chart graph showing the total number of bytes read and written to the given XFS file system `loop1`:

```
#kmchart
version 1

chart title "Filesystem Throughput /loop1" style stacking antialiasing off
plot legend "Read rate" metric xfs.read_bytes instance "loop1"
plot legend "Write rate" metric xfs.write_bytes instance "loop1"
```

Additional resources

- **pmchart(1)** and **pmtime(1)** man pages
- **Tools distributed with PCP**

### 7.3. COLLECTING DATA FROM SQL SERVER USING PCP

The SQL Server agent is available in Performance Co-Pilot (PCP), which helps you to monitor and analyze database performance issues.

This procedure describes how to collect data for Microsoft SQL Server via **pcp** on your system.

**Prerequisites**

- You have installed Microsoft SQL Server for Red Hat Enterprise Linux and established a ‘trusted’ connection to an SQL server.
- You have installed the Microsoft ODBC driver for SQL Server for Red Hat Enterprise Linux.

**Procedure**

1. Install PCP:

   ```bash
   # dnf install pcp-zeroconf
   ```

2. Install packages required for the **pyodbc** driver:

   ```bash
   # dnf install python3-pyodbc
   ```

3. Install the **mssql** agent:

   a. Install the Microsoft SQL Server domain agent for PCP:

      ```bash
      # dnf install pcp-pmda-mssql
      ```
b. Edit the `/etc/pcp/mssql/mssql.conf` file to configure the SQL server account’s username and password for the `mssql` agent. Ensure that the account you configure has access rights to performance data.

```plaintext
username: user_name
password: user_password
```

Replace `user_name` with the SQL Server account and `user_password` with the SQL Server user password for this account.

4. Install the agent:

```bash
# cd /var/lib/pcp/pmdas/mssql
# ./Install
Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Check mssql metrics have appeared ... 168 metrics and 598 values
[...]
```

Verification steps

- Using the `pcp` command, verify if the SQL Server PMDA (`mssql`) is loaded and running:

```bash
$ pcp
Performance Co-Pilot configuration on rhel.local:
```

- View the complete list of metrics that PCP can collect from the SQL Server:

```bash
# pminfo mssql
```

- After viewing the list of metrics, you can report the rate of transactions. For example, to report on the overall transaction count per second, over a five second time window:

```bash
# pmval -t 1 -T 5 mssql.databases.transactions
```

- View the graphical chart of these metrics on your system by using the `pmchart` command. For more information, see [Visually tracing PCP log archives with the PCP Charts application](#).

Additional resources

- `pcp(1)`, `pminfo(1)`, `pmval(1)`, `pmchart(1)`, and `pmdamssql(1)` man pages
7.4. GENERATING PCP ARCHIVES FROM SADC ARCHIVES

You can use the sadf tool provided by the sysstat package to generate PCP archives from native sadc archives.

Prerequisites

- A sadc archive has been created:
  
  ```
  # /usr/lib64/sa/sadc 1 5 -
  ```

  In this example, sadc is sampling system data 1 time in a 5 second interval. The outfile is specified as - which results in sadc writing the data to the standard system activity daily data file. This file is named saDD and is located in the /var/log/sa directory by default.

Procedure

- Generate a PCP archive from a sadc archive:
  
  ```
  # sadf -l -O pcparchive=/tmp/recording -2
  ```

  In this example, using the -2 option results in sadf generating a PCP archive from a sadc archive recorded 2 days ago.

Verification steps

You can use PCP commands to inspect and analyze the PCP archive generated from a sadc archive as you would a native PCP archive. For example:

- To show a list of metrics in the PCP archive generated from an sadc archive archive, run:
  
  ```
  $ pminfo --archive /tmp/recording
  Disk.dev.avactive
  Disk.dev.read
  Disk.dev.write
  Disk.dev.blkread
  [...] 
  ```

- To show the timespace of the archive and hostname of the PCP archive, run:
  
  ```
  $ pmdumplog --label /tmp/recording
  Log Label (Log Format Version 2)
  Performance metrics from host shard
  commencing Tue Jul 20 00:10:30.642477 2021
  ending Wed Jul 21 00:10:30.222176 2021 
  ```

- To plot performance metrics values into graphs, run:
  
  ```
  $ pmchart --archive /tmp/recording 
  ```
CHAPTER 8. PERFORMANCE ANALYSIS OF XFS WITH PCP

The XFS PMDA ships as part of the pcp package and is enabled by default during the installation. It is used to gather performance metric data of XFS file systems in Performance Co-Pilot (PCP).

This section describes how to analyze XFS file system’s performance using PCP.

8.1. INSTALLING XFS PMDA MANUALLY

If the XFS PMDA is not listed in the pcp configuration output, install the PMDA agent manually.

This procedure describes how to manually install the PMDA agent.

Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.

Procedure

1. Navigate to the xfs directory:

   ```
   # cd /var/lib/pcp/pmdas/xfs/
   ```

Verification steps

- Verify that the pmcd process is running on the host and the XFS PMDA is listed as enabled in the configuration:

  ```
  # pcp
  Performance Co-Pilot configuration on workstation:
  platform: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019 x86_64
  hardware: 12 cpus, 2 disks, 1 node, 36023MB RAM
  timezone: CEST-2
  services: pmcd
  pmda: root pmcd proc xfs linux mmv kvm jbd2
  ```

Additional resources

- pmcd(1) man page
- Tools distributed with PCP

8.2. EXAMINING XFS PERFORMANCE METRICS WITH PMINFO

PCP enables XFS PMDA to allow the reporting of certain XFS metrics per each of the mounted XFS file systems. This makes it easier to pinpoint specific mounted file system issues and evaluate performance.

The pminfo command provides per-device XFS metrics for each mounted XFS file system.
This procedure displays a list of all available metrics provided by the XFS PMDA.

Prerequisites

- PCP is installed. For more information, see Installing and enabling PCP.

Procedure

- Display the list of all available metrics provided by the XFS PMDA:

  ```bash
  # pminfo xfs
  ```

- Display information for the individual metrics. The following examples examine specific XFS read and write metrics using the `pminfo` tool:

  - Display a short description of the `xfs.write_bytes` metric:

    ```bash
    # pminfo --oneline xfs.write_bytes
    xfs.write_bytes [number of bytes written in XFS file system write operations]
    ```

  - Display a long description of the `xfs.read_bytes` metric:

    ```bash
    # pminfo --helptext xfs.read_bytes
    xfs.read_bytes
    Help:
    This is the number of bytes read via read(2) system calls to files in XFS file systems. It can be used in conjunction with the read_calls count to calculate the average size of the read operations to file in XFS file systems.
    ```

  - Obtain the current performance value of the `xfs.read_bytes` metric:

    ```bash
    # pminfo --fetch xfs.read_bytes
    xfs.read_bytes
    value 4891346238
    ```

  - Obtain per-device XFS metrics with `pminfo`:

    ```bash
    # pminfo --fetch --oneline xfs.perdev.read xfs.perdev.write
    xfs.perdev.read [number of XFS file system read operations]
    inst [0 or "loop1"] value 0
    inst [0 or "loop2"] value 0
    xfs.perdev.write [number of XFS file system write operations]
    inst [0 or "loop1"] value 86
    inst [0 or "loop2"] value 0
    ```

Additional resources
8.3. RESETTING XFS PERFORMANCE METRICS WITH PMSTORE

With PCP, you can modify the values of certain metrics, especially if the metric acts as a control variable, such as the `xfs.control.reset` metric. To modify a metric value, use the `pmstore` tool.

This procedure describes how to reset XFS metrics using the `pmstore` tool.

**Prerequisites**

- PCP is installed. For more information, see [Installing and enabling PCP](#).

**Procedure**

1. Display the value of a metric:

   ```
   $ pminfo -f xfs.write
   xfs.write
   value 325262
   ```

2. Reset all the XFS metrics:

   ```
   # pmstore xfs.control.reset 1
   xfs.control.reset old value=0 new value=1
   ```

**Verification steps**

- View the information after resetting the metric:

  ```
  $ pminfo --fetch xfs.write
  xfs.write
  value 0
  ```

**Additional resources**

- `pmstore(1)` and `pminfo(1)` man pages
- Tools distributed with PCP
- PCP metric groups for XFS

8.4. PCP METRIC GROUPS FOR XFS

The following table describes the available PCP metric groups for XFS.

**PCP metric groups for XFS**

<table>
<thead>
<tr>
<th>Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xfs.control</td>
<td>Control metrics for XFS</td>
</tr>
</tbody>
</table>
Table 8.1. Metric groups for XFS

<table>
<thead>
<tr>
<th>Metric Group</th>
<th>Metrics provided</th>
</tr>
</thead>
<tbody>
<tr>
<td>xfs.*</td>
<td>General XFS metrics including the read and write operation counts, read and write byte counts. Along with counters for the number of times inodes are flushed, clustered and number of failure to cluster.</td>
</tr>
<tr>
<td>xfs.allocs.*</td>
<td>Range of metrics regarding the allocation of objects in the file system, these include number of extent and block creations/frees. Allocation tree lookup and compares along with extend record creation and deletion from the btree.</td>
</tr>
<tr>
<td>xfs.alloc_btree.*</td>
<td></td>
</tr>
<tr>
<td>xfs.block_map.*</td>
<td>Metrics include the number of block map read/write and block deletions, extent list operations for insertion, deletions and lookups. Also operations counters for compares, lookups, insertions and deletion operations from the blockmap.</td>
</tr>
<tr>
<td>xfs.bmap_btree.*</td>
<td></td>
</tr>
<tr>
<td>xfs.dir_ops.*</td>
<td>Counters for directory operations on XFS file systems for creation, entry deletions, count of “getdent” operations.</td>
</tr>
<tr>
<td>xfs.transactions.*</td>
<td>Counters for the number of meta-data transactions, these include the count for the number of synchronous and asynchronous transactions along with the number of empty transactions.</td>
</tr>
<tr>
<td>xfs.inode_ops.*</td>
<td>Counters for the number of times that the operating system looked for an XFS inode in the inode cache with different outcomes. These count cache hits, cache misses, and so on.</td>
</tr>
<tr>
<td>xfs.log.*</td>
<td>Counters for the number of log buffer writes over XFS file systems includes the number of blocks written to disk. Metrics also for the number of log flushes and pinning.</td>
</tr>
<tr>
<td>xfs.log_tail.*</td>
<td></td>
</tr>
<tr>
<td>xfs.xstrat.*</td>
<td>Counts for the number of bytes of file data flushed out by the XFS flush deamon along with counters for number of buffers flushed to contiguous and non-contiguous space on disk.</td>
</tr>
<tr>
<td>xfs.attr.*</td>
<td>Counts for the number of attribute get, set, remove and list operations over all XFS file systems.</td>
</tr>
<tr>
<td>xfs.quota.*</td>
<td>Metrics for quota operation over XFS file systems, these include counters for number of quota reclaims, quota cache misses, cache hits and quota data reclaims.</td>
</tr>
</tbody>
</table>
### 8.5. PER-DEVICE PCP METRIC GROUPS FOR XFS

The following table describes the available per-device PCP metric group for XFS.

**Table 8.2. Per-device PCP metric groups for XFS**

<table>
<thead>
<tr>
<th>Metric Group</th>
<th>Metrics provided</th>
</tr>
</thead>
<tbody>
<tr>
<td>xfs.perdev.*</td>
<td>General XFS metrics including the read and write operation counts, read and write byte counts. Along with counters for the number of times inodes are flushed, clustered and number of failure to cluster.</td>
</tr>
<tr>
<td>xfs.perdev.allocs.*</td>
<td>Range of metrics regarding the allocation of objects in the file system, these include number of extent and block creations/frees. Allocation tree lookup and compares along with extend record creation and deletion from the btree.</td>
</tr>
<tr>
<td>xfs.perdev.alloc_btree.*</td>
<td>Metrics include the number of block map read/write and block deletions, extent list operations for insertion, deletions and lookups. Also operations counters for compares, lookups, insertions and deletion operations from the blockmap.</td>
</tr>
<tr>
<td>xfs.perdev.dir_ops.*</td>
<td>Counters for directory operations of XFS file systems for creation, entry deletions, count of &quot;getdent&quot; operations.</td>
</tr>
<tr>
<td>xfs.perdev.transactions.*</td>
<td>Counters for the number of meta-data transactions, these include the count for the number of synchronous and asynchronous transactions along with the number of empty transactions.</td>
</tr>
<tr>
<td>xfs.perdev.inode_ops.*</td>
<td>Counters for the number of times that the operating system looked for an XFS inode in the inode cache with different outcomes. These count cache hits, cache misses, and so on.</td>
</tr>
</tbody>
</table>
### xfs.perdev.log.*
Counters for the number of log buffer writes over XFS filesystems includes the number of blocks written to disk. Metrics also for the number of log flushes and pinning.

### xfs.perdev.log_tail.*

### xfs.perdev.xstrat.*
Counts for the number of bytes of file data flushed out by the XFS flush daemon along with counters for number of buffers flushed to contiguous and non-contiguous space on disk.

### xfs.perdev.attr.*
Counts for the number of attribute get, set, remove and list operations over all XFS file systems.

### xfs.perdev.quota.*
Metrics for quota operation over XFS file systems, these include counters for number of quota reclaims, quota cache misses, cache hits and quota data reclaims.

### xfs.perdev.buffer.*
Range of metrics regarding XFS buffer objects. Counters include the number of requested buffer calls, successful buffer locks, waited buffer locks, miss_locks, miss_retries and buffer hits when looking up pages.

### xfs.perdev.btree.*
Metrics regarding the operations of the XFS btree.
CHAPTER 9. SETTING UP GRAPHICAL REPRESENTATION OF PCP METRICS

Using a combination of **pcp**, **grafana**, **pcp redis**, **pcp bpftrace**, and **pcp vector** provides graphs, based on the live data or data collected by Performance Co-Pilot (PCP).

This section describes how to set up and access the graphical representation of PCP metrics.

### 9.1. SETTING UP PCP WITH PCP-ZEROCONF

This procedure describes how to set up PCP on a system with the **pcp-zeroconf** package. Once the **pcp-zeroconf** package is installed, the system records the default set of metrics into archived files.

**Procedure**

- Install the **pcp-zeroconf** package:
  
  ```bash
  # dnf install pcp-zeroconf
  ```

**Verification steps**

- Ensure that the **pmlogger** service is active, and starts archiving the metrics:
  
  ```bash
  # pcp | grep pmlogger
  pmlogger: primary logger: /var/log/pcp/pmlogger/localhost.localdomain/20200401.00.12
  ```

**Additional resources**

- **pmlogger** man page
- Monitoring performance with Performance Co-Pilot

### 9.2. SETTING UP A GRAFANA-SERVER

Grafana generates graphs that are accessible from a browser. The **grafana-server** is a back-end server for the Grafana dashboard. It listens, by default, on all interfaces, and provides web services accessed through the web browser. The **grafana-pcp** plugin interacts with the **pmproxy** protocol in the backend.

This procedure describes how to set up a **grafana-server**.

**Prerequisites**

- PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.

**Procedure**

1. Install the following packages:

  ```bash
  # dnf install grafana grafana-pcp
  ```

2. Restart and enable the following service:
3. Open the server’s firewall for network traffic to the Grafana service.

```
# firewall-cmd --permanent --add-service=grafana
success
# firewall-cmd --reload
success
```

**Verification steps**

- Ensure that the `grafana-server` is listening and responding to requests:

```
# ss -ntlp | grep 3000
LISTEN 0 128 *:3000 *:* users:(("grafana-server",pid=19522,fd=7))
```

- Ensure that the `grafana-pcp` plugin is installed:

```
# grafana-cli plugins ls | grep performancecopilot-pcp-app
performancecopilot-pcp-app @ 3.1.0
```

**Additional resources**

- `pmproxy(1)` and `grafana-server` man pages

### 9.3. ACCESSING THE GRAFANA WEB UI

This procedure describes how to access the Grafana web interface.

Using the Grafana web interface, you can:

- add PCP Redis, PCP bpftrace, and PCP Vector data sources
- create dashboard
- view an overview of any useful metrics
- create alerts in PCP Redis

**Prerequisites**

1. PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.

2. The `grafana-server` is configured. For more information, see Setting up a grafana-server.

**Procedure**

1. On the client system, open a browser and access the `grafana-server` on port 3000, using `http://192.0.2.0:3000` link.
   Replace `192.0.2.0` with your machine IP.
2. For the first login, enter \texttt{admin} in both the Email or username and Password field. Grafana prompts to set a New password to create a secured account. If you want to set it later, click Skip.

3. From the menu, hover over the \textbf{Configuration} icon and then click \textbf{Plugins}.

4. In the Plugins tab, type performance co-pilot in the Search by name or type text box and then click Performance Co-Pilot (PCP) plugin.

5. In the Plugins / Performance Co-Pilot pane, click \textbf{Enable}.

6. Click Grafana icon. The Grafana Home page is displayed.

\textbf{Figure 9.1. Home Dashboard}

\textbf{NOTE}

The top corner of the screen has a similar \textbf{icon, but it controls the general Dashboard settings.}

7. In the Grafana Home page, click \textbf{Add your first data source} to add PCP Redis, PCP bpftrace, and PCP Vector data sources. For more information on adding data source, see:

- To add pcp redis data source, view default dashboard, create a panel, and an alert rule, see \textbf{Creating panels and alert in PCP Redis data source}.

- To add pcp bpftrace data source and view the default dashboard, see \textbf{Viewing the PCP bpftrace System Analysis dashboard}.

- To add pcp vector data source, view the default dashboard, and to view the vector checklist, see \textbf{Viewing the PCP Vector Checklist}.

8. Optional: From the menu, hover over the \textbf{admin profile} icon to change the Preferences including Edit Profile, Change Password, or to Sign out.
Additional resources

- grafana-cli and grafana-server man pages

### 9.4. CONFIGURING PCP REDIS

This section provides information for configuring PCP Redis data source.

Use the PCP Redis data source to:

- View data archives
- Query time series using pmseries language
- Analyze data across multiple hosts

**Prerequisites**

1. PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.
2. The grafana-server is configured. For more information, see Setting up a grafana-server.

**Procedure**

1. Install the redis package:

   ```bash
   # dnf install redis
   ```

2. Start and enable the following services:

   ```bash
   # systemctl start pmproxy redis
   # systemctl enable pmproxy redis
   ```

3. Mail transfer agent, for example, sendmail or postfix is installed and configured.

4. Ensure that the allow_loading_unsigned_plugins parameter is set to PCP Redis database in the grafana.ini file:

   ```bash
   # vi /etc/grafana/grafana.ini
   allow_loading_unsigned_plugins = pcp-redis-datasource
   ```

5. Restart the grafana-server.

   ```bash
   # systemctl restart grafana-server
   ```

**Verification steps**

- Ensure that the pmproxy and redis are working:

  ```bash
  # pmseries disk.dev.read
  2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
  ```
This command does not return any data if the redis package is not installed.

Additional resources

- `pmseries(1)` man page

## 9.5. CREATING PANELS AND ALERT IN PCP REDIS DATA SOURCE

After adding the PCP Redis data source, you can view the dashboard with an overview of useful metrics, add a query to visualize the load graph, and create alerts that help you to view the system issues after they occur.

**Prerequisites**

1. The PCP Redis is configured. For more information, see Configuring PCP Redis.
2. The grafana-server is accessible. For more information, see Accessing the Grafana web UI.

**Procedure**

1. Log into the Grafana web UI.
2. In the Grafana Home page, click Add your first data source
3. In the Add data source pane, type redis in the Filter by name or type text box and then click PCP Redis.
4. In the Data Sources / PCP Redis pane, perform the following:
   a. Add `http://localhost:44322` in the URL field and then click Save & Test.
   b. Click Dashboards tab → Import → PCP Redis: Host Overview to see a dashboard with an overview of any useful metrics.

**Figure 9.2. PCP Redis: Host Overview**

5. Add a new panel:
a. From the menu, hover over the icon to add a panel.

b. In the Query tab, select the PCP Redis from the query list instead of the selected default option and in the text field of A, enter metric, for example, `kernel.all.load` to visualize the kernel load graph.

c. Optional: Add Panel title and Description, and update other options from the Settings.

d. Click Save to apply changes and save the dashboard. Add Dashboard name.

e. Click Apply to apply changes and go back to the dashboard.

Figure 9.3. PCP Redis query panel

6. Create an alert rule:

a. In the PCP Redis query panel click Alert and then click Create Alert.

b. Edit the Name, Evaluate query, and For fields from the Rule, and specify the Conditions for your alert.

c. Click Save to apply changes and save the dashboard. Click Apply to apply changes and go back to the dashboard.
d. Optional: In the same panel, scroll down and click Delete icon to delete the created rule.

e. Optional: From the menu, click Alerting icon to view the created alert rules with different alert statuses, to edit the alert rule, or to pause the existing rule from the Alert Rules tab.
   To add a notification channel for the created alert rule to receive an alert notification from Grafana, see Adding notification channels for alerts.

9.6. ADDING NOTIFICATION CHANNELS FOR ALERTS

By adding notification channels, you can receive an alert notification from Grafana whenever the alert rule conditions are met and the system needs further monitoring.

You can receive these alerts after selecting any one type from the supported list of notifiers, which includes DingDing, Discord, Email, Google Hangouts Chat, HipChat, Kafka REST Proxy, LINE, Microsoft Teams, OpsGenie, PagerDuty, Prometheus Alertmanager, Pushover, Sensu, Slack, Telegram, Threema Gateway, VictorOps, and webhook.

Prerequisites

1. The grafana-server is accessible. For more information, see Accessing the Grafana web UI.

2. An alert rule is created. For more information, see Creating panels and alert in PCP Redis data source.

3. Configure SMTP and add a valid sender’s email address in the grafana/grafana.ini file:

```
# vi /etc/grafana/grafana.ini

[smtp]
enabled = true
from_address = abc@gmail.com
```

Replace abc@gmail.com by a valid email address.

Procedure
1. From the menu, hover over the Alerting icon → click Notification channels → Add channel.

2. In the Add notification channel details pane, perform the following:
   a. Enter your name in the Name text box
   b. Select the communication Type, for example, Email and enter the email address. You can add multiple email addresses using the ; separator.
   c. Optional: Configure Optional Email settings and Notification settings.

3. Click Save.

4. Select a notification channel in the alert rule:
   a. From the menu, hover over the Alerting icon and then click Alert rules.
   b. From the Alert Rules tab, click the created alert rule.
   c. On the Notifications tab, select your notification channel name from the Send to option, and then add an alert message.
   d. Click Apply.

Additional resources

- Upstream Grafana documentation for alert notifications

### 9.7. SETTING UP AUTHENTICATION BETWEEN PCP COMPONENTS

You can setup authentication using the **scram-sha-256** authentication mechanism, which is supported by PCP through the Simple Authentication Security Layer (SASL) framework.

**Procedure**

1. Install the sasl framework for the **scram-sha-256** authentication mechanism:

   ```bash
   # dnf install cyrus-sasl-scram cyrus-sasl-lib
   ```

2. Specify the supported authentication mechanism and the user database path in the **pmcd.conf** file:

   ```bash
   # vi /etc/sasl2/pmcd.conf
   mech_list: scram-sha-256
   sasldb_path: /etc/pcp/passwd.db
   ```

3. Create a new user:

   ```bash
   # useradd -r metrics
   ```
Replace *metrics* by your user name.

4. Add the created user in the user database:

```bash
# saslpasswd2 -a pmcd metrics
```

Password:
Again (for verification):

To add the created user, you are required to enter the *metrics* account password.

5. Set the permissions of the user database:

```bash
# chown root:pcp /etc/pcp/passwd.db
# chmod 640 /etc/pcp/passwd.db
```

6. Restart the `pmcd` service:

```bash
# systemctl restart pmcd
```

**Verification steps**

- Verify the `sasl` configuration:

```bash
# pminfo -f -h "pcp://127.0.0.1?username=metrics" disk.dev.read
```

Password:
```
disk.dev.read
```

inst [0 or "sda"] value 19540

**Additional resources**

- `saslauthd(8)`, `pminfo(1)`, and `sha256` man pages
- How can I setup authentication between PCP components, like PMDAs and pmcd in RHEL 8.2?

### 9.8. INSTALLING PCP BPFTRACE

Install the PCP `bpfftrace` agent to introspect a system and to gather metrics from the kernel and user-space tracepoints.

The `bpfftrace` agent uses bpfftrace scripts to gather the metrics. The `bpfftrace` scripts use the enhanced Berkeley Packet Filter (eBPF).

This procedure describes how to install a `pcp bpfftrace`.

**Prerequisites**

1. PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.
2. The `grafana-server` is configured. For more information, see Setting up a grafana-server.
3. The `scram-sha-256` authentication mechanism is configured. For more information, see Setting up authentication between PCP components.
Procedure

1. Install the `pcp-pmda-bpftrace` package:

   ```
   # dnf install pcp-pmda-bpftrace
   ```

2. Edit the `bpftrace.conf` file and add the user that you have created in the `setting-up-authentication-between-pcp-components`:

   ```
   # vi /var/lib/pcp/pmdas/bpftrace/bpftrace.conf
   
   [dynamic_scripts]
   enabled = true
   auth_enabled = true
   allowed_users = root, metrics
   ```

   Replace `metrics` by your user name.

3. Install `bpftrace` PMDA:

   ```
   # cd /var/lib/pcp/pmdas/bpftrace/
   # ./Install
   
   Updating the Performance Metrics Name Space (PMNS) ...
   Terminate PMDA if already installed ...
   Updating the PMCD control file, and notifying PMCD ...
   Check bpftrace metrics have appeared ... 7 metrics and 6 values
   ```

   The `pmda-bpftrace` is now installed, and can only be used after authenticating your user. For more information, see Viewing the PCP bpftrace System Analysis dashboard.

Additional resources

- `pmdabpftrace(1)` and `bpftrace` man pages

9.9. VIEWING THE PCP BPFTRACE SYSTEM ANALYSIS DASHBOARD

Using the PCP bpftrace data source, you can access the live data from sources which are not available as normal data from the `pmlogger` or archives.

In the PCP bpftrace data source, you can view the dashboard with an overview of useful metrics.

Prerequisites

1. The PCP bpftrace is installed. For more information, see Installing PCP bpftrace.

2. The `grafana-server` is accessible. For more information, see Accessing the Grafana web UI.

Procedure

1. Log into the Grafana web UI.

2. In the Grafana Home page, click Add your first data source
3. In the **Add data source** pane, type `bpftrace` in the **Filter by name or type** text box and then click **PCP bpftrace**.

4. In the **Data Sources / PCP bpftrace** pane, perform the following:
   b. Toggle the **Basic Auth** option and add the created user credentials in the **User** and **Password** field.
   c. Click **Save & Test**.

![Figure 9.5. Adding PCP bpftrace in the data source](image)

   d. Click **Dashboards tab → Import → PCP bpftrace: System Analysis** to see a dashboard with an overview of any useful metrics.

![Figure 9.6. PCP bpftrace: System Analysis](image)

### 9.10. INSTALLING PCP VECTOR

This procedure describes how to install a **pcp vector**.
Prerequisites

1. PCP is configured. For more information, see Setting up PCP with pcp-zeroconf.

2. The grafana-server is configured. For more information, see Setting up a grafana-server.

Procedure

1. Install the pcp-pmda-bcc package:

   ```bash
   # dnf install pcp-pmda-bcc
   ```

2. Install the bcc PMDA:

   ```bash
   # cd /var/lib/pcp/pmdas/bcc
   # ./Install
   [Wed Apr  1 00:27:48] pmdabcc(22341) Info: Initializing, currently in 'notready' state.
   [Wed Apr  1 00:27:48] pmdabcc(22341) Info: Enabled modules:
   [Wed Apr  1 00:27:48] pmdabcc(22341) Info: ['biolatency', 'sysfork',
   [...
   Updating the Performance Metrics Name Space (PMNS) ...
   Terminate PMDA if already installed ...
   Updating the PMCD control file, and notifying PMCD ...
   Check bcc metrics have appeared ... 1 warnings, 1 metrics and 0 values
   ```

Additional resources

- pmdabcc(1) man page

9.11. VIEWING THE PCP VECTOR CHECKLIST

The PCP Vector data source displays live metrics and uses the pcp metrics. It analyzes data for individual hosts.

After adding the PCP Vector data source, you can view the dashboard with an overview of useful metrics and view the related troubleshooting or reference links in the checklist.

Prerequisites

1. The PCP Vector is installed. For more information, see Installing PCP Vector.

2. The grafana-server is accessible. For more information, see Accessing the Grafana web UI.

Procedure

1. Log into the Grafana web UI.

2. In the Grafana Home page, click Add your first data source.

3. In the Add data source pane, type vector in the Filter by name or type text box and then click PCP Vector.

4. In the Data Sources / PCP Vector pane, perform the following:
   a. Add http://localhost:44322 in the URL field and then click Save & Test.
b. Click **Dashboards tab → Import → PCP Vector: Host Overview** to see a dashboard with an overview of any useful metrics.

**Figure 9.7. PCP Vector: Host Overview**

5. From the menu, hover over the **Performance Co-Pilot** plugin and then click **PCP Vector Checklist**.

In the PCP checklist, click **help** or **warning** icon to view the related troubleshooting or reference links.

**Figure 9.8. Performance Co-Pilot / PCP Vector Checklist**

9.12. **TROUBLESHOOTING GRAFANA ISSUES**

This section describes how to troubleshoot Grafana issues, such as, Grafana does not display any data, the dashboard is black, or similar issues.

**Procedure**

- Verify that the **pmlogger** service is up and running by executing the following command:
Verify if files were created or modified to the disk by executing the following command:

```
$ ls /var/log/pcp/pmlogger/$(hostname)/ -rlt
```

```
total 4024
-rw-r--r--. 1 pcp pcp   45996 Oct 13  2019 20191013.20.07.meta.xz
-rw-r--r--. 1 pcp pcp     412 Oct 13  2019 20191013.20.07.index
-rw-r--r--. 1 pcp pcp   32188 Oct 13  2019 20191013.20.07.0.xz
-rw-r--r--. 1 pcp pcp   44756 Oct 13  2019 20191013.20.30-00.meta.xz
[...]
```

Verify that the **pmproxy** service is running by executing the following command:

```
$ systemctl status pmproxy
```

Verify that **pmproxy** is running, time series support is enabled, and a connection to Redis is established by viewing the `/var/log/pcp/pmproxy/pmproxy.log` file and ensure that it contains the following text:

```
pmproxy(1716) Info: Redis slots, command keys, schema version setup
```

Here, **1716** is the PID of pmproxy, which will be different for every invocation of **pmproxy**.

Verify if the Redis database contains any keys by executing the following command:

```
$ redis-cli dbsize
(integer) 34837
```

Verify if any PCP metrics are in the Redis database and **pmproxy** is able to access them by executing the following commands:

```
$ pmseries disk.dev.read
2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df

$ pmseries "disk.dev.read[count:10]"
2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
70e83e88d4e1857a3a316056d1333755f2dd17c
[Mon Jul 26 12:21:00.087401000 2021] 117758
70e83e88d4e1857a3a316056d1333755f2dd17c
70e83e88d4e1857a3a316056d1333755f2dd17c
[...]
```

```
$ redis-cli --scan --pattern "*(pmseries 'disk.dev.read')*"
```

```
pcp:metric.name:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:values:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:desc:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:labelvalue:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:instances:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
pcp:labelflags:series:2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
```
Verify if there are any errors in the Grafana logs by executing the following command:

```
$ journalctl -e -u grafana-server
-- Logs begin at Mon 2021-07-26 11:55:10 IST, end at Mon 2021-07-26 12:30:15 IST. --

```
Learn how to set a performance profile in the RHEL web console to optimize the performance of the system for a selected task.

10.1. PERFORMANCE TUNING OPTIONS IN THE WEB CONSOLE

Red Hat Enterprise Linux 9 provides several performance profiles that optimize the system for the following tasks:

- Systems using the desktop
- Throughput performance
- Latency performance
- Network performance
- Low power consumption
- Virtual machines

The TuneD service optimizes system options to match the selected profile.

In the web console, you can set which performance profile your system uses.

Additional resources

- Getting started with TuneD

10.2. SETTING A PERFORMANCE PROFILE IN THE WEB CONSOLE

This procedure uses the web console to optimize the system performance for a selected task.

Prerequisites

- Make sure the web console is installed and accessible. For details, see Installing the web console.

Procedure

1. Log into the RHEL web console. For details, see Logging in to the web console.

2. Click Overview.

3. In the Performance Profile field, click the current performance profile.
4. In the **Change Performance Profile** dialog box, change the profile if necessary.

5. Click **Change Profile**.

---

**Verification steps**

- The **Overview** tab now shows the selected performance profile.

---

**10.3. MONITORING PERFORMANCE USING THE WEB CONSOLE**

Red Hat’s web console uses the Utilization Saturation and Errors (USE) Method for troubleshooting. The new performance metrics page has a historical view of your data organized chronologically with the newest data at the top.

Here, you can view the events, errors, and graphical representation for resource utilization and saturation.

**Prerequisites**

1. Make sure the web console is installed and accessible. For details, see [Installing the web console](#).

2. Install the **cockpit-pcp** package, which enables collecting the performance metrics:

   ```bash
   # dnf install cockpit-pcp
   ```

**Procedure**

1. Log into the RHEL 9 web console. For details, see [Logging in to the web console](#).

2. Click **Overview**.
3. Click **View details and history** to view the **Performance Metrics**.
CHAPTER 11. SETTING THE DISK SCHEDULER

The disk scheduler is responsible for ordering the I/O requests submitted to a storage device.

You can configure the scheduler in several different ways:

- Set the scheduler using **TuneD**, as described in Setting the disk scheduler using TuneD
- Set the scheduler using **udev**, as described in Setting the disk scheduler using udev rules
- Temporarily change the scheduler on a running system, as described in Temporarily setting a scheduler for a specific disk

**NOTE**

In Red Hat Enterprise Linux 9, block devices support only multi-queue scheduling. This enables the block layer performance to scale well with fast solid-state drives (SSDs) and multi-core systems.

The traditional, single-queue schedulers, which were available in Red Hat Enterprise Linux 7 and earlier versions, have been removed.

11.1. AVAILABLE DISK SCHEDULERS

The following multi-queue disk schedulers are supported in Red Hat Enterprise Linux 9:

**none**

Implements a first-in first-out (FIFO) scheduling algorithm. It merges requests at the generic block layer through a simple last-hit cache.

**mq-deadline**

Attempts to provide a guaranteed latency for requests from the point at which requests reach the scheduler.

The **mq-deadline** scheduler sorts queued I/O requests into a read or write batch and then schedules them for execution in increasing logical block addressing (LBA) order. By default, read batches take precedence over write batches, because applications are more likely to block on read I/O operations. After **mq-deadline** processes a batch, it checks how long write operations have been starved of processor time and schedules the next read or write batch as appropriate.

This scheduler is suitable for most use cases, but particularly those in which the write operations are mostly asynchronous.

**bfq**

Targets desktop systems and interactive tasks.

The **bfq** scheduler ensures that a single application is never using all of the bandwidth. In effect, the storage device is always as responsive as if it was idle. In its default configuration, **bfq** focuses on delivering the lowest latency rather than achieving the maximum throughput.

**bfq** is based on **cfq** code. It does not grant the disk to each process for a fixed time slice but assigns a budget measured in number of sectors to the process.

This scheduler is suitable while copying large files and the system does not become unresponsive in this case.
The scheduler tunes itself to achieve a latency goal by calculating the latencies of every I/O request submitted to the block I/O layer. You can configure the target latencies for read, in the case of cache-misses, and synchronous write requests.

This scheduler is suitable for fast devices, for example NVMe, SSD, or other low latency devices.

11.2. DIFFERENT DISK SCHEDULERS FOR DIFFERENT USE CASES

Depending on the task that your system performs, the following disk schedulers are recommended as a baseline prior to any analysis and tuning tasks:

Table 11.1. Disk schedulers for different use cases

<table>
<thead>
<tr>
<th>Use case</th>
<th>Disk scheduler</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traditional HDD with a SCSI interface</td>
<td>Use <strong>mq-deadline</strong> or <strong>bfq</strong>.</td>
</tr>
<tr>
<td>High-performance SSD or a CPU-bound system with fast storage</td>
<td>Use <strong>none</strong>, especially when running enterprise applications. Alternatively, use <strong>kyber</strong>.</td>
</tr>
<tr>
<td>Desktop or interactive tasks</td>
<td>Use <strong>bfq</strong>.</td>
</tr>
<tr>
<td>Virtual guest</td>
<td>Use <strong>mq-deadline</strong>. With a host bus adapter (HBA) driver that is multi-queue capable, use <strong>none</strong>.</td>
</tr>
</tbody>
</table>

11.3. THE DEFAULT DISK SCHEDULER

Block devices use the default disk scheduler unless you specify another scheduler.

**NOTE**

For **non-volatile Memory Express (NVMe)** block devices specifically, the default scheduler is **none** and Red Hat recommends not changing this.

The kernel selects a default disk scheduler based on the type of device. The automatically selected scheduler is typically the optimal setting. If you require a different scheduler, Red Hat recommends to use **udev** rules or the **TuneD** application to configure it. Match the selected devices and switch the scheduler only for those devices.

11.4. DETERMINING THE ACTIVE DISK SCHEDULER

This procedure determines which disk scheduler is currently active on a given block device.

**Procedure**

- Read the content of the `/sys/block/device/queue/scheduler` file:

  ```bash
  # cat /sys/block/device/queue/scheduler
  [mq-deadline] kyber bfq none
  ```
In the file name, replace device with the block device name, for example sdc.

The active scheduler is listed in square brackets ([ ]).

11.5. SETTING THE DISK SCHEDULER USING TUNED

This procedure creates and enables a TuneD profile that sets a given disk scheduler for selected block devices. The setting persists across system reboots.

In the following commands and configuration, replace:

- device with the name of the block device, for example sdf
- selected-scheduler with the disk scheduler that you want to set for the device, for example bfq

Prerequisites

- The TuneD service is installed and enabled. For details, see Installing and enabling TuneD.

Procedure

1. Optional: Select an existing TuneD profile on which your profile will be based. For a list of available profiles, see TuneD profiles distributed with RHEL.
   To see which profile is currently active, use:
   ```bash
   $ tuned-adm active
   ```

2. Create a new directory to hold your TuneD profile:
   ```bash
   # mkdir /etc/tuned/my-profile
   ```

3. Find the system unique identifier of the selected block device:
   ```bash
   $ udevadm info --query=property --name=/dev/device | grep -E '(WWN|SERIAL)'
   ID_WWN=0x5002538d00000000_
   ID_SERIAL= Generic-_SD_MMC_20120501030900000-0:0
   ID_SERIAL_SHORT=20120501030900000
   ```

   **NOTE**
   The command in this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the device system unique ID.

4. Create the /etc/tuned/my-profile/tuned.conf configuration file. In the file, set the following options:
   a. Optional: Include an existing profile:
b. Set the selected disk scheduler for the device that matches the WWN identifier:

```
[disk]
devices_udev_regex=IDNAME=device system unique id
elevator=selected-scheduler
```

Here:

- Replace `IDNAME` with the name of the identifier being used (for example, `ID_WWN`).
- Replace `device system unique id` with the value of the chosen identifier (for example, `0x5002538d00000000`).

To match multiple devices in the `devices_udev_regex` option, enclose the identifiers in parentheses and separate them with vertical bars:

```
devices_udev_regex=(ID_WWN=0x5002538d00000000) | (ID_WWN=0x1234567800000000)
```

5. Enable your profile:

```
# tuned-adm profile my-profile
```

**Verification steps**

1. Verify that the TuneD profile is active and applied:

```
$ tuned-adm active
Current active profile: my-profile
```

```
$ tuned-adm verify
Verification succeeded, current system settings match the preset profile. See TuneD log file ('/var/log/tuned/tuned.log') for details.
```

2. Read the contents of the `/sys/block/device/queue/scheduler` file:

```
# cat /sys/block/device/queue/scheduler
[mq-deadline] kyber bfq none
```

In the file name, replace `device` with the block device name, for example `sdc`.

The active scheduler is listed in square brackets ([ ]).

**Additional resources**

- [Customizing TuneD profiles](#)
11.6. SETTING THE DISK SCHEDULER USING UDEV RULES

This procedure sets a given disk scheduler for specific block devices using udev rules. The setting persists across system reboots.

In the following commands and configuration, replace:

- `device` with the name of the block device, for example `sdf`
- `selected-scheduler` with the disk scheduler that you want to set for the device, for example `bfq`

Procedure

1. Find the system unique identifier of the block device:

```bash
$ udevadm info --name=/dev/device | grep -E '(WWN|SERIAL)'
E: ID_WWN=0x5002538d00000000
E: ID_SERIAL=Generic-_SD_MMC_20120501030900000-0:0
E: ID_SERIAL_SHORT=20120501030900000
```

**NOTE**

The command in the this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the device system unique ID.

2. Configure the udev rule. Create the `/etc/udev/rules.d/99-scheduler.rules` file with the following content:

```bash
ACTION=="add|change", SUBSYSTEM=="block", ENV{IDNAME}=="device system unique id", ATTR{queue/scheduler}="selected-scheduler"
```

Here:

- Replace `IDNAME` with the name of the identifier being used (for example, `ID_WWN`).
- Replace `device system unique id` with the value of the chosen identifier (for example, `0x5002538d00000000`).

3. Reload udev rules:

```bash
# udevadm control --reload-rules
```

4. Apply the scheduler configuration:

```bash
# udevadm trigger --type=devices --action=change
```

Verification steps

- Verify the active scheduler:
11.7. TEMPORARILY SETTING A SCHEDULER FOR A SPECIFIC DISK

This procedure sets a given disk scheduler for specific block devices. The setting does not persist across system reboots.

Procedure

- Write the name of the selected scheduler to the `/sys/block/device/queue/scheduler` file:

  ```
  # echo selected-scheduler > /sys/block/device/queue/scheduler
  ```

  In the file name, replace `device` with the block device name, for example `sdc`.

Verification steps

- Verify that the scheduler is active on the device:

  ```
  # cat /sys/block/device/queue/scheduler
  ```
CHAPTER 12. TUNING THE PERFORMANCE OF A SAMBA SERVER

This chapter describes what settings can improve the performance of Samba in certain situations, and which settings can have a negative performance impact.

Parts of this section were adopted from the Performance Tuning documentation published in the Samba Wiki. License: CC BY 4.0. Authors and contributors: See the history tab on the Wiki page.

Prerequisites

- Samba is set up as a file or print server

12.1. SETTING THE SMB PROTOCOL VERSION

Each new SMB version adds features and improves the performance of the protocol. The recent Windows and Windows Server operating systems always supports the latest protocol version. If Samba also uses the latest protocol version, Windows clients connecting to Samba benefit from the performance improvements. In Samba, the default value of the server max protocol is set to the latest supported stable SMB protocol version.

**NOTE**

To always have the latest stable SMB protocol version enabled, do not set the `server max protocol` parameter. If you set the parameter manually, you will need to modify the setting with each new version of the SMB protocol, to have the latest protocol version enabled.

The following procedure explains how to use the default value in the `server max protocol` parameter.

**Procedure**

1. Remove the `server max protocol` parameter from the `[global]` section in the `/etc/samba/smb.conf` file.

2. Reload the Samba configuration

   ```bash
   # smbcontrol all reload-config
   ```

12.2. TUNING SHARES WITH DIRECTORIES THAT CONTAIN A LARGE NUMBER OF FILES

Linux supports case-sensitive file names. For this reason, Samba needs to scan directories for uppercase and lowercase file names when searching or accessing a file. You can configure a share to create new files only in lowercase or uppercase, which improves the performance.

Prerequisites

- Samba is configured as a file server

**Procedure**
1. Rename all files on the share to lowercase.

   **NOTE**

   Using the settings in this procedure, files with names other than in lowercase will no longer be displayed.

2. Set the following parameters in the share's section:

   ```
   case sensitive = true
   default case = lower
   preserve case = no
   short preserve case = no
   ```

   For details about the parameters, see their descriptions in the `smb.conf(5)` man page.

3. Verify the `/etc/samba/smb.conf` file:

   ```
   # testparm
   ```

4. Reload the Samba configuration:

   ```
   # smbcontrol all reload-config
   ```

After you applied these settings, the names of all newly created files on this share use lowercase. Because of these settings, Samba no longer needs to scan the directory for uppercase and lowercase, which improves the performance.

**12.3. SETTINGS THAT CAN HAVE A NEGATIVE PERFORMANCE IMPACT**

By default, the kernel in Red Hat Enterprise Linux is tuned for high network performance. For example, the kernel uses an auto-tuning mechanism for buffer sizes. Setting the `socket options` parameter in the `/etc/samba/smb.conf` file overrides these kernel settings. As a result, setting this parameter decreases the Samba network performance in most cases.

To use the optimized settings from the Kernel, remove the `socket options` parameter from the `[global]` section in the `/etc/samba/smb.conf`.
Virtual machines (VMs) always experience some degree of performance deterioration in comparison to the host. The following sections explain the reasons for this deterioration and provide instructions on how to minimize the performance impact of virtualization in RHEL 9, so that your hardware infrastructure resources can be used as efficiently as possible.

13.1. WHAT INFLUENCES VIRTUAL MACHINE PERFORMANCE

VMs are run as user-space processes on the host. The hypervisor therefore needs to convert the host’s system resources so that the VMs can use them. As a consequence, a portion of the resources is consumed by the conversion, and the VM therefore cannot achieve the same performance efficiency as the host.

The impact of virtualization on system performance

More specific reasons for VM performance loss include:

- Virtual CPUs (vCPUs) are implemented as threads on the host, handled by the Linux scheduler.
- VMs do not automatically inherit optimization features, such as NUMA or huge pages, from the host kernel.
- Disk and network I/O settings of the host might have a significant performance impact on the VM.
- Network traffic typically travels to a VM through a software-based bridge.
- Depending on the host devices and their models, there might be significant overhead due to emulation of particular hardware.

The severity of the virtualization impact on the VM performance is influenced by a variety factors, which include:

- The number of concurrently running VMs.
- The amount of virtual devices used by each VM.
- The device types used by the VMs.

Reducing VM performance loss

RHEL 9 provides a number of features you can use to reduce the negative performance effects of virtualization. Notably:

- **The TuneD service** can automatically optimize the resource distribution and performance of your VMs.
- **Block I/O tuning** can improve the performances of the VM’s block devices, such as disks.
- **NUMA tuning** can increase vCPU performance.
- **Virtual networking** can be optimized in various ways.
IMPORTANT

Tuning VM performance can have adverse effects on other virtualization functions. For example, it can make migrating the modified VM more difficult.

13.2. OPTIMIZING VIRTUAL MACHINE PERFORMANCE USING TUNED

The **TuneD** utility is a tuning profile delivery mechanism that adapts RHEL for certain workload characteristics, such as requirements for CPU-intensive tasks or storage-network throughput responsiveness. It provides a number of tuning profiles that are pre-configured to enhance performance and reduce power consumption in a number of specific use cases. You can edit these profiles or create new profiles to create performance solutions tailored to your environment, including virtualized environments.

To optimize RHEL 9 for virtualization, use the following profiles:

- For RHEL 9 virtual machines, use the **virtual-guest** profile. It is based on the generally applicable **throughput-performance** profile, but also decreases the swappiness of virtual memory.
- For RHEL 9 virtualization hosts, use the **virtual-host** profile. This enables more aggressive writeback of dirty memory pages, which benefits the host performance.

Prerequisites

- The **TuneD** service is **installed and enabled**.

Procedure

To enable a specific **TuneD** profile:

1. List the available **TuneD** profiles.

```
# tuned-adm list
```

Available profiles:
- balanced   - General non-specialized TuneD profile
- desktop   - Optimize for the desktop use-case
[...]
- virtual-guest   - Optimize for running inside a virtual guest
- virtual-host   - Optimize for running KVM guests
Current active profile: balanced

2. **Optional:** Create a new **TuneD** profile or edit an existing **TuneD** profile. For more information, see **Customizing TuneD profiles**.

3. Activate a **TuneD** profile.

```
# tuned-adm profile selected-profile
```

- To optimize a virtualization host, use the **virtual-host** profile.

```
# tuned-adm profile virtual-host
```

- On a RHEL guest operating system, use the **virtual-guest** profile.
# tuned-adm profile virtual-guest

Additional resources

- Monitoring and managing system status and performance

## 13.3. OPTIMIZING LIBVIRT DAEMONS

The libvirt virtualization suite works as a management layer for the RHEL hypervisor, and your libvirt configuration significantly impacts your virtualization host. Notably, RHEL 9 contains two different types of libvirt daemons, monolithic or modular, and which type of daemons you use affects how granularly you can configure individual virtualization drivers.

### 13.3.1. Types of libvirt daemons

RHEL 9 supports the following libvirt daemon types:

**Monolithic libvirt**

The traditional libvirt daemon, libvirtd, controls a wide variety of virtualization drivers, using a single configuration file - /etc/libvirt/libvirtd.conf. As such, libvirtd allows for centralized hypervisor configuration, but may use system resources inefficiently. Therefore, libvirtd will become unsupported in a future major release of RHEL.

However, if you updated to RHEL 9 from RHEL 8, your host still uses libvirtd by default.

**Modular libvirt**

Newly introduced in RHEL 9, modular libvirt provides a specific daemon for each virtualization driver. These include the following:

- **virtqemud** - A primary daemon for hypervisor management
- **virtinterfaced** - A secondary daemon for host NIC management
- **virtnetworkd** - A secondary daemon for virtual network management
- **vrtndevd** - A secondary daemon for host physical device management
- **virtnwfilterd** - A secondary daemon for host firewall management
- **virtsecreted** - A secondary daemon for host secret management
- **virtstoraged** - A secondary daemon for storage management

Each of the daemons has a separate configuration file - for example /etc/libvirt/virtqemud.conf. As such, modular libvirt daemons provide better options for fine-tuning libvirt resource management.

If you performed a fresh install of RHEL 9, modular libvirt is configured by default.

### Next steps

- If your RHEL 9 uses libvirtd, Red Hat recommends switching to modular daemons. For instructions, see [Enabling modular libvirt daemons](#).
13.3.2. Enabling modular libvirt daemons

In RHEL 9, the libvirt library uses modular daemons that handle individual virtualization driver sets on your host. For example, the virtqemud daemon handles QEMU drivers.

If you performed a fresh install of a RHEL 9 host, your hypervisor uses modular libvirt daemons by default. However, if you upgraded your host from RHEL 8 to RHEL 9, your hypervisor uses the monolithic libvirtd daemon, which is the default in RHEL 8.

If that is the case, Red Hat recommends enabling the modular libvirt daemons instead, because they provide better options for fine-tuning libvirt resource management. In addition, libvirtd will become unsupported in a future major release of RHEL.

Prerequisites

- Your hypervisor is using the monolithic libvirtd service. To learn whether this is the case:

  ```bash
  # systemctl is-active libvirtd.service
  active
  ```

  If this command displays `active`, you are using libvirtd.

- Your virtual machines are shut down.

Procedure

1. Stop libvirtd and its sockets.

   ```bash
   # systemctl stop libvirtd.service
   # systemctl stop libvirtd{,-ro,-admin,-tcp,-tls}.socket
   ```

2. Disable libvirtd to prevent it from starting on boot.

   ```bash
   $ systemctl disable libvirtd.service
   $ systemctl disable libvirtd{,-ro,-admin,-tcp,-tls}.socket
   ```

3. Enable the modular libvirt daemons.

   ```bash
   # for drv in qemu interface network nodev network nodedev nwfilter secret storage; do systemctl
   # unmask virt${drv}d.service; systemctl unmask virt${drv}d{,-ro,-admin}.socket;
   # systemctl enable virt${drv}d.service; systemctl enable virt${drv}d{,-ro,-admin}.socket;
   done
   ```

4. Start the sockets for the modular daemons.

   ```bash
   # for drv in qemu network nodev network nwfilter secret storage; do systemctl start
   # virt${drv}d{,-ro,-admin}.socket; done
   ```

5. Optional: If you require connecting to your host from remote hosts, enable and start the virtualization proxy daemon.

   ```bash
   # systemctl unmask virtproxyd.service
   # systemctl unmask virtproxyd{,-ro,-admin,-tls}.socket
   # systemctl enable virtproxyd.service
   ```
# systemctl enable virtproxyd{,-ro,-admin,-tls}.socket
# systemctl start virtproxyd{,-ro,-admin,-tls}.socket

Verification

1. Activate the enabled virtualization daemons.
   
   ```bash
   # virsh uri
   qemu:///system
   ```

2. Ensure your host is using the **virtqemud** modular daemon.

   ```bash
   # systemctl is-active virtqemud.service
   active
   ```

   If this command displays `active`, you have successfully enabled modular **libvirt** daemons.

### 13.4. CONFIGURING VIRTUAL MACHINE MEMORY

To improve the performance of a virtual machine (VM), you can assign additional host RAM to the VM. Similarly, you can decrease the amount of memory allocated to a VM so the host memory can be allocated to other VMs or tasks.

To perform these actions, you can use the **web console** or the **command-line interface**.

#### 13.4.1. Adding and removing virtual machine memory using the web console

To improve the performance of a virtual machine (VM) or to free up the host resources it is using, you can use the web console to adjust amount of memory allocated to the VM.

**Prerequisites**

- The guest OS is running the memory balloon drivers. To verify this is the case:
  
  1. Ensure the VM’s configuration includes the **memballoon** device:

     ```bash
     # virsh dumpxml testguest | grep membalo
     <memballoon model="virtio">
     </memballoon>
     ```

     If this commands displays any output and the model is not set to **none**, the **memballoon** device is present.

  2. Ensure the balloon drivers are running in the guest OS.

     - In Windows guests, the drivers are installed as a part of the **virtio-win** driver package. For instructions, see Installing paravirtualized KVM drivers for Windows virtual machines.

     - In Linux guests, the drivers are generally included by default and activate when the **memballoon** device is present.

- The web console VM plug-in is installed on your system.
### Procedure

1. **Optional:** Obtain the information about the maximum memory and currently used memory for a VM. This will serve as a baseline for your changes, and also for verification.

   ```
   # virsh dominfo testguest
   Max memory:  2097152 KiB
   Used memory: 2097152 KiB
   ```

2. In the **Virtual Machines** interface, click the VM whose information you want to see. A new page opens with an Overview section with basic information about the selected VM and a Console section to access the VM’s graphical interface.

3. Click **edit** next to the **Memory** line in the Overview pane. The **Memory Adjustment** dialog appears.

4. Configure the virtual CPUs for the selected VM.

   - **Maximum allocation** - Sets the maximum amount of host memory that the VM can use for its processes. You can specify the maximum memory when creating the VM or increase it later. You can specify memory as multiples of MiB or GiB. Adjusting maximum memory allocation is only possible on a shut-off VM.

   - **Current allocation** - Sets the actual amount of memory allocated to the VM. This value can be less than the Maximum allocation but cannot exceed it. You can adjust the value to regulate the memory available to the VM for its processes. You can specify memory as multiples of MiB or GiB. If you do not specify this value, the default allocation is the **Maximum allocation** value.

5. Click **Save**. The memory allocation of the VM is adjusted.

### Additional resources

- Adding and removing virtual machine memory using the command-line interface
- Optimizing virtual machine CPU performance

### 13.4.2. Adding and removing virtual machine memory using the command-line interface

To improve the performance of a virtual machine (VM) or to free up the host resources it is using, you can use the CLI to adjust amount of memory allocated to the VM.
Prerequisites

- The guest OS is running the memory balloon drivers. To verify this is the case:

  1. Ensure the VM’s configuration includes the `memballoon` device:

     ```
     # virsh dumpxml testguest | grep memballoon
     <memballoon model='virtio'>
     </memballoon>
     ```

     If this command displays any output and the model is not set to `none`, the `memballoon` device is present.

  2. Ensure the balloon drivers are running in the guest OS.

     - In Windows guests, the drivers are installed as a part of the `virtio-win` driver package. For instructions, see Installing paravirtualized KVM drivers for Windows virtual machines.
     - In Linux guests, the drivers are generally included by default and activate when the `memballoon` device is present.

Procedure

1. **Optional:** Obtain the information about the maximum memory and currently used memory for a VM. This will serve as a baseline for your changes, and also for verification.

   ```
   # virsh dominfo testguest
   Max memory:     2097152 KiB
   Used memory:    2097152 KiB
   ```

2. Adjust the maximum memory allocated to a VM. Increasing this value improves the performance potential of the VM, and reducing the value lowers the performance footprint the VM has on your host. Note that this change can only be performed on a shut-off VM, so adjusting a running VM requires a reboot to take effect.

   For example, to change the maximum memory that the `testguest` VM can use to 4096 MiB:

   ```
   # virt-xml testguest --edit --memory memory=4096,currentMemory=4096
   Domain 'testguest' defined successfully.
   Changes will take effect after the domain is fully powered off.
   ```

   To increase the maximum memory of a running VM, you can attach a memory device to the VM. This is also referred to as memory hot plug. For details, see Attaching devices to virtual machines.

   **WARNING**

   Removing memory devices from a running VM (also referred as a memory hot unplug) is not supported, and highly discouraged by Red Hat.
3. **Optional**: You can also adjust the memory currently used by the VM, up to the maximum allocation. This regulates the memory load that the VM has on the host until the next reboot, without changing the maximum VM allocation.

```bash
# virsh setmem testguest --current 2048
```

**Verification**

1. Confirm that the memory used by the VM has been updated:

```bash
# virsh dominfo testguest
Max memory:     4194304 KiB
Used memory:    2097152 KiB
```

2. **Optional**: If you adjusted the current VM memory, you can obtain the memory balloon statistics of the VM to evaluate how effectively it regulates its memory use.

```bash
# virsh domstats --balloon testguest
Domain: 'testguest'
  balloon.current=365624
  balloon.maximum=4194304
  balloon.swap_in=0
  balloon.swap_out=0
  balloon.major_fault=306
  balloon.minor_fault=156117
  balloon.unused=3834448
  balloon.available=4035008
  balloon.usable=3746340
  balloon.last-update=1587971682
  balloon.disk_caches=75444
  balloon.hugetlb_pgalloc=0
  balloon.hugetlb_pgfail=0
  balloon.rss=1005456
```

**Additional resources**

- Adding and removing virtual machine memory using the web console
- Optimizing virtual machine CPU performance

### 13.4.3. Additional resources

- Attaching devices to virtual machines

### 13.5. OPTIMIZING VIRTUAL MACHINE I/O PERFORMANCE

The input and output (I/O) capabilities of a virtual machine (VM) can significantly limit the VM’s overall efficiency. To address this, you can optimize a VM’s I/O by configuring block I/O parameters.

#### 13.5.1. Tuning block I/O in virtual machines

When multiple block devices are being used by one or more VMs, it might be important to adjust the I/O priority of specific virtual devices by modifying their I/O weights.
Increasing the I/O weight of a device increases its priority for I/O bandwidth, and therefore provides it with more host resources. Similarly, reducing a device’s weight makes it consume less host resources.

**NOTE**

Each device’s `weight` value must be within the **100** to **1000** range. Alternatively, the value can be **0**, which removes that device from per-device listings.

**Procedure**

To display and set a VM’s block I/O parameters:

1. Display the current `<blkio>` parameters for a VM:

   ```
   # virsh dumpxml VM-name
   ```

   ```xml
   <domain>
   [...]  
   <blkiotune>  
   <weight>800</weight>  
   <device>  
   <path>/dev/sda</path>  
   <weight>1000</weight>  
   </device>  
   <device>  
   <path>/dev/sdb</path>  
   <weight>500</weight>  
   </device>  
   </blkiotune>  
   [...]  
   </domain>
   ```

2. Edit the I/O weight of a specified device:

   ```
   # virsh blktune VM-name --device-weights device, I/O-weight
   ```

   For example, the following changes the weight of the `/dev/sda` device in the `liftrul` VM to 500.

   ```
   # virsh blktune liftrul --device-weights /dev/sda, 500
   ```

**13.5.2. Disk I/O throttling in virtual machines**

When several VMs are running simultaneously, they can interfere with system performance by using excessive disk I/O. Disk I/O throttling in KVM virtualization provides the ability to set a limit on disk I/O requests sent from the VMs to the host machine. This can prevent a VM from over-utilizing shared resources and impacting the performance of other VMs.

To enable disk I/O throttling, set a limit on disk I/O requests sent from each block device attached to VMs to the host machine.

**Procedure**

1. Use the `virsh domblklist` command to list the names of all the disk devices on a specified VM.

   ```
   # virsh domblklist rollin-coal
   ```
2. Find the host block device where the virtual disk that you want to throttle is mounted. For example, if you want to throttle the `sdb` virtual disk from the previous step, the following output shows that the disk is mounted on the `/dev/nvme0n1p3` partition.

```
$ lsblk
NAME                      MAJ:MIN   RM  SIZE RO TYPE    MOUNTPOINT
zram0                     252:0      0   4G  0 disk [SWAP]
nvme0n1                   259:0      0 238.5G 0 disk
  └─nvme0n1p1              259:1      0  600M 0 part /boot/efi
  └─nvme0n1p2              259:2      0   1G  0 part /boot
└─nvme0n1p3                259:3      0 236.9G 0 part
  └─luks-a1123911-6f37-463c-b4eb-fxzy1ac12fea 253:0 0 236.9G 0 crypt /home
```

3. Set I/O limits for the block device using the `virsh blkiotune` command.

```
# virsh blkiotune VM-name --parameter device,limit
```

The following example throttles the `sdb` disk on the `rollin-coal` VM to 1000 read and write I/O operations per second and to 50 MB per second read and write throughput.

```
# virsh blkiotune rollin-coal --device-read-iops-sec /dev/nvme0n1p3,1000 --device-write-iops-sec /dev/nvme0n1p3,1000 --device-write-bytes-sec /dev/nvme0n1p3,52428800 --device-read-bytes-sec /dev/nvme0n1p3,52428800
```

Additional information

- Disk I/O throttling can be useful in various situations, for example when VMs belonging to different customers are running on the same host, or when quality of service guarantees are given for different VMs. Disk I/O throttling can also be used to simulate slower disks.

- I/O throttling can be applied independently to each block device attached to a VM and supports limits on throughput and I/O operations.

- Red Hat does not support using the `virsh blkdeviotune` command to configure I/O throttling in VMs. For more information on unsupported features when using RHEL 9 as a VM host, see [Unsupported features in RHEL 9 virtualization](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/9/html/migration_guide/unsupported-features-in-rhel-9-virtualization).

13.5.3. Enabling multi-queue virtio-scsi

When using `virtio-scsi` storage devices in your virtual machines (VMs), the `multi-queue virtio-scsi` feature provides improved storage performance and scalability. It enables each virtual CPU (vCPU) to have a separate queue and interrupt to use without affecting other vCPUs.

**Procedure**

- To enable multi-queue virtio-scsi support for a specific VM, add the following to the VM’s XML configuration, where `N` is the total number of vCPU queues:
13.6. OPTIMIZING VIRTUAL MACHINE CPU PERFORMANCE

Much like physical CPUs in host machines, vCPUs are critical to virtual machine (VM) performance. As a result, optimizing vCPUs can have a significant impact on the resource efficiency of your VMs. To optimize your vCPU:

1. Adjust how many host CPUs are assigned to the VM. You can do this using the CLI or the web console.

2. Ensure that the vCPU model is aligned with the CPU model of the host. For example, to set the `testguest1` VM to use the CPU model of the host:

   ```bash
   # virt-xml testguest1 --edit --cpu host-model
   ```

3. Manage kernel same-page merging (KSM).

4. If your host machine uses Non-Uniform Memory Access (NUMA), you can also configure NUMA for its VMs. This maps the host’s CPU and memory processes onto the CPU and memory processes of the VM as closely as possible. In effect, NUMA tuning provides the vCPU with a more streamlined access to the system memory allocated to the VM, which can improve the vCPU processing effectiveness.

   For details, see Configuring NUMA in a virtual machine and Sample vCPU performance tuning scenario.

13.6.1. Adding and removing virtual CPUs using the command-line interface

To increase or optimize the CPU performance of a virtual machine (VM), you can add or remove virtual CPUs (vCPUs) assigned to the VM.

When performed on a running VM, this is also referred to as vCPU hot plugging and hot unplugging. However, note that vCPU hot unplug is not supported in RHEL 9, and Red Hat highly discourages its use.

Prerequisites

- **Optional:** View the current state of the vCPUs in the targeted VM. For example, to display the number of vCPUs on the `testguest` VM:

  ```bash
  # virsh vcpucount testguest
  maximum config 4
  maximum live 2
  current config 2
  current live 1
  ```

  This output indicates that `testguest` is currently using 1 vCPU, and 1 more vCPU can be hot plugged to it to increase the VM’s performance. However, after reboot, the number of vCPUs `testguest` uses will change to 2, and it will be possible to hot plug 2 more vCPUs.

Procedure

<controller type='scsi' index='0' model='virtio-scsi'>
  <driver queues='N'/>
</controller>
1. Adjust the maximum number of vCPUs that can be attached to a VM, which takes effect on the VM’s next boot. For example, to increase the maximum vCPU count for the testguest VM to 8:

   ```bash
   # virsh setvcpus testguest 8 --maximum --config
   ```

   Note that the maximum may be limited by the CPU topology, host hardware, the hypervisor, and other factors.

2. Adjust the current number of vCPUs attached to a VM, up to the maximum configured in the previous step. For example:

   - To increase the number of vCPUs attached to the running testguest VM to 4:
     ```bash
     # virsh setvcpus testguest 4 --live
     ```
     This increases the VM’s performance and host load footprint of testguest until the VM’s next boot.

   - To permanently decrease the number of vCPUs attached to the testguest VM to 1:
     ```bash
     # virsh setvcpus testguest 1 --config
     ```
     This decreases the VM’s performance and host load footprint of testguest after the VM’s next boot. However, if needed, additional vCPUs can be hot plugged to the VM to temporarily increase its performance.

Verification

- Confirm that the current state of vCPU for the VM reflects your changes.

   ```bash
   # virsh vcpucount testguest
   maximum  config     8
   maximum  live        4
   current   config     1
   current   live        4
   ```

Additional resources

- Managing virtual CPUs using the web console

13.6.2. Managing virtual CPUs using the web console

Using the RHEL 9 web console, you can review and configure virtual CPUs used by virtual machines (VMs) to which the web console is connected.

Prerequisites

- The web console VM plug-in is installed on your system.

Procedure

1. In the Virtual Machines interface, click the VM whose information you want to see.
A new page opens with an Overview section with basic information about the selected VM and a Console section to access the VM’s graphical interface.

2. Click **edit** next to the number of vCPUs in the Overview pane. The vCPU details dialog appears.

![Grid_v2 vCPU details](image)

1. Configure the virtual CPUs for the selected VM.
   - **vCPU Count** - The number of vCPUs currently in use.
     
     **NOTE**
     
     The vCPU count cannot be greater than the vCPU Maximum.

   - **vCPU Maximum** - The maximum number of virtual CPUs that can be configured for the VM. If this value is higher than the **vCPU Count**, additional vCPUs can be attached to the VM.

   - **Sockets** - The number of sockets to expose to the VM.

   - **Cores per socket** - The number of cores for each socket to expose to the VM.

   - **Threads per core** - The number of threads for each core to expose to the VM.

   Note that the **Sockets**, **Cores per socket**, and **Threads per core** options adjust the CPU topology of the VM. This may be beneficial for vCPU performance and may impact the functionality of certain software in the guest OS. If a different setting is not required by your deployment, keep the default values.

2. Click **Apply**.

The virtual CPUs for the VM are configured.

**NOTE**

Changes to virtual CPU settings only take effect after the VM is restarted.

Additional resources

- Adding and removing virtual CPUs using the command-line interface

**13.6.3. Configuring NUMA in a virtual machine**
The following methods can be used to configure Non-Uniform Memory Access (NUMA) settings of a virtual machine (VM) on a RHEL 9 host.

Prerequisites

- The host is a NUMA-compatible machine. To detect whether this is the case, use the `virsh nodeinfo` command and see the NUMA cell(s) line:

  ```
  # virsh nodeinfo
  CPU model:           x86_64
  CPU(s):              48
  CPU frequency:       1200 MHz
  CPU socket(s):       1
  Core(s) per socket:  12
  Thread(s) per core:  2
  NUMA cell(s):        2
  Memory size:         67012964 KiB
  ```

  If the value of the line is 2 or greater, the host is NUMA-compatible.

Procedure

For ease of use, you can set up a VM’s NUMA configuration using automated utilities and services. However, manual NUMA setup is more likely to yield a significant performance improvement.

Automatic methods

- Set the VM’s NUMA policy to Preferred. For example, to do so for the `testguest5` VM:

  ```
  # virt-xml testguest5 --edit --vcpus placement=auto
  # virt-xml testguest5 --edit --numatune mode=preferred
  ```

- Enable automatic NUMA balancing on the host:

  ```
  # echo 1 > /proc/sys/kernel/numa_balancing
  ```

- Use the `numad` command to automatically align the VM CPU with memory resources.

  ```
  # numad
  ```

Manual methods

1. Pin specific vCPU threads to a specific host CPU or range of CPUs. This is also possible on non-NUMA hosts and VMs, and is recommended as a safe method of vCPU performance improvement.

   For example, the following commands pin vCPU threads 0 to 5 of the `testguest6` VM to host CPUs 1, 3, 5, 7, 9, and 11, respectively:

   ```
   # virsh vcpupin testguest6 0 1
   # virsh vcpupin testguest6 1 3
   # virsh vcpupin testguest6 2 5
   # virsh vcpupin testguest6 3 7
   # virsh vcpupin testguest6 4 9
   # virsh vcpupin testguest6 5 11
   ```
Afterwards, you can verify whether this was successful:

```
# virsh vcpupin testguest6
VCPU   CPU Affinity
--------------------
0      1
1      3
2      5
3      7
4      9
5      11
```

2. After pinning vCPU threads, you can also pin QEMU process threads associated with a specified VM to a specific host CPU or range of CPUs. For example, the following commands pin the QEMU process thread of `testguest6` to CPUs 13 and 15, and verify this was successful:

```
# virsh emulatorpin testguest6 13,15
# virsh emulatorpin testguest6
emulator: CPU Affinity
----------------------------------
*: 13,15
```

3. Finally, you can also specify which host NUMA nodes will be assigned specifically to a certain VM. This can improve the host memory usage by the VM’s vCPU. For example, the following commands set `testguest6` to use host NUMA nodes 3 to 5, and verify this was successful:

```
# virsh numatune testguest6 --nodeset 3-5
# virsh numatune testguest6
```

**NOTE**

For best performance results, it is recommended to use all of the manual tuning methods listed above.

**Known issues**

- NUMA tuning currently cannot be performed on IBM Z hosts.

**Additional resources**

- Sample vCPU performance tuning scenario
- View the current NUMA configuration of your system using the `numastat` utility

### 13.6.4. Sample vCPU performance tuning scenario

To obtain the best vCPU performance possible, Red Hat recommends using manual `vcpupin`, `emulatorpin`, and `numatune` settings together, for example like in the following scenario.

**Starting scenario**

- Your host has the following hardware specifics:
  - 2 NUMA nodes
○ 3 CPU cores on each node
○ 2 threads on each core

The output of `virsh nodeinfo` of such a machine would look similar to:

```
# virsh nodeinfo
cpu model:           x86_64
cpu(s):              12
CPU frequency:       3661 MHz
CPU socket(s):       2
Core(s) per socket:  3
Thread(s) per core:  2
NUMA cell(s):        2
Memory size:         31248692 KiB
```

● You intend to modify an existing VM to have 8 vCPUs, which means that it will not fit in a single NUMA node. Therefore, you should distribute 4 vCPUs on each NUMA node and make the vCPU topology resemble the host topology as closely as possible. This means that vCPUs that run as sibling threads of a given physical CPU should be pinned to host threads on the same core. For details, see the Solution below:

Solution

1. Obtain the information on the host topology:

```
# virsh capabilities
```

The output should include a section that looks similar to the following:

```
<topology>
  <cells num="2">
    <cell id="0">
      <memory unit="KiB">15624346</memory>
      <pages unit="KiB" size="4">3906086</pages>
      <pages unit="KiB" size="2048">0</pages>
      <pages unit="KiB" size="1048576">0</pages>
      <distances>
        <sibling id="0" value="10"/>
        <sibling id="1" value="21"/>
      </distances>
    </cell>
    <cell id="1">
      <memory unit="KiB">15624346</memory>
      <pages unit="KiB" size="4">3906086</pages>
      <pages unit="KiB" size="2048">0</pages>
    </cell>
  </cells>
  <cpus num="6">
    <cpu id="0" socket_id="0" core_id="0" siblings="0,3"/>
    <cpu id="1" socket_id="0" core_id="1" siblings="1,4"/>
    <cpu id="2" socket_id="0" core_id="2" siblings="2,5"/>
    <cpu id="3" socket_id="0" core_id="0" siblings="0,3"/>
    <cpu id="4" socket_id="0" core_id="1" siblings="1,4"/>
    <cpu id="5" socket_id="0" core_id="2" siblings="2,5"/>
  </cpus>
</topology>
```
2. **Optional:** Test the performance of the VM using the applicable tools and utilities.

3. Set up and mount 1 GiB huge pages on the host:
   a. Add the following line to the host's kernel command line:
      ```
      default_hugepagesz=1G hugepagesz=1G
      ```
   b. Create the `/etc/systemd/system/hugetlb-gigantic-pages.service` file with the following content:
      ```
      [Unit]
      Description=HugeTLB Gigantic Pages Reservation
      DefaultDependencies=no
      Before=dev-hugepages.mount
      ConditionPathExists=/sys/devices/system/node
      ConditionKernelCommandLine=hugepagesz=1G

      [Service]
      Type=oneshot
      RemainAfterExit=yes
      ExecStart=/etc/systemd/hugetlb-reserve-pages.sh

      [Install]
      WantedBy=sysinit.target
      ```
   c. Create the `/etc/systemd/hugetlb-reserve-pages.sh` file with the following content:
      ```bash
      #!/bin/sh

      nodes_path=/sys/devices/system/node/
      if [ ! -d $nodes_path ]; then
        echo "ERROR: $nodes_path does not exist"
        exit 1
      fi

      reserve_pages()
      {
      ```
This reserves four 1GiB huge pages from node1 and four 1GiB huge pages from node2.

d. Make the script created in the previous step executable:

```bash
# chmod +x /etc/systemd/hugetlb-reserve-pages.sh
```

e. Enable huge page reservation on boot:

```bash
# systemctl enable hugetlb-gigantic-pages
```

4. Use the `virsh edit` command to edit the XML configuration of the VM you wish to optimize, in this example `super-VM`:

```bash
# virsh edit super-vm
```

5. Adjust the XML configuration of the VM in the following way:

a. Set the VM to use 8 static vCPUs. Use the `<vcpu/>` element to do this.

b. Pin each of the vCPU threads to the corresponding host CPU threads that it mirrors in the topology. To do so, use the `<vcpupin/>` elements in the `<cputune/>` section. Note that, as shown by the `virsh capabilities` utility above, host CPU threads are not ordered sequentially in their respective cores. In addition, the vCPU threads should be pinned to the highest available set of host cores on the same NUMA node. For a table illustration, see the Sample topology section below.

The XML configuration for steps a. and b. can look similar to:

```xml
<memoryBacking>
  <hugepages>
    <page size='1' unit='GiB'/>
  </hugepages>
</memoryBacking>
```

c. Set the VM to use 1 GiB huge pages:

```xml
<cpu>
  <vcpupin vcpu='0' cpuset='1'/>
  <vcpupin vcpu='1' cpuset='4'/>
  <vcpupin vcpu='2' cpuset='2'/>
  <vcpupin vcpu='3' cpuset='5'/>
  <vcpupin vcpu='4' cpuset='7'/>
  <vcpupin vcpu='5' cpuset='10'/>
  <vcpupin vcpu='6' cpuset='8'/>
  <vcpupin vcpu='7' cpuset='11'/>
  <emulatorpin cpuset='6,9'/>
</cpu>
```
d. Configure the VM's NUMA nodes to use memory from the corresponding NUMA nodes on the host. To do so, use the `<memnode/>` elements in the `<numatune/>` section:

```
<numatune>
  <memory mode="preferred" nodeset="1"/>
  <memnode cellid="0" mode="strict" nodeset="0"/>
  <memnode cellid="1" mode="strict" nodeset="1"/>
</numatune>
```

e. Ensure the CPU mode is set to host-passthrough, and that the CPU uses cache in passthrough mode:

```
<cpu mode="host-passthrough">
  <topology sockets="2" cores="2" threads="2"/>
  <cache mode="passthrough"/>
</cpu>
```

Verification

1. Confirm that the resulting XML configuration of the VM includes a section similar to the following:

```
[...]
<memoryBacking>
  <hugepages>
    <page size='1' unit='GiB'/>
  </hugepages>
</memoryBacking>
<vcpu placement='static'>8</vcpu>
<cpu>
  <vcpupin vcpu='0' cpuset='1'/>
  <vcpupin vcpu='1' cpuset='4'/>
  <vcpupin vcpu='2' cpuset='2'/>
  <vcpupin vcpu='3' cpuset='5'/>
  <vcpupin vcpu='4' cpuset='7'/>
  <vcpupin vcpu='5' cpuset='10'/>
  <vcpupin vcpu='6' cpuset='8'/>
  <vcpupin vcpu='7' cpuset='11'/>
  <emulatorpin cpuset='6,9'/>
</cpu>
<numatune>
  <memory mode="preferred" nodeset="1"/>
  <memnode cellid="0" mode="strict" nodeset="0"/>
  <memnode cellid="1" mode="strict" nodeset="1"/>
</numatune>
<cpu mode="host-passthrough">
  <topology sockets="2" cores="2" threads="2"/>
  <cache mode="passthrough"/>
</cpu>
<numa>
  <cell id="0" cpus="0-3" memory="2" unit="GiB">
    <distances>
      <sibling id="0" value="10"/>
      <sibling id="1" value="21"/>
    </distances>
  </cell>
  <cell id="1" cpus="4-7" memory="2" unit="GiB"/>
```
2. **Optional:** Test the performance of the VM using the applicable tools and utilities to evaluate the impact of the VM's optimization.

Sample topology

- The following tables illustrate the connections between the vCPUs and the host CPUs they should be pinned to:

<table>
<thead>
<tr>
<th>Table 13.1. Host topology</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU threads</td>
</tr>
<tr>
<td>Cores</td>
</tr>
<tr>
<td>Sockets</td>
</tr>
<tr>
<td>NUMA nodes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Table 13.2. VM topology</th>
</tr>
</thead>
<tbody>
<tr>
<td>vCPU threads</td>
</tr>
<tr>
<td>Cores</td>
</tr>
<tr>
<td>Sockets</td>
</tr>
<tr>
<td>NUMA nodes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Table 13.3. Combined host and VM topology</th>
</tr>
</thead>
<tbody>
<tr>
<td>vCPU threads</td>
</tr>
<tr>
<td>Host CPU threads</td>
</tr>
<tr>
<td>Cores</td>
</tr>
<tr>
<td>Sockets</td>
</tr>
<tr>
<td>NUMA nodes</td>
</tr>
</tbody>
</table>
In this scenario, there are 2 NUMA nodes and 8 vCPUs. Therefore, 4 vCPU threads should be pinned to each node.

In addition, Red Hat recommends leaving at least a single CPU thread available on each node for host system operations.

Because in this example, each NUMA node houses 3 cores, each with 2 host CPU threads, the set for node 0 translates as follows:

```
<vcpupin vcpu='0' cpuset='1'/>
<vcpupin vcpu='1' cpuset='4'/>
<vcpupin vcpu='2' cpuset='2'/>
<vcpupin vcpu='3' cpuset='5'/>
```

13.6.5. Managing kernel same-page merging

Kernel Same-Page Merging (KSM) improves memory density by sharing identical memory pages between virtual machines (VMs). However, enabling KSM increases CPU utilization, and might adversely affect overall performance depending on the workload.

Depending on your requirements, you can either enable or disable KSM for a single session or persistently.

**NOTE**

In RHEL 9 and later, KSM is disabled by default.

Prerequisites

- Root access to your host system.

Procedure

- Disable KSM:

  - To deactivate KSM for a single session, use the `systemctl` utility to stop `ksm` and `ksmtuned` services.
    
    ```
    # systemctl stop ksm
    # systemctl stop ksmtuned
    ```

  - To deactivate KSM persistently, use the `systemctl` utility to disable `ksm` and `ksmtuned` services.
    
    ```
    # systemctl disable ksm
    Removed /etc/systemd/system/multi-user.target.wants/ksm.service.
    # systemctl disable ksmtuned
    Removed /etc/systemd/system/multi-user.target.wants/ksmtuned.service.
    ```
NOTE

Memory pages shared between VMs before deactivating KSM will remain shared. To stop sharing, delete all the PageKSM pages in the system using the following command:

```
# echo 2 > /sys/kernel/mm/ksm/run
```

After anonymous pages replace the KSM pages, the khugepaged kernel service will rebuild transparent hugepages on the VM’s physical memory.

- Enable KSM:

WARNING

Enabling KSM increases CPU utilization and affects overall CPU performance.

1. Install the ksmtuned service:

```
# yum install ksmtuned
```

2. Start the service:

   - To enable KSM for a single session, use the systemctl utility to start the ksm and ksmtuned services.

```
# systemctl start ksm
# systemctl start ksmtuned
```

   - To enable KSM persistently, use the systemctl utility to enable the ksm and ksmtuned services.

```
# systemctl enable ksm
Created symlink /etc/systemd/system/multi-user.target.wants/ksm.service → /usr/lib/systemd/system/ksm.service

# systemctl enable ksmtuned
Created symlink /etc/systemd/system/multi-user.target.wants/ksmtuned.service → /usr/lib/systemd/system/ksmtuned.service
```

13.7. OPTIMIZING VIRTUAL MACHINE NETWORK PERFORMANCE

Due to the virtual nature of a VM’s network interface card (NIC), the VM loses a portion of its allocated host network bandwidth, which can reduce the overall workload efficiency of the VM. The following tips can minimize the negative impact of virtualization on the virtual NIC (vNIC) throughput.

**Procedure**

Use any of the following methods and observe if it has a beneficial effect on your VM network performance:
Enable the vhost_net module

On the host, ensure the `vhost_net` kernel feature is enabled:

```
# lsmod | grep vhost
vhost_net              32768  1
vhost                  53248  1 vhost_net
tap                    24576  1 vhost_net
tun                    57344  6 vhost_net
```

If the output of this command is blank, enable the `vhost_net` kernel module:

```
# modprobe vhost_net
```

Set up multi-queue virtio-net

To set up the multi-queue virtio-net feature for a VM, use the `virsh edit` command to edit the XML configuration of the VM. In the XML, add the following to the `<devices>` section, and replace `N` with the number of vCPUs in the VM, up to 16:

```
<interface type='network'>
  <source network='default'/>
  <model type='virtio'/>
  <driver name='vhost' queues='N'/>
</interface>
```

If the VM is running, restart it for the changes to take effect.

Batching network packets

In Linux VM configurations with a long transmission path, batching packets before submitting them to the kernel may improve cache utilization. To set up packet batching, use the following command on the host, and replace `tap0` with the name of the network interface that the VMs use:

```
# ethtool -C tap0 rx-frames 64
```

SR-IOV

If your host NIC supports SR-IOV, use SR-IOV device assignment for your vNICs. For more information, see Managing SR-IOV devices.

Additional resources

- Understanding virtual networking

**13.8. VIRTUAL MACHINE PERFORMANCE MONITORING TOOLS**

To identify what consumes the most VM resources and which aspect of VM performance needs optimization, performance diagnostic tools, both general and VM-specific, can be used.

Default OS performance monitoring tools

For standard performance evaluation, you can use the utilities provided by default by your host and guest operating systems:
On your RHEL 9 host, as root, use the `top` utility or the `system monitor` application, and look for `qemu` and `virt` in the output. This shows how much host system resources your VMs are consuming.

- If the monitoring tool displays that any of the `qemu` or `virt` processes consume a large portion of the host CPU or memory capacity, use the `perf` utility to investigate. For details, see below.

- In addition, if a `vhost_net` thread process, named for example `vhost_net-1234`, is displayed as consuming an excessive amount of host CPU capacity, consider using virtual network optimization features, such as `multi-queue virtio-net`.

On the guest operating system, use performance utilities and applications available on the system to evaluate which processes consume the most system resources.

- On Linux systems, you can use the `top` utility.

- On Windows systems, you can use the `Task Manager` application.

**perf kvm**

You can use the `perf` utility to collect and analyze virtualization-specific statistics about the performance of your RHEL 9 host. To do so:

1. On the host, install the `perf` package:

   ```
   # dnf install perf
   ```

2. Use one of the `perf kvm stat` commands to display perf statistics for your virtualization host:

   - For real-time monitoring of your hypervisor, use the `perf kvm stat live` command.

   - To log the perf data of your hypervisor over a period of time, activate the logging using the `perf kvm stat record` command. After the command is canceled or interrupted, the data is saved in the `perf.data.guest` file, which can be analyzed using the `perf kvm stat report` command.

3. Analyze the `perf` output for types of VM-EXIT events and their distribution. For example, the PAUSE_INSTRUCTION events should be infrequent, but in the following output, the high occurrence of this event suggests that the host CPUs are not handling the running vCPUs well. In such a scenario, consider shutting down some of your active VMs, removing vCPUs from these VMs, or tuning the performance of the vCPUs.

   ```
   # perf kvm stat report
   ```

   Analyze events for all VMs, all VCPUs:

<table>
<thead>
<tr>
<th>VM-EXIT</th>
<th>Samples</th>
<th>Samples%</th>
<th>Time%</th>
<th>Min Time</th>
<th>Max Time</th>
<th>Avg time</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL_INTERRUPT</td>
<td>365634</td>
<td>31.59%</td>
<td>18.04%</td>
<td>0.42us</td>
<td>58780.59us</td>
<td></td>
</tr>
<tr>
<td></td>
<td>204.08us</td>
<td></td>

<td>0.72us</td>
<td>29655.25us</td>
<td>256.77us</td>
</tr>
</tbody>
</table>
   ```
Other event types that can signal problems in the output of `perf kvm stat` include:

- **INSN_EMULATION** - suggests suboptimal VM I/O configuration.

For more information on using `perf` to monitor virtualization performance, see the `perf-kvm` man page.

**numastat**

To see the current NUMA configuration of your system, you can use the `numastat` utility, which is provided by installing the `numactl` package.

The following shows a host with 4 running VMs, each obtaining memory from multiple NUMA nodes. This is not optimal for vCPU performance, and warrants adjusting:

```bash
# numastat -c qemu-kvm

Per-node process memory usage (in MBs)

<table>
<thead>
<tr>
<th>PID</th>
<th>Node 0</th>
<th>Node 1</th>
<th>Node 2</th>
<th>Node 3</th>
<th>Node 4</th>
<th>Node 5</th>
<th>Node 6</th>
<th>Node 7</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>51722 (qemu-kvm)</td>
<td>68</td>
<td>16</td>
<td>357</td>
<td>6936</td>
<td>2</td>
<td>3</td>
<td>147</td>
<td>598</td>

</tr>
</tbody>
</table>

Total                  0  0  8072  0  8072  0  8114  8110  32368
```

13.9. ADDITIONAL RESOURCES
- Optimizing Windows virtual machines
CHAPTER 14. MANAGING POWER CONSUMPTION WITH POWERTOP

As a system administrator, you can use the Powertop tool to analyze and manage power consumption.

14.1. THE PURPOSE OF POWERTOP

Powertop is a program that diagnoses issues related to power consumption and provides suggestions on how to extend battery lifetime.

The Powertop tool can provide an estimate of the total power usage of the system and also individual power usage for each process, device, kernel worker, timer, and interrupt handler. The tool can also identify specific components of kernel and user-space applications that frequently wake up the CPU.

Red Hat Enterprise Linux 9 uses version 2.x of Powertop.

14.2. USING POWERTOP

Prerequisites

To be able to use Powertop, make sure that the powertop package has been installed on your system:

```
# dnf install powertop
```

14.2.1. Starting Powertop

Procedure

To run Powertop, use the following command:

```
# powertop
```

IMPORTANT

Laptops should run on battery power when running the powertop command.

14.2.2. Calibrating Powertop

Procedure

1. On a laptop, you can calibrate the power estimation engine by running the following command:

```
# powertop --calibrate
```

2. Let the calibration finish without interacting with the machine during the process. Calibration takes time because the process performs various tests, cycles through brightness levels and switches devices on and off.
3. When the calibration process is completed, **PowerTOP** starts as normal. Let it run for approximately an hour to collect data. When enough data is collected, power estimation figures will be displayed in the first column of the output table.

**NOTE**

Note that `powertop --calibrate` can only be used on laptops.

### 14.2.3. Setting the measuring interval

By default, **PowerTOP** takes measurements in 20 seconds intervals.

If you want to change this measuring frequency, use the following procedure:

**Procedure**

- Run the `powertop` command with the `--time` option:

  ```
  # powertop --time=time in seconds
  ```

### 14.2.4. Additional resources

For more details on how to use **PowerTOP**, see the `powertop` man page.

### 14.3. POWERTOP STATISTICS

While it runs, **PowerTOP** gathers statistics from the system.

**PowerTOP**'s output provides multiple tabs:

- **Overview**
- **Idle stats**
- **Frequency stats**
- **Device stats**
- **Tunables**
- **WakeUp**

You can use the **Tab** and **Shift+Tab** keys to cycle through these tabs.

#### 14.3.1. The Overview tab

In the **Overview** tab, you can view a list of the components that either send wakeups to the CPU most frequently or consume the most power. The items within the **Overview** tab, including processes, interrupts, devices, and other resources, are sorted according to their utilization.

The adjacent columns within the **Overview** tab provide the following pieces of information:

**Usage**
Power estimation of how the resource is being used.

**Events/s**

Wakes per second. The number of wakeupes per second indicates how efficiently the services or the devices and drivers of the kernel are performing. Less wakeups means that less power is consumed. Components are ordered by how much further their power usage can be optimized.

**Category**

Classification of the component; such as process, device, or timer.

**Description**

Description of the component.

If properly calibrated, a power consumption estimation for every listed item in the first column is shown as well.

Apart from this, the **Overview** tab includes the line with summary statistics such as:

- Total power consumption
- Remaining battery life (only if applicable)
- Summary of total wakeups per second, GPU operations per second, and virtual file system operations per second

### 14.3.2. The Idle stats tab

The **Idle stats** tab shows usage of C-states for all processors and cores, while the **Frequency stats** tab shows usage of P-states including the Turbo mode, if applicable, for all processors and cores. The duration of C- or P-states is an indication of how well the CPU usage has been optimized. The longer the CPU stays in the higher C- or P-states (for example C4 is higher than C3), the better the CPU usage optimization is. Ideally, residency is 90% or more in the highest C- or P-state when the system is idle.

### 14.3.3. The Device stats tab

The **Device stats** tab provides similar information to the **Overview** tab but only for devices.

### 14.3.4. The Tunables tab

The **Tunables** tab contains PowerTOP’s suggestions for optimizing the system for lower power consumption.

Use the `up` and `down` keys to move through suggestions, and the `enter` key to toggle the suggestion on or off.

### 14.3.5. The WakeUp tab

The **WakeUp** tab displays the device wakeup settings available for users to change as and when required.

Use the `up` and `down` keys to move through the available settings, and the `enter` key to enable or disable a setting.
14.4. WHY POWERTOP DOES NOT DISPLAY FREQUENCY STATS VALUES IN SOME INSTANCES

While using the Intel P-State driver, PowerTOP only displays values in the Frequency Stats tab if the driver is in passive mode. But, even in this case, the values may be incomplete.

In total, there are three possible modes of the Intel P-State driver:

- Active mode with Hardware P-States (HWP)
- Active mode without HWP
- Passive mode

Switching to the ACPI CPUfreq driver results in complete information being displayed by PowerTOP. However, it is recommended to keep your system on the default settings.

To see what driver is loaded and in what mode, run:

```
# cat /sys/devices/system/cpu/cpu0/cpufreq/scaling_driver
```

- `intel_pstate` is returned if the Intel P-State driver is loaded and in active mode.
- `intel_cpufreq` is returned if the Intel P-State driver is loaded and in passive mode.
- `acpi-cpufreq` is returned if the ACPI CPUfreq driver is loaded.

While using the Intel P-State driver, add the following argument to the kernel boot command line to force the driver to run in passive mode:

```
inTEL_pstate=passive
```
To disable the Intel P-State driver and use, instead, the ACPI CPUfreq driver, add the following argument to the kernel boot command line:

```
intel_pstate=disable
```

### 14.5. GENERATING AN HTML OUTPUT

Apart from the powertop’s output in terminal, you can also generate an HTML report.

**Procedure**

- Run the `powertop` command with the `--html` option:

  ```
  # powertop --html=htmlfile.html
  ```

  Replace the `htmlfile.html` parameter with the required name for the output file.

### 14.6. OPTIMIZING POWER CONSUMPTION

To optimize power consumption, you can use either the `powertop` service or the `powertop2tuned` utility.

#### 14.6.1. Optimizing power consumption using the powertop service

You can use the `powertop` service to automatically enable all PowerTOP’s suggestions from the Tunables tab on the boot:

**Procedure**

- Enable the `powertop` service:

  ```
  # systemctl enable powertop
  ```

#### 14.6.2. The powertop2tuned utility

The `powertop2tuned` utility allows you to create custom TuneD profiles from PowerTOP suggestions.

By default, `powertop2tuned` creates profiles in the `/etc/tuned/` directory, and bases the custom profile on the currently selected TuneD profile. For safety reasons, all PowerTOP tunings are initially disabled in the new profile.

To enable the tunings, you can:

- Uncomment them in the `/etc/tuned/profile_name/tuned.conf` file.

- Use the `--enable` or `-e` option to generate a new profile that enables most of the tunings suggested by PowerTOP.

  Certain potentially problematic tunings, such as the USB autosuspend, are disabled by default and need to be uncommented manually.

#### 14.6.3. Optimizing power consumption using the powertop2tuned utility

---

**CHAPTER 14. MANAGING POWER CONSUMPTION WITH POWERTOP**

143
Prerequisites

- The `powertop2tuned` utility is installed on the system:

  # dnf install tuned-utils

Procedure

1. Create a custom profile:

   # powertop2tuned new_profile_name

2. Activate the new profile:

   # tuned-adm profile new_profile_name

Additional information

- For a complete list of options that `powertop2tuned` supports, use:

  $ powertop2tuned --help

14.6.4. Comparison of powertop.service and powertop2tuned

Optimizing power consumption with `powertop2tuned` is preferred over `powertop.service` for the following reasons:

- The `powertop2tuned` utility represents integration of **PowerTOP** into **TuneD**, which enables to benefit of advantages of both tools.

- The `powertop2tuned` utility allows for fine-grained control of enabled tuning.

- With `powertop2tuned`, potentially dangerous tuning are not automatically enabled.

- With `powertop2tuned`, rollback is possible without reboot.
As a system administrator, you can use the `perf` tool to collect and analyze performance data of your system.

**15.1. INTRODUCTION TO PERF**

The `perf` user-space tool interfaces with the kernel-based subsystem *Performance Counters for Linux* (PCL). `perf` is a powerful tool that uses the Performance Monitoring Unit (PMU) to measure, record, and monitor a variety of hardware and software events. `perf` also supports tracepoints, kprobes, and uprobes.

**15.2. INSTALLING PERF**

This procedure installs the `perf` user-space tool.

**Procedure**

- Install the `perf` tool:

  ```
  # dnf install perf
  ```

**15.3. COMMON PERF COMMANDS**

This section provides an overview of commonly used `perf` commands.

**Commonly used perf commands**

**perf stat**

This command provides overall statistics for common performance events, including instructions executed and clock cycles consumed. Options allow for selection of events other than the default measurement events.

**perf record**

This command records performance data into a file, `perf.data`, which can be later analyzed using the `perf report` command.

**perf report**

This command reads and displays the performance data from the `perf.data` file created by `perf record`.

**perf list**

This command lists the events available on a particular machine. These events will vary based on performance monitoring hardware and software configuration of the system.

**perf top**

This command performs a similar function to the `top` utility. It generates and displays a performance counter profile in realtime.

**perf trace**

This command performs a similar function to the `strace` tool. It monitors the system calls used by a specified thread or process and all signals received by that application.

**perf help**
This command displays a complete list of `perf` commands.

Additional resources

- Add the `--help` option to a subcommand to open the man page.
CHAPTER 16. PROFILING CPU USAGE IN REAL TIME WITH PERF TOP

You can use the `perf top` command to measure CPU usage of different functions in real time.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

16.1. THE PURPOSE OF PERF TOP

The `perf top` command is used for real time system profiling and functions similarly to the `top` utility. However, where the `top` utility generally shows you how much CPU time a given process or thread is using, `perf top` shows you how much CPU time each specific function uses. In its default state, `perf top` tells you about functions being used across all CPUs in both the user-space and the kernel-space. To use `perf top` you need root access.

16.2. PROFILING CPU USAGE WITH PERF TOP

This procedure activates `perf top` and profiles CPU usage in real time.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.
- You have root access

Procedure

- Start the `perf top` monitoring interface:

```
# perf top
```

The monitoring interface looks similar to the following:

```
Samples: 8K of event 'cycles', 2000 Hz, Event count (approx.): 4579432780 lost: 0/0 drop: 0/0
Overhead  Shared Object       Symbol
 2.20%  [kernel]            [k] do_syscall_64
 2.17%  [kernel]            [k] module_get_kallsym
 1.49%  [kernel]            [k] copy_user_enhanced_fast_string
 1.37%  libpthread-2.29.so  [.] pthread_mutex_lock 1.31% [unknown] [.] 0000000000000000
 1.07% [kernel] [k] psi_task_change 1.04% [kernel] [k] switch_mm_irqs_off 0.94% [kernel] [k] fget
 0.74%  [kernel]            [k] entry_SYSCALL_64
 0.69%  [kernel]            [k] syscall_return_via_sysret
 0.69%  libxul.so           [.] 0x0000000000113f9b0
 0.67%  [kernel]            [k] kallsyms_expand_symbol.constprop.0
 0.65%  firefox             [.] moz_xmalloc
 0.65%  libpthread-2.29.so  [.] _pthread_mutex_unlock_usercnt
 0.60%  firefox             [.] free
 0.60%  libxul.so           [.] 0x000000000241d1cd
 0.60%  [kernel]            [k] do_sys_poll
```
In this example, the kernel function `do_syscall_64` is using the most CPU time.

Additional resources

- `perf-top(1)` man page

### 16.3. INTERPRETATION OF PERF TOP OUTPUT

The `perf top` monitoring interface displays the data in several columns:

**The "Overhead" column**

Displays the percent of CPU a given function is using.

**The "Shared Object" column**

Displays name of the program or library which is using the function.

**The "Symbol" column**

Displays the function name or symbol. Functions executed in the kernel-space are identified by `[k]` and functions executed in the user-space are identified by `[.]`.

### 16.4. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES

For kernel functions, `perf` uses the information from the `/proc/kallsyms` file to map the samples to their respective function names or symbols. For functions executed in the user space, however, you might see raw function addresses because the binary is stripped.

The `debuginfo` package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information turned on (the `-g` option in GCC) to display the function names or symbols in such a situation.

**NOTE**

It is not necessary to re-run the `perf record` command after installing the `debuginfo` associated with an executable. Simply re-run the `perf report` command.

Additional Resources

- **Enabling debugging with debugging information**

### 16.5. ENABLING DEBUG AND SOURCE REPOSITORIES

A standard installation of Red Hat Enterprise Linux does not enable the debug and source repositories. These repositories contain information needed to debug the system components and measure their performance.

**Procedure**
Enable the source and debug information package channels: The \$(uname -i) part is automatically replaced with a matching value for architecture of your system:

<table>
<thead>
<tr>
<th>Architecture name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>64-bit Intel and AMD</td>
<td>x86_64</td>
</tr>
<tr>
<td>64-bit ARM</td>
<td>aarch64</td>
</tr>
<tr>
<td>IBM POWER</td>
<td>ppc64le</td>
</tr>
<tr>
<td>64-bit IBM Z</td>
<td>s390x</td>
</tr>
</tbody>
</table>

16.6. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB

Debugging information is required to debug code. For code that is installed from a package, the GNU Debugger (GDB) automatically recognizes missing debug information, resolves the package name and provides concrete advice on how to get the package.

Prerequisites

- The application or library you want to debug must be installed on the system.
- GDB and the debuginfo-install tool must be installed on the system. For details, see Setting up to debug applications.
- Channels providing debuginfo and debugsource packages must be configured and enabled on the system.

Procedure

1. Start GDB attached to the application or library you want to debug. GDB automatically recognizes missing debugging information and suggests a command to run.

   ```
   $ gdb -q /bin/ls
   Reading symbols from /bin/ls...Reading symbols from .gnu_debugdata for /usr/bin/ls...(no debugging symbols found)...done.
   (no debugging symbols found)...done.
   Missing separate debuginfos, use: dnf debuginfo-install coreutils-8.30-6.el8.x86_64
   (gdb)
   ```

2. Exit GDB: type q and confirm with Enter.

   ```
   (gdb) q
   ```

3. Run the command suggested by GDB to install the required debuginfo packages:

   ```
   # dnf debuginfo-install coreutils-8.30-6.el8.x86_64
   ```

The dnf package management tool provides a summary of the changes, asks for confirmation and once you confirm, downloads and installs all the necessary files.
4. In case GDB is not able to suggest the `debuginfo` package, follow the procedure described in
   Getting debuginfo packages for an application or library manually.

Additional resources

- Red Hat Developer Toolset User Guide, section Installing Debugging Information
- How can I download or install debuginfo packages for RHEL systems? – Red Hat
  Knowledgebase solution
CHAPTER 17. COUNTING EVENTS DURING PROCESS EXECUTION WITH PERF STAT

You can use the `perf stat` command to count hardware and software events during process execution.

Prerequisites
- You have the `perf` user space tool installed as described in Installing perf.

17.1. THE PURPOSE OF PERF STAT

The `perf stat` command executes a specified command, keeps a running count of hardware and software event occurrences during the commands execution, and generates statistics of these counts. If you do not specify any events, then `perf stat` counts a set of common hardware and software events.

17.2. COUNTING EVENTS WITH PERF STAT

You can use `perf stat` to count hardware and software event occurrences during command execution and generate statistics of these counts. By default, `perf stat` operates in per-thread mode.

Prerequisites
- You have the `perf` user space tool installed as described in Installing perf.

Procedure
- Count the events.
  - Running the `perf stat` command without root access will only count events occurring in the user space:

```
$ perf stat ls
```

Example 17.1. Output of perf stat ran without root access

```
Desktop Documents Downloads Music Pictures Public Templates Videos

Performance counter stats for 'ls':

<table>
<thead>
<tr>
<th>Event</th>
<th>Count</th>
<th>Rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.28 msec task-clock:u</td>
<td>0.165</td>
<td>CPUs utilized</td>
</tr>
<tr>
<td>0 context-switches:u</td>
<td>0.000</td>

0.007717000 seconds sys
As you can see in the previous example, when `perf stat` runs without root access the event names are followed by `.u`, indicating that these events were counted only in the user-space.

- To count both user-space and kernel-space events, you must have root access when running `perf stat`:

  ```
  # perf stat ls
  ```

**Example 17.2. Output of perf stat ran with root access**

```
Desktop  Documents  Downloads  Music  Pictures  Public  Templates  Videos

Performance counter stats for 'ls' :

  3.09 msec task-clock                #    0.119 CPUs utilized
  18      context-switches          #    0.006 M/sec
  3      cpu-migrations            #    0.969 K/sec
  108      page-faults               #    0.035 M/sec
  6,576,004      cycles                    #    2.125 GHz
  5,694,223      instructions              #    0.87  insn per cycle
  1,092,372      branches                  #  352.960 M/sec
  31,515      branch-misses             #    2.89% of all branches

0.026020043 seconds time elapsed
0.000000000 seconds user
0.014061000 seconds sys
```

- By default, `perf stat` operates in per-thread mode. To change to CPU-wide event counting, pass the `-a` option to `perf stat`. To count CPU-wide events, you need root access:

  ```
  # perf stat -a ls
  ```

**Additional resources**

- `perf-stat(1)` man page

### 17.3. INTERPRETATION OF PERF STAT OUTPUT

`perf stat` executes a specified command and counts event occurrences during the commands execution and displays statistics of these counts in three columns:

1. The number of occurrences counted for a given event
2. The name of the event that was counted
3. When related metrics are available, a ratio or percentage is displayed after the hash sign (`#`) in the right-most column.

For example, when running in default mode, `perf stat` counts both cycles and instructions and, therefore, calculates and displays instructions per cycle in the right-most column. You can see similar behavior with regard to branch-misses as a percent of all branches since both events are
17.4. ATTACHING PERF STAT TO A RUNNING PROCESS

You can attach `perf stat` to a running process. This will instruct `perf stat` to count event occurrences only in the specified processes during the execution of a command.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

- Attach `perf stat` to a running process:

  $ perf stat -p ID1,ID2 sleep seconds

  The previous example counts events in the processes with the IDs of `ID1` and `ID2` for a time period of `seconds` seconds as dictated by using the `sleep` command.

Additional resources

- `perf-stat(1)` man page
CHAPTER 18. RECORDING AND ANALYZING PERFORMANCE PROFILES WITH PERF

The **perf** tool allows you to record performance data and analyze it at a later time.

**Prerequisites**
- You have the **perf** user space tool installed as described in Installing perf.

### 18.1. THE PURPOSE OF PERF RECORD

The **perf record** command samples performance data and stores it in a file, **perf.data**, which can be read and visualized with other **perf** commands. **perf.data** is generated in the current directory and can be accessed at a later time, possibly on a different machine.

If you do not specify a command for **perf record** to record during, it will record until you manually stop the process by pressing **Ctrl+C**. You can attach **perf record** to specific processes by passing the `-p` option followed by one or more process IDs. You can run **perf record** without root access, however, doing so will only sample performance data in the user space. In the default mode, **perf record** uses CPU cycles as the sampling event and operates in per-thread mode with inherit mode enabled.

### 18.2. RECORDING A PERFORMANCE PROFILE WITHOUT ROOT ACCESS

You can use **perf record** without root access to sample and record performance data in the user-space only.

**Prerequisites**
- You have the **perf** user space tool installed as described in Installing perf.

**Procedure**
- Sample and record the performance data:

  ```
  $ perf record command
  ```

  Replace **command** with the command you want to sample data during. If you do not specify a command, then **perf record** will sample data until you manually stop it by pressing **Ctrl+C**.

**Additional resources**
- **perf-record(1)** man page

### 18.3. RECORDING A PERFORMANCE PROFILE WITH ROOT ACCESS

You can use **perf record** with root access to sample and record performance data in both the user-space and the kernel-space simultaneously.

**Prerequisites**
- You have the **perf** user space tool installed as described in Installing perf.
You have root access.

Procedure

- Sample and record the performance data:
  
  # perf record command

Replace command with the command you want to sample data during. If you do not specify a command, then perf record will sample data until you manually stop it by pressing Ctrl+C.

Additional resources

- perf-record(1) man page

18.4. RECORDING A PERFORMANCE PROFILE IN PER-CPU MODE

You can use perf record in per-CPU mode to sample and record performance data in both user-space and the kernel-space simultaneously across all threads on a monitored CPU. By default, per-CPU mode monitors all online CPUs.

Prerequisites

- You have the perf user space tool installed as described in Installing perf.

Procedure

- Sample and record the performance data:
  
  # perf record -a command

Replace command with the command you want to sample data during. If you do not specify a command, then perf record will sample data until you manually stop it by pressing Ctrl+C.

Additional resources

- perf-record(1) man page

18.5. CAPTURING CALL GRAPH DATA WITH PERF RECORD

You can configure the perf record tool so that it records which function is calling other functions in the performance profile. This helps to identify a bottleneck if several processes are calling the same function.

Prerequisites

- You have the perf user space tool installed as described in Installing perf.

Procedure

- Sample and record performance data with the --call-graph option:
  
  $ perf record --call-graph method command
Replace **command** with the command you want to sample data during. If you do not specify a command, then **perf record** will sample data until you manually stop it by pressing **Ctrl+C**.

- Replace **method** with one of the following unwinding methods:
  
  **fp**
  Uses the frame pointer method. Depending on compiler optimization, such as with binaries built with the GCC option `--fomit-frame-pointer`, this may not be able to unwind the stack.
  
  **dwarf**
  Uses DWARF Call Frame Information to unwind the stack.
  
  **lbr**
  Uses the last branch record hardware on Intel processors.

Additional resources
- **perf-record**(1) man page

### 18.6. ANALYZING PERF.DATA WITH PERF REPORT

You can use **perf report** to display and analyze a **perf.data** file.

**Prerequisites**
- You have the **perf** user space tool installed as described in Installing perf.
- There is a **perf.data** file in the current directory.
- If the **perf.data** file was created with root access, you need to run **perf report** with root access too.

**Procedure**
- Display the contents of the **perf.data** file for further analysis:

  ```
  # perf report
  ```

  This command displays output similar to the following:

  ```
  Samples: 2K of event 'cycles', Event count (approx.): 235462960
  Overhead Command Shared Object Symbol
  2.36%  kswapd0 [kernel.kallsyms] [k] page_vma_mapped_walk
  2.13%  sssd_kcm libc-2.28.so [.] memset_avx2_erms 2.13% perf
  [kernel.kallsyms] [k] smp_call_function_single 1.53% gnome-shell libc-2.28.so [.] strmp_avx2
  1.17%  gnome-shell libglib-2.0.so.0.5600.4 [.] g_hash_table_lookup
  0.93%  Xorg libc-2.28.so [.] memmove_avx_unaligned_erms 0.89% gnome-shell libgobject-2.0.so.0.5600.4 [.] g_object_unref 0.87% kswapd0 [kernel.kallsyms] [k] page_referenced_one 0.86% gnome-shell libc-2.28.so [.] memmove_avx_unaligned_erms
  0.83%  Xorg [kernel.kallsyms] [k] alloc_vmap_area
  0.63%  gnome-shell libglib-2.0.so.0.5600.4 [.] g_slice_alloc
  0.53%  gnome-shell libgirepository-1.0.so.1.0.0 [.] g_base_info_unref
  ```
18.7. INTERPRETATION OF PERF REPORT OUTPUT

The table displayed by running the `perf report` command sorts the data into several columns:

The 'Overhead' column
Indicates what percentage of overall samples were collected in that particular function.

The 'Command' column
Tells you which process the samples were collected from.

The 'Shared Object' column
Displays the name of the ELF image where the samples come from (the name `[kernel.kallsyms]` is used when the samples come from the kernel).

The 'Symbol' column
Displays the function name or symbol.

In default mode, the functions are sorted in descending order with those with the highest overhead displayed first.

18.8. GENERATING A PERF.DATA FILE THAT IS READABLE ON A DIFFERENT DEVICE

You can use the `perf` tool to record performance data into a `perf.data` file to be analyzed on a different device.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

- The kernel debuginfo package is installed. For more information, see Getting debuginfo packages for an application or library using GDB.

Procedure

1. Capture performance data you are interested in investigating further:

   ```bash
   # perf record -a --call-graph fp sleep seconds
   ```

   Additional resources

   - `perf-report(1)` man page
This example would generate a `perf.data` over the entire system for a period of \textit{seconds} seconds as dictated by the use of the `sleep` command. It would also capture call graph data using the frame pointer method.

2. Generate an archive file containing debug symbols of the recorded data:

   ```bash
   # perf archive
   ```

Verification steps

- Verify that the archive file has been generated in your current active directory:

  ```bash
  # ls perf.data*
  ```

  The output will display every file in your current directory that begins with `perf.data`. The archive file will be named either:

  ```bash
  perf.data.tar.gz
  ```
  or

  ```bash
  perf.data.tar.bz2
  ```

Additional resources

- Recording and analyzing performance profiles with perf
- Capturing call graph data with perf record

### 18.9. ANALYZING A PERF.DATA FILE THAT WAS CREATED ON A DIFFERENT DEVICE

You can use the `perf` tool to analyze a `perf.data` file that was generated on a different device.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.
- A `perf.data` file and associated archive file generated on a different device are present on the current device being used.

Procedure

1. Copy both the `perf.data` file and the archive file into your current active directory.

2. Extract the archive file into `~/.debug`:

   ```bash
   # mkdir -p ~/.debug
   # tar xf perf.data.tar.bz2 -C ~/.debug
   ```
NOTE

The archive file might also be named `perf.data.tar.gz`.

3. Open the `perf.data` file for further analysis:

```
# perf report
```

### 18.10. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES

For kernel functions, `perf` uses the information from the `/proc/kallsyms` file to map the samples to their respective function names or symbols. For functions executed in the user space, however, you might see raw function addresses because the binary is stripped.

The `debuginfo` package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information turned on (the `-g` option in GCC) to display the function names or symbols in such a situation.

NOTE

It is not necessary to re-run the `perf record` command after installing the `debuginfo` associated with an executable. Simply re-run the `perf report` command.

**Additional Resources**

- Enabling debugging with debugging information

### 18.11. ENABLING DEBUG AND SOURCE REPOSITORIES

A standard installation of Red Hat Enterprise Linux does not enable the debug and source repositories. These repositories contain information needed to debug the system components and measure their performance.

**Procedure**

- Enable the source and debug information package channels: The `$ (uname -i)` part is automatically replaced with a matching value for architecture of your system:

<table>
<thead>
<tr>
<th>Architecture name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>64-bit Intel and AMD</td>
<td>x86_64</td>
</tr>
<tr>
<td>64-bit ARM</td>
<td>aarch64</td>
</tr>
<tr>
<td>IBM POWER</td>
<td>ppc64le</td>
</tr>
<tr>
<td>64-bit IBM Z</td>
<td>s390x</td>
</tr>
</tbody>
</table>
18.12. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB

Debugging information is required to debug code. For code that is installed from a package, the GNU Debugger (GDB) automatically recognizes missing debug information, resolves the package name and provides concrete advice on how to get the package.

Prerequisites

- The application or library you want to debug must be installed on the system.
- GDB and the debuginfo-install tool must be installed on the system. For details, see Setting up to debug applications.
- Channels providing debuginfo and debugsource packages must be configured and enabled on the system.

Procedure

1. Start GDB attached to the application or library you want to debug. GDB automatically recognizes missing debugging information and suggests a command to run.

   ```
   $ gdb -q /bin/ls
   Reading symbols from /bin/ls...Reading symbols from .gnu_debugdata for /usr/bin/ls...(no debugging symbols found)...done.
   (no debugging symbols found)...done.
   Missing separate debuginfos, use: dnf debuginfo-install coreutils-8.30-6.el8.x86_64
   (gdb)
   ```

2. Exit GDB: type q and confirm with Enter.

   ```
   (gdb) q
   ```

3. Run the command suggested by GDB to install the required debuginfo packages:

   ```
   # dnf debuginfo-install coreutils-8.30-6.el8.x86_64
   ```

   The dnf package management tool provides a summary of the changes, asks for confirmation and once you confirm, downloads and installs all the necessary files.

4. In case GDB is not able to suggest the debuginfo package, follow the procedure described in Getting debuginfo packages for an application or library manually.

Additional resources

- Red Hat Developer Toolset User Guide, section Installing Debugging Information
- How can I download or install debuginfo packages for RHEL systems? — Red Hat Knowledgebase solution
CHAPTER 19. INVESTIGATING BUSY CPUS WITH PERF

When investigating performance issues on a system, you can use the `perf` tool to identify and monitor the busiest CPUs in order to focus your efforts.

19.1. DISPLAYING WHICH CPU EVENTS WERE COUNTED ON WITH PERF STAT

You can use `perf stat` to display which CPU events were counted on by disabling CPU count aggregation. You must count events in system-wide mode by using the `-a` flag in order to use this functionality.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

- Count the events with CPU count aggregation disabled:

  ```
  # perf stat -a -A sleep seconds
  ```

  The previous example displays counts of a default set of common hardware and software events recorded over a time period of `seconds` seconds, as dictated by using the `sleep` command, over each individual CPU in ascending order, starting with CPU0. As such, it may be useful to specify an event such as cycles:

  ```
  # perf stat -a -A -e cycles sleep seconds
  ```

19.2. DISPLAYING WHICH CPU SAMPLES WERE TAKEN ON WITH PERF REPORT

The `perf record` command samples performance data and stores this data in a `perf.data` file which can be read with the `perf report` command. The `perf record` command always records which CPU samples were taken on. You can configure `perf report` to display this information.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

- There is a `perf.data` file created with `perf record` in the current directory. If the `perf.data` file was created with root access, you need to run `perf report` with root access too.

Procedure

- Display the contents of the `perf.data` file for further analysis while sorting by CPU:

  ```
  # perf report --sort cpu
  ```

  You can sort by CPU and command to display more detailed information about where CPU time is being spent:
Additional resources

- Recording and analyzing performance profiles with perf

19.3. DISPLAYING SPECIFIC CPUS DURING PROFILING WITH PERF TOP

You can configure perf top to display specific CPUs and their relative usage while profiling your system in real time.

Prerequisites

- You have the perf user space tool installed as described in Installing perf.

Procedure

- Start the perf top interface while sorting by CPU:

  ```
  # perf top --sort cpu
  ```

  This example will list CPUs and their respective overhead in descending order of overhead usage in real time.

  - You can sort by CPU and command for more detailed information of where CPU time is being spent:

  ```
  # perf top --sort cpu,comm
  ```

  This example will list commands by total overhead in descending order of overhead usage and identify the CPU the command was executed on in real time.

19.4. MONITORING SPECIFIC CPUS WITH PERF RECORD AND PERF REPORT

You can configure perf record to only sample specific CPUs of interest and analyze the generated perf.data file with perf report for further analysis.

Prerequisites

- You have the perf user space tool installed as described in Installing perf.

Procedure

1. Sample and record the performance data in the specific CPU’s, generating a perf.data file:

   - Using a comma separated list of CPUs:
The previous example samples and records data in CPUs 0 and 1 for a period of *seconds* seconds as dictated by the use of the `sleep` command.

- Using a range of CPUs:

```
# perf record -C 0-2 sleep seconds
```

The previous example samples and records data in all CPUs from CPU 0 to 2 for a period of *seconds* seconds as dictated by the use of the `sleep` command.

2. Display the contents of the `perf.data` file for further analysis:

```
# perf report
```

This example will display the contents of `perf.data`. If you are monitoring several CPUs and want to know which CPU data was sampled on, see Displaying which CPU samples were taken on with `perf report`.
CHAPTER 20. MONITORING APPLICATION PERFORMANCE WITH PERF

This section describes how to use the `perf` tool to monitor application performance.

20.1. ATTACHING PERF RECORD TO A RUNNING PROCESS

You can attach `perf record` to a running process. This will instruct `perf record` to only sample and record performance data in the specified processes.

**Prerequisites**
- You have the `perf` user space tool installed as described in `Installing perf`.

**Procedure**
- Attach `perf record` to a running process:

  ```
  $ perf record -p ID1,ID2 sleep seconds
  ```

  The previous example samples and records performance data of the processes with the process ID’s `ID1` and `ID2` for a time period of `seconds` seconds as dictated by using the `sleep` command. You can also configure `perf` to record events in specific threads:

  ```
  $ perf record -t ID1,ID2 sleep seconds
  ```

  **NOTE**
  When using the `-t` flag and stipulating thread ID’s, `perf` disables inheritance by default. You can enable inheritance by adding the `--inherit` option.

20.2. CAPTURING CALL GRAPH DATA WITH PERF RECORD

You can configure the `perf record` tool so that it records which function is calling other functions in the performance profile. This helps to identify a bottleneck if several processes are calling the same function.

**Prerequisites**
- You have the `perf` user space tool installed as described in `Installing perf`.

**Procedure**
- Sample and record performance data with the `--call-graph` option:

  ```
  $ perf record --call-graph method command
  ```

  Replace `command` with the command you want to sample data during. If you do not specify a command, then `perf record` will sample data until you manually stop it by pressing `Ctrl+C`.

  Replace `method` with one of the following unwinding methods:
Uses the frame pointer method. Depending on compiler optimization, such as with binaries built with the GCC option `--fomit-frame-pointer`, this may not be able to unwind the stack.

**dwarf**

Uses DWARF Call Frame Information to unwind the stack.

**lbr**

Uses the last branch record hardware on Intel processors.

Additional resources

- `perf-record(1)` man page

## 20.3. ANALYZING PERF.DATA WITH PERF REPORT

You can use `perf report` to display and analyze a `perf.data` file.

### Prerequisites

- You have the `perf` user space tool installed as described in [Installing perf](#).
- There is a `perf.data` file in the current directory.
- If the `perf.data` file was created with root access, you need to run `perf report` with root access too.

### Procedure

- Display the contents of the `perf.data` file for further analysis:

  ```
  # perf report
  ```

  This command displays output similar to the following:

  ```
  Samples: 2K of event 'cycles', Event count (approx.): 235462960
  Overhead Command Shared Object Symbol
  2.36% kswapd0 [kernel.kallsyms] [k] page_vma_mapped_walk
  2.13% sssd_kcm libc-2.28.so [.] memset_avx2_erms 2.13% perf
  [kernel.kallsyms] [k] smp_call_function_single 1.53% gnome-shell libc-2.28.so [.] strcmp_avx2
  1.17% gnome-shell libglib-2.0.so.5600.4 [.] g_hash_table_lookup
  0.93% Xorg libc-2.28.so [.] memmove_avx_unaligned_erms 0.89%
  gnome-shell libgobject-2.0.so.5600.4 [.] g_object_unref 0.87% kswapd0 [kernel.kallsyms]
  [k] page_referenced_one 0.86% gnome-shell libc-2.28.so [.] memmove_avx_unaligned_erms
  0.83% Xorg [kernel.kallsyms] [k] alloc_vmap_area
  0.63% gnome-shell libglib-2.0.so.5600.4 [.] g_slice_alloc
  0.53% gnome-shell libgirepository-1.0.so.1.0.0 [.] g_base_info_unref
  0.53% gnome-shell ld-2.28.so [.] _dl_find_dso_for_object
  0.49% kswapd0 [kernel.kallsyms] [k] vma_interval_tree_iter_next

  2.0.so.5600.4 [.] g_slice_free1 0.45% gnome-shell libgobject-2.0.so.5600.4 [.] g_type_check_instance_is_fundamentally_a 0.44% gnome-shell libc-2.28.so [.] malloc 0.41%
  ```
swapper [kernel.kallsyms] [k] apic_timer_interrupt 0.40% gnome-shell ld-2.28.so [.]
_dl_lookup_symbol_x 0.39% kswapd0 [kernel.kallsyms] [k]
raw_callee_save___pv_queued_spin_unlock

Additional resources

- perf-report(1) man page
CHAPTER 21. CREATING UPROBES WITH PERF

21.1. CREATING UPROBES AT THE FUNCTION LEVEL WITH PERF

You can use the `perf` tool to create dynamic tracepoints at arbitrary points in a process or application. These tracepoints can then be used in conjunction with other `perf` tools such as `perf stat` and `perf record` to better understand the process or applications behavior.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

1. Create the uprobe in the process or application you are interested in monitoring at a location of interest within the process or application:

   ```bash
   # perf probe -x /path/to/executable -a function
   Added new event:
   probe_executable:function (on function in /path/to/executable)
   
   You can now use it in all perf tools, such as:
   
   perf record -e probe_executable:function -aR sleep 1
   ```

Additional resources

- `perf-probe` man page
- Recording and analyzing performance profiles with perf
- Counting events during process execution with perf stat

21.2. CREATING UPROBES ON LINES WITHIN A FUNCTION WITH PERF

These tracepoints can then be used in conjunction with other `perf` tools such as `perf stat` and `perf record` to better understand the process or applications behavior.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.
- You have gotten the debugging symbols for your executable:

  ```bash
  # objdump -t ./your_executable | head
  ```

NOTE

To do this, the debuginfo package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information, the `-g` option in GCC.
Procedure

1. View the function lines where you can place a uprobe:

   \$ perf probe -x ./your_executable -L main

   Output of this command looks similar to:

   <main@/home/user/my_executable:0>
     0 int main(int argc, const char **argv)
       1 {
           int err;
           const char *cmd;
           char sbuf[STRERR_BUFSIZE];

           /* libsubcmd init */
           7     exec_cmd_init("perf", PREFIX, PERF_EXEC_PATH,
                            EXEC_PATH_ENVIRONMENT);
           8     pager_init(PERF_PAGER_ENVIRONMENT);

2. Create the uprobe for the desired function line:

   # perf probe -x ./my_executable main:8
   Added new event:
     probe_my_executable:main_L8  (on main:8 in /home/user/my_executable)

   You can now use it in all perf tools, such as:

     perf record -e probe_my_executable:main_L8 -aR sleep 1

21.3. PERF SCRIPT OUTPUT OF DATA RECORDED OVER UPROBES

A common method to analyze data collected using uprobes is using the perf script command to read a perf.data file and display a detailed trace of the recorded workload.

In the perf script example output: * A uprobe is added to the function isprime() in a program called my_prog * a is a function argument added to the uprobe. Alternatively, a could be an arbitrary variable visible in the code scope of where you add your uprobe:

# perf script
my_prog 1367 [007] 10802159.906593: probe_my_prog:isprime: (400551) a=2
my_prog 1367 [007] 10802159.906623: probe_my_prog:isprime: (400551) a=3
my_prog 1367 [007] 10802159.906625: probe_my_prog:isprime: (400551) a=4
my_prog 1367 [007] 10802159.906627: probe_my_prog:isprime: (400551) a=5

CHAPTER 22. PROFILING MEMORY ACCESSES WITH PERF MEM

You can use the `perf mem` command to sample memory accesses on your system.

22.1. THE PURPOSE OF PERF MEM

The `mem` subcommand of the `perf` tool enables the sampling of memory accesses (loads and stores). The `perf mem` command provides information about memory latency, types of memory accesses, functions causing cache hits and misses, and, by recording the data symbol, the memory locations where these hits and misses occur.

22.2. SAMPLING MEMORY ACCESS WITH PERF MEM

This procedure describes how to use the `perf mem` command to sample memory accesses on your system. The command takes the same options as `perf record` and `perf report` as well as some options exclusive to the `mem` subcommand. The recorded data is stored in a `perf.data` file in the current directory for later analysis.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

1. Sample the memory accesses:

   ```bash
   # perf mem record -a sleep seconds
   ```

   This example samples memory accesses across all CPUs for a period of `seconds` seconds as dictated by the `sleep` command. You can replace the `sleep` command for any command during which you want to sample memory access data. By default, `perf mem` samples both memory loads and stores. You can select only one memory operation by using the `-t` option and specifying either "load" or "store" between `perf mem` and `record`. For loads, information over the memory hierarchy level, TLB memory accesses, bus snoops, and memory locks is captured.

2. Open the `perf.data` file for analysis:

   ```bash
   # perf mem report
   ```

   If you have used the example commands, the output is:

   ```
   Available samples
   35k cpu/mem-loads,ldlat=30/P
   54k cpu/mem-stores/P
   ```

   The `cpu/mem-loads,ldlat=30/P` line denotes data collected over memory loads and the `cpu/mem-stores/P` line denotes data collected over memory stores. Highlight the category of interest and press Enter to view the data:

   ```
   Samples: 35K of event 'cpu/mem-loads,ldlat=30/P', Event count (approx.): 4067062
   Overhead Samples Local Weight Memory access Symbol
   ```

</tbody>
</table>
Alternatively, you can sort your results to investigate different aspects of interest when displaying the data. For example, to sort data over memory loads by type of memory accesses occurring during the sampling period in descending order of overhead they account for:

```
# perf mem -t load report --sort=mem
```

For example, the output can be:

```
Samples: 35K of event 'cpu/mem-loads,ldlat=30/P', Event count (approx.): 40670
Overhead       Samples  Memory access
31.53%          9725  LFB or LFB hit
29.70%         12201  L1 or L1 hit
23.03%          9725  L3 or L3 hit
12.91%         2316   Local RAM or RAM hit
 2.37%          743   L2 or L2 hit
 0.34%           9    Uncached or N/A hit
 0.10%           69    I/O or N/A hit
 0.02%          825    L3 miss
```

- `perf-mem(1)` man page.

### 22.3. INTERPRETATION OF PERF MEM REPORT OUTPUT

The table displayed by running the `perf mem report` command without any modifiers sorts the data into several columns:

**The 'Overhead' column**
- Indicates percentage of overall samples collected in that particular function.

**The 'Samples' column**
- Displays the number of samples accounted for by that row.

**The 'Local Weight' column**
- Displays the access latency in processor core cycles.

**The 'Memory Access' column**
- Displays the type of memory access that occurred.

**The 'Symbol' column**
- Displays the function name or symbol.

**The 'Shared Object' column**
- Displays the name of the ELF image where the samples come from (the name `kernel.kallsyms` is used when the samples come from the kernel).

**The 'Data Symbol' column**
- Displays the address of the memory location that row was targeting.

**IMPORTANT**

Oftentimes, due to dynamic allocation of memory or stack memory being accessed, the 'Data Symbol' column will display a raw address.
The "Snoop" column
Displays bus transactions.

The 'TLB Access' column
Displays TLB memory accesses.

The 'Locked' column
Indicates if a function was or was not memory locked.

In default mode, the functions are sorted in descending order with those with the highest overhead displayed first.
CHAPTER 23. DETECTING FALSE SHARING

False sharing occurs when a processor core on a Symmetric Multi Processing (SMP) system modifies data items on the same cache line that is in use by other processors to access other data items that are not being shared between the processors.

This initial modification requires that the other processors using the cache line invalidate their copy and request an updated one despite the processors not needing, or even necessarily having access to, an updated version of the modified data item.

You can use the `perf c2c` command to detect false sharing.

23.1. THE PURPOSE OF PERF C2C

The `c2c` subcommand of the `perf` tool enables Shared Data Cache-to-Cache (C2C) analysis. You can use the `perf c2c` command to inspect cache-line contention to detect both true and false sharing.

Cache-line contention occurs when a processor core on a Symmetric Multi Processing (SMP) system modifies data items on the same cache line that is in use by other processors. All other processors using this cache-line must then invalidate their copy and request an updated one. This can lead to degraded performance.

The `perf c2c` command provides the following information:

- Cache lines where contention has been detected
- Processes reading and writing the data
- Instructions causing the contention
- The Non-Uniform Memory Access (NUMA) nodes involved in the contention

23.2. DETECTING CACHE-LINE CONTENTION WITH PERF C2C

Use the `perf c2c` command to detect cache-line contention in a system.

The `perf c2c` command supports the same options as `perf record` as well as some options exclusive to the `c2c` subcommand. The recorded data is stored in a `perf.data` file in the current directory for later analysis.

Prerequisites

- The `perf` user space tool is installed. For more information, see [installing perf](#).

Procedure

- Use `perf c2c` to detect cache-line contention:

  ```bash
  # perf c2c record -a sleep seconds
  ```

  This example samples and records cache-line contention data across all CPU’s for a period of `seconds` as dictated by the `sleep` command. You can replace the `sleep` command with any command you want to collect cache-line contention data over.
23.3. VISUALIZING A PERF.DATA FILE RECORDED WITH PERF C2C RECORD

This procedure describes how to visualize the `perf.data` file, which is recorded using the `perf c2c` command.

**Prerequisites**

- The `perf` user space tool is installed. For more information, see Installing perf.
- A `perf.data` file recorded using the `perf c2c` command is available in the current directory. For more information, see Detecting cache-line contention with perf c2c.

**Procedure**

1. Open the `perf.data` file for further analysis:

   ```bash
   # perf c2c report --stdio
   ```

   This command visualizes the `perf.data` file into several graphs within the terminal:

**CHAPTER 23. DETECTING FALSE SHARING**

---

175
## 23.4. INTERPRETATION OF PERF C2C REPORT OUTPUT

This section describes how to interpret the output of the `perf c2c report` command.

The visualization displayed by running the `perf c2c report --stdio` command sorts the data into several tables:

**Trace Events Information**

This table provides a high level summary of all the load and store samples, which are collected by the `perf c2c record` command.

**Global Shared Cache Line Event Information**

This table provides statistics over the shared cache lines.

**c2c Details**

This table provides information about what events were sampled and how the `perf c2c report` data is organized within the visualization.
Shared Data Cache Line Table
This table provides a one line summary for the hottest cache lines where false sharing is detected and is sorted in descending order by the amount of remote Hitm detected per cache line by default.

Shared Cache Line Distribution Pareto
This tables provides a variety of information about each cache line experiencing contention:

- The cache lines are numbered in the NUM column, starting at 0.
- The virtual address of each cache line is contained in the Data address Offset column and followed subsequently by the offset into the cache line where different accesses occurred.
- The Pid column contains the process ID.
- The Code Address column contains the instruction pointer code address.
- The columns under the cycles label show average load latencies.
- The cpu cnt column displays how many different CPUs samples came from (essentially, how many different CPUs were waiting for the data indexed at that given location).
- The Symbol column displays the function name or symbol.
- The Shared Object column displays the name of the ELF image where the samples come from (the name [kernel.kallsyms] is used when the samples come from the kernel).
- The Source:Line column displays the source file and line number.
- The Node{cpu list} column displays which specific CPUs samples came from for each node.

23.5. DETECTING FALSE SHARING WITH PERF C2C
This procedure describes how to detect false sharing using the perf c2c command.

Prerequisites

- The perf user space tool is installed. For more information, see installing perf.
- A perf.data file recorded using the perf c2c command is available in the current directory. For more information, see Detecting cache-line contention with perf c2c.

Procedure

1. Open the perf.data file for further analysis:

   # perf c2c report --stdio

   This opens the perf.data file in the terminal.

2. In the "Trace Event Information" table, locate the row containing the values for LLC Misses to Remote Cache (HITM):
   The percentage in the value column of the LLC Misses to Remote Cache (HITM) row represents the percentage of LLC misses that were occurring across NUMA nodes in modified cache-lines and is a key indicator false sharing has occurred.
Trace Event Information

Total records : 329219
Locked Load/Store Operations : 14654
Load Operations : 69679
Loads - uncacheable : 0
Loads - IO : 0
Loads - Miss : 3972
Loads - no mapping : 0
Load Fill Buffer Hit : 11958
Load L1D hit : 17235
Load L2D hit : 21
Load LLC hit : 14219
Load Local HITM : 3402
Load Remote HITM : 12757
Load Remote HIT : 5295
Load Local DRAM : 976
Load Remote DRAM : 3246
Load MESI State Exclusive : 4222
Load MESI State Shared : 0
Load LLC Misses : 22274
LLC Misses to Local DRAM : 4.4%
LLC Misses to Remote DRAM : 14.6%
LLC Misses to Remote cache (HIT) : 23.8%
LLC Misses to Remote cache (HITM) : 57.3%

Store Operations : 259539
Store - uncacheable : 0
Store - no mapping : 11
Store L1D Hit : 256696
Store L1D Miss : 2832
No Page Map Rejects : 2376
Unable to parse data source : 1

3. Inspect the Rmt column of the LLC Load Hitm field of the the Shared Data Cache Line Table

Shared Data Cache Line Table

#                              Total      Rmt ----- LLC Load Hitm ----- ---- Store Reference ---- ----
Load Dram ---- LLC Total ---- Core Load Hit ---- -- LLC Load Hit --
# Index Cacheline records Hitm Total Lcl Rmt Total L1Hit L1Miss Rmt Ld Miss Loads FB L1 L2 Llc
# Index Cacheline records Hitm Total Lcl Rmt Total L1Hit L1Miss Rmt Ld Miss Loads FB L1 L2 Llc Rmt
#
# 0 x602180 149904 77.09% 12103 2269 9834 109504 109036
# Load Dram ---- 468 727 2657 13747 40400 5355 16154 0 2875 529
# Load Dram ---- 1 0x602100 12128 22.20% 3951 1119 2832 0 0 0 65
# Load Dram ---- 2 0xffff883ffb6a7e80 260 0.09% 15 3 12 161 161 0 1
# Load Dram ---- 2 0xffff883ffb6a7e80 260 0.09% 15 3 12 161 161 0 1
# Load Dram ---- 3 0xffffffff81aec000 157 0.07% 9 0 9 1 0 1 0 7
This table is sorted in descending order by the amount of remote Hitm detected per cache line. A high number in the Rmt column of the LLC Load Hitm section indicates false sharing and requires further inspection of the cache line on which it occurred to debug the false sharing activity.
CHAPTER 24. GETTING STARTED WITH FLAMEGRAPHS

As a system administrator, you can use flamegraphs to create visualizations of system performance data recorded with the perf tool. As a software developer, you can use flamegraphs to create visualizations of application performance data recorded with the perf tool.

Sampling stack traces is a common technique for profiling CPU performance with the perf tool. Unfortunately, the results of profiling stack traces with perf can be extremely verbose and labor-intensive to analyze. flamegraphs are visualizations created from data recorded with perf to make identifying hot code-paths faster and easier.

24.1. INSTALLING FLAMEGRAPHS

To begin using flamegraphs, install the required package.

Procedure

- Install the flamegraphs package:
  
  # dnf install js-d3-flame-graph

24.2. CREATING FLAMEGRAPHS OVER THE ENTIRE SYSTEM

This procedure describes how to visualize performance data recorded over an entire system using flamegraphs.

Prerequisites

- flamegraphs are installed as described in installing flamegraphs.
- The perf tool is installed as described in installing perf.

Procedure

- Record the data and create the visualization:
  
  # perf script flamegraph -a -F 99 sleep 60

This command samples and records performance data over the entire system for 60 seconds, as stipulated by use of the sleep command, and then constructs the visualization which will be stored in the current active directory as flamegraph.html. The command samples call-graph data by default and takes the same arguments as the perf tool, in this particular case:

  -a
  Stipulates to record data over the entire system.

  -F
  To set the sampling frequency per second.

Verification steps

- For analysis, view the generated visualization:
24.3. CREATING FLAMEGRAPHS OVER SPECIFIC PROCESSES

You can use flamegraphs to visualize performance data recorded over specific running processes.

Prerequisites

- flamegraphs are installed as described in installing flamegraphs.
- The perf tool is installed as described in installing perf.

Procedure

- Record the data and create the visualization:

  ```
  # perf script flamegraph -a -F 99 -p ID1,ID2 sleep 60
  ```

  This command samples and records performance data of the processes with the process ID’s `ID1` and `ID2` for 60 seconds, as stipulated by use of the `sleep` command, and then constructs the visualization which will be stored in the current active directory as `flamegraph.html`. The command samples call-graph data by default and takes the same arguments as the `perf` tool, in this particular case:

  `-a`
  Stipulates to record data over the entire system.

  `-F`
  To set the sampling frequency per second.

  `-p`
  To stipulate specific process ID’s to sample and record data over.

Verification steps

- For analysis, view the generated visualization:

  ```
  # xdg-open flamegraph.html
  ```

  This command opens the visualization in the default browser:
24.4. INTERPRETING FLAMEGRAPHS

Each box in the flamegraph represents a different function in the stack. The y-axis shows the depth of the stack with the topmost box in each stack being the function that was actually on-CPU and everything below it being ancestry. The x-axis displays the population of the sampled call-graph data.

The children of a stack in a given row are displayed based on the number of samples taken of each respective function in descending order along the x-axis; the x-axis does not represent the passing of time. The wider an individual box is, the more frequent it was on-CPU or part of an on-CPU ancestry at the time the data was being sampled.

Procedure

- To reveal the names of functions which may have not been displayed previously and further investigate the data click on a box within the flamegraph to zoom into the stack at that given location:

- To return to the default view of the flamegraph, click Reset Zoom.
IMPORTANT

Boxes representing user-space functions may be labeled as Unknown in flamegraphs because the binary of the function is stripped. The debuginfo package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information. Use the -g option in GCC, to display the function names or symbols in such a situation.

Additional resources

- Why perf displays some function names as raw functions addresses
- Enabling debugging with debugging information
CHAPTER 25. MONITORING PROCESSES FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS

You can create circular buffers that take event-specific snapshots of data with the `perf` tool in order to monitor performance bottlenecks in specific processes or parts of applications running on your system. In such cases, `perf` only writes data to a `perf.data` file for later analysis if a specified event is detected.

25.1. CIRCULAR BUFFERS AND EVENT-SPECIFIC SNAPSHOTS WITH PERF

When investigating performance issues in a process or application with `perf`, it may not be affordable or appropriate to record data for hours preceding a specific event of interest occurring. In such cases, you can use `perf record` to create custom circular buffers that take snapshots after specific events.

The `--overwrite` option makes `perf record` store all data in an overwritable circular buffer. When the buffer gets full, `perf record` automatically overwrites the oldest records which, therefore, never get written to a `perf.data` file.

Using the `--overwrite` and `--switch-output-event` options together configures a circular buffer that records and dumps data continuously until it detects the `--switch-output-event` trigger event. The trigger event signals to `perf record` that something of interest to the user has occurred and to write the data in the circular buffer to a `perf.data` file. This collects specific data you are interested in while simultaneously reducing the overhead of the running `perf` process by not writing data you do not want to a `perf.data` file.

25.2. COLLECTING SPECIFIC DATA TO MONITOR FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS

With the `perf` tool, you can create circular buffers that are triggered by events you specify in order to only collect data you are interested in. To create circular buffers that collect event-specific data, use the `--overwrite` and `--switch-output-event` options for `perf`.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.
- You have placed a uprobe in the process or application you are interested in monitoring at a location of interest within the process or application:

```
# perf probe -x /path/to/executable -a function
Added new event:
    probe_executable:function (on function in /path/to/executable)
```

You can now use it in all perf tools, such as:

```
perf record -e probe_executable:function -aR sleep 1
```

Procedure

- Create the circular buffer with the uprobe as the trigger event:
This example initiates the executable and collects cpu cycles, specified after the -e option, until `perf` detects the uprobe, the trigger event specified after the `--switch-output-event` option. At that point, `perf` takes a snapshot of all the data in the circular buffer and stores it in a unique `perf.data` file identified by timestamp. This example produced a total of 2 snapshots, the last `perf.data` file was forced by pressing `Ctrl+c`. 
CHAPTER 26. ADDING AND REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

By using the control pipe interface to enable and disable different tracepoints in a running `perf` collector, you can dynamically adjust what data you are collecting without having to stop or restart `perf`. This ensures you do not lose performance data that would have otherwise been recorded during the stopping or restarting process.

26.1. ADDING TRACEPOINTS TO A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

Add tracepoints to a running `perf` collector using the control pipe interface to adjust the data you are recording without having to stop `perf` and losing performance data.

Prerequisites

- You have the `perf` user space tool installed as described in Installing perf.

Procedure

1. Configure the control pipe interface:
   ```bash
   # mkfifo control ack perf.pipe
   ```

2. Run `perf record` with the control file setup and events you are interested in enabling:
   ```bash
   # perf record --control=fifo:control,ack -D -1 --no-buffering -e 'sched:*' -o - > perf.pipe
   ```
   In this example, declaring `sched:*` after the `-e` option starts `perf record` with scheduler events.

3. In a second terminal, start the read side of the control pipe:
   ```bash
   # cat perf.pipe | perf --no-pager script -i -
   ```
   Starting the read side of the control pipe triggers the following message in the first terminal:
   ```
   Events disabled
   ```

4. In a third terminal, enable a tracepoint using the control file:
   ```bash
   # echo 'enable sched:sched_process_fork' > control
   ```
   This command triggers `perf` to scan the current event list in the control file for the declared event. If the event is present, the tracepoint is enabled and the following message appears in the first terminal:
   ```
   event sched:sched_process_fork enabled
   ```
   Once the tracepoint is enabled, the second terminal displays the output from `perf` detecting the tracepoint:
26.2. REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

Remove tracepoints from a running `perf` collector using the control pipe interface to reduce the scope of data you are collecting without having to stop `perf` and losing performance data.

**Prerequisites**

- You have the `perf` user space tool installed as described in [Installing perf](#).
- You have added tracepoints to a running `perf` collector via the control pipe interface. For more information, see [Adding tracepoints to a running perf collector without stopping or restarting perf](#).

**Procedure**

- Remove the tracepoint:

  ```bash
  # echo 'disable sched:sched_process_fork' > control
  ```

  **NOTE**

  This example assumes you have previously loaded scheduler events into the control file and enabled the tracepoint `sched:sched_process_fork`.

  This command triggers `perf` to scan the current event list in the control file for the declared event. If the event is present, the tracepoint is disabled and the following message appears in the terminal used to configure the control pipe:

  ```bash
  event sched:sched_process_fork disabled
  ```
CHAPTER 27. PROFILING MEMORY ALLOCATION WITH NUMASTAT

With the `numastat` tool, you can display statistics over memory allocations in a system.

The `numastat` tool displays data for each NUMA node separately. You can use this information to investigate memory performance of your system or the effectiveness of different memory policies on your system.

27.1. DEFAULT NUMASTAT STATISTICS

By default, the `numastat` tool displays statistics over these categories of data for each NUMA node:

- **numa_hit**
  The number of pages that were successfully allocated to this node.

- **numa_miss**
  The number of pages that were allocated on this node because of low memory on the intended node. Each `numa_miss` event has a corresponding `numa_foreign` event on another node.

- **numa_foreign**
  The number of pages initially intended for this node that were allocated to another node instead. Each `numa_foreign` event has a corresponding `numa_miss` event on another node.

- **interleave_hit**
  The number of interleave policy pages successfully allocated to this node.

- **local_node**
  The number of pages successfully allocated on this node by a process on this node.

- **other_node**
  The number of pages allocated on this node by a process on another node.

**NOTE**

High `numa_hit` values and low `numa_miss` values (relative to each other) indicate optimal performance.

27.2. VIEWING MEMORY ALLOCATION WITH NUMASTAT

You can view the memory allocation of the system by using the `numastat` tool.

**Prerequisites**

- Install the `numactl` package:

  ```
  # dnf install numactl
  ```

**Procedure**

- View the memory allocation of your system:

  ```
  $ numastat node0 node1
  ```
<table>
<thead>
<tr>
<th></th>
<th>Hit Count</th>
<th>Miss Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>numa_hit</td>
<td>76557759</td>
<td>92126519</td>
</tr>
<tr>
<td>numa_miss</td>
<td>30772308</td>
<td>30827638</td>
</tr>
<tr>
<td>numa_foreign</td>
<td>30827638</td>
<td>30772308</td>

CHAPTER 28. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE CPU UTILIZATION

This section describes how to configure the operating system to optimize CPU utilization across their workloads.

28.1. TOOLS FOR MONITORING AND DIAGNOSING PROCESSOR ISSUES

The following are the tools available in Red Hat Enterprise Linux 9 to monitor and diagnose processor-related performance issues:

- **turbostat** tool prints counter results at specified intervals to help administrators identify unexpected behavior in servers, such as excessive power usage, failure to enter deep sleep states, or system management interrupts (SMIs) being created unnecessarily.

- **numactl** utility provides a number of options to manage processor and memory affinity. The **numactl** package includes the **libnuma** library which offers a simple programming interface to the NUMA policy supported by the kernel, and can be used for more fine-grained tuning than the **numactl** application.

- **numastat** tool displays per-NUMA node memory statistics for the operating system and its processes, and shows administrators whether the process memory is spread throughout a system or is centralized on specific nodes. This tool is provided by the **numactl** package.

- **numad** is an automatic NUMA affinity management daemon. It monitors NUMA topology and resource usage within a system in order to dynamically improve NUMA resource allocation and management.

- **/proc/interrupts** file displays the interrupt request (IRQ) number, the number of similar interrupt requests handled by each processor in the system, the type of interrupt sent, and a comma-separated list of devices that respond to the listed interrupt request.

- **pqos** utility is available in the **intel-cmt-cat** package. It monitors CPU cache and memory bandwidth on recent Intel processors. It monitors:
  - The instructions per cycle (IPC).
  - The count of last level cache MISSES.
  - The size in kilobytes that the program executing in a given CPU occupies in the LLC.
  - The bandwidth to local memory (MBL).
  - The bandwidth to remote memory (MBR).

- **x86_energy_perf_policy** tool allows administrators to define the relative importance of performance and energy efficiency. This information can then be used to influence processors that support this feature when they select options that trade off between performance and energy efficiency.

- **taskset** tool is provided by the **util-linux** package. It allows administrators to retrieve and set the processor affinity of a running process, or launch a process with a specified processor affinity.

*Additional resources*
28.2. TYPES OF SYSTEM TOPOLOGY

In modern computing, the idea of a CPU is a misleading one, as most modern systems have multiple processors. The topology of the system is the way these processors are connected to each other and to other system resources. This can affect system and application performance, and the tuning considerations for a system.

The following are the two primary types of topology used in modern computing:

Symmetric Multi-Processor (SMP) topology

SMP topology allows all processors to access memory in the same amount of time. However, because shared and equal memory access inherently forces serialized memory accesses from all the CPUs, SMP system scaling constraints are now generally viewed as unacceptable. For this reason, practically all modern server systems are NUMA machines.

Non-Uniform Memory Access (NUMA) topology

NUMA topology was developed more recently than SMP topology. In a NUMA system, multiple processors are physically grouped on a socket. Each socket has a dedicated area of memory and processors that have local access to that memory, these are referred to collectively as a node. Processors on the same node have high speed access to that node’s memory bank, and slower access to memory banks not on their node.

Therefore, there is a performance penalty when accessing non-local memory. Thus, performance sensitive applications on a system with NUMA topology should access memory that is on the same node as the processor executing the application, and should avoid accessing remote memory wherever possible.

Multi-threaded applications that are sensitive to performance may benefit from being configured to execute on a specific NUMA node rather than a specific processor. Whether this is suitable depends on your system and the requirements of your application. If multiple application threads access the same cached data, then configuring those threads to execute on the same processor may be suitable. However, if multiple threads that access and cache different data execute on the same processor, each thread may evict cached data accessed by a previous thread. This means that each thread ‘misses’ the cache and wastes execution time fetching data from memory and replacing it in the cache. Use the `perf` tool to check for an excessive number of cache misses.

28.2.1. Displaying system topologies

There are a number of commands that help understand the topology of a system. This procedure describes how to determine the system topology.

Procedure

- To display an overview of your system topology:

  ```
  $ numactl --hardware
  available: 4 nodes (0-3)
  node 0 cpus: 0 4 8 12 16 20 24 28 32 36
  node 0 size: 65415 MB
  node 0 free: 43971 MB
  [...] 
  ```
To gather the information about the CPU architecture, such as the number of CPUs, threads, cores, sockets, and NUMA nodes:

```
$ lscpu
Architecture:          x86_64
CPU op-mode(s):        32-bit, 64-bit
Byte Order:            Little Endian
CPU(s):                40
On-line CPU(s) list:   0-39
Thread(s) per core:    1
Core(s) per socket:    10
Socket(s):             4
NUMA node(s):          4
Vendor ID:             GenuineIntel
CPU family:            6
Model:                 47
Model name:            Intel(R) Xeon(R) CPU E7- 4870 @ 2.40GHz
Stepping:              2
CPU MHz:               2394.204
BogoMIPS:              4787.85
Virtualization:        VT-x
L1d cache:             32K
L1i cache:             32K
L2 cache:              256K
L3 cache:              30720K
NUMA node0 CPU(s):     0,4,8,12,16,20,24,28,32,36
NUMA node1 CPU(s):     2,6,10,14,18,22,26,30,34,38
NUMA node2 CPU(s):     1,5,9,13,17,21,25,29,33,37
NUMA node3 CPU(s):     3,7,11,15,19,23,27,31,35,39
```

To view a graphical representation of your system:

```
# dnf install hwloc-gui
# lstopo
```
Figure 28.1. The *lstopo* output

```
# dnf install hwloc
# lstopo-no-graphics
Machine (15GB)

### 28.3. CONFIGURING KERNEL TICK TIME
By default, Red Hat Enterprise Linux 9 uses a tickless kernel, which does not interrupt idle CPUs in order to reduce power usage and allow new processors to take advantage of deep sleep states.

Red Hat Enterprise Linux 9 also offers a dynamic tickless option, which is useful for latency-sensitive workloads, such as high performance computing or realtime computing. By default, the dynamic tickless option is disabled. Red Hat recommends using the cpu-partitioning TuneD profile to enable the dynamic tickless option for cores specified as isolated_cores.

This procedure describes how to manually persistently enable dynamic tickless behavior.

**Procedure**

1. To enable dynamic tickless behavior in certain cores, specify those cores on the kernel command line with the nohz_full parameter. On a 16 core system, append this parameter on the GRUB_CMDLINE_LINUX option in the /etc/default/grub file:

   ```
   nohz_full=1-15
   ```

   This enables dynamic tickless behavior on cores 1 through 15, moving all timekeeping to the only unspecified core (core 0).

2. To persistently enable the dynamic tickless behavior, regenerate the GRUB2 configuration using the edited default file. On systems with BIOS firmware, execute the following command:

   ```
   # grub2-mkconfig -o /etc/grub2.cfg
   ```

   On systems with UEFI firmware, execute the following command:

   ```
   # grub2-mkconfig -o /etc/grub2-efi.cfg
   ```

3. When the system boots, manually move the rcu threads to the non-latency-sensitive core, in this case core 0:

   ```
   # for i in `pgrep rcu[^c]` ; do taskset -pc 0 $i ; done
   ```

4. Optional: Use the isolcpus parameter on the kernel command line to isolate certain cores from user-space tasks.

5. Optional: Set the CPU affinity for the kernel’s write-back bdi-flush threads to the housekeeping core:

   ```
   echo 1 > /sys/bus/workqueue/devices/writeback/cpumask
   ```

**Verification steps**

- Once the system is rebooted, verify if dynticks are enabled:

  ```
  # journalctl -xe | grep dynticks
  ```

- Verify that the dynamic tickless configuration is working correctly:

  ```
  # perf stat -C 1 -e irq_vectors:local_timer_entry taskset -c 1 sleep 3
  ```
This command measures ticks on CPU 1 while telling CPU 1 to sleep for 3 seconds.

- The default kernel timer configuration shows around 3100 ticks on a regular CPU:

```bash
# perf stat -C 0 -e irq_vectors:local_timer_entry taskset -c 0 sleep 3
```

```
Performance counter stats for 'CPU(s) 0':
3,107  irq_vectors:local_timer_entry
3.001342790 seconds time elapsed
```

- With the dynamic tickless kernel configured, you should see around 4 ticks instead:

```bash
# perf stat -C 1 -e irq_vectors:local_timer_entry taskset -c 1 sleep 3
```

```
Performance counter stats for 'CPU(s) 1':
4  irq_vectors:local_timer_entry
3.001544078 seconds time elapsed
```

### 28.4. OVERVIEW OF AN INTERRUPT REQUEST

An interrupt request or IRQ is a signal for immediate attention sent from a piece of hardware to a processor. Each device in a system is assigned one or more IRQ numbers which allow it to send unique interrupts. When interrupts are enabled, a processor that receives an interrupt request immediately pauses execution of the current application thread in order to address the interrupt request.

Because interrupt halts normal operation, high interrupt rates can severely degrade system performance. It is possible to reduce the amount of time taken by interrupts by configuring interrupt affinity or by sending a number of lower priority interrupts in a batch (coalescing a number of interrupts).

Interrupt requests have an associated affinity property, `smp_affinity`, which defines the processors that handle the interrupt request. To improve application performance, assign interrupt affinity and process affinity to the same processor, or processors on the same core. This allows the specified interrupt and application threads to share cache lines.

On systems that support interrupt steering, modifying the `smp_affinity` property of an interrupt request sets up the hardware so that the decision to service an interrupt with a particular processor is made at the hardware level with no intervention from the kernel.

#### 28.4.1. Balancing interrupts manually
If your BIOS exports its NUMA topology, the `irqbalance` service can automatically serve interrupt requests on the node that is local to the hardware requesting service.

**Procedure**

1. Check which devices correspond to the interrupt requests that you want to configure.

2. Find the hardware specification for your platform. Check if the chipset on your system supports distributing interrupts.
   
   a. If it does, you can configure interrupt delivery as described in the following steps. Additionally, check which algorithm your chipset uses to balance interrupts. Some BIOSes have options to configure interrupt delivery.
   
   b. If it does not, your chipset always routes all interrupts to a single, static CPU. You cannot configure which CPU is used.

3. Check which Advanced Programmable Interrupt Controller (APIC) mode is in use on your system:

   ```
   $ journalctl --dmesg | grep APIC
   ``

   Here,

   - If your system uses a mode other than `flat`, you can see a line similar to `Setting APIC routing to physical flat`.
   
   - If you can see no such message, your system uses `flat` mode. If your system uses `x2apic` mode, you can disable it by adding the `nox2apic` option to the kernel command line in the bootloader configuration.

     Only non-physical flat mode (`flat`) supports distributing interrupts to multiple CPUs. This mode is available only for systems that have up to 8 CPUs.

4. Calculate the `smp_affinity mask`. For more information on how to calculate the `smp_affinity mask`, see Setting the `smp_affinity mask`.

**Additional resources**

- `journalctl(1)` and `taskset(1)` man pages

### 28.4.2. Setting the `smp_affinity` mask

The `smp_affinity` value is stored as a hexadecimal bit mask representing all processors in the system. Each bit configures a different CPU. The least significant bit is CPU 0.

The default value of the mask is $f$, which means that an interrupt request can be handled on any processor in the system. Setting this value to 1 means that only processor 0 can handle the interrupt.

**Procedure**

1. In binary, use the value 1 for CPUs that handle the interrupts. For example, to set CPU 0 and CPU 7 to handle interrupts, use `0000000010000001` as the binary code:

   Table 28.1. Binary Bits for CPUs
2. Convert the binary code to hexadecimal:
For example, to convert the binary code using Python:

```python
>>> hex(int('0000000010000001', 2))
'0x81'
```

On systems with more than 32 processors, you must delimit the `smp_affinity` values for discrete 32 bit groups. For example, if you want only the first 32 processors of a 64 processor system to service an interrupt request, use `0xffffffff,00000000`.

3. The interrupt affinity value for a particular interrupt request is stored in the associated `/proc/irq/irq_number/smp_affinity` file. Set the `smp_affinity` mask in this file:

```bash
# echo mask > /proc/irq/irq_number/smp_affinity
```

- `journalctl(1)`, `irqbalance(1)`, and `taskset(1)` man pages
CHAPTER 29. TUNING SCHEDULING POLICY

In Red Hat Enterprise Linux, the smallest unit of process execution is called a thread. The system scheduler determines which processor runs a thread, and for how long the thread runs. However, because the scheduler’s primary concern is to keep the system busy, it may not schedule threads optimally for application performance.

For example, say an application on a NUMA system is running on Node A when a processor on Node B becomes available. To keep the processor on Node B busy, the scheduler moves one of the application’s threads to Node B. However, the application thread still requires access to memory on Node A. But, this memory will take longer to access because the thread is now running on Node B and Node A memory is no longer local to the thread. Thus, it may take longer for the thread to finish running on Node B than it would have taken to wait for a processor on Node A to become available, and then to execute the thread on the original node with local memory access.

29.1. CATEGORIES OF SCHEDULING POLICIES

Performance sensitive applications often benefit from the designer or administrator determining where threads are run. The Linux scheduler implements a number of scheduling policies which determine where and for how long a thread runs.

The following are the two major categories of scheduling policies:

Normal policies
  Normal threads are used for tasks of normal priority.

Realtime policies
  Realtime policies are used for time-sensitive tasks that must complete without interruptions. Realtime threads are not subject to time slicing. This means the thread runs until they block, exit, voluntarily yield, or are preempted by a higher priority thread.
  The lowest priority realtime thread is scheduled before any thread with a normal policy. For more information, see Static priority scheduling with SCHED_FIFO and Round robin priority scheduling with SCHED_RR.

Additional resources
  - sched(7), sched_setaffinity(2), sched_getaffinity(2), sched_setscheduler(2), and sched_getscheduler(2) man pages

29.2. STATIC PRIORITY SCHEDULING WITH SCHED_FIFO

The SCHED_FIFO, also called static priority scheduling, is a realtime policy that defines a fixed priority for each thread. This policy allows administrators to improve event response time and reduce latency. It is recommended to not execute this policy for an extended period of time for time sensitive tasks.

When SCHED_FIFO is in use, the scheduler scans the list of all the SCHED_FIFO threads in order of priority and schedules the highest priority thread that is ready to run. The priority level of a SCHED_FIFO thread can be any integer from 1 to 99, where 99 is treated as the highest priority. Red Hat recommends starting with a lower number and increasing priority only when you identify latency issues.
WARNING

Because realtime threads are not subject to time slicing, Red Hat does not recommend setting a priority as 99. This keeps your process at the same priority level as migration and watchdog threads; if your thread goes into a computational loop and these threads are blocked, they will not be able to run. Systems with a single processor will eventually hang in this situation.

Administrators can limit SCHED_FIFO bandwidth to prevent realtime application programmers from initiating realtime tasks that monopolize the processor.

The following are some of the parameters used in this policy:

/proc/sys/kernel/sched_rt_period_us

This parameter defines the time period, in microseconds, that is considered to be one hundred percent of the processor bandwidth. The default value is 1000000 µs, or 1 second.

/proc/sys/kernel/sched_rt_runtime_us

This parameter defines the time period, in microseconds, that is devoted to running real-time threads. The default value is 950000 µs, or 0.95 seconds.

29.3. ROUND ROBIN PRIORITY SCHEDULING WITH SCHED_RR

The SCHED_RR is a round-robin variant of the SCHED_FIFO. This policy is useful when multiple threads need to run at the same priority level.

Like SCHED_FIFO, SCHED_RR is a realtime policy that defines a fixed priority for each thread. The scheduler scans the list of all SCHED_RR threads in order of priority and schedules the highest priority thread that is ready to run. However, unlike SCHED_FIFO, threads that have the same priority are scheduled in a round-robin style within a certain time slice.

You can set the value of this time slice in milliseconds with the sched_rr_timeslice_ms kernel parameter in the /proc/sys/kernel/sched_rr_timeslice_ms file. The lowest value is 1 millisecond.

29.4. NORMAL SCHEDULING WITH SCHED_OTHER

The SCHED_OTHER is the default scheduling policy in Red Hat Enterprise Linux 9. This policy uses the Completely Fair Scheduler (CFS) to allow fair processor access to all threads scheduled with this policy. This policy is most useful when there are a large number of threads or when data throughput is a priority, as it allows more efficient scheduling of threads over time.

When this policy is in use, the scheduler creates a dynamic priority list based partly on the niceness value of each process thread. Administrators can change the niceness value of a process, but cannot change the scheduler’s dynamic priority list directly.

29.5. SETTING SCHEDULER POLICIES

Check and adjust scheduler policies and priorities by using the chrt command line tool. It can start new processes with the desired properties, or change the properties of a running process. It can also be used for setting the policy at runtime.
**Procedure**

1. View the process ID (PID) of the active processes:

   ```
   # ps
   ```

   Use the `--pid` or `-p` option with the `ps` command to view the details of the particular PID.

2. Check the scheduling policy, PID, and priority of a particular process:

   ```
   # chrt -p 468
   pid 468's current scheduling policy: SCHED_FIFO
   pid 468's current scheduling priority: 85
   
   # chrt -p 476
   pid 476's current scheduling policy: SCHED_OTHER
   pid 476's current scheduling priority: 0
   ```

   Here, 468 and 476 are PID of a process.

3. Set the scheduling policy of a process:

   a. For example, to set the process with PID 1000 to SCHED_FIFO, with a priority of 50:

      ```
      # chrt -f -p 50 1000
      ```

   b. For example, to set the process with PID 1000 to SCHED_OTHER, with a priority of 0:

      ```
      # chrt -o -p 0 1000
      ```

   c. For example, to set the process with PID 1000 to SCHED_RR, with a priority of 10:

      ```
      # chrt -r -p 10 1000
      ```

   d. To start a new application with a particular policy and priority, specify the name of the application:

      ```
      # chrt -f 36 /bin/my-app
      ```

**Additional resources**

- [chrt(1) man page](#)
- [Policy Options for the chrt command](#)
- [Changing the priority of services during the boot process](#)

## 29.6. POLICY OPTIONS FOR THE CHRT COMMAND

Using the `chrt` command, you can view and set the scheduling policy of a process.

The following table describes the appropriate policy options, which can be used to set the scheduling policy of a process.
### Table 29.1. Policy Options for the chrt Command

<table>
<thead>
<tr>
<th>Short option</th>
<th>Long option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f</td>
<td>--fifo</td>
<td>Set schedule to <strong>SCHED_FIF</strong></td>
</tr>
<tr>
<td>-o</td>
<td>--other</td>
<td>Set schedule to <strong>SCHED_OTHER</strong></td>
</tr>
<tr>
<td>-r</td>
<td>--rr</td>
<td>Set schedule to <strong>SCHED_RR</strong></td>
</tr>
</tbody>
</table>

#### 29.7. CHANGING THE PRIORITY OF SERVICES DURING THE BOOT PROCESS

Using the **systemd** service, it is possible to set up real-time priorities for services launched during the boot process. The *unit configuration directives* are used to change the priority of a service during the boot process.

The boot process priority change is done by using the following directives in the service section:

**CPUSchedulingPolicy=**

Sets the CPU scheduling policy for executed processes. It is used to set `other`, `fifo`, and `rr` policies.

**CPUSchedulingPriority=**

Sets the CPU scheduling priority for executed processes. The available priority range depends on the selected CPU scheduling policy. For real-time scheduling policies, an integer between 1 (lowest priority) and 99 (highest priority) can be used.

The following procedure describes how to change the priority of a service, during the boot process, using the **mcelog** service.

#### Prerequisites

1. Install the TuneD package:

   ```
   # dnf install tuned
   ```

2. Enable and start the TuneD service:

   ```
   # systemctl enable --now tuned
   ```

#### Procedure

1. View the scheduling priorities of running threads:

   ```
   # tuna --show_threads
   thread       ctxt_switches       pid SCHED_rtpri affinity voluntary nonvoluntary      cmd
   ------------  ------------------  ------  ------------  ------------  ------------  ------------  ----
   thread       ctxt_switches       pid SCHED_rtpri affinity voluntary nonvoluntary      cmd
   1 OTHER       0xff               3181      292          0          0      systemd
   2 OTHER       0xff               254       0            0          0      kthreadd
   3 OTHER       0xff               2         0           0          0      rcu_gp
   4 OTHER       0xff               2         0           0          0      rcu_par_gp
   ```
2. Create a supplementary `mcelog` service configuration directory file and insert the policy name and priority in this file:

```bash
# cat <<-EOF > /etc/systemd/system/mcelog.system.d/priority.conf
>
[SERVICE]
CPUSchedulingPolicy=_fifo_
CPUSchedulingPriority=_20_
EOF
```

3. Reload the `systemd` scripts configuration:

```bash
# systemctl daemon-reload
```

4. Restart the `mcelog` service:

```bash
# systemctl restart mcelog
```

**Verification steps**

- Display the `mcelog` priority set by `systemd` issue:

```bash
# tuna -t mcelog -P
thread ctxt_switches
pid SCHED_rtpri affinity voluntary nonvoluntary cmd
826  FIFO  20 0,1,2,3 13 0 mcelog
```

**Additional resources**

- `systemd(1)` and `tuna(8)` man pages
- **Description of the priority range**

### 29.8. PRIORITY MAP

Priorities are defined in groups, with some groups dedicated to certain kernel functions. For real-time scheduling policies, an integer between 1 (lowest priority) and 99 (highest priority) can be used.

The following table describes the priority range, which can be used while setting the scheduling policy of a process.

**Table 29.2. Description of the priority range**
### Table: Priority, Threads, Description

<table>
<thead>
<tr>
<th>Priority</th>
<th>Threads</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Low priority kernel threads</td>
<td>This priority is usually reserved for the tasks that need to be just above SCHED_OTHER.</td>
</tr>
<tr>

<tr>
<td>50</td>
<td>Default hard-IRQ value</td>
<td></td>
</tr>
<tr>
<td>51 - 98</td>
<td>High priority threads</td>
<td>Use this range for threads that execute periodically and must have quick response times. Do not use this range for CPU-bound threads as you will starve interrupts.</td>
</tr>
<tr>
<td>99</td>
<td>Watchdogs and migration</td>
<td>System threads that must run at the highest priority.</td>
</tr>
</tbody>
</table>

### 29.9. TUNED CPU-PARTITIONING PROFILE

For tuning Red Hat Enterprise Linux 9 for latency-sensitive workloads, Red Hat recommends to use the `cpu-partitioning` TuneD profile.

Prior to Red Hat Enterprise Linux 9, the low-latency Red Hat documentation described the numerous low-level steps needed to achieve low-latency tuning. In Red Hat Enterprise Linux 9, you can perform low-latency tuning more efficiently by using the `cpu-partitioning` TuneD profile. This profile is easily customizable according to the requirements for individual low-latency applications.

The following figure is an example to demonstrate how to use the `cpu-partitioning` profile. This example uses the CPU and node layout.

**Figure 29.1. Figure cpu-partitioning**

You can configure the `cpu-partitioning` profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the following configuration options:

**Isolated CPUs with load balancing**
In the cpu-partitioning figure, the blocks numbered from 4 to 23, are the default isolated CPUs. The kernel scheduler’s process load balancing is enabled on these CPUs. It is designed for low-latency processes with multiple threads that need the kernel scheduler load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the `isolated_cores=cpu-list` option, which lists CPUs to isolate that will use the kernel scheduler load balancing.

The list of isolated CPUs is comma-separated or you can specify a range using a dash, such as `3-5`. This option is mandatory. Any CPU missing from this list is automatically considered a housekeeping CPU.

### Isolated CPUs without load balancing

In the cpu-partitioning figure, the blocks numbered 2 and 3, are the isolated CPUs that do not provide any additional kernel scheduler process load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the `no_balance_cores=cpu-list` option, which lists CPUs to isolate that will not use the kernel scheduler load balancing.

Specifying the `no_balance_cores` option is optional, however any CPUs in this list must be a subset of the CPUs listed in the `isolated_cores` list.

Application threads using these CPUs need to be pinned individually to each CPU.

### Housekeeping CPUs

Any CPU not isolated in the `cpu-partitioning-variables.conf` file is automatically considered a housekeeping CPU. On the housekeeping CPUs, all services, daemons, user processes, movable kernel threads, interrupt handlers, and kernel timers are permitted to execute.

### Additional resources

- `tuned-profiles-cpu-partitioning(7)` man page

### 29.10. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING

This procedure describes how to tune a system for low-latency using the TuneD’s `cpu-partitioning` profile. It uses the example of a low-latency application that can use `cpu-partitioning` and the CPU layout as mentioned in the `cpu-partitioning` figure.

The application in this case uses:

- One dedicated reader thread that reads data from the network will be pinned to CPU 2.
- A large number of threads that process this network data will be pinned to CPUs 4-23.
- A dedicated writer thread that writes the processed data to the network will be pinned to CPU 3.

### Prerequisites

- You have installed the `cpu-partitioning` TuneD profile by using the `dnf install tuned-profiles-cpu-partitioning` command as root.
Procedure

1. Edit `/etc/tuned/cpu-partitioning-variables.conf` file and add the following information:
   
   ```
   isolated_cores=2-23
   no_balance_cores=2,3
   ```

2. Set the `cpu-partitioning` TuneD profile:
   
   ```
   # tuned-adm profile cpu-partitioning
   ```

3. Reboot
   
   After rebooting, the system is tuned for low-latency, according to the isolation in the `cpu-partitioning` figure. The application can use `taskset` to pin the reader and writer threads to CPUs 2 and 3, and the remaining application threads on CPUs 4-23.

Additional resources

- `tuned-profiles-cpu-partitioning(7)` man page

### 29.11. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE

You can extend the TuneD profile to make additional tuning changes.

For example, the `cpu-partitioning` profile sets the CPUs to use `cstate=1`. In order to use the `cpu-partitioning` profile but to additionally change the CPU cstate from `cstate1` to `cstate0`, the following procedure describes a new TuneD profile named `my_profile`, which inherits the `cpu-partitioning` profile and then sets C state-0.

Procedure

1. Create the `/etc/tuned/my_profile` directory:
   
   ```
   # mkdir /etc/tuned/my_profile
   ```

2. Create a `tuned.conf` file in this directory, and add the following content:
   
   ```
   [main]
   summary=Customized tuning on top of cpu-partitioning
   include=cpu-partitioning
   [cpu]
   force_latency=cstate.id:0|1
   ```

3. Use the new profile:
   
   ```
   # tuned-adm profile my_profile
   ```
NOTE

In the shared example, a reboot is not required. However, if the changes in the my_profile profile require a reboot to take effect, then reboot your machine.

- tuned-profiles-cpu-partitioning(7) man page
CHAPTER 30. FACTORS AFFECTING I/O AND FILE SYSTEM PERFORMANCE

The appropriate settings for storage and file system performance are highly dependent on the storage purpose.

I/O and file system performance can be affected by any of the following factors:

- Data write or read patterns
- Sequential or random
- Buffered or Direct IO
- Data alignment with underlying geometry
- Block size
- File system size
- Journal size and location
- Recording access times
- Ensuring data reliability
- Pre-fetching data
- Pre-allocating disk space
- File fragmentation
- Resource contention

30.1. TOOLS FOR MONITORING AND DIAGNOSING I/O AND FILE SYSTEM ISSUES

The following tools are available in Red Hat Enterprise Linux 9 for monitoring system performance and diagnosing performance problems related to I/O, file systems, and their configuration:

- **vmstat** tool reports on processes, memory, paging, block I/O, interrupts, and CPU activity across the entire system. It can help administrators determine whether the I/O subsystem is responsible for any performance issues. If analysis with vmstat shows that the I/O subsystem is responsible for reduced performance, administrators can use the iostat tool to determine the responsible I/O device.

- **iostat** reports on I/O device load in your system. It is provided by the sysstat package.

- **blktrace** provides detailed information about how time is spent in the I/O subsystem. The companion utility blkparse reads the raw output from blktrace and produces a human readable summary of input and output operations recorded by blktrace.

- **btt** analyzes blktrace output and displays the amount of time that data spends in each area of the I/O stack, making it easier to spot bottlenecks in the I/O subsystem. This utility is provided as part of the blktrace package. Some of the important events tracked by the blktrace mechanism and analyzed by btt are:
• Queuing of the I/O event (Q)
• Dispatch of the I/O to the driver event (D)
• Completion of I/O event (C)

• iowatcher can use the blktrace output to graph I/O over time. It focuses on the Logical Block Address (LBA) of disk I/O, throughput in megabytes per second, the number of seeks per second, and I/O operations per second. This can help to identify when you are hitting the operations-per-second limit of a device.

• BPF Compiler Collection (BCC) is a library, which facilitates the creation of the extended Berkeley Packet Filter (eBPF) programs. The eBPF programs are triggered on events, such as disk I/O, TCP connections, and process creations. The BCC tools are installed in the /usr/share/bcc/tools/ directory. The following bcc-tools helps to analyze performance:
  • biolatency summarizes the latency in block device I/O (disk I/O) in histogram. This allows the distribution to be studied, including two modes for device cache hits and for cache misses, and latency outliers.
  • biosnoop is a basic block I/O tracing tool for displaying each I/O event along with the issuing process ID, and the I/O latency. Using this tool, you can investigate disk I/O performance issues.
  • biotop is used for block i/o operations in the kernel.
  • filelife tool traces the stat() syscalls.
  • fileslower traces slow synchronous file reads and writes.
  • filetop displays file reads and writes by process.
  • ext4slower, nfsslower, and xfsslower are tools that show file system operations slower than a certain threshold, which defaults to 10ms. For more information, see the Analyzing system performance with BPF Compiler Collection.

• bpftace is a tracing language for eBPF used for analyzing performance issues. It also provides trace utilities like BCC for system observation, which is useful for investigating I/O performance issues.

• The following SystemTap scripts may be useful in diagnosing storage or file system performance problems:
  • disktop.stp: Checks the status of reading or writing disk every 5 seconds and outputs the top ten entries during that period.
  • iotime.stp: Prints the amount of time spent on read and write operations, and the number of bytes read and written.
  • traceio.stp: Prints the top ten executable based on cumulative I/O traffic observed, every second.
  • traceio2.stp: Prints the executable name and process identifier as reads and writes to the specified device occur.
  • Inodewatch.stp: Prints the executable name and process identifier each time a read or write occurs to the specified inode on the specified major or minor device.
- `inodewatch2.stp`: Prints the executable name, process identifier, and attributes each time the attributes are changed on the specified inode on the specified major or minor device.

Additional resources

- `vmstat(8), iostat(1), blktrace(8), blkparse(1), btt(1), bpftrace`, and `iowatcher(1)` man pages
- Analyzing system performance with BPF Compiler Collection

### 30.2. AVAILABLE TUNING OPTIONS FOR FORMATTING A FILE SYSTEM

Some file system configuration decisions cannot be changed after the device is formatted.

The following are the options available before formatting a storage device:

**Size**

Create an appropriately-sized file system for your workload. Smaller file systems require less time and memory for file system checks. However, if a file system is too small, its performance suffers from high fragmentation.

**Block size**

The block is the unit of work for the file system. The block size determines how much data can be stored in a single block, and therefore the smallest amount of data that is written or read at one time. The default block size is appropriate for most use cases. However, your file system performs better and stores data more efficiently if the block size or the size of multiple blocks is the same as or slightly larger than the amount of data that is typically read or written at one time. A small file still uses an entire block. Files can be spread across multiple blocks, but this can create additional runtime overhead.

Additionally, some file systems are limited to a certain number of blocks, which in turn limits the maximum size of the file system. Block size is specified as part of the file system options when formatting a device with the `mkfs` command. The parameter that specifies the block size varies with the file system.

**Geometry**

File system geometry is concerned with the distribution of data across a file system. If your system uses striped storage, like RAID, you can improve performance by aligning data and metadata with the underlying storage geometry when you format the device.

Many devices export recommended geometry, which is then set automatically when the devices are formatted with a particular file system. If your device does not export these recommendations, or you want to change the recommended settings, you must specify geometry manually when you format the device with the `mkfs` command.

The parameters that specify file system geometry vary with the file system.

**External journals**

Journaling file systems document the changes that will be made during a write operation in a journal file prior to the operation being executed. This reduces the likelihood that a storage device will become corrupted in the event of a system crash or power failure, and speeds up the recovery process.
NOTE

Red Hat does not recommend using the external journals option.

Metadata-intensive workloads involve very frequent updates to the journal. A larger journal uses more memory, but reduces the frequency of write operations. Additionally, you can improve the seek time of a device with a metadata-intensive workload by placing its journal on dedicated storage that is as fast as, or faster than, the primary storage.

WARNING

Ensure that external journals are reliable. Losing an external journal device causes file system corruption. External journals must be created at format time, with journal devices being specified at mount time.

Additional resources

- `mkfs(8)` and `mount(8)` man pages
- Overview of available file systems

30.3. AVAILABLE TUNING OPTIONS FOR MOUNTING A FILE SYSTEM

The following are the options available to most file systems and can be specified as the device is mounted:

Access Time

Every time a file is read, its metadata is updated with the time at which access occurred (atime). This involves additional write I/O. The relatime is the default atime setting for most file systems. However, if updating this metadata is time consuming, and if accurate access time data is not required, you can mount the file system with the noatime mount option. This disables updates to metadata when a file is read. It also enables nodiratime behavior, which disables updates to metadata when a directory is read.

NOTE

Disabling atime updates by using the noatime mount option can break applications that rely on them, for example, backup programs.

Read-ahead

Read-ahead behavior speeds up file access by pre-fetching data that is likely to be needed soon and loading it into the page cache, where it can be retrieved more quickly than if it were on disk. The higher the read-ahead value, the further ahead the system pre-fetches data. Red Hat Enterprise Linux attempts to set an appropriate read-ahead value based on what it detects about your file system. However, accurate detection is not always possible. For example, if a storage array presents itself to the system as a single LUN, the system detects the single LUN, and does not set the appropriate read-ahead value for an array.
Workloads that involve heavy streaming of sequential I/O often benefit from high read-ahead values. The storage-related tuned profiles provided with Red Hat Enterprise Linux raise the read-ahead value, as does using LVM striping, but these adjustments are not always sufficient for all workloads.

Additional resources
- `mount(8)`, `xfs(5)`, and `ext4(5)` man pages

### 30.4. TYPES OF DISCARDING UNUSED BLOCKS

Regularly discarding blocks that are not in use by the file system is a recommended practice for both solid-state disks and thinly-provisioned storage.

The following are the two methods of discarding unused blocks:

**Batch discard**

This type of discard is part of the `fstrim` command. It discards all unused blocks in a file system that match criteria specified by the administrator. Red Hat Enterprise Linux 9 supports batch discard on XFS and ext4 formatted devices that support physical discard operations.

**Online discard**

This type of discard operation is configured at mount time with the `discard` option, and runs in real time without user intervention. However, it only discards blocks that are transitioning from used to free. Red Hat Enterprise Linux 9 supports online discard on XFS and ext4 formatted devices. Red Hat recommends batch discard, except where online discard is required to maintain performance, or where batch discard is not feasible for the system’s workload.

Pre-allocation marks disk space as being allocated to a file without writing any data into that space. This can be useful in limiting data fragmentation and poor read performance. Red Hat Enterprise Linux 9 supports pre-allocating space on XFS, ext4, and GFS2 file systems. Applications can also benefit from pre-allocating space by using the `fallocate(2) glibc` call.

Additional resources
- `mount(8)` and `fallocate(2)` man pages

### 30.5. SOLID-STATE DISKS TUNING CONSIDERATIONS

Solid-state disks (SSD) use NAND flash chips rather than rotating magnetic platters to store persistent data. SSD provides a constant access time for data across their full Logical Block Address range, and does not incur measurable seek costs like their rotating counterparts. They are more expensive per gigabyte of storage space and have a lesser storage density, but they also have lower latency and greater throughput than HDDs.

Performance generally degrades as the used blocks on an SSD approach the capacity of the disk. The degree of degradation varies by vendor, but all devices experience degradation in this circumstance. Enabling discard behavior can help to alleviate this degradation. For more information, see Types of discarding unused blocks.

The default I/O scheduler and virtual memory options are suitable for use with SSDs. Consider the following factors when configuring settings that can affect SSD performance:

**I/O Scheduler**
Any I/O scheduler is expected to perform well with most SSDs. However, as with any other storage type, Red Hat recommends benchmarking to determine the optimal configuration for a given workload. When using SSDs, Red Hat advises changing the I/O scheduler only for benchmarking particular workloads. For instructions on how to switch between I/O schedulers, see the `/usr/share/doc/kernel-version/Documentation/block/switching-sched.txt` file.

For single queue HBA, the default I/O scheduler is `deadline`. For multiple queue HBA, the default I/O scheduler is `none`. For information on how to set the I/O scheduler, see Setting the disk scheduler.

Virtual Memory

Like the I/O scheduler, virtual memory (VM) subsystem requires no special tuning. Given the fast nature of I/O on SSD, try turning down the `vm.dirty_background_ratio` and `vm.dirty_ratio` settings, as increased write-out activity does not usually have a negative impact on the latency of other operations on the disk. However, this tuning can generate more overall I/O, and is therefore not generally recommended without workload-specific testing.

Swap

An SSD can also be used as a swap device, and is likely to produce good page-out and page-in performance.

30.6. GENERIC BLOCK DEVICE TUNING PARAMETERS

The generic tuning parameters listed in this section are available in the `/sys/block/sdX/queue/` directory.

The following listed tuning parameters are separate from I/O scheduler tuning, and are applicable to all I/O schedulers:

add_random

Some I/O events contribute to the entropy pool for the `/dev/random`. This parameter can be set to 0 if the overhead of these contributions become measurable.

iostats

By default, iostats is enabled and the default value is 1. Setting iostats value to 0 disables the gathering of I/O statistics for the device, which removes a small amount of overhead with the I/O path. Setting iostats to 0 might slightly improve performance for very high performance devices, such as certain NVMe solid-state storage devices. It is recommended to leave iostats enabled unless otherwise specified for the given storage model by the vendor.

If you disable iostats, the I/O statistics for the device are no longer present within the `/proc/diskstats` file. The content of `/sys/diskstats` file is the source of I/O information for monitoring I/O tools, such as sar or iostats. Therefore, if you disable the iostats parameter for a device, the device is no longer present in the output of I/O monitoring tools.

max_sectors_kb

Specifies the maximum size of an I/O request in kilobytes. The default value is 512 KB. The minimum value for this parameter is determined by the logical block size of the storage device. The maximum value for this parameter is determined by the value of the `max_hw_sectors_kb`. Red Hat recommends max_sectors_kb to always be a multiple of the optimal I/O size and the internal erase block size. Use a value of logical_block_size for either parameter if they are zero or not specified by the storage device.

nomerges

Most workloads benefit from request merging. However, disabling merges can be useful for debugging purposes. By default, the nomerges parameter is set to 0, which enables merging. To disable simple one-hit merging, set nomerges to 1. To disable all types of merging, set nomerges
to 2.

**nr_requests**

It is the maximum allowed number of the queued I/O. If the current I/O scheduler is none, this number can only be reduced; otherwise the number can be increased or reduced.

**optimal_io_size**

Some storage devices report an optimal I/O size through this parameter. If this value is reported, Red Hat recommends that applications issue I/O aligned to and in multiples of the optimal I/O size wherever possible.

**read_ahead_kb**

Defines the maximum number of kilobytes that the operating system may read ahead during a sequential read operation. As a result, the necessary information is already present within the kernel page cache for the next sequential read, which improves read I/O performance. Device mappers often benefit from a high read_ahead_kb value. 128 KB for each device to be mapped is a good starting point, but increasing the read_ahead_kb value up to request queue’s max_sectors_kb of the disk might improve performance in application environments where sequential reading of large files takes place.

**rotational**

Some solid-state disks do not correctly advertise their solid-state status, and are mounted as traditional rotational disks. Manually set the rotational value to 0 to disable unnecessary seek-reducing logic in the scheduler.

**rq_affinity**

The default value of the rq_affinity is 1. It completes the I/O operations on one CPU core, which is in the same CPU group of the issued CPU core. To perform completions only on the processor that issued the I/O request, set the rq_affinity to 2. To disable the mentioned two abilities, set it to 0.

**scheduler**

To set the scheduler or scheduler preference order for a particular storage device, edit the /sys/block/devname/queue/scheduler file, where devname is the name of the device you want to configure.
CHAPTER 31. USING SYSTEMD TO MANAGE RESOURCES USED BY APPLICATIONS

RHEL 9 moves the resource management settings from the process level to the application level by binding the system of cgroup hierarchies with the systemd unit tree. Therefore, you can manage the system resources with the systemctl command, or by modifying the systemd unit files.

To achieve this, systemd takes various configuration options from the unit files or directly via the systemctl command. Then systemd applies those options to specific process groups by utilizing the Linux kernel system calls and features like cgroups and namespaces.

NOTE
You can review the full set of configuration options for systemd in the following manual pages:

- systemd.resource-control(5)
- systemd.exec(5)

31.1. ALLOCATING SYSTEM RESOURCES USING SYSTEMD
To modify the distribution of system resources, you can apply one or more of the following distribution models:

Weights
You can distribute the resource by adding up the weights of all sub-groups and giving each sub-group the fraction matching its ratio against the sum.
For example, if you have 10 cgroups, each with weight of value 100, the sum is 1000. Each cgroup receives one tenth of the resource.

Weight is usually used to distribute stateless resources. For example the CPUWeight= option is an implementation of this resource distribution model.

Limits
A cgroup can consume up to the configured amount of the resource. The sum of sub-group limits can exceed the limit of the parent cgroup. Therefore it is possible to overcommit resources in this model.
For example the MemoryMax= option is an implementation of this resource distribution model.

Protections
You can set up a protected amount of a resource for a cgroup. If the resource usage is below the protection boundary, the kernel will try not to penalize this cgroup in favor of other cgroups that compete for the same resource. An overcommit is also possible.
For example the MemoryLow= option is an implementation of this resource distribution model.

Allocations
Exclusive allocations of an absolute amount of a finite resource. An overcommit is not possible. An example of this resource type in Linux is the real-time budget.

unit file option
A setting for resource control configuration.
For example, you can configure CPU resource with options like `CPUAccounting=`, or `CPUQuota=`. Similarly, you can configure memory or I/O resources with options like `AllowedMemoryNodes=` and `IOAccounting=`.

**Procedure**

To change the required value of the unit file option of your service, you can adjust the value in the unit file, or use `systemctl` command:

1. Check the assigned values for the service of your choice.
   ```
   # systemctl show --property <unit file option> <service name>
   ```

2. Set the required value of the CPU time allocation policy option:
   ```
   # systemctl set-property <service name> <unit file option>=<value>
   ```

**Verification steps**

- Check the newly assigned values for the service of your choice.
  ```
  # systemctl show --property <unit file option> <service name>
  ```

**Additional resources**

- `systemd.resource-control(5)`, `systemd.exec(5)` manual pages

**31.2. ROLE OF SYSTEMD IN RESOURCE MANAGEMENT**

The core function of `systemd` is service management and supervision. The `systemd` system and service manager ensures that managed services start at the right time and in the correct order during the boot process. The services have to run smoothly to use the underlying hardware platform optimally. Therefore, `systemd` also provides capabilities to define resource management policies, and to tune various options, which can improve the performance of the service.

**IMPORTANT**

In general, Red Hat recommends you use `systemd` for controlling the usage of system resources. You should manually configure the `cgroups` virtual file system only in special cases. For example, when you need to use `cgroup-v1` controllers that have no equivalents in `cgroup-v2` hierarchy.

**31.3. OVERVIEW OF SYSTEMD HIERARCHY FOR CGROUPS**

On the backend, the `systemd` system and service manager makes use of the `slice`, the `scope` and the `service` units to organize and structure processes in the control groups. You can further modify this hierarchy by creating custom unit files or using the `systemctl` command. Also, `systemd` automatically mounts hierarchies for important kernel resource controllers at the `/sys/fs/cgroup/` directory.

Three `systemd` unit types are used for resource control:
- **Service** - A process or a group of processes, which **systemd** started according to a unit configuration file. Services encapsulate the specified processes so that they can be started and stopped as one set. Services are named in the following way:

  ```
  <name>.service
  ```

- **Scope** - A group of externally created processes. Scopes encapsulate processes that are started and stopped by the arbitrary processes through the `fork()` function and then registered by **systemd** at runtime. For example, user sessions, containers, and virtual machines are treated as scopes. Scopes are named as follows:

  ```
  <name>.scope
  ```

- **Slice** - A group of hierarchically organized units. Slices organize a hierarchy in which scopes and services are placed. The actual processes are contained in scopes or in services. Every name of a slice unit corresponds to the path to a location in the hierarchy. The dash ("-" ) character acts as a separator of the path components to a slice from the `-slice` root slice. In the following example:

  ```
  <parent-name>.slice
  ```

  *parent-name.slice* is a sub-slice of *parent.slice*, which is a sub-slice of the `-slice` root slice. *parent-name.slice* can have its own sub-slice named *parent-name-name2.slice*, and so on.

The **service**, the **scope**, and the **slice** units directly map to objects in the control group hierarchy. When these units are activated, they map directly to control group paths built from the unit names.

The following is an abbreviated example of a control group hierarchy:

```
Control group /:
- .slice
  | - user.slice
  |   | - user-42.slice
  |   |   | - session-c1.scope
  |   |   | - 967 gdm-session-worker [pam/gdm-launch-environment]
  |   |   | - 1035 /usr/libexec/gdm-x-session gnome-session --autostart
  |   | - /usr/share/gdm/greeter/autostart
  |   |   | - 1054 /usr/libexec/Xorg vt1 -displayfd 3 -auth /run/user/42/gdm/Xauthority -background none
  |   |   | - noreset -keeptty -verbose 3
  |   |   | - 1212 /usr/libexec/gnome-session-binary --autostart /usr/share/gdm/greeter/autostart
  |   |   | - 1369 /usr/bin/gnome-shell
  |   |   | - 1732 ibus-daemon --xim --panel disable
  |   |   | - 1752 /usr/libexec/ibus-dconf
  |   |   | - 1762 /usr/libexec/ibus-x11 --kill-daemon
  |   |   | - 1912 /usr/libexec/gsd-xsettings
  |   |   | - 1917 /usr/libexec/gsd-a11y-settings
  |   |   | - 1920 /usr/libexec/gsd-clipboard
  |   | ...-
  | - init.scope
  |   | - 1 /usr/lib/systemd/systemd --switched-root --system --deserialize 18
  | - system.slice
  | - mgd.service
  | - 800 /sbin/mdg -f
  | - systemd-udevd.service
  | - 659 /usr/lib/systemd/systemd-udevd
```
The example above shows that services and scopes contain processes and are placed in slices that do not contain processes of their own.

### Additional resources

- *Configuring basic system settings* in Red Hat Enterprise Linux
- What are kernel resource controllers
- `systemd.resource-control(5), systemd.exec(5), cgroups(7), fork(), fork(2)` manual pages
- Understanding cgroups

### 31.4. LISTING SYSTEMD UNITS

The following procedure describes how to use the *systemd* system and service manager to list its units.

#### Procedure

- To list all active units on the system, execute the `# systemctl` command and the terminal will return an output similar to the following example:

```bash
# systemctl
UNIT Load Active Sub Description
... init.scope loaded active running System and Service Manager
session-2.scope loaded active running Session 2 of user jdoe
abrt-ccpp.service loaded active exited Install ABRT coredump hook
abrt-oops.service loaded active running ABRT kernel log watcher
abrt-vmcore.service loaded active exited Harvest vmcores for ABRT
abrt-xorg.service loaded active running ABRT Xorg log watcher
.-.slice loaded active active Root Slice
machine.slice loaded active active Virtual Machine and Container
Slice system-getty.slice loaded active active
system-getty.slice loaded active active
system-lvm2x2dpvscan.slice loaded active active system-
lvm2x2dpvscan.slice loaded active active system-
system-sshdx2dkeygen.slice loaded active active system-
sshdx2dkeygen.slice loaded active active system-
... system-systemd\x2dhibernate\x2dresume.slice loaded active active system-
systemd\x2dhibernate\x2dresume> loaded active active system-
system-user\x2druntime\x2ddir.slice loaded active active system-
```
UNIT - a name of a unit that also reflects the unit position in a control group hierarchy. The units relevant for resource control are a slice, a scope, and a service.

LOAD - indicates whether the unit configuration file was properly loaded. If the unit file failed to load, the field contains the state error instead of loaded. Other unit load states are: stub, merged, and masked.

ACTIVE - the high-level unit activation state, which is a generalization of SUB.

SUB - the low-level unit activation state. The range of possible values depends on the unit type.

DESCRIPTION - the description of the unit content and functionality.

To list inactive units, execute:

```
# systemctl --all
```

To limit the amount of information in the output, execute:

```
# systemctl --type service,masked
```

The --type option requires a comma-separated list of unit types such as a service and a slice, or unit load states such as loaded and masked.

Additional resources

- Configuring basic system settings in RHEL
- systemd.resource-control(5), systemd.exec(5) manual pages

31.5. VIEWING SYSTEMD CONTROL GROUP HIERARCHY

The following procedure describes how to display control groups (cgroups) hierarchy and processes running in specific cgroups.

Procedure

- To display the whole cgroups hierarchy on your system, execute # systemd-cgls:

```
# systemd-cgls
Control group /:
  -.slice
    └─user.slice
      └─user-42.slice
        └─session-c1.scope
          └─965 gdm-session-worker [pam/gdm-launch-environment]
          └─1040 /usr/libexec/gdm-x-session gnome-session --autostart
```

Red Hat Enterprise Linux 9.0 Monitoring and managing system status and performance
The example output returns the entire *cgroups* hierarchy, where the highest level is formed by *slices*.

- To display the *cgroups* hierarchy filtered by a resource controller, execute `# systemd-cgls <resource_controller>`:

    # systemd-cgls memory
    Controller memory; Control group /:
    └─1 /usr/lib/systemd/systemd --switched-root --system --deserialize 18
        └─user.slice
            └─session-c1.scope
                └─965 gdm-session-worker [pam/gdm-launch-environment]
    └─system.slice

The example output of the above command lists the services that interact with the selected controller.

- To display detailed information about a certain unit and its part of the *cgroups* hierarchy, execute `# systemctl status <system_unit>`:

    # systemctl status example.service
    ● example.service - My example service
    Loaded: loaded (/usr/lib/systemd/system/example.service; enabled; vendor preset: disabled)
    Active: active (running) since Tue 2019-04-16 12:12:39 CEST; 3s ago
    Main PID: 17737 (bash)  
    Tasks: 2 (limit: 11522)  
    Memory: 496.0K (limit: 1.5M)  
    CGroup: /system.slice/example.service
        └─17737 /bin/bash /home/jdoe/example.sh
            └─17743 sleep 1
31.6. VIEWING CGROUPS OF PROCESSES

The following procedure describes how to learn which control group (cgroup) a process belongs to. Then you can check the cgroup to learn which controllers and controller-specific configurations it uses.

Procedure

1. To view which cgroup a process belongs to, run the `# cat /proc/<PID>/cgroup` command:

   ```
   # cat /proc/2467/cgroup
   0::/system.slice/example.service
   ```

   The example output relates to a process of interest. In this case, it is a process identified by PID 2467, which belongs to the example.service unit. You can determine whether the process was placed in a correct control group as defined by the systemd unit file specifications.

2. To display what controllers the cgroup utilizes and the respective configuration files, check the cgroup directory:

   ```
   # cat /sys/fs/cgroup/system.slice/example.service/cgroup.controllers
   memory pids
   # ls /sys/fs/cgroup/system.slice/example.service/
   cgroup.controllers
   cgroup.events
   ...
   cpu.pressure
   cpu.stat
   io.pressure
   memory.current
   memory.events
   ...
   pids.current
   pids.events
   pids.max
   ```

   **NOTE**

   The version 1 hierarchy of cgroups uses a per-controller model. Therefore the output from the /proc/PID/cgroup file shows, which cgroups under each controller the PID belongs to. You can find the respective cgroups under the controller directories at /sys/fs/cgroup/<controller_name>.
### 31.7. MONITORING RESOURCE CONSUMPTION

The following procedure describes how to view a list of currently running control groups (cgroups) and their resource consumption in real-time.

**Procedure**

1. To see a dynamic account of currently running cgroups, execute the `# systemd-cgtop` command:

   ```
   # systemd-cgtop
   Control Group    Tasks  %CPU   Memory  Input/s Output/s
   /              607   29.8     1.5G        -        -
   /system.slice   125   428.7M        -        -
   /system.slice/ModemManager.service  3 - 8.6M        -        -
   /system.slice/NetworkManager.service  3 - 12.8M        -        -
   /system.slice/accounts-daemon.service  3 - 1.8M        -        -
   /system.slice/boot.mount - - 48.0K        -        -
   /system.slice/chronyd.service  1 - 2.0M        -        -
   /system.slice/cockpit.socket - - 1.3M        -        -
   /system.slice/colord.service  3 - 3.5M        -        -
   /system.slice/crond.service  1 - 1.8M        -        -
   /system.slice/cups.service  1 - 3.1M        -        -
   /system.slice/dev-hugepages.mount - - 244.0K        -        -
   /system.slice/dev-mapper-rhel\x2dswap.swap - - 912.0K        -        -
   /system.slice/dev-mqueue.mount - - 48.0K        -        -
   /system.slice/example.service  2 - 2.0M        -        -
   /system.slice/firewalld.service  2 - 28.8M        -        -
   ...
   ```

   The example output displays currently running cgroups ordered by their resource usage (CPU, memory, disk I/O load). The list refreshes every 1 second by default. Therefore, it offers a dynamic insight into the actual resource usage of each control group.

**Additional resources**

- systemd-cgtop(1) manual page

### 31.8. USING SYSTEMD UNIT FILES TO SET LIMITS FOR APPLICATIONS

Each existing or running unit is supervised by the systemd, which also creates control groups for them. The units have configuration files in the `/usr/lib/systemd/system/` directory. You can manually modify the unit files to set limits, prioritize, or control access to hardware resources for groups of processes.

**Prerequisites**
You have the root privileges.

**Procedure**

1. Modify the `/usr/lib/systemd/system/example.service` file to limit the memory usage of a service:

   ```
   [Service]
   MemoryMax=1500K
   ...
   ```

   The configuration above places a maximum memory limit, which the processes in a control group cannot exceed. The `example.service` service is part of such a control group which has imposed limitations. You can use suffixes K, M, G, or T to identify Kilobyte, Megabyte, Gigabyte, or Terabyte as a unit of measurement.

2. Reload all unit configuration files:

   ```
   # systemctl daemon-reload
   ```

3. Restart the service:

   ```
   # systemctl restart example.service
   ```

   **NOTE**

   You can review the full set of configuration options for systemd in the following manual pages:

   - `systemd.resource-control(5)`
   - `systemd.exec(5)`

**Verification**

1. Check that the changes took effect:

   ```
   # cat /sys/fs/cgroup/system.slice/example.service/memory.max
   1536000
   ```

   The example output shows that the memory consumption was limited at around 1500 KB.

**Additional resources**

- Understanding cgroups
- *Configuring basic system settings* in Red Hat Enterprise Linux
- `systemd.resource-control(5), systemd.exec(5), cgroups(7)` manual pages

**31.9. USING SYSTEMCTL COMMAND TO SET LIMITS TO APPLICATIONS**
CPU affinity settings help you restrict the access of a particular process to some CPUs. Effectively, the CPU scheduler never schedules the process to run on the CPU that is not in the affinity mask of the process.

The default CPU affinity mask applies to all services managed by systemd.

To configure CPU affinity mask for a particular systemd service, systemd provides CPUAffinity= both as a unit file option and a manager configuration option in the /etc/systemd/system.conf file.

The CPUAffinity= unit file option sets a list of CPUs or CPU ranges that are merged and used as the affinity mask.

After configuring CPU affinity mask for a particular systemd service, you must restart the service to apply the changes.

Procedure

To set CPU affinity mask for a particular systemd service using the CPUAffinity unit file option:

1. Check the values of the CPUAffinity unit file option in the service of your choice:

   $ systemctl show --property <CPU affinity configuration option> <service name>

2. As a root, set the required value of the CPUAffinity unit file option for the CPU ranges used as the affinity mask:

   # systemctl set-property <service name> CPUAffinity=<value>

3. Restart the service to apply the changes.

   # systemctl restart <service name>

NOTE

You can review the full set of configuration options for systemd in the following manual pages:

- systemd.resource-control(5)
- systemd.exec(5)

31.10. SETTING GLOBAL DEFAULT CPU AFFINITY THROUGH MANAGER CONFIGURATION

The CPUAffinity option in the /etc/systemd/system.conf file defines an affinity mask for the process identification number (PID) 1 and all processes forked off of PID1. You can then override the CPUAffinity on a per-service basis.

To set default CPU affinity mask for all systemd services using the manager configuration option:

1. Set the CPU numbers for the CPUAffinity= option in the /etc/systemd/system.conf file.

2. Save the edited file and reload the systemd service:
# systemctl daemon-reload

3. Reboot the server to apply the changes.

NOTE

You can review the full set of configuration options for systemd in the following manual pages:

- systemd.resource-control(5)
- systemd.exec(5)

31.11. CONFIGURING NUMA POLICIES USING SYSTEMD

Non-uniform memory access (NUMA) is a computer memory subsystem design, in which the memory access time depends on the physical memory location relative to the processor.

Memory close to the CPU has lower latency (local memory) than memory that is local for a different CPU (foreign memory) or is shared between a set of CPUs.

In terms of the Linux kernel, NUMA policy governs where (for example, on which NUMA nodes) the kernel allocates physical memory pages for the process.

systemd provides unit file options NUMAPolicy and NUMAMask to control memory allocation policies for services.

Procedure

To set the NUMA memory policy through the NUMAPolicy unit file option:

1. Check the values of the NUMAPolicy unit file option in the service of your choice:

   $ systemctl show --property <NUMA policy configuration option> <service name>

2. As a root, set the required policy type of the NUMAPolicy unit file option:

   # systemctl set-property <service name> NUMAPolicy=<value>

3. Restart the service to apply the changes.

   # systemctl restart <service name>

To set a global NUMAPolicy setting through the manager configuration option:

1. Search in the /etc/systemd/system.conf file for the NUMAPolicy option.

2. Edit the policy type and save the file.

3. Reload the systemd configuration:

   # systemctl daemon-reload

4. Reboot the server.
IMPORTANT

When you configure a strict NUMA policy, for example `bind`, make sure that you also appropriately set the `CPUAffinity=` unit file option.

Additional resources

- Using `systemctl` command to set limits to applications

31.12. NUMA POLICY CONFIGURATION OPTIONS FOR SYSTEMD

Systemd provides the following options to configure the NUMA policy:

**NUMAPolicy**

Controls the NUMA memory policy of the executed processes. The following policy types are possible:

- default
- preferred
- bind
- interleave
- local

**NUMAMask**

Controls the NUMA node list which is associated with the selected NUMA policy. Note that the `NUMAMask` option is not required to be specified for the following policies:

- default
- local

For the preferred policy, the list specifies only a single NUMA node.

Additional resources

- `systemd.resource-control(5), systemd.exec(5), set_mempolicy(2)` manual pages

31.13. CREATING TRANSIENT CGROUPS USING SYSTEMD-RUN COMMAND

The transient `cgroups` set limits on resources consumed by a unit (service or scope) during its runtime.

**Procedure**

- To create a transient control group, use the `systemd-run` command in the following format:

  ```bash
  # systemd-run --unit=<name> --slice=<name>.slice <command>
  ```
This command creates and starts a transient service or a scope unit and runs a custom command in such a unit.

- The `--unit=<name>` option gives a name to the unit. If `--unit` is not specified, the name is generated automatically.

- The `--slice=<name>.slice` option makes your service or scope unit a member of a specified slice. Replace `<name>.slice` with the name of an existing slice (as shown in the output of `systemctl -t slice`), or create a new slice by passing a unique name. By default, services and scopes are created as members of the `system.slice`.

- Replace `<command>` with the command you wish to execute in the service or the scope unit.

The following message is displayed to confirm that you created and started the service or the scope successfully:

```
# Running as unit <name>.service
```

- Optionally, keep the unit running after its processes finished to collect run-time information:

```
# systemctl stop <name>.service
```

```
# systemctl kill <name>.service --kill-who=PID,... --signal=<signal>
```

The command above uses the `--kill-who` option to select process(es) from the control group

---

**Additional resources**

- Understanding control groups
- Configuring basic system settings in RHEL
- `systemd-run(1)` manual page

**31.14. REMOVING TRANSIENT CONTROL GROUPS**

You can use the `systemd` system and service manager to remove transient control groups (cgroups) if you no longer need to limit, prioritize, or control access to hardware resources for groups of processes.

Transient cgroups are automatically released once all the processes that a service or a scope unit contains, finish.

**Procedure**

- To stop the service unit with all its processes, execute:

```
# systemctl stop <name>.service
```

- To terminate one or more of the unit processes, execute:

```
# systemctl kill <name>.service --kill-who=PID,... --signal=<signal>
```

The command above uses the `--kill-who` option to select process(es) from the control group.
you wish to terminate. To kill multiple processes at the same time, pass a comma-separated list of PIDs. The `--signal` option determines the type of POSIX signal to be sent to the specified processes. The default signal is `SIGTERM`.

### Additional resources

- Understanding control groups
- What are kernel resource controllers
- `systemd.resource-control(5), cgroups(7)` manual pages

- *Configuring basic system settings* in RHEL
CHAPTER 32. UNDERSTANDING CGROUPS

You can use the control groups (cgroups) kernel functionality to set limits, prioritize or isolate the hardware resources of processes. This allows you to granularly control resource usage of applications to utilize them more efficiently.

32.1. UNDERSTANDING CONTROL GROUPS

Control groups is a Linux kernel feature that enables you to organize processes into hierarchically ordered groups - cgroups. The hierarchy (control groups tree) is defined by providing structure to cgroups virtual file system, mounted by default on the /sys/fs/cgroup/ directory. The systemd system and service manager utilizes cgroups to organize all units and services that it governs. Alternatively, you can manage cgroups hierarchies manually by creating and removing sub-directories in the /sys/fs/cgroup/ directory.

The resource controllers (a kernel component) then modify the behavior of processes in cgroups by limiting, prioritizing or allocating system resources, (such as CPU time, memory, network bandwidth, or various combinations) of those processes.

The added value of cgroups is process aggregation which enables division of hardware resources among applications and users. Thereby an increase in overall efficiency, stability and security of users’ environment can be achieved.

Control groups version 1

Control groups version 1 (cgroups-v1) provide a per-resource controller hierarchy. It means that each resource, such as CPU, memory, I/O, and so on, has its own control group hierarchy. It is possible to combine different control group hierarchies in a way that one controller can coordinate with another one in managing their respective resources. However, the two controllers may belong to different process hierarchies, which does not permit their proper coordination.

The cgroups-v1 controllers were developed across a large time span and as a result, the behavior and naming of their control files is not uniform.

Control groups version 2

The problems with controller coordination, which stemmed from hierarchy flexibility, led to the development of control groups version 2.

Control groups version 2 (cgroups-v2) provides a single control group hierarchy against which all resource controllers are mounted.

The control file behavior and naming is consistent among different controllers.

IMPORTANT

RHEL 9, by default, mounts and utilizes cgroups-v2.

This sub-section was based on a Devconf.cz 2019 presentation.[2]

Additional resources

- What are kernel resource controllers
- cgroups(7) manual page
32.2. WHAT ARE KERNEL RESOURCE CONTROLLERS

The functionality of control groups is enabled by kernel resource controllers. RHEL 9 supports various controllers for control groups version 1 (cgroups-v1) and control groups version 2 (cgroups-v2).

A resource controller, also called a control group subsystem, is a kernel subsystem that represents a single resource, such as CPU time, memory, network bandwidth or disk I/O. The Linux kernel provides a range of resource controllers that are mounted automatically by the systemd system and service manager. Find a list of currently mounted resource controllers in the /proc/cgroups file.

The following controllers are available for cgroups-v1:

- **blkio** - can set limits on input/output access to and from block devices.
- **cpu** - can adjust the parameters of the Completely Fair Scheduler (CFS) scheduler for control group’s tasks. It is mounted together with the cpuacct controller on the same mount.
- **cpuacct** - creates automatic reports on CPU resources used by tasks in a control group. It is mounted together with the cpu controller on the same mount.
- **cpuset** - can be used to restrict control group tasks to run only on a specified subset of CPUs and to direct the tasks to use memory only on specified memory nodes.
- **devices** - can control access to devices for tasks in a control group.
- **freezer** - can be used to suspend or resume tasks in a control group.
- **memory** - can be used to set limits on memory use by tasks in a control group and generates automatic reports on memory resources used by those tasks.
- **net_cls** - tags network packets with a class identifier (classid) that enables the Linux traffic controller (the tc command) to identify packets that originate from a particular control group task. A subsystem of net_cls, the net_filter (iptables), can also use this tag to perform actions on such packets. The net_filter tags network sockets with a firewall identifier (fwid) that allows the Linux firewall (through iptables command) to identify packets originating from a particular control group task.
- **net_prio** - sets the priority of network traffic.
- **pids** - can set limits for a number of processes and their children in a control group.
- **perf_event** - can group tasks for monitoring by the perf performance monitoring and reporting utility.
- **rdma** - can set limits on Remote Direct Memory Access/InfiniBand specific resources in a control group.
- **hugetlb** - can be used to limit the usage of large size virtual memory pages by tasks in a control group.

The following controllers are available for cgroups-v2:

- **io** - A follow-up to blkio of cgroups-v1.
- **memory** - A follow-up to memory of cgroups-v1.
- **pids** - Same as pids in cgroups-v1.
- **rdma** - Same as rdma in cgroups-v1.
- **cpu** - A follow-up to cpu and cpuacct of cgroups-v1.
- **cpuset** - Supports only the core functionality (cpus{,.effective}, mems{,.effective}) with a new partition feature.
- **perf_event** - Support is inherent, no explicit control file. You can specify a v2 cgroup as a parameter to the perf command that will profile all the tasks within that cgroup.

**IMPORTANT**

A resource controller can be used either in a cgroups-v1 hierarchy or a cgroups-v2 hierarchy, not simultaneously in both.

**Additional resources**

- [cgroups(7) manual page](#)

### 32.3. WHAT ARE NAMESPACES

Namespaces are one of the most important methods for organizing and identifying software objects.

A namespace wraps a global system resource (for example a mount point, a network device, or a hostname) in an abstraction that makes it appear to processes within the namespace that they have their own isolated instance of the global resource. One of the most common technologies that utilize namespaces are containers.

Changes to a particular global resource are visible only to processes in that namespace and do not affect the rest of the system or other namespaces.

To inspect which namespaces a process is a member of, you can check the symbolic links in the /proc/<PID>/ns/ directory.

The following table shows supported namespaces and resources which they isolate:

<table>
<thead>
<tr>
<th>Namespace</th>
<th>Isolates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mount</td>
<td>Mount points</td>
</tr>
<tr>
<td>UTS</td>
<td>Hostname and NIS domain name</td>
</tr>
<tr>
<td>IPC</td>
<td>System V IPC, POSIX message queues</td>
</tr>
<tr>
<td>PID</td>
<td>Process IDs</td>
</tr>
</tbody>
</table>
CHAPTER 32. UNDERSTANDING CGROUPS

<table>
<thead>
<tr>
<th>Namespace</th>

CHAPTER 33. IMPROVING SYSTEM PERFORMANCE WITH ZSWAP

You can improve system performance by enabling the `zswap` kernel feature.

33.1. WHAT IS ZSWAP

This section explains what `zswap` is and how it can lead to system performance improvement.

`zswap` is a kernel feature that provides a compressed RAM cache for swap pages. The mechanism works as follows: `zswap` takes pages that are in the process of being swapped out and attempts to compress them into a dynamically allocated RAM-based memory pool. When the pool becomes full or the RAM becomes exhausted, `zswap` evicts pages from compressed cache on an LRU basis (least recently used) to the backing swap device. After the page has been decompressed into the swap cache, `zswap` frees the compressed version in the pool.

The benefits of `zswap`

- significant I/O reduction
- significant improvement of workload performance

In Red Hat Enterprise Linux 9, `zswap` is enabled by default.

Additional resources

- What is Zswap?

33.2. ENABLING ZSWAP AT RUNTIME

You can enable the `zswap` feature at system runtime using the `sysfs` interface.

Prerequisites

- You have root permissions.

Procedure

- Enable `zswap`:

  ```
  # echo 1 > /sys/module/zswap/parameters/enabled
  ```

Verification step

- Verify that `zswap` is enabled:

  ```
  # grep -r . /sys/kernel/debug/zswap
  duplicate_entry:0
  pool_limit_hit:13422200
  pool_total_size:6184960 (pool size in total in pages)
  reject_alloc_fail:5
  ```
Additional resources

- How to enable Zswap feature?

### 33.3. ENABLING ZSWAP PERMANENTLY

You can enable the **zswap** feature permanently by providing the `zswap.enabled=1` kernel command-line parameter.

**Prerequisites**

- You have root permissions.
- The **grubby** or **zipl** utility is installed on your system.

**Procedure**

1. Enable **zswap** permanently:
   ```bash
   # grubby --update-kernel=/boot/vmlinuz-$(uname -r) --args="zswap.enabled=1"
   ```

2. Reboot the system for the changes to take effect.

**Verification steps**

- Verify that **zswap** is enabled:
  ```bash
  # cat /proc/cmdline
  BOOT_IMAGE=(hd0,msdos1)/vmlinuz-5.14.0-70.5.1.el9_0.x86_64
  root=/dev/mapper/rhel-root ro crashkernel=1G-4G:192M,4G-64G:256M,64G-:512M
  resume=/dev/mapper/rhel-swap rd.lvm.lv=rhel/root
  rd.lvm.lv=rhel/swap rhgb quiet
  ```
  ```bash
  zswap.enabled=1
  ```

**Additional resources**

- How to enable Zswap feature?
- Configuring kernel command-line parameters
CHAPTER 34. USING CGROUPFS TO MANUALLY MANAGE CGROUPS

You can manage cgroup hierarchies on your system by creating directories on the cgroupfs virtual file system. The file system is mounted by default on the /sys/fs/cgroup/ directory and you can specify desired configurations in dedicated control files.

IMPORTANT

In general, Red Hat recommends you use systemd for controlling the usage of system resources. You should manually configure the cgroups virtual file system only in special cases. For example, when you need to use cgroup-v1 controllers that have no equivalents in cgroup-v2 hierarchy.

34.1. CREATING CGROUPS AND ENABLING CONTROLLERS IN CGROUPS-V2 FILE SYSTEM

You can manage the control groups (cgroups) by creating or removing directories and by writing to files in the cgroups virtual file system. The file system is by default mounted on the /sys/fs/cgroup/ directory. To use settings from the cgroups controllers, you also need to enable the desired controllers for child cgroups. The root cgroup has, by default, enabled the memory and pids controllers for its child cgroups. Therefore, Red Hat recommends to create at least two levels of child cgroups inside the /sys/fs/cgroup/ root cgroup. This way you optionally remove the memory and pids controllers from the child cgroups and maintain better organizational clarity of cgroup files.

Prerequisites

- You have root permissions.

Procedure

1. Create the /sys/fs/cgroup/Example/ directory:

   # mkdir /sys/fs/cgroup/Example /

   The /sys/fs/cgroup/Example/ directory defines a child group. When you create the /sys/fs/cgroup/Example/ directory, some cgroups-v2 interface files are automatically created in the directory. The /sys/fs/cgroup/Example/ directory contains also controller-specific files for the memory and pids controllers.

2. Optionally, inspect the newly created child control group:

   # ll /sys/fs/cgroup/Example/
   -r---r--. 1 root root 0 Jun  1 10:33 cgroup.controllers
   -r---r--. 1 root root 0 Jun  1 10:33 cgroup.events
   -rw-r--r-- 1 root root 0 Jun  1 10:33 cgroup.freeze
   -rw-r--r-- 1 root root 0 Jun  1 10:33 cgroup.procs
   ...
   -rw-r--r-- 1 root root 0 Jun  1 10:33 cgroup.subtree_control
   -r---r--. 1 root root 0 Jun  1 10:33 memory.events.local
   -rw-r--r-- 1 root root 0 Jun  1 10:33 memory.high
   -rw-r--r-- 1 root root 0 Jun  1 10:33 memory.low
   ...

234
The example output shows general cgroup control interface files such as cgroup.procs or cgroup.controllers. These files are common to all control groups, regardless of enabled controllers.

The files such as memory.high and pids.max relate to the memory and pids controllers, which are in the root control group (/sys/fs/cgroup/), and are enabled by default by systemd.

By default, the newly created child group inherits all settings from the parent cgroup. In this case, there are no limits from the root cgroup.

3. Verify that the desired controllers are available in the /sys/fs/cgroup/cgroup.controllers file:

```
# cat /sys/fs/cgroup/cgroup.controllers
cpuset cpu io memory hugetlb pids rdma
```

4. Enable the desired controllers. In this example it is cpu and cpuset controllers:

```
# echo "+cpu" >> /sys/fs/cgroup/cgroup.subtree_control
# echo "+cpuset" >> /sys/fs/cgroup/cgroup.subtree_control
```

These commands enable the cpu and cpuset controllers for the immediate child groups of the /sys/fs/cgroup/ root control group. Including the newly created Example control group. A child group is where you can specify processes and apply control checks to each of the processes based on your criteria.

Users can read the contents of the cgroup.subtree_control file at any level to get an idea of what controllers are going to be available for enablement in the immediate child group.

**NOTE**

By default, the /sys/fs/cgroup/cgroup.subtree_control file in the root control group contains memory and pids controllers.

5. Enable the desired controllers for child cgroups of the Example control group:

```
# echo "+cpu +cpuset" >> /sys/fs/cgroup/Example/cgroup.subtree_control
```

This command ensures that the immediate child control group will only have controllers relevant to regulate the CPU time distribution - not to memory or pids controllers.

6. Create the /sys/fs/cgroup/Example/tasks/ directory:

```
# mkdir /sys/fs/cgroup/Example/tasks/
```

The /sys/fs/cgroup/Example/tasks/ directory defines a child group with files that relate purely to cpu and cpuset controllers. You can now assign processes to this control group and utilize cpu and cpuset controller options for your processes.

7. Optionally, inspect the child control group:
# ll /sys/fs/cgroup/Example/tasks
-r--r--r-- 1 root root 0 Jun 11:45 cgroup.controllers
-r--r--r-- 1 root root 0 Jun 11:45 cgroup.events
-rw-r--r-- 1 root root 0 Jun 11:45 cgroup.freeze
-rw-r--r-- 1 root root 0 Jun 11:45 cgroup.max_depth
-rw-r--r-- 1 root root 0 Jun 11:45 cgroup.max.descendants
-rw-r--r-- 1 root root 0 Jun 11:45 cgroup.procs
-r--r--r-- 1 root root 0 Jun 11:45 cgroup.stat
-rw-r--r-- 1 root root 0 Jun 11:45 cgroup.subtree_control
-rw-r--r-- 1 root root 0 Jun 11:45 cgroup.type
-rw-r--r-- 1 root root 0 Jun 11:45 cpu.max
-rw-r--r-- 1 root root 0 Jun 11:45 cpu.pressure
-rw-r--r-- 1 root root 0 Jun 11:45 cpuset.cpus
-r--r--r-- 1 root root 0 Jun 11:45 cpuset.cpus.effective
-rw-r--r-- 1 root root 0 Jun 11:45 cpuset.cpus.partition
-rw-r--r-- 1 root root 0 Jun 11:45 cpuset.mems
-r--r--r-- 1 root root 0 Jun 11:45 cpuset.mems.effective
-r--r--r-- 1 root root 0 Jun 11:45 cpu.stat
-rw-r--r-- 1 root root 0 Jun 11:45 cpu.weight
-rw-r--r-- 1 root root 0 Jun 11:45 cpu.weight.nice
-rw-r--r-- 1 root root 0 Jun 11:45 io.pressure
-rw-r--r-- 1 root root 0 Jun 11:45 memory.pressure

**IMPORTANT**

The **cpu** controller is only activated if the relevant child control group has at least 2 processes which compete for time on a single CPU.

**Verification steps**

- Optional: confirm that you have created a new **cgroup** with only the desired controllers active:

  ```
  # cat /sys/fs/cgroup/Example/tasks/cgroup.controllers
  cpuset cpu
  ```

**Additional resources**

- Understanding control groups
- What are kernel resource controllers
- Mounting cgroups-v1
- cgroups(7), sysfs(5) manual pages

### 34.2. CONTROLLING DISTRIBUTION OF CPU TIME FOR APPLICATIONS BY ADJUSTING CPU WEIGHT

You need to assign values to the relevant files of the **cpu** controller to regulate distribution of the CPU time to applications under the specific cgroup tree.

**Prerequisites**
You have root permissions.

You have applications for which you want to control distribution of CPU time.

You created a two level hierarchy of child control groups inside the /sys/fs/cgroup/ root control group as in the following example:

```
... Example
    ├── g1
    │    └── g2
    │         └── g3
    ... 
```

You enabled the `cpu` controller in the parent control group and in child control groups similarly as described in Creating cgroups and enabling controllers in cgroups-v2 file system.

Procedure

1. Configure desired CPU weights to achieve resource restrictions within the control groups:

   ```
   # echo "150" > /sys/fs/cgroup/Example/g1/cpu.weight
   # echo "100" > /sys/fs/cgroup/Example/g2/cpu.weight
   # echo "50" > /sys/fs/cgroup/Example/g3/cpu.weight
   ```

2. Add the applications' PIDs to the g1, g2, and g3 child groups:

   ```
   # echo "33373" > /sys/fs/cgroup/Example/g1/cgroup.procs
   # echo "33374" > /sys/fs/cgroup/Example/g2/cgroup.procs
   # echo "33377" > /sys/fs/cgroup/Example/g3/cgroup.procs
   ```

The example commands ensure that desired applications become members of the Example/g*/ child cgroups and will get their CPU time distributed as per the configuration of those cgroups.

The weights of the children cgroups (g1, g2, g3) that have running processes are summed up at the level of the parent cgroup (Example). The CPU resource is then distributed proportionally based on the respective weights.

As a result, when all processes run at the same time, the kernel allocates to each of them the proportionate CPU time based on their respective cgroup's `cpu.weight` file:

<table>
<thead>
<tr>
<th>Child cgroup</th>
<th>cpu.weight file</th>
<th>CPU time allocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>g1</td>
<td>150</td>
<td>~50% (150/300)</td>
</tr>
<tr>
<td>g2</td>
<td>100</td>
<td>~33% (100/300)</td>
</tr>
<tr>
<td>g3</td>
<td>50</td>
<td>~16% (50/300)</td>
</tr>
</tbody>
</table>

The value of the `cpu.weight` controller file is not a percentage.
If one process stopped running, leaving cgroup \( g2 \) with no running processes, the calculation would omit the cgroup \( g2 \) and only account weights of cgroups \( g1 \) and \( g3 \):

<table>
<thead>
<tr>
<th>Child cgroup</th>
<th>cpu.weight file</th>
<th>CPU time allocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>( g1 )</td>
<td>150</td>
<td>(~75%) ( (150/200) )</td>
</tr>
<tr>
<td>( g3 )</td>
<td>50</td>
<td>(~25%) ( (50/200) )</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If a child cgroup had multiple running processes, the CPU time allocated to the respective cgroup would be distributed equally to the member processes of that cgroup.

**Verification**

1. Verify that the applications run in the specified control groups:

   ```bash
   # cat /proc/33373/cgroup /proc/33374/cgroup /proc/33377/cgroup
   0::/Example/g1
   0::/Example/g2
   0::/Example/g3
   ``

   The command output shows the processes of the specified applications that run in the `Example/g*`/ child cgroups.

2. Inspect the current CPU consumption of the throttled applications:

   ```bash
   # top
   top - 05:17:18 up 1 day, 18:25,  1 user,  load average: 3.03, 3.03, 3.00
   Tasks:   95 total,   4 running,  91 sleeping,  0 stopped,  0 zombie
   %Cpu(s): 18.1 us, 81.6 sy,  0.0 ni,  0.0 id,  0.0 wa,  0.3 hi,  0.0 si,  0.0 st
   MiB Mem : 3737.0 total, 3233.7 free, 132.8 used,  370.5 buff/cache
   MiB Swap: 4060.0 total, 4060.0 free, 0.0 used. 3373.1 avail Mem
   
   PID USER      PR  NI    VIRT    RES    SHR S  %CPU  %MEM     TIME+ COMMAND
   33373 root      20   0   18720   1748   1460 R  49.5 0.0 415:05.87 sha1sum
   33374 root      20   0   18720   1756   1464 R  32.9 0.0 412:58.33 sha1sum
   33377 root      20   0   18720   1860   1568 R  16.3 0.0 411:03.12 sha1sum
   760 root      20   0  416620  28540  15296 S   0.3   0.7   0:10.23 tuned
   1 root      20   0  186328  14108   9484 S   0.4   0.4   0:02.00 systemd
   2 root      20   0   0     0     0 S   0.0   0.0   0:00.01 kthread
   ...
   ``

**NOTE**

We forced all the example processes to run on a single CPU for clearer illustration. The CPU weight applies the same principles also when used on multiple CPUs.
Notice that the CPU resource for the **PID 33373**, **PID 33374**, and **PID 33377** was allocated based on the weights, 150, 100, 50, you assigned to the respective child cgroups. The weights correspond to around 50%, 33%, and 16% allocation of CPU time for each application.

**Additional resources**
- Understanding control groups
- What are kernel resource controllers
- Creating cgroups and enabling controllers in cgroups-v2 file system
- Resource Distribution Models
- *cgroups*(7), *sysfs*(5) manual pages

### 34.3. MOUNTING CGROUPS-V1

During the boot process, RHEL 9 mounts the **cgroup-v2** virtual filesystem by default. To utilize **cgroup-v1** functionality in limiting resources for your applications, manually configure the system.

**NOTE**

Both **cgroup-v1** and **cgroup-v2** are fully enabled in the kernel. There is no default control group version from the kernel point of view, and is decided by **systemd** to mount at startup.

**Prerequisites**
- You have root permissions.

**Procedure**

1. Configure the system to mount **cgroups-v1** by default during system boot by the **systemd** system and service manager:

   ```
   # grubby --update-kernel=/boot/vmlinuz-$(uname -r) --
   args="systemd.unified_cgroup_hierarchy=0
   systemd.legacy_systemd_cgroup_controller"
   ```

   This adds the necessary kernel command-line parameters to the current boot entry.

   To add the same parameters to all kernel boot entries:

   ```
   # grubby --update-kernel=ALL --args="systemd.unified_cgroup_hierarchy=0
   systemd.legacy_systemd_cgroup_controller"
   ```

2. Reboot the system for the changes to take effect.

**Verification**

1. Optionally, verify that the **cgroups-v1** filesystem was mounted:

   ```
   # mount -l | grep cgroup
   ```
The cgroups-v1 filesystems that correspond to various cgroup-v1 controllers, were successfully mounted on the /sys/fs/cgroup/ directory.

2. Optionally, inspect the contents of the /sys/fs/cgroup/ directory:

```
# ll /sys/fs/cgroup/
```

```
dr-xr-xr-x. 10 root root 0 Mar 16 09:34 blkio
lrwxrwxrwx. 1 root root 11 Mar 16 09:34 cpu → cpu,cpuacct
lrwxrwxrwx. 1 root root 11 Mar 16 09:34 cpuacct → cpu,cpuacct
dr-xr-xr-x. 10 root root 0 Mar 16 09:34 cpu,cpuacct
dr-xr-xr-x. 2 root root 0 Mar 16 09:34 cpuset
dr-xr-xr-x. 10 root root 0 Mar 16 09:34 devices
dr-xr-xr-x. 2 root root 0 Mar 16 09:34 freezer
dr-xr-xr-x. 2 root root 0 Mar 16 09:34 hugetlb
dr-xr-xr-x. 10 root root 0 Mar 16 09:34 memory
dr-xr-xr-x. 2 root root 0 Mar 16 09:34 misc
```

```
lrwxrwxrwx. 1 root root 16 Mar 16 09:34 net_cls → net_cls,net_prio
dlwxrwxrwx. 2 root root 0 Mar 16 09:34 net_cls,net_prio
lrwxrwxrwx. 1 root root 16 Mar 16 09:34 net_prio → net_cls,net_prio
dlwxrwxrwx. 2 root root 0 Mar 16 09:34 perf_event
dlwxrwxrwx. 10 root root 0 Mar 16 09:34 pids
dlwxrwxrwx. 2 root root 0 Mar 16 09:34 rdma
dlwxrwxrwx. 11 root root 0 Mar 16 09:34 systemd
```

The /sys/fs/cgroup/ directory, also called the root control group, by default, contains controller-specific directories such as cpuset. In addition, there are some directories related to systemd.

Additional resources

- Understanding control groups
34.4. SETTING CPU LIMITS TO APPLICATIONS USING CGROUPS-V1

Sometimes an application consumes a lot of CPU time, which may negatively impact the overall health of your environment. Use the /sys/fs/ virtual file system to configure CPU limits to an application using control groups version 1 (cgroups-v1).

Prerequisites

- You have root permissions.
- You have an application whose CPU consumption you want to restrict.
- You configured the system to mount cgroups-v1 by default during system boot by the systemd system and service manager:

  ```
  # grubby --update-kernel=/boot/vmlinuz-$(uname -r) --
  args="systemd.unified_cgroup_hierarchy=0
  systemd.legacy_systemd_cgroup_controller"
  ```

  This adds the necessary kernel command-line parameters to the current boot entry.

Procedure

1. Identify the process ID (PID) of the application you want to restrict in CPU consumption:

   ```
   # top
   top - 11:34:09 up 11 min,  1 user,  load average: 0.51, 0.27, 0.22
   Tasks: 267 total,   3 running, 264 sleeping,   0 stopped,   0 zombie
   %Cpu(s): 49.0 us,  3.3 sy,  0.0 ni, 47.5 id,  0.0 wa,  0.2 hi,  0.0 si,  0.0 st
   MiB Mem : 1826.8 total,   303.4 free,   1046.8 used,   476.5 buff/cache
   MiB Swap: 1536.0 total,  1396.0 free,  140.0 used.   616.4 avail Mem
   PID USER      PR  NI    VIRT    RES    SHR S  %CPU  %MEM     TIME+ COMMAND
   6955 root      20   0  228440   1752   1472 R  99.3   0.1   0:32.71 sha1sum
   5760 jdoe      20   0 3603868 205188  64196 S   3.7  11.0   0:17.19 gnome-shell
   6448 jdoe      20   0  743648  30640  19488 S   0.7   1.6   0:02.73 gnome-terminal-
   1 root      20   0  245300  6568  4116 S   0.3   0.4   0:01.87 systemd
   505 root      20   0   0    0   0  0  0:00.75 kworker/u4:4-events_unbound
   ... 
   ```

   The example output of the top program reveals that PID 6955 (illustrative application sha1sum) consumes a lot of CPU resources.

2. Create a sub-directory in the cpu resource controller directory:

   ```
   # mkdir /sys/fs/cgroup/cpu/Example/
   ```
The directory above represents a control group, where you can place specific processes and apply certain CPU limits to the processes. At the same time, some cgroups-v1 interface files and cpu controller-specific files will be created in the directory.

3. Optionally, inspect the newly created control group:

```
# ll /sys/fs/cgroup/cpu/Example/
-rw-r--r-- 1 root root 0 Mar 11 11:42 cgroup.clone_children
-rw-r--r-- 1 root root 0 Mar 11 11:42 cgroup.procs
-r--r--r-- 1 root root 0 Mar 11 11:42 cpuacct.stat
-r--r--r-- 1 root root 0 Mar 11 11:42 cpuacct.usage
-r--r--r-- 1 root root 0 Mar 11 11:42 cpuacct.usage_all
-r--r--r-- 1 root root 0 Mar 11 11:42 cpuacct.usage_percpu
-r--r--r-- 1 root root 0 Mar 11 11:42 cpuacct.usage_percpu_sys
-r--r--r-- 1 root root 0 Mar 11 11:42 cpuacct.usage_percpu_user
-r--r--r-- 1 root root 0 Mar 11 11:42 cpuacct.usage_sys
-r--r--r-- 1 root root 0 Mar 11 11:42 cpuacct.usage_user
-rw-r--r-- 1 root root 0 Mar 11 11:42 cpu.cfs_period_us
-rw-r--r-- 1 root root 0 Mar 11 11:42 cpu.cfs_quota_us
-rw-r--r-- 1 root root 0 Mar 11 11:42 cpu.rt_period_us
-rw-r--r-- 1 root root 0 Mar 11 11:42 cpu.rt_runtime_us
-rw-r--r-- 1 root root 0 Mar 11 11:42 cpu.shares
-r--r--r-- 1 root root 0 Mar 11 11:42 cpu.stat
-rw-r--r-- 1 root root 0 Mar 11 11:42 notify_on_release
-rw-r--r-- 1 root root 0 Mar 11 11:42 tasks
```

The example output shows files, such as cpuacct.usage, cpu.cfs._period_us, that represent specific configurations and/or limits, which can be set for processes in the Example control group. Notice that the respective file names are prefixed with the name of the control group controller to which they belong.

By default, the newly created control group inherits access to the system’s entire CPU resources without a limit.

4. Configure CPU limits for the control group:

```
# echo "1000000" > /sys/fs/cgroup/cpu/Example/cpu.cfs_period_us
# echo "200000" > /sys/fs/cgroup/cpu/Example/cpu.cfs_quota_us
```

The cpu.cfs_period_us file represents a period of time in microseconds (µs, represented here as "us") for how frequently a control group’s access to CPU resources should be reallocated. The upper limit is 1 second and the lower limit is 1000 microseconds.

The cpu.cfs_quota_us file represents the total amount of time in microseconds for which all processes collectively in a control group can run during one period (as defined by cpu.cfs_period_us). As soon as processes in a control group, during a single period, use up all the time specified by the quota, they are throttled for the remainder of the period and not allowed to run until the next period. The lower limit is 1000 microseconds.

The example commands above set the CPU time limits so that all processes collectively in the Example control group will be able to run only for 0.2 seconds (defined by cpu.cfs_quota_us) out of every 1 second (defined by cpu.cfs_period_us).

5. Optionally, verify the limits:

```
# cat /sys/fs/cgroup/cpu/Example/cpu.cfs_period_us
```
6. Add the application’s PID to the **Example** control group:

```bash
# echo "6955" > /sys/fs/cgroup/cpu/Example/cgroup.procs
```

or

```bash
# echo "6955" > /sys/fs/cgroup/cpu/Example/tasks
```

The previous command ensures that a desired application becomes a member of the **Example** control group and hence does not exceed the CPU limits configured for the **Example** control group. The PID should represent an existing process in the system. The **PID 6955** here was assigned to process `sha1sum /dev/zero &`, used to illustrate the use-case of the **cpu** controller.

7. Verify that the application runs in the specified control group:

```bash
# cat /proc/6955/cgroup
12:cpuset:/
11:hugetlb:/
10:net_cls,net_prio:/
9:memory:/user.slice/user-1000.slice/user@1000.service
8:devices:/user.slice
7:blkio:/
6:freezer:/
5:rdma:/
4:pids:/user.slice/user-1000.slice/user@1000.service
3:perf_event:/
2:cpu,cpuacct:/Example
1:name=systemd:/user.slice/user-1000.slice/user@1000.service/gnome-terminal-server.service
```

The example output above shows that the process of the desired application runs in the **Example** control group, which applies CPU limits to the application’s process.

8. Identify the current CPU consumption of your throttled application:

```bash
# top
```

```
PID USER      PR  NI    VIRT    RES    SHR S  %CPU  %MEM     TIME+ COMMAND
6955 root      20   0  228440   1752   1472 R 20.6 0.1  47:11.43 sha1sum
5760 jdoe      20   0 3604956 208832  65316 R 2.3 11.2  0:43.50 gnome-shell
6448 jdoe      20   0  743836  31736  19488 S 0.7 1.7  0:08.25 gnome-terminal
505 root      20  0  743836  31736  19488 S 0.3 0.1  0:03.39 kworker/u4:4-events_unbound
4217 root      20  0  74192  1612  1320  R 0.3 0.1  0:01.19 spice-vdagentd
...
```

Notice that the CPU consumption of the **PID 6955** has decreased from 99% to 20%.
IMPORTANT

The cgroups-v2 counterpart for cpu.cfs_period_us and cpu.cfs_quota_us is the cpu.max file. The cpu.max file is available through the cpu controller.

CHAPTER 35. ANALYZING SYSTEM PERFORMANCE WITH BPF COMPILER COLLECTION

As a system administrator, you can use the BPF Compiler Collection (BCC) library to create tools for analyzing the performance of your Linux operating system and gathering information, which could be difficult to obtain through other interfaces.

35.1. AN INTRODUCTION TO BCC

BPF Compiler Collection (BCC) is a library, which facilitates the creation of the extended Berkeley Packet Filter (eBPF) programs. The main utility of eBPF programs is analyzing OS performance and network performance without experiencing overhead or security issues.

BCC removes the need for users to know deep technical details of eBPF, and provides many out-of-the-box starting points, such as the *bcc-tools* package with pre-created eBPF programs.

**NOTE**

The eBPF programs are triggered on events, such as disk I/O, TCP connections, and process creations. It is unlikely that the programs should cause the kernel to crash, loop or become unresponsive because they run in a safe virtual machine in the kernel.

35.2. INSTALLING THE BCC-TOOLS PACKAGE

This section describes how to install the *bcc-tools* package, which also installs the BPF Compiler Collection (BCC) library as a dependency.

**Procedure**

1. Install *bcc-tools*:

   ```
   # dnf install bcc-tools
   ```

   The BCC tools are installed in the */usr/share/bcc/tools/* directory.

2. Optionally, inspect the tools:

   ```
   # ll /usr/share/bcc/tools/
   ...
   -rwxr-xr-x. 1 root root 4198 Dec 14 17:53 dcsnoop
   -rwxr-xr-x. 1 root root 3931 Dec 14 17:53 dcstat
   -rwxr-xr-x. 1 root root 20040 Dec 14 17:53 deadlock_detector
   -rw-r--r--. 1 root root 7105 Dec 14 17:53 deadlock_detector.c
   drwxr-xr-x. 3 root root 8192 Mar 11 10:28 doc
   -rwxr-xr-x. 1 root root 7588 Dec 14 17:53 execsnoop
   -rwxr-xr-x. 1 root root 6373 Dec 14 17:53 ext4dist
   -rwxr-xr-x. 1 root root 10401 Dec 14 17:53 ext4slower
   ...
   ```

   The *doc* directory in the listing above contains documentation for each tool.

35.3. USING SELECTED BCC-TOOLS FOR PERFORMANCE ANALYSES
This section describes how to use certain pre-created programs from the BPF Compiler Collection (BCC) library to efficiently and securely analyze the system performance on the per-event basis. The set of pre-created programs in the BCC library can serve as examples for creation of additional programs.

Prerequisites

- Installed bcc-tools package
- Root permissions

Using execsnoop to examine the system processes

1. Execute the `execsnoop` program in one terminal:

   ```sh
   # /usr/share/bcc/tools/execsnoop
   ```

2. In another terminal execute for example:

   ```sh
   $ ls /usr/share/bcc/tools/doc/
   ```

   The above creates a short-lived process of the `ls` command.

3. The terminal running `execsnoop` shows the output similar to the following:

   ```
   PCOMM PID    PPID   RET ARGS
   ls    8382   8287     0 /usr/bin/ls --color=auto /usr/share/bcc/tools/doc/
   ...
   ```

   The `execsnoop` program prints a line of output for each new process, which consumes system resources. It even detects processes of programs that run very shortly, such as `ls`, and most monitoring tools would not register them.

   The `execsnoop` output displays the following fields:

   - **PCOMM** - The parent process name. (`ls`)
   - **PID** - The process ID. (`8382`)
   - **PPID** - The parent process ID. (`8287`)
   - **RET** - The return value of the `exec()` system call (0), which loads program code into new processes.
   - **ARGS** - The location of the started program with arguments.

   To see more details, examples, and options for `execsnoop`, refer to the `/usr/share/bcc/tools/doc/execsnoop_example.txt` file.

   For more information about `exec()`, see `exec(3)` manual pages.

Using opensnoop to track what files a command opens

1. Execute the `opensnoop` program in one terminal:

   ```sh
   # /usr/share/bcc/tools/opensnoop -n uname
   ```
The above prints output for files, which are opened only by the process of the `uname` command.

2. In another terminal execute:

```bash
$ uname
```

The command above opens certain files, which are captured in the next step.

3. The terminal running `opensnoop` shows the output similar to the following:

```
+-----+----------+---+---+-----------------------------------------------+
<table>
<thead>
<tr>
<th>PID</th>
<th>COMM</th>
<th>FD</th>
<th>ERR</th>
<th>PATH</th>
</tr>
</thead>
<tbody>
<tr>
<td>8596</td>
<td>uname</td>
<td>3</td>
<td>0</td>
<td>/etc/ld.so.cache</td>
</tr>
<tr>
<td>8596</td>
<td>uname</td>
<td>3</td>
<td>0</td>
<td>/lib64/libc.so.6</td>
</tr>
<tr>
<td>8596</td>
<td>uname</td>
<td>3</td>
<td>0</td>
<td>/usr/lib/locale/locale-archive</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>...</td>
</tr>
</tbody>
</table>
```

The `opensnoop` program watches the `open()` system call across the whole system, and prints a line of output for each file that `uname` tried to open along the way.

The `opensnoop` output displays the following fields:

- **PID** - The process ID. (8596)
- **COMM** - The process name. (uname)
- **FD** - The file descriptor - a value that `open()` returns to refer to the open file. (3)
- **ERR** - Any errors.
- **PATH** - The location of files that `open()` tried to open.
  
  If a command tries to read a non-existent file, then the FD column returns -1 and the ERR column prints a value corresponding to the relevant error. As a result, `opensnoop` can help you identify an application that does not behave properly.

To see more details, examples, and options for `opensnoop`, refer to the `/usr/share/bcc/tools/doc/opensnoop_example.txt` file.

For more information about `open()`, see `open(2)` manual pages.

### Using biotop to examine the I/O operations on the disk

1. Execute the `biotop` program in one terminal:

```bash
# /usr/share/bcc/tools/ biotop 30
```

The command enables you to monitor the top processes, which perform I/O operations on the disk. The argument ensures that the command will produce a 30 second summary.

**NOTE**

When no argument provided, the output screen by default refreshes every 1 second.

2. In another terminal execute for example:
# dd if=/dev/vda of=/dev/zero

The command above reads the content from the local hard disk device and writes the output to the /dev/zero file. This step generates certain I/O traffic to illustrate **biotop**.

3. The terminal running **biotop** shows the output similar to the following:

```
PID    COMM             D MAJ MIN DISK       I/O  Kbytes     AVGms
9568   dd               R 252 0   vda      16294 14440636.0  3.69
48     kswapd0          W 252 0   vda       1763 120696.0    1.65
7571   gnome-shell      R 252 0   vda        834 83612.0     0.33
1891   gnome-shell      R 252 0   vda        954 19458.0     0.14
7515   Xorg             R 252 0   vda        680 5670.0      0.11
7579   llvmpipe-1       R 252 0   vda        280  9940.0     0.28
9515   gnome-control-c  R 252 0   vda         62  6444.0     0.43
7578   llvmpipe-0       R 252 0   vda        228  6928.0     0.19
1982   llvmpipe-1       R 252 0   vda         39   724.0      0.08
1983   llvmpipe-0       R 252 0   vda         36   652.0      0.06
```

The **biotop** output displays the following fields:

- **PID** - The process ID. (9568)
- **COMM** - The process name. (dd)
- **DISK** - The disk performing the read operations. (vda)
- **I/O** - The number of read operations performed. (16294)
- **Kbytes** - The amount of Kbytes reached by the read operations. (14,440,636)
- **AVGms** - The average I/O time of read operations. (3.69)

To see more details, examples, and options for **biotop**, refer to the `/usr/share/bcc/tools/doc/biotop_example.txt` file.

For more information about **dd**, see **dd(1)** manual pages.

**Using xfsslower to expose unexpectedly slow file system operations**

1. Execute the **xfsslower** program in one terminal:

```
# /usr/share/bcc/tools/xfsslower 1
```

The command above measures the time the XFS file system spends in performing read, write, open or sync (**fsync**) operations. The 1 argument ensures that the program shows only the operations that are slower than 1 ms.
NOTE

When no arguments provided, `xfsslower` by default displays operations slower than 10 ms.

2. In another terminal execute, for example, the following:

```bash
$ vim text
```

The command above creates a text file in the `vim` editor to initiate certain interaction with the XFS file system.

3. The terminal running `xfsslower` shows something similar upon saving the file from the previous step:

```
TIME     COMM           PID    T BYTES   OFF_KB   LAT(ms) FILENAME
13:07:14 b'bash'        4754   R 256     0           7.11 b'vim'
13:07:14 b'vim'         4754   R 832     0           4.03 b'libgpm.so.2.1.0'
13:07:14 b'vim'         4754   R 32      20          1.04 b'libgpm.so.2.1.0'
13:07:14 b'vim'         4754   R 1982    0           2.30 b'vimrc'
13:07:14 b'vim'         4754   R 1393    0           2.52 b'getscriptPlugin.vim'
13:07:45 b'vim'         4754   S 0       0           6.71 b'text'
13:07:45 b'pool'        2588   R 16      0           5.58 b'text'
...```

Each line above represents an operation in the file system, which took more time than a certain threshold. `xfsslower` is good at exposing possible file system problems, which can take form of unexpectedly slow operations.

The `xfsslower` output displays the following fields:

- **COMM** - The process name. ( b'bash'
- **T** - The operation type. ( R)
  - Read
  - Write
  - Sync
- **OFF_KB** - The file offset in KB. (0)
- **FILENAME** - The file being read, written, or synced.

To see more details, examples, and options for `xfsslower`, refer to the `/usr/share/bcc/tools/doc/xfsslower_example.txt` file.

For more information about `fsync`, see `fsync(2)` manual pages.
CHAPTER 36. CONFIGURING HUGE PAGES

Physical memory is managed in fixed-size chunks called pages. On the x86_64 architecture, supported by Red Hat Enterprise Linux 9, the default size of a memory page is 4 KB. This default page size has proved to be suitable for general-purpose operating systems, such as Red Hat Enterprise Linux, which supports many different kinds of workloads.

However, specific applications can benefit from using larger page sizes in certain cases. For example, an application that works with a large and relatively fixed data set of hundreds of megabytes or even dozens of gigabytes can have performance issues when using 4 KB pages. Such data sets can require a huge amount of 4 KB pages, which can lead to overhead in the operating system and the CPU.

This section provides information about huge pages available in RHEL 9 and how you can configure them.

36.1. AVAILABLE HUGE PAGE FEATURES

With Red Hat Enterprise Linux 9, you can use huge pages for applications that work with big data sets, and improve the performance of such applications.

The following are the huge page methods, which are supported in RHEL 9:

**HugeTLB pages**

HugeTLB pages are also called static huge pages. There are two ways of reserving HugeTLB pages:

- **At boot time:** It increases the possibility of success because the memory has not yet been significantly fragmented. However, on NUMA machines, the number of pages is automatically split among the NUMA nodes. For more information on parameters that influence HugeTLB page behavior at boot time, see Parameters for reserving HugeTLB pages at boot time and how to use these parameters to configure HugeTLB pages at boot time, see Configuring HugeTLB at boot time.

- **At run time:** It allows you to reserve the huge pages per NUMA node. If the run-time reservation is done as early as possible in the boot process, the probability of memory fragmentation is lower. For more information on parameters that influence HugeTLB page behavior at run time, see Parameters for reserving HugeTLB pages at run time and how to use these parameters to configure HugeTLB pages at run time, see Configuring HugeTLB at run time.

**Transparent HugePages (THP)**

With THP, the kernel automatically assigns huge pages to processes, and therefore there is no need to manually reserve the static huge pages. The following are the two modes of operation in THP:

- **system-wide:** Here, the kernel tries to assign huge pages to a process whenever it is possible to allocate the huge pages and the process is using a large contiguous virtual memory area.

- **per-process:** Here, the kernel only assigns huge pages to the memory areas of individual processes which you can specify using the `madvise()` system call.

**NOTE**

The THP feature only supports 2 MB pages.
For more information on parameters that influence HugeTLB page behavior at boot time, see *Enabling transparent hugepages* and *Disabling transparent hugepages*.

### 36.2. PARAMETERS FOR RESERVING HUGETLB PAGES AT BOOT TIME

Use the following parameters to influence HugeTLB page behavior at boot time.

For more information on how to use these parameters to configure HugeTLB pages at boot time, see *Configuring HugeTLB at boot time*.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>hugepages</td>
<td>Defines the number of persistent huge pages configured in the kernel at boot time.</td>
<td>The default value is 0.</td>
</tr>
<tr>
<td></td>
<td>In a NUMA system, huge pages, that have this parameter defined, are divided equally between nodes.</td>
<td>To update this value at boot, change the value of this parameter in the <em>/proc/sys/vm/nr_hugepages</em> file.</td>
</tr>
<tr>
<td></td>
<td>You can assign huge pages to specific nodes at runtime by changing the value of the nodes in the <em>/sys/devices/system/node/node_id/hugepages/hugepages-size/nr_hugepages</em> file.</td>
<td></td>
</tr>
<tr>
<td>hugepagesz</td>
<td>Defines the size of persistent huge pages configured in the kernel at boot time.</td>
<td>Valid values are 2 MB and 1 GB.</td>
</tr>
<tr>
<td></td>
<td>The default value is 2 MB.</td>
<td></td>
</tr>
<tr>
<td>default_hugepagesz</td>
<td>Defines the default size of persistent huge pages configured in the kernel at boot time.</td>
<td>Valid values are 2 MB and 1 GB.</td>
</tr>
<tr>
<td></td>
<td>The default value is 2 MB.</td>
<td></td>
</tr>
</tbody>
</table>

### 36.3. CONFIGURING HUGETLB AT BOOT TIME

The page size, which the HugeTLB subsystem supports, depends on the architecture. The x86_64 architecture supports 2 MB huge pages and 1 GB gigantic pages.

This procedure describes how to reserve a 1 GB page at boot time.

**Procedure**

1. Create a HugeTLB pool for 1 GB pages by appending the following line to the kernel command-line options in the */etc/default/grub* file as root:

   default_hugepagesz=1G hugepagesz=1G
2. Regenerate the **GRUB2** configuration using the edited default file:

   a. If your system uses BIOS firmware, execute the following command:

   ```bash
   # grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

   b. If your system uses UEFI framework, execute the following command:

   ```bash
   # grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg
   ```

3. Create a new file called **hugetlb-gigantic-pages.service** in the `/usr/lib/systemd/system/` directory and add the following content:

   ```ini
   [Unit]
   Description=HugeTLB Gigantic Pages Reservation
   DefaultDependencies=no
   Before=dev-hugepages.mount
   ConditionPathExists=/sys/devices/system/node
   ConditionKernelCommandLine=hugepagesz=1G

   [Service]
   Type=oneshot
   RemainAfterExit=yes
   ExecStart=/usr/lib/systemd/hugetlb-reserve-pages.sh

   [Install]
   WantedBy=sysinit.target
   ```

4. Create a new file called **hugetlb-reserve-pages.sh** in the `/usr/lib/systemd/` directory and add the following content:

   ```bash
   #!/bin/sh

   nodes_path=/sys/devices/system/node/
   if [ ! -d $nodes_path ]; then
     echo "ERROR: $nodes_path does not exist"
     exit 1
   fi

   reserve_pages()
   {
     echo $1 > $nodes_path/$2/hugepages/hugepages-1048576kB/nr_hugepages
   }

   reserve_pages number_of_pages node

   For example, to reserve two 1 GB pages on node0 and one 1GB page on node1, replace `number_of_pages` with the number of 1GB pages you want to reserve, and `node` with the name of the node on which to reserve these pages:

   ```bash
   reserve_pages 2 node0
   reserve_pages 1 node1
   ```
5. Create an executable script:

```
# chmod +x /usr/lib/systemd/hugetlb-reserve-pages.sh
```

6. Enable early boot reservation:

```
# systemctl enable hugetlb-gigantic-pages
```

### NOTE

- You can try reserving more 1GB pages at runtime by writing to `nr_hugepages` at any time. However, such reservations can fail due to memory fragmentation. The most reliable way to reserve 1 GB pages is by using this `hugetlb-reserve-pages.sh` script, which runs early during boot.

- Reserving static huge pages can effectively reduce the amount of memory available to the system, and prevents it from properly utilizing its full memory capacity. Although a properly sized pool of reserved huge pages can be beneficial to applications that utilize it, an oversized or unused pool of reserved huge pages will eventually be detrimental to overall system performance. When setting a reserved huge page pool, ensure that the system can properly utilize its full memory capacity.

### Additional resources

- `systemd.service(5)` man page
- `/usr/share/doc/kernel-doc-kernel_version/Documentation/vm/hugetlbpage.txt` file

### 36.4. PARAMETERS FOR RESERVING HUGETLB PAGES AT RUN TIME

Use the following parameters to influence HugeTLB page behavior at run time.

For more information on how to use these parameters to configure HugeTLB pages at run time, see Configuring HugeTLB at run time.

**Table 36.2. Parameters used to configure HugeTLB pages at run time**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>File name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nr_hugepages</code></td>
<td>Defines the number of huge pages of a specified size assigned to a specified NUMA node.</td>
<td><code>/sys/devices/system/node/node_id/hugepages/hugepages-size/nr_hugepages</code></td>
</tr>
</tbody>
</table>
nr_overcommit_hugepages

Defines the maximum number of additional huge pages that can be created and used by the system through overcommitting memory.

Writing any non-zero value into this file indicates that the system obtains that number of huge pages from the kernel's normal page pool if the persistent huge page pool is exhausted. As these surplus huge pages become unused, they are then freed and returned to the kernel's normal page pool.

36.5. CONFIGURING HUGETLB AT RUN TIME

This procedure describes how to add 20 2048 kB huge pages to node2.

To reserve pages based on your requirements, replace:

- 20 with the number of huge pages you wish to reserve,
- 2048kB with the size of the huge pages,
- node2 with the node on which you wish to reserve the pages.

Procedure

1. Display the memory statistics:

```
# numastat -cm | egrep 'Node|Huge'
  Node 0  Node 1  Node 2  Node 3  Total  add
  AnonHugePages  0  2  0  8  10
  HugePages_Total  0  0  0  0  0
  HugePages_Free  0  0  0  0  0
  HugePages_Surp  0  0  0  0  0
```

2. Add the number of huge pages of a specified size to the node:

```
# echo 20 > /sys/devices/system/node/node2/hugepages/hugepages-2048kB/nr_hugepages
```

Verification steps

- Ensure that the number of huge pages are added:

```
# numastat -cm | egrep 'Node|Huge'
  Node 0  Node 1  Node 2  Node 3  Total
  AnonHugePages  0  2  0  8  10
```
Additional resources

- numastat(8) man page

36.6. ENABLING TRANSPARENT HUGEPAGES

THP is enabled by default in Red Hat Enterprise Linux 9. However, you can enable or disable THP.

This procedure describes how to enable THP.

Procedure

1. Check the current status of THP:

   # cat /sys/kernel/mm/transparent_hugepage/enabled

2. Enable THP:

   # echo always > /sys/kernel/mm/transparent_hugepage/enabled

3. To prevent applications from allocating more memory resources than necessary, disable the system-wide transparent huge pages and only enable them for the applications that explicitly request it through the madvise:

   # echo madvise > /sys/kernel/mm/transparent_hugepage/enabled

   **NOTE**

   Sometimes, providing low latency to short-lived allocations has higher priority than immediately achieving the best performance with long-lived allocations. In such cases, you can disable direct compaction while leaving THP enabled.

   Direct compaction is a synchronous memory compaction during the huge page allocation. Disabling direct compaction provides no guarantee of saving memory, but can decrease the risk of higher latencies during frequent page faults. Note that if the workload benefits significantly from THP, the performance decreases. Disable direct compaction:

   # echo madvise > /sys/kernel/mm/transparent_hugepage/defrag

Additional resources

- madvise(2) man page
- Disabling transparent hugepages.

36.7. DISABLING TRANSPARENT HUGEPAGES

THP is enabled by default in Red Hat Enterprise Linux 9. However, you can enable or disable THP.
This procedure describes how to disable THP.

**Procedure**

1. Check the current status of THP:
   ```bash
   # cat /sys/kernel/mm/transparent_hugepage/enabled
   ```
2. Disable THP:
   ```bash
   # echo never > /sys/kernel/mm/transparent_hugepage/enabled
   ```

**36.8. IMPACT OF PAGE SIZE ON TRANSLATION LOOKASIDE BUFFER SIZE**

Reading address mappings from the page table is time-consuming and resource-expensive, so CPUs are built with a cache for recently-used addresses, called the Translation Lookaside Buffer (TLB). However, the default TLB can only cache a certain number of address mappings.

If a requested address mapping is not in the TLB, called a TLB miss, the system still needs to read the page table to determine the physical to virtual address mapping. Because of the relationship between application memory requirements and the size of pages used to cache address mappings, applications with large memory requirements are more likely to suffer performance degradation from TLB misses than applications with minimal memory requirements. It is therefore important to avoid TLB misses wherever possible.

Both HugeTLB and Transparent Huge Page features allow applications to use pages larger than 4 KB. This allows addresses stored in the TLB to reference more memory, which reduces TLB misses and improves application performance.
CHAPTER 37. GETTING STARTED WITH SYSTEMTAP

As a system administrator, you can use SystemTap to identify underlying causes of a bug or performance problem on a running Linux system.

As an application developer, you can use SystemTap to monitor in fine detail how your application behaves within the Linux system.

37.1. THE PURPOSE OF SYSTEMTAP

SystemTap is a tracing and probing tool that you can use to study and monitor the activities of your operating system (particularly, the kernel) in fine detail. SystemTap provides information similar to the output of tools such as `netstat`, `ps`, `top`, and `iostat`. However, SystemTap provides more filtering and analysis options for collected information. In SystemTap scripts, you specify the information that SystemTap gathers.

SystemTap aims to supplement the existing suite of Linux monitoring tools by providing users with the infrastructure to track kernel activity and combining this capability with two attributes:

**Flexibility**

the SystemTap framework enables you to develop simple scripts for investigating and monitoring a wide variety of kernel functions, system calls, and other events that occur in kernel space. With this, SystemTap is not so much a tool as it is a system that allows you to develop your own kernel-specific forensic and monitoring tools.

**Ease-of-Use**

SystemTap enables you to monitor kernel activity without having to recompile the kernel or reboot the system.

37.2. INSTALLING SYSTEMTAP

To begin using SystemTap, install the required packages. To use SystemTap on more than one kernel where a system has multiple kernels installed, install the corresponding required kernel packages for each kernel version.

**Prerequisites**

- You have enabled debug repositories as described in Enabling debug and source repositories.

**Procedure**

1. Install the required SystemTap packages:

   ```
   # dnf install systemtap
   ```

2. Install the required kernel packages:

   a. Using `stap-prep`:

      ```
      # stap-prep
      ```

   b. If `stap-prep` does not work, install the required kernel packages manually:
# dnf install kernel-debuginfo-$(uname -r) kernel-debuginfo-common-$(uname -i)-$(uname -r) kernel-devel-$(uname -r)

$(uname -i) is automatically replaced with the hardware platform of your system and $(uname -r) is automatically replaced with the version of your running kernel.

Verification steps

- If the kernel to be probed with SystemTap is currently in use, test if your installation was successful:

  ```
  # stap -v -e 'probe kernel.function("vfs_read") {printf("read performed\n"); exit()}'
  ```

  A successful SystemTap deployment results in an output similar to the following:

  Pass 1: parsed user script and 45 library script(s) in 340usr/0sys/358real ms.
  Pass 2: analyzed script: 1 probe(s), 1 function(s), 0 embed(s), 0 global(s) in 290usr/260sys/568real ms.
  Pass 3: translated to C into "/tmp/stapiArgLX/stap_e5886fa50499994e6a87aadcd43cd392_399.c" in 490usr/430sys/938real ms.
  Pass 4: compiled C into "stap_e5886fa50499994e6a87aadcd43cd392_399.ko" in 3310usr/430sys/3714real ms.
  Pass 5: starting run.

  read performed

  Pass 5: run completed in 10usr/40sys/73real ms.

  The last three lines of output (beginning with Pass 5) indicate that:

  1. SystemTap successfully created the instrumentation to probe the kernel and ran the instrumentation.
  2. SystemTap detected the specified event (in this case, A VFS read).
  3. SystemTap executed a valid handler (printed text and then closed it with no errors).

37.3. PRIVILEGES TO RUN SYSTEMTAP

Running SystemTap scripts requires elevated system privileges but, in some instances, non-privileged users might need to run SystemTap instrumentation on their machine.

To allow users to run SystemTap without root access, add users to both of these user groups:

**stapdev**

Members of this group can use `stap` to run SystemTap scripts, or `staprun` to run SystemTap instrumentation modules.

Running `stap` involves compiling SystemTap scripts into kernel modules and loading them into the kernel. This requires elevated privileges to the system, which are granted to `stapdev` members. Unfortunately, such privileges also grant effective root access to `stapdev` members. As such, only grant `stapdev` group membership to users who can be trusted with root access.

**stapusr**

Members of this group can only use `staprun` to run SystemTap instrumentation modules. In addition,
Members of this group can only use `staprun` to run SystemTap instrumentation modules. In addition, they can only run those modules from the `/lib/modules/kernel_version/systemtap/` directory. This directory must be owned only by the root user, and must only be writable by the root user.

### 37.4. RUNNING SYSTEMTAP SCRIPTS

You can run SystemTap scripts from standard input or from a file.

Sample scripts that are distributed with the installation of SystemTap can be found in the `/usr/share/systemtap/examples` directory.

#### Prerequisites

1. SystemTap and the associated required kernel packages are installed as described in [Installing Systemtap](#).

2. To run SystemTap scripts as a normal user, add the user to the SystemTap groups:

   ```bash
   # usermod --append --groups stapdev,stapusr user-name
   ```

#### Procedure

- Run the SystemTap script:
  - From standard input:
    ```bash
    # echo "probe timer.s(1) {exit()}" | stap -
    ```
    This command instructs `stap` to run the script passed by `echo` to standard input. To add `stap` options, insert them before the `-` character. For example, to make the results from this command more verbose, the command is:
    ```bash
    # echo "probe timer.s(1) {exit()}" | stap -v -
    ```
  - From a file:
    ```bash
    # stap file_name
    ```
CHAPTER 38. CROSS-INSTRUMENTATION OF SYSTEMTAP

Cross-instrumentation of SystemTap is creating SystemTap instrumentation modules from a SystemTap script on one system to be used on another system that does not have SystemTap fully deployed.

38.1. SYSTEMTAP CROSS-INSTRUMENTATION

When you run a SystemTap script, a kernel module is built out of that script. SystemTap then loads the module into the kernel.

Normally, SystemTap scripts can run only on systems where SystemTap is deployed. To run SystemTap on ten systems, SystemTap needs to be deployed on all those systems. In some cases, this might be neither feasible nor desired. For example, corporate policy might prohibit you from installing packages that provide compilers or debug information on specific machines, which will prevent the deployment of SystemTap.

To work around this, use cross-instrumentation. Cross-instrumentation is the process of generating SystemTap instrumentation modules from a SystemTap script on one system to be used on another system. This process offers the following benefits:

- The kernel information packages for various machines can be installed on a single host machine.

  IMPORTANT

  Kernel packaging bugs may prevent the installation. In such cases, the **kernel-debuginfo** and **kernel-devel** packages for the **host system** and **target system** must match. If a bug occurs, report the bug at [https://bugzilla.redhat.com/](https://bugzilla.redhat.com/).

- Each **target machine** needs only one package to be installed to use the generated SystemTap instrumentation module: **systemtap-runtime**.

  IMPORTANT

  The **host system** must be the same architecture and running the same distribution of Linux as the **target system** in order for the built **instrumentation module** to work.
TERMINOLOGY

**instrumentation module**

The kernel module built from a SystemTap script; the SystemTap module is built on the *host system*, and will be loaded on the *target kernel* of the *target system*.

**host system**

The system on which the instrumentation modules (from SystemTap scripts) are compiled, to be loaded on *target systems*.

**target system**

The system in which the *instrumentation module* is being built (from SystemTap scripts).

**target kernel**

The kernel of the *target system*. This is the kernel that loads and runs the *instrumentation module*.

### 38.2. Initializing Cross-Instrumentation of SystemTap

Initialize cross-instrumentation of SystemTap to build SystemTap instrumentation modules from a SystemTap script on one system and use them on another system that does not have SystemTap fully deployed.

**Prerequisites**

- SystemTap is installed on the *host system* as described in [Installing Systemtap](#).
- The `systemtap-runtime` package is installed on each *target system*:
  
  ```bash
  # dnf install systemtap-runtime
  ```
- Both the *host system* and *target system* are the same architecture.
- Both the *host system* and *target system* are running the same major version of Red Hat Enterprise Linux (such as Red Hat Enterprise Linux 9).

**IMPORTANT**

Kernel packaging bugs may prevent multiple `kernel-debuginfo` and `kernel-devel` packages from being installed on one system. In such cases, the minor version for the *host system* and *target system* must match. If a bug occurs, report it at [https://bugzilla.redhat.com/](https://bugzilla.redhat.com/).

**Procedure**

1. Determine the kernel running on each *target system*:

   ```bash
   $ uname -r
   ```
   
   Repeat this step for each *target system*.

2. On the *host system*, install the *target kernel* and related packages for each *target system* by the method described in [Installing Systemtap](#).
3. Build an instrumentation module on the host system, copy this module to and run this module on the target system either:

a. Using remote implementation:

```
# stap --remote target_system script
```

This command remotely implements the specified script on the target system. You must ensure an SSH connection can be made to the target system from the host system for this to be successful.

b. Manually:

i. Build the instrumentation module on the host system:

```
# stap -r kernel_version script -m module_name -p 4
```

Here, kernel_version refers to the version of the target kernel determined in step 1, script refers to the script to be converted into an instrumentation module, and module_name is the desired name of the instrumentation module. The -p4 option tells SystemTap to not load and run the compiled module.

ii. Once the instrumentation module is compiled, copy it to the target system and load it using the following command:

```
# staprun module_name.ko
```
CHAPTER 39. MONITORING NETWORK ACTIVITY WITH SYSTEMTAP

You can use helpful example SystemTap scripts available in the /usr/share/systemtap/testsuite/systemtap.examples/ directory, upon installing the systemtap-testsuite package, to monitor and investigate the network activity of your system.

39.1. PROFILING NETWORK ACTIVITY WITH SYSTEMTAP

You can use the nettop.stp example SystemTap script to profile network activity. The script tracks which processes are generating network traffic on the system, and provides the following information about each process:

- **PID**
  - The ID of the listed process.

- **UID**
  - User ID. A user ID of 0 refers to the root user.

- **DEV**
  - Which ethernet device the process used to send or receive data (for example, eth0, eth1).

- **XMIT_PK**
  - The number of packets transmitted by the process.

- **RECV_PK**
  - The number of packets received by the process.

- **XMIT_KB**
  - The amount of data sent by the process, in kilobytes.

- **RECV_KB**
  - The amount of data received by the service, in kilobytes.

**Prerequisites**

- You have installed SystemTap as described in Installing SystemTap.

**Procedure**

- Run the nettop.stp script:

  ```
  # stap --example nettop.stp
  ```

  The nettop.stp script provides network profile sampling every 5 seconds.

  Output of the nettop.stp script looks similar to the following:

  ```
  [...] PID   UID    DEV     XMIT_PK RECV_PK XMIT_KB RECV_KB COMMAND
  0     0 eth0          0       5       0       0 swapper
  11178     0 eth0          2       0       0       0 synergyc
  2886     4 eth0         79       0       5       0 cups-polld
  11362     0 eth0          0      61       0       5 firefox
  ```
### 39.2. TRACING FUNCTIONS CALLED IN NETWORK SOCKET CODE WITH SYSTEMTAP

You can use the `socket-trace.stp` example SystemTap script to trace functions called from the kernel's `net/socket.c` file. This helps you identify, in finer detail, how each process interacts with the network at the kernel level.

**Prerequisites**

- You have installed SystemTap as described in [Installing SystemTap](#).

**Procedure**

- Run the `socket-trace.stp` script:

  ```bash
  # stap --example socket-trace.stp
  ```

  A 3-second excerpt of the output of the `socket-trace.stp` script looks similar to the following:

  ```
  [...]  
  0 Xorg(3611): -> sock_poll  
  3 Xorg(3611): <- sock_poll  
  0 Xorg(3611): -> sock_poll  
  3 Xorg(3611): <- sock_poll  
  0 gnome-terminal(11106): -> sock_poll  
  5 gnome-terminal(11106): <- sock_poll  
  0 scim-bridge(3883): -> sock_poll  
  3 scim-bridge(3883): <- sock_poll  
  0 scim-bridge(3883): -> sys_socketcall  
  4 scim-bridge(3883): -> sys_recv  
  8 scim-bridge(3883): -> sys_recvfrom  
  12 scim-bridge(3883): -> sock_from_file  
  16 scim-bridge(3883): <- sock_from_file  
  20 scim-bridge(3883): -> sock_recvmsg  
  24 scim-bridge(3883): <- sock_recvmsg  
  28 scim-bridge(3883): <- sys_recvfrom  
  31 scim-bridge(3883): <- sys_recv  
  35 scim-bridge(3883): <- sys_socketcall  
  [...]  
  ```
39.3. MONITORING NETWORK PACKET DROPS WITH SYSTEMTAP

The network stack in Linux can discard packets for various reasons. Some Linux kernels include a tracepoint, `kernel.trace("kfree_skb")`, which tracks where packets are discarded.

The `dropwatch.stp` SystemTap script uses `kernel.trace("kfree_skb")` to trace packet discards; the script summarizes what locations discard packets in every 5-second interval.

Prerequisites

- You have installed SystemTap as described in Installing SystemTap.

Procedure

- Run the `dropwatch.stp` script:

```
# stap --example dropwatch.stp
```

Running the `dropwatch.stp` script for 15 seconds results in output similar to the following:

```
Monitoring for dropped packets
51 packets dropped at location 0xffffffff8024cd0f
2 packets dropped at location 0xffffffff8044b472
51 packets dropped at location 0xffffffff8024cd0f
1 packets dropped at location 0xffffffff8044b472
97 packets dropped at location 0xffffffff8024cd0f
1 packets dropped at location 0xffffffff8044b472
Stopping dropped packet monitor
```

**NOTE**

To make the location of packet drops more meaningful, see the `/boot/System.map-$\{(uname -r)\}` file. This file lists the starting addresses for each function, enabling you to map the addresses in the output of the `dropwatch.stp` script to a specific function name. Given the following snippet of the `/boot/System.map-$\{(uname -r)\}` file, the address `0xffffffff8024cd0f` maps to the function `unix_stream_recvmsg` and the address `0xffffffff8044b472` maps to the function `arp_rcv`:

```
[...]
ffffffff8024c5cd T unlock_new_inode
ffffffff8024c5da t unix_stream_sendmsg
ffffffff8024c920 t unix_stream_recvmsg
ffffffff8024cea1 t udp_v4_lookup_longway
[...]
ffffffff8044adcc t arp_process
ffffffff8044b360 t arp_rcv
ffffffff8044b487 t parp_redo
ffffffff8044b48c t arp_solicit
[...]
```
CHAPTER 40. PROFILING KERNEL ACTIVITY WITH SYSTEMTAP

The following sections showcase scripts that profile kernel activity by monitoring function calls.

40.1. COUNTING FUNCTION CALLS WITH SYSTEMTAP

You can use the `functioncallcount.stp` SystemTap script to count specific kernel function calls. You can also use this script to target multiple kernel functions.

Prerequisites

- You have installed SystemTap as described in `Installing Systemtap`.

Procedure

- Run the `functioncallcount.stp` script:

  ```shell
  # stap --example functioncallcount.stp 'argument'
  ```

  This script takes the targeted kernel function as an argument. You can use the argument wildcards to target multiple kernel functions up to a certain extent.

  The output of the script, in alphabetical order, contains the names of the functions called and how many times it was called during the sample time.

  Consider the following example:

  ```shell
  # stap -w -v --example functioncallcount.stp "*/mm*.c" -c /bin/true
  ```

  where:

  - `-w` : Suppresses warnings.
  - `-v` : Makes the output of starting kernel visible.
  - `-c command` : Tells SystemTap to count function calls during the execution of a command, in this example being `/bin/true`.

  The output should look similar to the following:

  ```text
  [...]__vma_link 97
  __vma_link_file 66
  __vma_link_list 97
  __vma_link_rb 97
  __xchg 103
  add_page_to_active_list 102
  add_page_to_inactive_list 19
  add_to_page_cache 19
  add_to_page_cache_lru 7
  all_vm_events 6
  alloc_pages_node 4630
  alloc_slabmgmt 67
  ```
40.2. TRACING FUNCTION CALLS WITH SYSTEMTAP

You can use the para-callgraph.stp SystemTap script to trace function calls and function returns.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the para-callgraph.stp script.

```bash
# stap --example para-callgraph.stp 'argument1' 'argument2'
```

The script para-callgraph.stp takes two command-line arguments:

1. The name of the function(s) whose entry/exit you’d like to trace.
2. An optional trigger function, which enables or disables tracing on a per-thread basis. Tracing in each thread will continue as long as the trigger function has not exited yet.

Consider the following example:

```bash
# stap --example para-callgraph.stp 'kernel.function("@fs/proc.c")' 'kernel.function("vfs_read")' -c "cat /proc/sys/vm/* || true"
```

where:

- `-w` : Suppresses warnings.
- `-v` : Makes the output of starting kernel visible.
- `-c command` : Tells SystemTap to count function calls during the execution of a command, in this example being `/bin/true`.

The output should look similar to the following:

```plaintext
[...]
```
40.3. DETERMINING TIME SPENT IN KERNEL AND USER SPACE WITH SYSTEMTAP

You can use the thread-times.stp SystemTap script to determine the amount of time any given thread is spending in either the kernel or user-space.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the thread-times.stp script:

```
# stap --example thread-times.stp
```

This script will display the top 20 processes taking up CPU time during a 5-second period, along with the total number of CPU ticks made during the sample. The output of this script also notes the percentage of CPU time each process used, as well as whether that time was spent in kernel space or user space.

<table>
<thead>
<tr>
<th>tid</th>
<th>%user %kernel (of 20002 ticks)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.00%  87.88%</td>
</tr>
<tr>
<td>32169</td>
<td>5.24%  0.03%</td>
</tr>
<tr>
<td>9815</td>
<td>3.33%  0.36%</td>
</tr>
<tr>
<td>9859</td>
<td>0.95%  0.00%</td>
</tr>
<tr>

</tbody>
</table>
40.4. MONITORING POLLING APPLICATIONS WITH SYSTEMTAP

You can use timeout.stp SystemTap script to identify and monitor which applications are polling. Doing so allows you to track unnecessary or excessive polling, which helps you pinpoint areas for improvement in terms of CPU usage and power savings.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the timeout.stp script:

  ```bash
  # stap --example timeout.stp
  ```

  This script will track how many times each application uses the following system calls over time:

  - poll
  - select
  - epoll
  - itimer
  - futex
  - nanosleep
  - signal

In this example output you can see which process used which system call and how many times.

<table>
<thead>
<tr>
<th>uid</th>
<th>poll</th>
<th>select</th>
<th>epoll</th>
<th>itimer</th>
<th>futex</th>
<th>nanosleep</th>
<th>signal</th>
<th>process</th>
</tr>
</thead>

<td>0.00%</td>
<td></td>
</tr>
</tbody>
</table>
40.5. TRACKING MOST FREQUENTLY USED SYSTEM CALLS WITH SYSTEMTAP

You can use the `topsys.stp` SystemTap script to list the top 20 system calls used by the system per 5-second interval. It also lists how many times each system call was used during that period.

**Prerequisites**

- You have installed SystemTap as described in `Installing Systemtap`.

**Procedure**

- Run the `topsys.stp` script:

  ```
  # stap --example topsys.stp
  ```

  Consider the following example:

  ```
  # stap -v --example topsys.stp
  ```

  where `-v` makes the output of starting kernel visible.

  The output should look similar to the following:

  ```
  --------------------------------------------------------------
  SYSCALL      COUNT
  gettimeofday       1857
  read       1821
  ioctl       1568
  poll       1033
  close       638
  open        503
  select        455
  write        391
  writev        335
  futex        303
  recvmsg        251
  socket        137
  clock_gettime        124
  rt_sigprocmask        121
  sendto        120
  setitimer        106
  stat         90
  time         81
  sigreturn        72
  fstat         66
  --------------------------------------------------------------
  ```

40.6. TRACKING SYSTEM CALL VOLUME PER PROCESS WITH SYSTEMTAP

You can use the `syscalls_by_proc.stp` SystemTap script to see which processes are performing the highest volume of system calls. It displays 20 processes performing the most of system calls.
Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the `syscalls_by_proc.stp` script:

```
# stap --example syscalls_by_proc.stp
```

Output of the `syscalls_by_proc.stp` script looks similar to the following:

```
Collecting data... Type Ctrl-C to exit and display results
#SysCalls Process Name
1577  multiload-apple
692   synergyc
408   pcscd
376   mixer_applet2
299   gnome-terminal
293   Xorg
206   scim-panel-gtk
95    gnome-power-man
90    artsd
85    dhcdbd
84    scim-bridge
78    gnome-screensav
66    scim-launcher
[...]
```
CHAPTER 41. MONITORING DISK AND I/O ACTIVITY WITH SYSTEMTAP

The following sections showcase scripts that monitor disk and I/O activity.

41.1. SUMMARIZING DISK READ/WRITE TRAFFIC WITH SYSTEMTAP

You can use the `disktop.stp` SystemTap script to identify which processes are performing the heaviest disk reads and writes to the system.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the `disktop.stp` script:

```bash
# stap --example disktop.stp
```

The script displays the top ten processes responsible for the heaviest reads or writes to a disk.

The output includes the following data per listed process:

- **UID**: User ID. A user ID of 0 refers to the root user.
- **PID**: The ID of the listed process.
- **PPID**: The process ID of the listed process’s parent process.
- **CMD**: The name of the listed process.
- **DEVICE**: Which storage device the listed process is reading from or writing to.
- **T**: The type of action performed by the listed process, where W refers to write, and R refers to read.
- **BYTES**: The amount of data read to or written from disk.

Output of the `disktop.stp` script looks similar to the following:

```
[...]
Mon Sep 29 03:38:28 2008 , Average:  19Kb/sec, Read: 7Kb, Write: 89Kb
UID    PID     PPID                       CMD   DEVICE    T    BYTES
0    26319    26294                   firefox     sda5    W        90229
0     2758     2757           pam_timestamp_c     sda5    R         8064
0     2885        1                     cupsd     sda5    W         1678
Mon Sep 29 03:38:38 2008 , Average:   1Kb/sec, Read: 7Kb, Write: 1Kb
```
41.2. TRACKING I/O TIME FOR EACH FILE READ OR WRITE WITH SYSTEMTAP

You can use the `iotime.stp` SystemTap script to monitor the amount of time it takes for each process to read from or write to any file. This helps you to determine what files are slow to load on a system.

Prerequisites

- You have installed SystemTap as described in Installing Systemtap.

Procedure

- Run the `iotime.stp` script:

  ```
  # stap --example iotime.stp
  ```

  The script tracks each time a system call opens, closes, reads from, and writes to a file. For each file any system call accesses, it counts the number of microseconds it takes for any reads or writes to finish and tracks the amount of data, in bytes, read from or written to the file.

  The output contains:
  
  - A timestamp, in microseconds
  - Process ID and process name
  - An `access` or `iotime` flag
  - The file accessed

  If a process was able to read or write any data, a pair of access and `iotime` lines should appear together. The access line refers to the time that a given process started accessing a file. The end of the access line will show the amount of data read or written. The `iotime` line will show the amount of time, in microseconds, that the process took in order to perform the read or write.

  Output of the `iotime.stp` script looks similar to the following:

  ```
  [...]
  825946 3364 (NetworkManager) access /sys/class/net/eth0/carrier read: 8190 write: 0
  825955 3364 (NetworkManager) iotime /sys/class/net/eth0/carrier time: 9
  [...]
  117061 2460 (pcscd) access /dev/bus/usb/003/001 read: 43 write: 0
  117065 2460 (pcscd) iotime /dev/bus/usb/003/001 time: 7
  [...]
  3973737 2886 (sendmail) access /proc/loadavg read: 4096 write: 0
  3973744 2886 (sendmail) iotime /proc/loadavg time: 11
  [...]
  ```

41.3. TRACKING CUMULATIVE I/O WITH SYSTEMTAP
You can use the traceio.stp SystemTap script to track the cumulative amount of I/O to the system.

**Prerequisites**

- You have installed SystemTap as described in [Installing Systemtap](#).

**Procedure**

- Run the `traceio.stp` script:

  ```
  # stap --example traceio.stp
  ```

  The script prints the top ten executables generating I/O traffic over time. It also tracks the cumulative amount of I/O reads and writes done by those executables. This information is tracked and printed out in 1-second intervals, and in descending order.

  Output of the `traceio.stp` script looks similar to the following:

  ```
  [...]
  Xorg r:   583401 KiB w:       0 KiB
  floaters r:       96 KiB w:     7130 KiB
  multiload-apple r:    538 KiB w:    537 KiB
  sshd r:       71 KiB w:     72 KiB
  pam_timestamp_c r:    138 KiB w:     0 KiB
  staprun r:       51 KiB w:       51 KiB
  snmpd r:       46 KiB w: 0 KiB
  pcscd r:       28 KiB w:     0 KiB
  irqbalance r:    27 KiB w:        4 KiB
  cupsd r:        4 KiB w:     18 KiB
  Xorg r:   588140 KiB w:        0 KiB
  floaters r:       97 KiB w:    7143 KiB
  multiload-apple r:    543 KiB w:    542 KiB
  sshd r:       72 KiB w:     72 KiB
  pam_timestamp_c r:    138 KiB w:     0 KiB
  staprun r:       51 KiB w:       51 KiB
  snmpd r:       46 KiB w: 0 KiB
  pcscd r:       28 KiB w:     0 KiB
  irqbalance r:    27 KiB w:        4 KiB
  cupsd r:        4 KiB w:     18 KiB
  ```

41.4. MONITORING I/O ACTIVITY ON A SPECIFIC DEVICE WITH SYSTEMTAP

You can use the `traceio2.stp` SystemTap script to monitor I/O activity on a specific device.

**Prerequisites**

- You have installed SystemTap as described in [Installing Systemtap](#).

**Procedure**

- Run the `traceio2.stp` script.
This script takes the whole device number as an argument. To find this number you can use:

```
# stat -c "0x%D" directory
```

Where `directory` is located on the device you want to monitor.

The output contains following:

- The name and ID of any process performing a read or write
- The function it is performing (`vfs_read` or `vfs_write`)
- The kernel device number

Consider following output of `# stap traceio2.stp 0x805`

```
[...]
synergyc(3722) vfs_read 0x800005
synergyc(3722) vfs_read 0x800005
cupsd(2889) vfs_write 0x800005
cupsd(2889) vfs_write 0x800005
cupsd(2889) vfs_write 0x800005
[...]
```

**41.5. MONITORING READS AND WRITES TO A FILE WITH SYSTEMTAP**

You can use the `inodewatch.stp` SystemTap script to monitor reads from and writes to a file in real time.

**Prerequisites**

- You have installed SystemTap as described in [Installing Systemtap](#).

**Procedure**

- Run the `inodewatch.stp` script.

```
# stap --example inodewatch.stp 'argument1' 'argument2' 'argument3'
```

The script `inodewatch.stp` takes three command-line arguments:

1. The file's major device number.
2. The file's minor device number.
3. The file's inode number.

You can get these numbers using:

```
# stat -c '%D %i' filename
```
Where `filename` is an absolute path.

Consider following example:

```
# stat -c '%D %i' /etc/crontab
```

The output should look like:

```
805 1078319
```

where:

- **805** is the base-16 (hexadecimal) device number. The last two digits are the minor device number, and the remaining digits are the major number.
- **1078319** is the inode number.

To start monitoring `/etc/crontab`, run:

```
# stap inodewatch.stp 0x8 0x05 1078319
```

In the first two arguments you must use 0x prefixes for base-16 numbers.

The output contains following:

- The name and ID of any process performing a read or write
- The function it is performing (**vfs_read** or **vfs_write**)
- The kernel device number

The output of this example should look like:

```
cat(16437) vfs_read 0x800005/1078319
cat(16437) vfs_read 0x800005/1078319
```
