Securing Red Hat Enterprise Linux 9

Last Updated: 2022-09-20
Red Hat Enterprise Linux 9 Security hardening

Securing Red Hat Enterprise Linux 9
Abstract

This title assists users and administrators in learning the processes and practices of securing workstations and servers against local and remote intrusion, exploitation, and malicious activity. Focused on Red Hat Enterprise Linux but detailing concepts and techniques valid for all Linux systems, this guide details the planning and the tools involved in creating a secured computing environment for the data center, workplace, and home. With proper administrative knowledge, vigilance, and tools, systems running Linux can be both fully functional and secured from most common intrusion and exploit methods.
# Table of Contents

## MAKING OPEN SOURCE MORE INCLUSIVE

## PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

### CHAPTER 1. SECURING RHEL DURING INSTALLATION

1. BIOS AND UEFI SECURITY
   - 1.1. BIOS passwords
   - 1.2. Non-BIOS-based systems security
   - 1.3. RESTRICTING NETWORK CONNECTIVITY DURING THE INSTALLATION PROCESS
   - 1.4. INSTALLING THE MINIMUM AMOUNT OF PACKAGES REQUIRED
   - 1.5. POST-INSTALLATION PROCEDURES

### CHAPTER 2. INSTALLING THE SYSTEM IN FIPS MODE

1. FEDERAL INFORMATION PROCESSING STANDARD (FIPS)
   - 2.1. INSTALLING THE SYSTEM WITH FIPS MODE ENABLED
   - 2.3. ADDITIONAL RESOURCES

### CHAPTER 3. USING SYSTEM-WIDE CRYPTOGRAPHIC POLICIES

1. SYSTEM-WIDE CRYPTOGRAPHIC POLICIES
   - 3.1. Tool for managing crypto policies
   - 3.2. EXAMPLES OF OPTING OUT OF SYSTEM-WIDE CRYPTO POLICIES
   - 3.3. SWITCHING THE SYSTEM-WIDE CRYPTOGRAPHIC POLICY TO MODE COMPATIBLE WITH EARLIER RELEASES
   - 3.4. SWITCHING THE SYSTEM TO FIPS MODE
   - 3.5. ENABLING FIPS MODE IN A CONTAINER
   - 3.6. LIST OF RHEL APPLICATIONS USING CRYPTOGRAPHY THAT IS NOT COMPLIANT WITH FIPS 140-3
   - 3.7. CUSTOMIZING SYSTEM-WIDE CRYPTOGRAPHIC POLICIES WITH SUBPOLICIES
   - 3.8. RE-ENABLING SHA-1
   - 3.9. CREATING AND SETTING A CUSTOM SYSTEM-WIDE CRYPTOGRAPHIC POLICY

### CHAPTER 4. SETTING A CUSTOM CRYPTOGRAPHIC POLICY ACROSS SYSTEMS

1. CRYPTOGRAPHIC POLICIES SYSTEM ROLE VARIABLES AND FACTS
   - 4.1. SETTING A CUSTOM CRYPTOGRAPHIC POLICY USING THE CRYPTOGRAPHIC POLICIES SYSTEM ROLE
   - 4.3. ADDITIONAL RESOURCES

### CHAPTER 5. CONFIGURING APPLICATIONS TO USE CRYPTOGRAPHIC HARDWARE THROUGH PKCS #11

1. CRYPTOGRAPHIC HARDWARE SUPPORT THROUGH PKCS #11
   - 5.2. USING SSH KEYS STORED ON A SMART CARD
   - 5.3. CONFIGURING APPLICATIONS TO AUTHENTICATE USING CERTIFICATES FROM SMART CARDS
   - 5.4. USING HSMS PROTECTING PRIVATE KEYS IN APACHE
   - 5.5. USING HSMS PROTECTING PRIVATE KEYS IN NGINX
   - 5.6. ADDITIONAL RESOURCES

### CHAPTER 6. CONTROLLING ACCESS TO SMART CARDS USING POLKIT

1. SMART-CARD ACCESS CONTROL THROUGH POLKIT
   - 6.2. TROUBLESHOOTING PROBLEMS RELATED TO PC/SC AND POLKIT
   - 6.3. DISPLAYING MORE DETAILED INFORMATION ABOUT POLKIT AUTHORIZATION TO PC/SC
### Chapter 7. Using Shared System Certificates

- **7.1. The System-Wide Trust Store**
- **7.2. Adding New Certificates**
- **7.3. Managing Trusted System Certificates**
- **7.4. Additional Resources**

### Chapter 8. Scanning the System for Configuration Compliance and Vulnerabilities

- **8.1. Configuration Compliance Tools in RHEL**
- **8.2. Vulnerability Scanning**
  - 8.2.1. Red Hat Security Advisories OVAL feed
  - 8.2.2. Scanning the system for vulnerabilities
  - 8.2.3. Scanning remote systems for vulnerabilities
- **8.3. Configuration Compliance Scanning**
  - 8.3.1. Configuration compliance in RHEL
  - 8.3.2. Possible results of an OpenSCAP scan
  - 8.3.3. Viewing profiles for configuration compliance
  - 8.3.4. Assessing configuration compliance with a specific baseline
- **8.4. Remediating the System to Align with a Specific Baseline**
- **8.5. Remediating the System to Align with a Specific Baseline Using an SSG Ansible Playbook**
- **8.6. Creating a Remediation Ansible Playbook to Align the System with a Specific Baseline**
- **8.7. Creating a Remediation Bash Script for a Later Application**
- **8.8. Scanning the System with a Customized Profile Using SCAP Workbench**
  - 8.8.1. Using SCAP Workbench to scan and remediate the system
  - 8.8.2. Customizing a security profile with SCAP Workbench
  - 8.8.3. Additional resources
- **8.9. Deploying Systems That Are Compliant with a Security Profile Immediately After an Installation**
  - 8.9.1. Profiles not compatible with Server with GUI
  - 8.9.2. Deploying baseline-compliant RHEL systems using the graphical installation
  - 8.9.3. Deploying baseline-compliant RHEL systems using Kickstart
- **8.10. Scanning Container and Container Images for Vulnerabilities**
- **8.11. Assessing Security Compliance of a Container or a Container Image with a Specific Baseline**
- **8.12. SCAP Security Guide Profiles Supported in RHEL 9**
- **8.13. Additional Resources**

### Chapter 9. Checking Integrity with AIDE

- **9.1. Installing AIDE**
- **9.2. Performing Integrity Checks with AIDE**
- **9.3. Updating an AIDE Database**
- **9.4. File-Integrity Tools: AIDE and IMA**
- **9.5. Additional Resources**

### Chapter 10. Encrypting Block Devices Using LUKS

- **10.1. LUKS Disk Encryption**
- **10.2. LUKS Versions in RHEL**
- **10.3. Options for Data Protection During LUKS2 Re-Encryption**
- **10.4. Encrypting Existing Data on a Block Device Using LUKS2**
- **10.5. Encrypting Existing Data on a Block Device Using LUKS2 with a Detached Header**
- **10.6. Encrypting a Blank Block Device Using LUKS2**

---

6.4. ADDITIONAL RESOURCES  
CHAPTER 7. USING SHARED SYSTEM CERTIFICATES ........................................... 36  
7.1. THE SYSTEM-WIDE TRUST STORE ......................................................... 36  
7.2. ADDING NEW CERTIFICATES ................................................................. 36  
7.3. MANAGING TRUSTED SYSTEM CERTIFICATES ...................................... 37  
7.4. ADDITIONAL RESOURCES .................................................................... 38  
CHAPTER 8. SCANNING THE SYSTEM FOR CONFIGURATION COMPLIANCE AND VULNERABILITIES ................................................................. 39  
8.1. CONFIGURATION COMPLIANCE TOOLS IN RHEL .................................. 39  
8.2. VULNERABILITY SCANNING ................................................................. 39  
  - 8.2.1. Red Hat Security Advisories OVAL feed
  - 8.2.2. Scanning the system for vulnerabilities
  - 8.2.3. Scanning remote systems for vulnerabilities
- 8.3. CONFIGURATION COMPLIANCE SCANNING ....................................... 42  
  - 8.3.1. Configuration compliance in RHEL
  - 8.3.2. Possible results of an OpenSCAP scan
  - 8.3.3. Viewing profiles for configuration compliance
  - 8.3.4. Assessing configuration compliance with a specific baseline
- 8.4. REMEDIATING THE SYSTEM TO ALIGN WITH A SPECIFIC BASELINE ...... 45  
  - 8.4. REMEDIATING THE SYSTEM TO ALIGN WITH A SPECIFIC BASELINE USING AN SSG ANSIBLE PLAYBOOK
  - 8.6. CREATING A REMEDIATION ANSIBLE PLAYBOOK TO ALIGN THE SYSTEM WITH A SPECIFIC BASELINE
  - 8.7. CREATING A REMEDIATION BASH SCRIPT FOR A LATER APPLICATION
  - 8.8. SCANNING THE SYSTEM WITH A CUSTOMIZED PROFILE USING SCAP WORKBENCH
    - 8.8.1. Using SCAP Workbench to scan and remediate the system
    - 8.8.2. Customizing a security profile with SCAP Workbench
    - 8.8.3. Additional resources
  - 8.9. DEPLOYING SYSTEMS THAT ARE COMPLIANT WITH A SECURITY PROFILE IMMEDIATELY AFTER AN INSTALLATION
    - 8.9.1. Profiles not compatible with Server with GUI
    - 8.9.2. Deploying baseline-compliant RHEL systems using the graphical installation
    - 8.9.3. Deploying baseline-compliant RHEL systems using Kickstart
- 8.10. SCANNING CONTAINER AND CONTAINER IMAGES FOR VULNERABILITIES
- 8.11. ASSESSING SECURITY COMPLIANCE OF A CONTAINER OR A CONTAINER IMAGE WITH A SPECIFIC BASELINE
- 8.12. SCAP SECURITY GUIDE PROFILES SUPPORTED IN RHEL 9
- 8.13. ADDITIONAL RESOURCES

### Chapter 9. Checking Integrity with AIDE

- **9.1. Installing AIDE**
- **9.2. Performing Integrity Checks with AIDE**
- **9.3. Updating an AIDE Database**
- **9.4. File-Integrity Tools: AIDE and IMA**
- **9.5. Additional Resources**

### Chapter 10. Encrypting Block Devices Using LUKS

- **10.1. LUKS Disk Encryption**
- **10.2. LUKS Versions in RHEL**
- **10.3. Options for Data Protection During LUKS2 Re-Encryption**
- **10.4. Encrypting Existing Data on a Block Device Using LUKS2**
- **10.5. Encrypting Existing Data on a Block Device Using LUKS2 with a Detached Header**
- **10.6. Encrypting a Blank Block Device Using LUKS2**
10.7. CREATING A LUKS ENCRYPTED VOLUME USING THE STORAGE SYSTEM ROLE

CHAPTER 11. CONFIGURING AUTOMATED UNLOCKING OF ENCRYPTED VOLUMES USING POLICY-BASED DECRYPTION

11.1. NETWORK-BOUND DISK ENCRYPTION
11.2. INSTALLING AN ENCRYPTION CLIENT - CLEVIS
11.3. DEPLOYING A TANG SERVER WITH SELINUX IN ENFORCING MODE
11.4. ROTATING TANG SERVER KEYS AND UPDATING BINDINGS ON CLIENTS
11.5. CONFIGURING AUTOMATED UNLOCKING USING A TANG KEY IN THE WEB CONSOLE
11.6. BASIC NBDE AND TPM2 ENCRYPTION-CLIENT OPERATIONS
11.7. CONFIGURING MANUAL ENROLLMENT OF LUKS-ENCRYPTED VOLUMES
11.8. CONFIGURING MANUAL ENROLLMENT OF LUKS-ENCRYPTED VOLUMES USING A TPM 2.0 POLICY
11.9. REMOVING A CLEVIS PIN FROM A LUKS-ENCRYPTED VOLUME MANUALLY
11.10. CONFIGURING AUTOMATED ENROLLMENT OF LUKS-ENCRYPTED VOLUMES USING KICKSTART
11.11. CONFIGURING AUTOMATED UNLOCKING OF A LUKS-ENCRYPTED REMOVABLE STORAGE DEVICE
11.12. DEPLOYING HIGH-AVAILABILITY NBDE SYSTEMS
11.12.1. High-available NBDE using Shamir’s Secret Sharing
11.12.1.1. Example 1: Redundancy with two Tang servers
11.12.1.2. Example 2: Shared secret on a Tang server and a TPM device
11.13. DEPLOYMENT OF VIRTUAL MACHINES IN A NBDE NETWORK
11.14. BUILDING AUTOMATICALLY-ENROLLABLE VM IMAGES FOR CLOUD ENVIRONMENTS USING NBDE
11.15. DEPLOYING TANG AS A CONTAINER
11.16. INTRODUCTION TO THE CLEVIS AND TANG SYSTEM ROLES
11.17. USING THE NBDE SERVER SYSTEM ROLE FOR SETTING UP MULTIPLE TANG SERVERS
11.18. USING THE NBDE CLIENT SYSTEM ROLE FOR SETTING UP MULTIPLE CLEVIS CLIENTS
11.19. ADDITIONAL RESOURCES

CHAPTER 12. AUDITING THE SYSTEM

12.1. LINUX AUDIT
12.2. AUDIT SYSTEM ARCHITECTURE
12.3. CONFIGURING AUDITD FOR A SECURE ENVIRONMENT
12.4. STARTING AND CONTROLLING AUDITD
12.5. UNDERSTANDING AUDIT LOG FILES
12.6. USING AUDITCTL FOR DEFINING AND EXECUTING AUDIT RULES
12.7. DEFINING PERSISTENT AUDIT RULES
12.8. USING PRE-CONFIGURED RULES FILES
12.9. USING AUGENRULES TO DEFINE PERSISTENT RULES
12.10. DISABLING AUGENRULES
12.11. SETTING UP AUDIT TO MONITOR SOFTWARE UPDATES
12.12. MONITING USER LOGIN TIMES WITH AUDIT
12.13. ADDITIONAL RESOURCES

CHAPTER 13. BLOCKING AND ALLOWING APPLICATIONS USING FAPOLICYD

13.1. INTRODUCTION TO FAPOLICYD
13.2. DEPLOYING FAPOLICYD
13.3. MARKING FILES AS TRUSTED USING AN ADDITIONAL SOURCE OF TRUST
13.4. ADDING CUSTOM ALLOW AND DENY RULES FOR FAPOLICYD
13.5. ENABLING FAPOLICYD INTEGRITY CHECKS
13.6. TROUBLESHOOTING PROBLEMS RELATED TO FAPOLICYD
13.7. ADDITIONAL RESOURCES
CHAPTER 14. PROTECTING SYSTEMS AGAINST INTRUSIVE USB DEVICES ................................. 124
14.1. USBGUARD 124
14.2. INSTALLING USBGUARD 124
14.3. BLOCKING AND AUTHORIZING A USB DEVICE USING CLI 125
14.4. PERMANENTLY BLOCKING AND AUTHORIZING A USB DEVICE 126
14.5. CREATING A CUSTOM POLICY FOR USB DEVICES 127
14.6. CREATING A STRUCTURED CUSTOM POLICY FOR USB DEVICES 128
14.7. AUTHORIZING USERS AND GROUPS TO USE THE USBGUARD IPC INTERFACE 130
14.8. LOGGING USBGUARD AUTHORIZATION EVENTS TO THE LINUX AUDIT LOG 131
14.9. ADDITIONAL RESOURCES 131

CHAPTER 15. CONFIGURING A REMOTE LOGGING SOLUTION ............................................. 132
15.1. THE RSYSLOG LOGGING SERVICE 132
15.2. INSTALLING RSYSLOG DOCUMENTATION 132
15.3. CONFIGURING A SERVER FOR REMOTE LOGGING OVER TCP 133
15.4. CONFIGURING REMOTE LOGGING TO A SERVER OVER TCP 135
15.5. CONFIGURING TLS-ENCRYPTED REMOTE LOGGING 136
15.6. CONFIGURING A SERVER FOR RECEIVING REMOTE LOGGING INFORMATION OVER UDP 139
15.7. CONFIGURING REMOTE LOGGING TO A SERVER OVER UDP 141
15.8. LOAD BALANCING HELPER IN RSYSLOG 143
15.9. CONFIGURING RELIABLE REMOTE LOGGING 143
15.10. SUPPORTED RSYSLOG MODULES 145
15.11. ADDITIONAL RESOURCES 145

CHAPTER 16. USING THE LOGGING SYSTEM ROLE .......................................................... 146
16.1. THE LOGGING SYSTEM ROLE 146
16.2. LOGGING SYSTEM ROLE PARAMETERS 146
16.3. APPLYING A LOCAL LOGGING SYSTEM ROLE 147
16.4. FILTERING LOGS IN A LOCAL LOGGING SYSTEM ROLE 149
16.5. APPLYING A REMOTE LOGGING SOLUTION USING THE LOGGING SYSTEM ROLE 151
16.6. USING THE LOGGING SYSTEM ROLE WITH TLS 154
   16.6.1. Configuring client logging with TLS 154
   16.6.2. Configuring server logging with TLS 156
16.7. USING THE LOGGING SYSTEM ROLES WITH RELP 157
   16.7.1. Configuring client logging with RELP 158
   16.7.2. Configuring server logging with RELP 160
16.8. ADDITIONAL RESOURCES 161
MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your feedback on our documentation. Let us know how we can improve it.

Submitting comments on specific passages

1. View the documentation in the Multi-page HTML format and ensure that you see the Feedback button in the upper right corner after the page fully loads.
2. Use your cursor to highlight the part of the text that you want to comment on.
3. Click the Add Feedback button that appears near the highlighted text.
4. Add your feedback and click Submit.

Submitting feedback through Bugzilla (account required)

1. Log in to the Bugzilla website.
2. Select the correct version from the Version menu.
3. Enter a descriptive title in the Summary field.
4. Enter your suggestion for improvement in the Description field. Include links to the relevant parts of the documentation.
5. Click Submit Bug.
CHAPTER 1. SECURING RHEL DURING INSTALLATION

Security begins even before you start the installation of Red Hat Enterprise Linux. Configuring your system securely from the beginning makes it easier to implement additional security settings later.

1. BIOS AND UEFI SECURITY

Password protection for the BIOS (or BIOS equivalent) and the boot loader can prevent unauthorized users who have physical access to systems from booting using removable media or obtaining root privileges through single user mode. The security measures you should take to protect against such attacks depends both on the sensitivity of the information on the workstation and the location of the machine.

For example, if a machine is used in a trade show and contains no sensitive information, then it may not be critical to prevent such attacks. However, if an employee’s laptop with private, unencrypted SSH keys for the corporate network is left unattended at that same trade show, it could lead to a major security breach with ramifications for the entire company.

If the workstation is located in a place where only authorized or trusted people have access, however, then securing the BIOS or the boot loader may not be necessary.

1.1. BIOS passwords

The two primary reasons for password protecting the BIOS of a computer are[1]:

1. Preventing changes to BIOS settings – If an intruder has access to the BIOS, they can set it to boot from a CD-ROM or a flash drive. This makes it possible for them to enter rescue mode or single user mode, which in turn allows them to start arbitrary processes on the system or copy sensitive data.

2. Preventing system booting – Some BIOSes allow password protection of the boot process. When activated, an attacker is forced to enter a password before the BIOS launches the boot loader.

Because the methods for setting a BIOS password vary between computer manufacturers, consult the computer’s manual for specific instructions.

If you forget the BIOS password, it can either be reset with jumpers on the motherboard or by disconnecting the CMOS battery. For this reason, it is good practice to lock the computer case if possible. However, consult the manual for the computer or motherboard before attempting to disconnect the CMOS battery.

1.1.2. Non-BIOS-based systems security

Other systems and architectures use different programs to perform low-level tasks roughly equivalent to those of the BIOS on x86 systems. For example, the Unified Extensible Firmware Interface (UEFI) shell.

For instructions on password protecting BIOS-like programs, see the manufacturer’s instructions.

1.2. DISK PARTITIONING

Red Hat recommends creating separate partitions for the /boot, /, /home, /tmp, and /var/tmp/ directories.
This partition is the first partition that is read by the system during boot up. The boot loader and kernel images that are used to boot your system into Red Hat Enterprise Linux 9 are stored in this partition. This partition should not be encrypted. If this partition is included in / and that partition is encrypted or otherwise becomes unavailable then your system is not able to boot.

When user data (/home) is stored in / instead of in a separate partition, the partition can fill up causing the operating system to become unstable. Also, when upgrading your system to the next version of Red Hat Enterprise Linux 9 it is a lot easier when you can keep your data in the /home partition as it is not be overwritten during installation. If the root partition (/) becomes corrupt your data could be lost forever. By using a separate partition there is slightly more protection against data loss. You can also target this partition for frequent backups.

Both the /tmp and /var/tmp/ directories are used to store data that does not need to be stored for a long period of time. However, if a lot of data floods one of these directories it can consume all of your storage space. If this happens and these directories are stored within / then your system could become unstable and crash. For this reason, moving these directories into their own partitions is a good idea.

During the installation process, you have an option to encrypt partitions. You must supply a passphrase. This passphrase serves as a key to unlock the bulk encryption key, which is used to secure the partition’s data.

When installing Red Hat Enterprise Linux 9, the installation medium represents a snapshot of the system at a particular time. Because of this, it may not be up-to-date with the latest security fixes and may be vulnerable to certain issues that were fixed only after the system provided by the installation medium was released.

When installing a potentially vulnerable operating system, always limit exposure only to the closest necessary network zone. The safest choice is the “no network” zone, which means to leave your machine disconnected during the installation process. In some cases, a LAN or intranet connection is sufficient while the Internet connection is the riskiest. To follow the best security practices, choose the closest zone with your repository while installing Red Hat Enterprise Linux 9 from a network.

It is best practice to install only the packages you will use because each piece of software on your computer could possibly contain a vulnerability. If you are installing from the DVD media, take the opportunity to select exactly what packages you want to install during the installation. If you find you need another package, you can always add it to the system later.

The following steps are the security-related procedures that should be performed immediately after installation of Red Hat Enterprise Linux 9.

- Update your system. Enter the following command as root:
Even though the firewall service, firewalld, is automatically enabled with the installation of Red Hat Enterprise Linux, there are scenarios where it might be explicitly disabled, for example in the kickstart configuration. In such a case, it is recommended to consider re-enabling the firewall.

To start firewalld enter the following commands as root:

```
# systemctl start firewalld
# systemctl enable firewalld
```

To enhance security, disable services you do not need. For example, if there are no printers installed on your computer, disable the cups service using the following command:

```
# systemctl disable cups
```

To review active services, enter the following command:

```
$ systemctl list-units | grep service
```

---

Because system BIOSes differ between manufacturers, some may not support password protection of either type, while others may support one type but not the other.
CHAPTER 2. INSTALLING THE SYSTEM IN FIPS MODE

To enable the cryptographic module self-checks mandated by the Federal Information Processing Standard (FIPS) 140-3, you have to operate RHEL 9 in FIPS mode.

You can achieve this by:

- Starting the installation in FIPS mode.
- Switching the system into FIPS mode after the installation.

To avoid cryptographic key material regeneration and reevaluation of the compliance of the resulting system associated with converting already deployed systems, Red Hat recommends starting the installation in FIPS mode.

NOTE

The cryptographic modules of RHEL 9 are not yet certified for the FIPS 140-3 requirements.

2.1. FEDERAL INFORMATION PROCESSING STANDARD (FIPS)

The Federal Information Processing Standard (FIPS) Publication 140-3 is a computer security standard developed by the U.S. Government and industry working group to validate the quality of cryptographic modules. See the official FIPS publications at NIST Computer Security Resource Center.

The FIPS 140-3 standard ensures that cryptographic tools implement their algorithms correctly. One of the mechanisms for that is runtime self-checks. See the full FIPS 140-3 standard at FIPS PUB 140-3 for further details and other specifications of the FIPS standard.

To learn about compliance requirements, see the Red Hat Government Standards page.

2.2. INSTALLING THE SYSTEM WITH FIPS MODE ENABLED

To enable the cryptographic module self-checks mandated by the Federal Information Processing Standard (FIPS) Publication 140-3, enable FIPS mode during the system installation.

IMPORTANT

Red Hat recommends installing RHEL with FIPS mode enabled, as opposed to enabling FIPS mode later. Enabling FIPS mode during the installation ensures that the system generates all keys with FIPS-approved algorithms and continuous monitoring tests in place.

Procedure

- Add the fips=1 option to the kernel command line during the system installation. During the software selection stage, do not install any third-party software.

After the installation, the system starts in FIPS mode automatically.

Verification

- After the system starts, check that FIPS mode is enabled:
$ fips-mode-setup --check
FIPS mode is enabled.

Additional resources

- Editing boot options section in the Performing an advanced RHEL installation

2.3. ADDITIONAL RESOURCES

- Switching the system to FIPS mode
- Enabling FIPS mode in a container
CHAPTER 3. USING SYSTEM-WIDE CRYPTOGRAPHIC POLICIES

The system-wide cryptographic policies is a system component that configures the core cryptographic subsystems, covering the TLS, IPSec, SSH, DNSSec, and Kerberos protocols. It provides a small set of policies, which the administrator can select.

3.1. SYSTEM-WIDE CRYPTOGRAPHIC POLICIES

When a system-wide policy is set up, applications in RHEL follow it and refuse to use algorithms and protocols that do not meet the policy, unless you explicitly request the application to do so. That is, the policy applies to the default behavior of applications when running with the system-provided configuration but you can override it if required.

RHEL 9 contains the following predefined policies:

<table>
<thead>
<tr>
<th>Policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DEFAULT</strong></td>
<td>The default system-wide cryptographic policy level offers secure settings for current threat models. It allows the TLS 1.2 and 1.3 protocols, as well as the IKEv2 and SSH2 protocols. The RSA keys and Diffie-Hellman parameters are accepted if they are at least 2048 bits long.</td>
</tr>
<tr>
<td><strong>LEGACY</strong></td>
<td>This policy ensures maximum compatibility with Red Hat Enterprise Linux 6 and earlier; it is less secure due to an increased attack surface. SHA-1 is allowed to be used as TLS hash, signature, and algorithm. CBC-mode ciphers are allowed to be used with SSH. Applications using GnuTLS allow certificates signed with SHA-1. It allows the TLS 1.2 and 1.3 protocols, as well as the IKEv2 and SSH2 protocols. The RSA keys and Diffie-Hellman parameters are accepted if they are at least 2048 bits long.</td>
</tr>
<tr>
<td><strong>FUTURE</strong></td>
<td>A conservative security level that is believed to withstand any near-term future attacks. This level does not allow the use of SHA-1 in DNSSec or as an HMAC. SHA2-224 and SHA3-224 hashes are disabled. 128-bit ciphers are disabled. CBC-mode ciphers are disabled except in Kerberos. It allows the TLS 1.2 and 1.3 protocols, as well as the IKEv2 and SSH2 protocols. The RSA keys and Diffie-Hellman parameters are accepted if they are at least 3072 bits long.</td>
</tr>
<tr>
<td><strong>FIPS</strong></td>
<td>A policy level that conforms with the FIPS 140-2 requirements. This is used internally by the <code>fips-mode-setup</code> tool, which switches the RHEL system into FIPS mode.</td>
</tr>
</tbody>
</table>

Red Hat continuously adjusts all policy levels so that all libraries, except when using the LEGACY policy, provide secure defaults. Even though the LEGACY profile does not provide secure defaults, it does not include any algorithms that are easily exploitable. As such, the set of enabled algorithms or acceptable key sizes in any provided policy may change during the lifetime of Red Hat Enterprise Linux.

Such changes reflect new security standards and new security research. If you must ensure interoperability with a specific system for the whole lifetime of Red Hat Enterprise Linux, you should opt-out from cryptographic-policies for components that interact with that system or re-enable specific algorithms using custom policies.
IMPORTANT

Because a cryptographic key used by a certificate on the Customer Portal API does not meet the requirements by the **FUTURE** system-wide cryptographic policy, the **redhat-support-tool** utility does not work with this policy level at the moment.

To work around this problem, use the **DEFAULT** crypto policy while connecting to the Customer Portal API.

NOTE

The specific algorithms and ciphers described in the policy levels as allowed are available only if an application supports them.

Tool for managing crypto policies

To view or change the current system-wide cryptographic policy, use the **update-crypto-policies** tool, for example:

```bash
$ update-crypto-policies --show
DEFAULT
# update-crypto-policies --set FUTURE
Setting system policy to FUTURE
```

To ensure that the change of the cryptographic policy is applied, restart the system.

Strong crypto defaults by removing insecure cipher suites and protocols

The following list contains cipher suites and protocols removed from the core cryptographic libraries in Red Hat Enterprise Linux 9. They are not present in the sources, or their support is disabled during the build, so applications cannot use them.

- DES (since RHEL 7)
- All export grade cipher suites (since RHEL 7)
- MD5 in signatures (since RHEL 7)
- SSLv2 (since RHEL 7)
- SSLv3 (since RHEL 8)
- All ECC curves < 224 bits (since RHEL 6)
- All binary field ECC curves (since RHEL 6)

Algorithms disabled in all policy levels

The following algorithms are disabled in **LEGACY, DEFAULT, FUTURE** and **FIPS** cryptographic policies included in RHEL 9. They can be enabled only by applying a custom cryptographic policy or by an explicit configuration of individual applications, but the resulting configuration would not be considered supported.

- TLS older than version 1.2 (since RHEL 9, was < 1.0 in RHEL 8)
- DTLS older than version 1.2 (since RHEL 9, was < 1.0 in RHEL 8)
- DH with parameters < 2048 bits (since RHEL 9, was < 1024 bits in RHEL 8)
- RSA with key size < 2048 bits (since RHEL 9, was < 1024 bits in RHEL 8)
- DSA (since RHEL 9, was < 1024 bits in RHEL 8)
- 3DES (since RHEL 9)
- RC4 (since RHEL 9)
- FFDHE-1024 (since RHEL 9)
- DHE-DSS (since RHEL 9)
- Camellia (since RHEL 9)
- ARIA
- IKEv1 (since RHEL 8)

### Algorithms enabled in the crypto-policies levels

The following table shows the comparison of all four crypto-policies levels with regard to select algorithms.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>LEGACY</th>
<th>DEFAULT</th>
<th>FIPS</th>
<th>FUTURE</th>
</tr>
</thead>
<tbody>
<tr>
<td>IKEv1</td>
<td>no</td>
<td>no</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>3DES</td>
<td>no</td>
<td>no</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>RC4</td>
<td>no</td>
<td>no</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>DH</td>
<td>min. 2048-bit</td>
<td>min. 2048-bit</td>
<td>min. 2048-bit</td>
<td>min. 3072-bit</td>
</tr>
<tr>
<td>RSA</td>
<td>min. 2048-bit</td>
<td>min. 2048-bit</td>
<td>min. 2048-bit</td>
<td>min. 3072-bit</td>
</tr>

### 3.2. SWITCHING THE SYSTEM-WIDE CRYPTOGRAPHIC POLICY TO MODE COMPATIBLE WITH EARLIER RELEASES

The default system-wide cryptographic policy in Red Hat Enterprise Linux 9 does not allow communication using older, insecure protocols. For environments that require to be compatible with Red Hat Enterprise Linux 6 and in some cases also with earlier releases, the less secure **LEGACY** policy level is available.

**WARNING**

Switching to the **LEGACY** policy level results in a less secure system and applications.

**Procedure**

1. To switch the system-wide cryptographic policy to the **LEGACY** level, enter the following command as `root`:

```
# update-crypto-policies --set LEGACY
```

Setting system policy to **LEGACY**

**Additional resources**

- For the list of available cryptographic policy levels, see the **update-crypto-policies(8)** man page.

- For defining custom cryptographic policies, see the **Custom Policies** section in the **update-crypto-policies(8)** man page and the **Crypto Policy Definition Format** section in the **crypto-policies(7)** man page.

### 3.3. SWITCHING THE SYSTEM TO FIPS MODE

The system-wide cryptographic policies contain a policy level that enables cryptographic modules self-checks in accordance with the requirements by the Federal Information Processing Standard (FIPS)
Publication 140-3. The `fips-mode-setup` tool that enables or disables FIPS mode internally uses the FIPS system-wide cryptographic policy level.

**IMPORTANT**

Red Hat recommends installing Red Hat Enterprise Linux 9 with FIPS mode enabled, as opposed to enabling FIPS mode later. Enabling FIPS mode during the installation ensures that the system generates all keys with FIPS-approved algorithms and continuous monitoring tests in place.

**NOTE**

The cryptographic modules of RHEL 9 are not yet certified for the FIPS 140-3 requirements.

**Procedure**

1. To switch the system to FIPS mode:

   ```
   # fips-mode-setup --enable
   Kernel initramdisks are being regenerated. This might take some time.
   Setting system policy to FIPS
   Note: System-wide crypto policies are applied on application start-up.
   It is recommended to restart the system for the change of policies to fully take place.
   FIPS mode will be enabled.
   Please reboot the system for the setting to take effect.
   ```

2. Restart your system to allow the kernel to switch to FIPS mode:

   ```
   # reboot
   ```

**Verification**

1. After the restart, you can check the current state of FIPS mode:

   ```
   # fips-mode-setup --check
   FIPS mode is enabled.
   ```

**Additional resources**

- `fips-mode-setup(8)` man page
- Installing the system in FIPS mode
- Security Requirements for Cryptographic Modules on the National Institute of Standards and Technology (NIST) web site.

**3.4. ENABLING FIPS MODE IN A CONTAINER**

On systems with FIPS mode enabled, the `podman` utility automatically configures containers to FIPS mode. On systems not in FIPS mode, you can switch a container to FIPS mode by using a single command later.
NOTE

The `fips-mode-setup` command does not work correctly in containers, and it cannot be used to enable or check FIPS mode in this scenario.

NOTE

The cryptographic modules of RHEL 9 are not yet certified for the FIPS 140-3 requirements.

Prerequisites

- The host system must be in FIPS mode.

Procedure

- Use the following command in a container that you want to switch to FIPS mode:

  ```bash
  # mount --bind /usr/share/crypto-policies/back-ends/FIPS /etc/crypto-policies/back-ends
  ```

Additional resources

- Switching the system to FIPS mode.
- Installing the system in FIPS mode

3.5. LIST OF RHEL APPLICATIONS USING CRYPTOGRAPHY THAT IS NOT COMPLIANT WITH FIPS 140-3

Red Hat recommends utilizing libraries from the core crypto components set, as they are guaranteed to pass all relevant crypto certifications, such as FIPS 140-3, and also follow the RHEL system-wide crypto policies.

See the RHEL core crypto components article for an overview of the core cryptographic components, the information on how are they selected, how are they integrated into the operating system, how do they support hardware security modules and smart cards, and how do cryptographic certifications apply to them.

Table 3.1. List of RHEL 8 applications using cryptography that is not compliant with FIPS 140-3

<table>
<thead>
<tr>
<th>Application</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bacula</td>
<td>Implements the CRAM-MD5 authentication protocol.</td>

<tr>
<td>PostgreSQL</td>
<td>KDF uses SHA-1.</td>
</tr>
<tr>
<td>QAT Engine</td>
<td>Mixed hardware and software implementation of cryptographic primitives (RSA, EC, DH, AES, …)</td>
</tr>
</tbody>
</table>
Ruby | Provides insecure MD5 and SHA-1 library functions.
---|---
Samba | Preserves support for RC4 and DES (interoperability with Windows).
Syslinux | BIOS passwords use SHA-1.
Unbound | DNS specification requires that DNSSEC resolvers use a SHA-1-based algorithm in DNSKEY records for validation.
Valgrind | AES, SHA hashes.\([a]\)

\([a]\) Re-implements in software hardware-offload operations, such as AES-NI or SHA-1 and SHA-2 on ARM.

3.6. EXCLUDING AN APPLICATION FROM FOLLOWING SYSTEM-WIDE CRYPTO POLICIES

You can customize cryptographic settings used by your application preferably by configuring supported cipher suites and protocols directly in the application.

You can also remove a symlink related to your application from the `/etc/crypto-policies/back-ends` directory and replace it with your customized cryptographic settings. This configuration prevents the use of system-wide cryptographic policies for applications that use the excluded back end. Furthermore, this modification is not supported by Red Hat.

3.6.1. Examples of opting out of system-wide crypto policies

**wget**

To customize cryptographic settings used by the `wget` network downloader, use `--secure-protocol` and `--ciphers` options. For example:

```
$ wget --secure-protocol=TLSv1_1 --ciphers="SECURE128" https://example.com
```

See the HTTPS (SSL/TLS) Options section of the `wget(1)` man page for more information.

**curl**

To specify ciphers used by the `curl` tool, use the `--ciphers` option and provide a colon-separated list of ciphers as a value. For example:

```
$ curl https://example.com --ciphers '@SECLEVEL=0:DES-CBC3-SHA:RSA-DES-CBC3-SHA'
```

See the `curl(1)` man page for more information.

**Firefox**

Even though you cannot opt out of system-wide cryptographic policies in the `Firefox` web browser, you can further restrict supported ciphers and TLS versions in Firefox's Configuration Editor. Type
about:config in the address bar and change the value of the security.tls.version.min option as required. Setting security.tls.version.min to 1 allows TLS 1.0 as the minimum required, security.tls.version.min 2 enables TLS 1.1, and so on.

OpenSSH

To opt out of system-wide crypto policies for your OpenSSH client, perform one of the following tasks:

- For a given user, override the global ssh_config with a user-specific configuration in the ~/.ssh/config file.
- For the entire system, specify the crypto policy in a drop-in configuration file located in the /etc/ssh/ssh_config.d/ directory, with a two-digit number prefix smaller than 50, so that it lexicographically precedes the 50-redhat.conf file, and with a .conf suffix, for example, 49-crypto-policy-override.conf.

See the ssh_config(5) man page for more information.

Libreswan

See the Configuring IPsec connections that opt out of the system-wide crypto policies in the Securing networks document for detailed information.

Additional resources

- update-crypto-policies(8) man page

3.7. CUSTOMIZING SYSTEM-WIDE CRYPTOGRAPHIC POLICIES WITH SUBPOLICIES

Use this procedure to adjust the set of enabled cryptographic algorithms or protocols.

You can either apply custom subpolicies on top of an existing system-wide cryptographic policy or define such a policy from scratch.

The concept of scoped policies allows enabling different sets of algorithms for different back ends. You can limit each configuration directive to specific protocols, libraries, or services.

Furthermore, directives can use asterisks for specifying multiple values using wildcards.

The /etc/crypto-policies/state/CURRENT.pol file lists all settings in the currently applied system-wide cryptographic policy after wildcard expansion. To make your cryptographic policy more strict, consider using values listed in the /usr/share/crypto-policies/policies/FUTURE.pol file.

Procedure

1. Checkout to the /etc/crypto-policies/policies/modules/ directory:

   # cd /etc/crypto-policies/policies/modules/

2. Create subpolicies for your adjustments, for example:

   # touch MYCRYPTO-1.pmod
   # touch SCOPES-AND-WILDCARDS.pmod
IMPORTANT

Use upper-case letters in file names of policy modules.

3. Open the policy modules in a text editor of your choice and insert options that modify the system-wide cryptographic policy, for example:

```bash
# vi MYCRYPTO-1.pmod

min_rsa_size = 3072
hash = SHA2-384 SHA2-512 SHA3-384 SHA3-512

# vi SCOPES-AND-WILDCARDS.pmod

# Disable the AES-128 cipher, all modes
cipher = -AES-128-*

# Disable CHACHA20-POLY1305 for the TLS protocol (OpenSSL, GnuTLS, NSS, and OpenJDK)
cipher@TLS = -CHACHA20-POLY1305

# Allow using the FFDHE-1024 group with the SSH protocol (libssh and OpenSSH)
group@SSH = FFDHE-1024+

# Disable all CBC mode ciphers for the SSH protocol (libssh and OpenSSH)
cipher@SSH = -*-CBC

# Allow the AES-256-CBC cipher in applications using libssh
cipher@libssh = AES-256-CBC+
```

4. Save the changes in the module files.

5. Apply your policy adjustments to the DEFAULT system-wide cryptographic policy level:

```bash
# update-crypto-policies --set DEFAULT:MYCRYPTO-1:SCOPES-AND-WILDCARDS
```

6. To make your cryptographic settings effective for already running services and applications, restart the system:

```bash
# reboot
```

Verification

- Check that the `/etc/crypto-policies/state/CURRENT.pol` file contains your changes, for example:

```bash
$ cat /etc/crypto-policies/state/CURRENT.pol | grep rsa_size
min_rsa_size = 3072
```

Additional resources

- Custom Policies section in the `update-crypto-policies(8)` man page
3.8. RE-ENABLING SHA-1

The use of the SHA-1 algorithm for creating and verifying signatures is restricted in the DEFAULT cryptographic policy. If your scenario requires the use of SHA-1 for verifying existing or third-party cryptographic signatures, you can enable it by applying the SHA1 subpolicy, which RHEL 9 provides by default. Note that it weakens the security of the system.

Prerequisites

- The system uses the DEFAULT system-wide cryptographic policy.

Procedure

1. Apply the SHA1 subpolicy to the DEFAULT cryptographic policy:

   ```bash
   # update-crypto-policies --set DEFAULT:SHA1
   Setting system policy to DEFAULT:SHA1
   Note: System-wide crypto policies are applied on application start-up. It is recommended to restart the system for the change of policies to fully take place.
   ```

2. Restart the system:

   ```bash
   # reboot
   ```

Verification

- Display the current cryptographic policy:

  ```bash
  # update-crypto-policies --show
  DEFAULT:SHA1
  ```

**IMPORTANT**

Switching to the LEGACY cryptographic policy by using the update-crypto-policies --set LEGACY command also enables SHA-1 for signatures. However, the LEGACY cryptographic policy makes your system much more vulnerable by also enabling other weak cryptographic algorithms. Use this workaround only for scenarios that require the enablement of other legacy cryptographic algorithms than SHA-1 signatures.

Additional resources

- SSH from RHEL 9 to RHEL 6 systems does not work  KCS article
- Packages signed with SHA-1 cannot be installed or upgraded  KCS article

3.9. CREATING AND SETTING A CUSTOM SYSTEM-WIDE CRYPTOGRAPHIC POLICY
The following steps demonstrate customizing the system-wide cryptographic policies by a complete policy file.

**Procedure**

1. Create a policy file for your customizations:
   ```
   # cd /etc/crypto-policies/policies/
   # touch MYPOLICY.pol
   ```

   Alternatively, start by copying one of the four predefined policy levels:
   ```
   # cp /usr/share/crypto-policies/policies/DEFAULT.pol /etc/crypto-policies/policies/MYPOLICY.pol
   ```

2. Edit the file with your custom cryptographic policy in a text editor of your choice to fit your requirements, for example:
   ```
   # vi /etc/crypto-policies/policies/MYPOLICY.pol
   ```

3. Switch the system-wide cryptographic policy to your custom level:
   ```
   # update-crypto-policies --set MYPOLICY
   ```

4. To make your cryptographic settings effective for already running services and applications, restart the system:
   ```
   # reboot
   ```

**Additional resources**

- **Custom Policies** section in the `update-crypto-policies(8)` man page and the **Crypto Policy Definition Format** section in the `crypto-policies(7)` man page
- **How to customize crypto policies in RHEL** Red Hat blog article
CHAPTER 4. SETTING A CUSTOM CRYPTOGRAPHIC POLICY ACROSS SYSTEMS

As an administrator, you can use the Cryptographic Policies RHEL System Role to quickly and consistently configure custom cryptographic policies across many different systems using the Ansible Core package.

4.1. CRYPTOGRAPHIC POLICIES SYSTEM ROLE VARIABLES AND FACTS

In a Cryptographic Policies System Role playbook, you can define the parameters for the crypto policies configuration file according to your preferences and limitations.

If you do not configure any variables, the System Role does not configure the system and only reports the facts.

Selected variables for the Cryptographic Policies System Role

- **crypto_policies_policy**
  - Determines the cryptographic policy the system role applies to the managed nodes. For details about the different crypto policies, see System-wide cryptographic policies.

- **crypto_policies_reload**
  - If set to **yes**, the affected services, currently the *ipsec*, *bind*, and *sshd* services, reload after applying a crypto policy. Defaults to **yes**.

- **crypto_policies_reboot_ok**
  - If set to **yes**, and a reboot is necessary after the system role changes the crypto policy, it sets **crypto_policies_reboot_required** to **yes**. Defaults to **no**.

Facts set by the Cryptographic Policies System Role

- **crypto_policies_active**
  - Lists the currently selected policy.

- **crypto_policies_available_policies**
  - Lists all available policies available on the system.

- **crypto_policies_available_subpolicies**
  - Lists all available subpolicies available on the system.

Additional resources

- Creating and setting a custom system-wide cryptographic policy.

4.2. SETTING A CUSTOM CRYPTOGRAPHIC POLICY USING THE CRYPTOGRAPHIC POLICIES SYSTEM ROLE

You can use the Cryptographic Policies System Role to configure a large number of managed nodes consistently from a single control node.

Prerequisites
- Access and permissions to one or more managed nodes, which are systems you want to configure with the Crypto Policies System Role.

- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems.

  On the control node:

  - The ansible-core and rhel-system-roles packages are installed.

**IMPORTANT**

RHEL 8.0-8.5 provided access to a separate Ansible repository that contains Ansible Engine 2.9 for automation based on Ansible. Ansible Engine contains command-line utilities such as ansible, ansible-playbook, connectors such as docker and podman, and many plugins and modules. For information on how to obtain and install Ansible Engine, see the [How to download and install Red Hat Ansible Engine](#) Knowledgebase article.

RHEL 8.6 and 9.0 have introduced Ansible Core (provided as the ansible-core package), which contains the Ansible command-line utilities, commands, and a small set of built-in Ansible plugins. RHEL provides this package through the AppStream repository, and it has a limited scope of support. For more information, see the [Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories](#) Knowledgebase article.

- An inventory file which lists the managed nodes.

**Procedure**

1. Create a new playbook.yml file with the following content:

   ```yml
   ---
   - hosts: all
     tasks:
       - name: Configure crypto policies
         include_role:
           name: rhel-system-roles.crypto_policies
         vars:
           - crypto_policies_policy: FUTURE
           - crypto_policies_reboot_ok: true
   ```

   You can replace the \textit{FUTURE} value with your preferred crypto policy, for example: DEFAULT, LEGACY, and FIPS:OSPP.

   The \texttt{crypto\_policies\_reboot\_ok: true} variable causes the system to reboot after the System Role changes the cryptographic policy.

   For more details, see [Crypto Policies System Role variables and facts](#).

2. Optional: Verify playbook syntax.

   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook on your inventory file:

   ```bash
   # ansible-playbook -i inventory_file playbook.yml
   ```
Verification

1. On the control node, create another playbook named, for example, `verify_playbook.yml`:

```
- hosts: all
  tasks:
    - name: Verify active crypto policy
      include_role:
        name: rhel-system-roles.crypto_policies
    - debug:
      var: crypto_policies_active
```

This playbook does not change any configurations on the system, only reports the active policy on the managed nodes.

2. Run the playbook on the same inventory file:

```
# ansible-playbook -i inventory_file verify_playbook.yml
```

```
TASK [debug] ***************
ok: [host] => {
    "crypto_policies_active": "FUTURE"
}
```

The "crypto_policies_active": variable shows the policy active on the managed node.

4.3. ADDITIONAL RESOURCES

- `/usr/share/ansible/roles/rhel-system-roles.crypto_policies/README.md` file.
- `ansible-playbook(1)` man page.
- `Installing RHEL System Roles`.
- `Applying a system role`.
CHAPTER 5. CONFIGURING APPLICATIONS TO USE CRYPTOGRAPHIC HARDWARE THROUGH PKCS #11

Separating parts of your secret information on dedicated cryptographic devices, such as smart cards and cryptographic tokens for end-user authentication and hardware security modules (HSM) for server applications, provides an additional layer of security. In RHEL, support for cryptographic hardware through the PKCS #11 API is consistent across different applications, and the isolation of secrets on cryptographic hardware is not a complicated task.

5.1. CRYPTOGRAPHIC HARDWARE SUPPORT THROUGH PKCS #11

PKCS #11 (Public-Key Cryptography Standard) defines an application programming interface (API) to cryptographic devices that hold cryptographic information and perform cryptographic functions. These devices are called tokens, and they can be implemented in a hardware or software form.

A PKCS #11 token can store various object types including a certificate; a data object; and a public, private, or secret key. These objects are uniquely identifiable through the PKCS #11 URI scheme.

A PKCS #11 URI is a standard way to identify a specific object in a PKCS #11 module according to the object attributes. This enables you to configure all libraries and applications with the same configuration string in the form of a URI.

RHEL provides the OpenSC PKCS #11 driver for smart cards by default. However, hardware tokens and HSMs can have their own PKCS #11 modules that do not have their counterpart in the system. You can register such PKCS #11 modules with the `p11-kit` tool, which acts as a wrapper over the registered smart-card drivers in the system.

To make your own PKCS #11 module work on the system, add a new text file to the `/etc/pkcs11/modules/` directory.

You can add your own PKCS #11 module into the system by creating a new text file in the `/etc/pkcs11/modules/` directory. For example, the OpenSC configuration file in `p11-kit` looks as follows:

```
$ cat /usr/share/p11-kit/modules/opensc.module
module: opensc-pkcs11.so
```

Additional resources:
- The PKCS #11 URI Scheme
- Controlling access to smart cards

5.2. USING SSH KEYS STORED ON A SMART CARD

Red Hat Enterprise Linux enables you to use RSA and ECDSA keys stored on a smart card on OpenSSH clients. Use this procedure to enable authentication using a smart card instead of using a password.

Prerequisites:
- On the client side, the `opensc` package is installed and the `pcscd` service is running.

Procedure
1. List all keys provided by the OpenSC PKCS #11 module including their PKCS #11 URIs and save the output to the `keys.pub` file:

   ```
   $ ssh-keygen -D pkcs11: > keys.pub
   $ ssh-keygen -D pkcs11:
   ssh-rsa AAAAB3NzaC1yc2E...KKZMzcQZzx
   pkcs11:id=%02;object=SIGN%20pubkey;token=SSH%20key;manufacturer=piv_II?module-path=/usr/lib64/pkcs11/opensc-pkcs11.so
   ecdsa-sha2-nistp256 AAA...J0hkYnnsM=
   pkcs11:id=%01;object=PIV%20AUTH%20pubkey;token=SSH%20key;manufacturer=piv_II?
   module-path=/usr/lib64/pkcs11/opensc-pkcs11.so
   ```

2. To enable authentication using a smart card on a remote server (example.com), transfer the public key to the remote server. Use the `ssh-copy-id` command with `keys.pub` created in the previous step:

   ```
   $ ssh-copy-id -f -i keys.pub username@example.com
   ```

3. To connect to example.com using the ECDSA key from the output of the `ssh-keygen -D` command in step 1, you can use just a subset of the URI, which uniquely references your key, for example:

   ```
   $ ssh -i "pkcs11:id=%01?module-path=/usr/lib64/pkcs11/opensc-pkcs11.so" example.com
   Enter PIN for 'SSH key':
   [example.com] $
   ```

4. You can use the same URI string in the `~/.ssh/config` file to make the configuration permanent:

   ```
   $ cat ~/.ssh/config
   IdentityFile "pkcs11:id=%01?module-path=/usr/lib64/pkcs11/opensc-pkcs11.so"
   $ ssh example.com
   Enter PIN for 'SSH key':
   [example.com] $
   ```

   Because OpenSSH uses the `p11-kit-proxy` wrapper and the OpenSC PKCS #11 module is registered to PKCS#11 Kit, you can simplify the previous commands:

   ```
   $ ssh -i "pkcs11:id=%01" example.com
   Enter PIN for 'SSH key':
   [example.com] $
   ```

   If you skip the `id=` part of a PKCS #11 URI, OpenSSH loads all keys that are available in the proxy module. This can reduce the amount of typing required:

   ```
   $ ssh -i pkcs11: example.com
   Enter PIN for 'SSH key':
   [example.com] $
   ```

**Additional resources**

- [Fedora 28: Better smart card support in OpenSSH](http://example.com)
- [p11-kit(8), opensc.conf(5), pcscd(8), ssh(1), and ssh-keygen(1) man pages](http://example.com)
5.3. CONFIGURING APPLICATIONS TO AUTHENTICATE USING CERTIFICATES FROM SMART CARDS

Authentication using smart cards in applications may increase security and simplify automation.

- The **wget** network downloader enables you to specify PKCS #11 URIs instead of paths to locally stored private keys, and thus simplifies creating scripts for tasks that require safely stored private keys and certificates. For example:

```bash
$ wget --private-key 'pkcs11:token=softhsm;id=%01;type=private?pin-value=111111' --certificate 'pkcs11:token=softhsm;id=%01;type=cert' https://example.com/
```

See the **wget(1)** man page for more information.

- Specifying PKCS #11 URI for use by the **curl** tool is analogous:

```bash
$ curl --key 'pkcs11:token=softhsm;id=%01;type=private?pin-value=111111' --cert 'pkcs11:token=softhsm;id=%01;type=cert' https://example.com/
```

See the **curl(1)** man page for more information.

**NOTE**
Because a PIN is a security measure that controls access to keys stored on a smart card and the configuration file contains the PIN in the plain-text form, consider additional protection to prevent an attacker from reading the PIN. For example, you can use the **pin-source** attribute and provide a **file**: URI for reading the PIN from a file. See RFC 7512: PKCS #11 URI Scheme Query Attribute Semantics for more information. Note that using a command path as a value of the **pin-source** attribute is not supported.

- The **Firefox** web browser automatically loads the **p11-kit-proxy** module. This means that every supported smart card in the system is automatically detected. For using TLS client authentication, no additional setup is required and keys from a smart card are automatically used when a server requests them.

Using PKCS #11 URLs in custom applications

If your application uses the **GnuTLS** or **NSS** library, support for PKCS #11 URIs is ensured by their built-in support for PKCS #11. Also, applications relying on the **OpenSSL** library can access cryptographic hardware modules thanks to the **openssl-pkcs11** engine.

With applications that require working with private keys on smart cards and that do not use **NSS**, **GnuTLS**, and **OpenSSL**, use **p11-kit** to implement registering PKCS #11 modules.

**Additional resources**

- **p11-kit(8)** man page.

5.4. USING HSMS PROTECTING PRIVATE KEYS IN APACHE

The **Apache** HTTP server can work with private keys stored on hardware security modules (HSMs), which helps to prevent the keys’ disclosure and man-in-the-middle attacks. Note that this usually requires high-performance HSMs for busy servers.
For secure communication in the form of the HTTPS protocol, the Apache HTTP server (httpd) uses the OpenSSL library. OpenSSL does not support PKCS #11 natively. To use HSMs, you have to install the openssl-pkcs11 package, which provides access to PKCS #11 modules through the engine interface. You can use a PKCS #11 URI instead of a regular file name to specify a server key and a certificate in the /etc/httpd/conf.d/ssl.conf configuration file, for example:

```
SSLCertificateFile    "pkcs11:id=%01;token=softhsm;type=cert"
SSLCertificateKeyFile "pkcs11:id=%01;token=softhsm;type=private?pin-value=111111"
```

Install the httpd-manual package to obtain complete documentation for the Apache HTTP Server, including TLS configuration. The directives available in the /etc/httpd/conf.d/ssl.conf configuration file are described in detail in the /usr/share/httpd/manual/mod/mod_ssl.html file.

### 5.5. USING HSMS PROTECTING PRIVATE KEYS IN NGINX

The Nginx HTTP server can work with private keys stored on hardware security modules (HSMs), which helps to prevent the keys' disclosure and man-in-the-middle attacks. Note that this usually requires high-performance HSMs for busy servers.

Because Nginx also uses the OpenSSL for cryptographic operations, support for PKCS #11 must go through the openssl-pkcs11 engine. Nginx currently supports only loading private keys from an HSM, and a certificate must be provided separately as a regular file. Modify the `ssl_certificate` and `ssl_certificate_key` options in the `server` section of the /etc/nginx/nginx.conf configuration file:

```
ssl_certificate     /path/to/cert.pem
ssl_certificate_key "engine:pkcs11:pkcs11:token=softhsm:id=%01:type=private?pin-value=111111";
```

Note that the `engine:pkcs11:` prefix is needed for the PKCS #11 URI in the Nginx configuration file. This is because the other `pkcs11` prefix refers to the engine name.

### 5.6. ADDITIONAL RESOURCES

- `pkcs11.conf(5)` man page.
CHAPTER 6. CONTROLLING ACCESS TO SMART CARDS USING POLKIT

To cover possible threats that cannot be prevented by mechanisms built into smart cards, such as PINs, PIN pads, and biometrics, and for more fine-grained control, RHEL uses the polkit framework for controlling access control to smart cards.

System administrators can configure polkit to fit specific scenarios, such as smart-card access for non-privileged or non-local users or services.

6.1. SMART-CARD ACCESS CONTROL THROUGH POLKIT

The Personal Computer/Smart Card (PC/SC) protocol specifies a standard for integrating smart cards and their readers into computing systems. In RHEL, the pcsc-lite package provides middleware to access smart cards that use the PC/SC API. A part of this package, the pcscd (PC/SC Smart Card) daemon, ensures that the system can access a smart card using the PC/SC protocol.

Because access-control mechanisms built into smart cards, such as PINs, PIN pads, and biometrics, do not cover all possible threats, RHEL uses the polkit framework for more robust access control. The polkit authorization manager can grant access to privileged operations. In addition to granting access to disks, you can use polkit also to specify policies for securing smart cards. For example, you can define which users can perform which operations with a smart card.

After installing the pcsc-lite package and starting the pcscd daemon, the system enforces policies defined in the /usr/share/polkit-1/actions/ directory. The default system-wide policy is in the /usr/share/polkit-1/actions/org.debian.pcsc-lite.policy file. Polkit policy files use the XML format and the syntax is described in the polkit(8) man page.

The polkitd service monitors the /etc/polkit-1/rules.d/ and /usr/share/polkit-1/rules.d/ directories for any changes in rule files stored in these directories. The files contain authorization rules in JavaScript format. System administrators can add custom rule files in both directories, and polkitd reads them in lexical order based on their file name. If two files have the same names, then the file in /etc/polkit-1/rules.d/ is read first.

Additional resources

- polkit(8), polkitd(8), and pcscd(8) man pages.

6.2. TROUBLESHOOTING PROBLEMS RELATED TO PC/SC AND POLKIT

Polkit policies that are automatically enforced after you install the pcsc-lite package and start the pcscd daemon may ask for authentication in the user’s session even if the user does not directly interact with a smart card. In GNOME, you can see the following error message:

```
Authentication is required to access the PC/SC daemon
```

Note that the system can install the pcsc-lite package as a dependency when you install other packages related to smart cards such as opensc.

If your scenario does not require any interaction with smart cards and you want to prevent displaying authorization requests for the PC/SC daemon, you can remove the pcsc-lite package. Keeping the minimum of necessary packages is a good security practice anyway.
If you use smart cards, start troubleshooting by checking the rules in the system-provided policy file at
`/usr/share/polkit-1/actions/org.debian.pcsc-lite.policy`. You can add your custom rule files to the
policy in the `/etc/polkit-1/rules.d/` directory, for example, `03-allow-pcscd.rules`. Note that the rule files
use the JavaScript syntax, the policy file is in the XML format.

To understand what authorization requests the system displays, check the Journal log, for example:

```bash
$ journalctl -b | grep pcsc
... Process 3087 (user: 1001) is NOT authorized for action: access_pcsc
...
```

The previous log entry means that the user is not authorized to perform an action by the policy. You can
solve this denial by adding a corresponding rule to `/etc/polkit-1/rules.d/`.

You can search also for log entries related to the `polkitd` unit, for example:

```bash
$ journalctl -u polkit
... polkitd[NNN]: Error compiling script /etc/polkit-1/rules.d/00-debug-pcscd.rules
... polkitd[NNN]: Operator of unix-session:c2 FAILED to authenticate to gain authorization for action
org.debian.pcsc-lite.access_pcsc for unix-process:4800:14441 [/usr/libexec/gsd-smartcard] (owned
by unix-user:group)
... 
```

In the previous output, the first entry means that the rule file contains some syntax error. The second
entry means that the user failed to gain the access to `pcscd`.

You can also list all applications that use the PC/SC protocol by a short script. Create an executable file,
for example, `pcsc-apps.sh`, and insert the following code:

```bash
#!/bin/bash

cd /proc
for p in [0-9]*
do if grep libpcsclite.so.1.0.0 $p/maps &> /dev/null then
  echo -n "process: "
cat $p/cmdline
  echo " ($p)"
fi
done
```

Run the script as `root`:

```bash
# ./pcsc-apps.sh
process: /usr/libexec/gsd-smartcard (3048)
enable-sync --auto-ssl-client-auth --enable-crashpad (4828)
...
```

Additional resources
6.3. DISPLAYING MORE DETAILED INFORMATION ABOUT POLKIT AUTHORIZATION TO PC/SC

In the default configuration, the `polkit` authorization framework sends only limited information to the Journal log. You can extend `polkit` log entries related to the PC/SC protocol by adding new rules.

**Prerequisites**

- You have installed the `pcsc-lite` package on your system.
- The `pcscd` daemon is running.

**Procedure**

1. Create a new file in the `/etc/polkit-1/rules.d/` directory:
   
   ```
   # touch /etc/polkit-1/rules.d/00-test.rules
   ```

2. Edit the file in an editor of your choice, for example:
   
   ```
   # vi /etc/polkit-1/rules.d/00-test.rules
   ```

3. Insert the following lines:
   
   ```javascript
   polkit.addRule(function(action, subject) {
   if (action.id == "org.debian.pcsc-lite.access_pcsc" ||
   action.id == "org.debian.pcsc-lite.access_card") {
   polkit.log("action=\" + action);
   polkit.log("subject=\" + subject);
   }
   });
   ```

   Save the file, and exit the editor.

4. Restart the `pcscd` and `polkit` services:
   
   ```
   # systemctl restart pcscd.service pcscd.socket polkit.service
   ```

**Verification**

1. Make an authorization request for `pcscd`. For example, open the Firefox web browser or use the `pkcs11-tool -L` command provided by the `opensc` package.

2. Display the extended log entries, for example:
   
   ```
   # journalctl -u polkit --since "1 hour ago"
   polkitd[1224]: <no filename>:4: action="[Action id=org.debian.pcsc-lite.access_pcsc"
   polkitd[1224]: <no filename>:5: subject=[Subject pid=2020481 user=user'
   groups=user,wheel,mock,wireshark seat=null session=null local=true active=true]
Additional resources

- polkit(8) and polkitd(8) man pages.

6.4. ADDITIONAL RESOURCES

- Controlling access to smart cards Red Hat Blog article.
CHAPTER 7. USING SHARED SYSTEM CERTIFICATES

The shared system certificates storage enables NSS, GnuTLS, OpenSSL, and Java to share a default source for retrieving system certificate anchors and block-list information. By default, the trust store contains the Mozilla CA list, including positive and negative trust. The system allows updating the core Mozilla CA list or choosing another certificate list.

7.1. THE SYSTEM-WIDE TRUST STORE

In Red Hat Enterprise Linux, the consolidated system-wide trust store is located in the /etc/pki/ca-trust/ and /usr/share/pki/ca-trust-source/ directories. The trust settings in /usr/share/pki/ca-trust-source/ are processed with lower priority than settings in /etc/pki/ca-trust/.

Certificate files are treated depending on the subdirectory they are installed to the following directories:

- for trust anchors
  - /usr/share/pki/ca-trust-source/anchors/ or /etc/pki/ca-trust/source/anchors/
- for distrusted certificates
  - /usr/share/pki/ca-trust-source/blacklist/ or /etc/pki/ca-trust/source/blacklist/
- for certificates in the extended BEGIN TRUSTED file format
  - /usr/share/pki/ca-trust-source/ or /etc/pki/ca-trust/source/

**NOTE**

In a hierarchical cryptographic system, a trust anchor is an authoritative entity which other parties consider being trustworthy. In the X.509 architecture, a root certificate is a trust anchor from which a chain of trust is derived. To enable chain validation, the trusting party must have access to the trust anchor first.

7.2. ADDING NEW CERTIFICATES

To acknowledge applications on your system with a new source of trust, add the corresponding certificate to the system-wide store, and use the `update-ca-trust` command.

**Prerequisites**

- The ca-certificates package is present on the system.

**Procedure**

1. To add a certificate in the simple PEM or DER file formats to the list of CAs trusted on the system, copy the certificate file to the /usr/share/pki/ca-trust-source/anchors/ or /etc/pki/ca-trust/source/anchors/ directory, for example:
# cp ~/certificate-trust-examples/Cert-trust-test-ca.pem/usr/share/pki/ca-trust-source/anchors/

2. To update the system-wide trust store configuration, use the `update-ca-trust` command:

```bash
# update-ca-trust
```

**NOTE**

While the Firefox browser is able to use an added certificate without executing `update-ca-trust`, Red Hat recommends to use the `update-ca-trust` command after a CA change. Also note that browsers, such as Firefox, Epiphany, or Chromium, cache files, and you might have to clear browser’s cache or restart your browser to load the current system certificates configuration.

### 7.3. MANAGING TRUSTED SYSTEM CERTIFICATES

The `trust` command provides a convenient way for managing certificates in the shared system-wide trust store.

- To list, extract, add, remove, or change trust anchors, use the `trust` command. To see the built-in help for this command, enter it without any arguments or with the `--help` directive:

```bash
$ trust
usage: trust command <args>...

Common trust commands are:
  list     List trust or certificates
  extract  Extract certificates and trust
  extract-compat Extract trust compatibility bundles
  anchor   Add, remove, change trust anchors
  dump     Dump trust objects in internal format

See 'trust <command> --help' for more information
```

- To list all system trust anchors and certificates, use the `trust list` command:

```bash
$ trust list
pkcs11:id=%d2%87%b4%e3%df%37%27%93%55%f6%56%ea%81%e5%36%cc%8c%1e%3f%bd;type=cert
type: certificate
label: ACCVRAIZ1
trust: anchor
category: authority

pkcs11:id=%a6%b3%e1%2b%2b%49%b6%d7%73%a1%aa%94%f5%01%e7%73%65%4c%ac%50;type=cert
type: certificate
label: ACEDICOM Root
trust: anchor
category: authority
...
To store a trust anchor into the system-wide trust store, use the trust anchor sub-command and specify a path to a certificate. Replace path.to/certificate.crt by a path to your certificate and its file name:

```
# trust anchor path.to/certificate.crt
```

To remove a certificate, use either a path to a certificate or an ID of a certificate:

```
# trust anchor --remove path.to/certificate.crt
# trust anchor --remove "pkcs11:id=%AA%BB%CC%DD%EE;type=cert"
```

Additional resources

- All sub-commands of the trust commands offer a detailed built-in help, for example:

```
$ trust list --help
usage: trust list --filter=<what>

--filter=<what>    filter of what to export
    ca-anchors    certificate anchors
...                 ...
--purpose=<usage>  limit to certificates usable for the purpose
    server-auth    for authenticating servers
...                 ...
```

7.4. ADDITIONAL RESOURCES

- update-ca-trust(8) and trust(1) man pages
CHAPTER 8. SCANNING THE SYSTEM FOR CONFIGURATION COMPLIANCE AND VULNERABILITIES

A compliance audit is a process of determining whether a given object follows all the rules specified in a compliance policy. The compliance policy is defined by security professionals who specify the required settings, often in the form of a checklist, that a computing environment should use.

Compliance policies can vary substantially across organizations and even across different systems within the same organization. Differences among these policies are based on the purpose of each system and its importance for the organization. Custom software settings and deployment characteristics also raise a need for custom policy checklists.

8.1. CONFIGURATION COMPLIANCE TOOLS IN RHEL

Red Hat Enterprise Linux provides tools that enable you to perform a fully automated compliance audit. These tools are based on the Security Content Automation Protocol (SCAP) standard and are designed for automated tailoring of compliance policies.

- **SCAP Workbench** - The `scap-workbench` graphical utility is designed to perform configuration and vulnerability scans on a single local or remote system. You can also use it to generate security reports based on these scans and evaluations.

- **OpenSCAP** - The `OpenSCAP` library, with the accompanying `oscap` command-line utility, is designed to perform configuration and vulnerability scans on a local system, to validate configuration compliance content, and to generate reports and guides based on these scans and evaluations.

- **SCAP Security Guide (SSG)** - The `scap-security-guide` package provides the latest collection of security policies for Linux systems. The guidance consists of a catalog of practical hardening advice, linked to government requirements where applicable. The project bridges the gap between generalized policy requirements and specific implementation guidelines.

- **Script Check Engine (SCE)** - SCE is an extension to the SCAP protocol that enables administrators to write their security content using a scripting language, such as Bash, Python, and Ruby. The SCE extension is provided in the `openscap-engine-sce` package. The SCE itself is not part of the SCAP standard.

To perform automated compliance audits on multiple systems remotely, you can use the OpenSCAP solution for Red Hat Satellite.

Additional resources

8.2. VULNERABILITY SCANNING

8.2.1. Red Hat Security Advisories OVAL feed
Red Hat Enterprise Linux security auditing capabilities are based on the Security Content Automation Protocol (SCAP) standard. SCAP is a multi-purpose framework of specifications that supports automated configuration, vulnerability and patch checking, technical control compliance activities, and security measurement.

SCAP specifications create an ecosystem where the format of security content is well-known and standardized although the implementation of the scanner or policy editor is not mandated. This enables organizations to build their security policy (SCAP content) once, no matter how many security vendors they employ.

The Open Vulnerability Assessment Language (OVAL) is the essential and oldest component of SCAP. Unlike other tools and custom scripts, OVAL describes a required state of resources in a declarative manner. OVAL code is never executed directly but using an OVAL interpreter tool called scanner. The declarative nature of OVAL ensures that the state of the assessed system is not accidentally modified.

Like all other SCAP components, OVAL is based on XML. The SCAP standard defines several document formats. Each of them includes a different kind of information and serves a different purpose.

Because of differences between platforms, versions, and other factors, Red Hat Product Security qualitative severity ratings of vulnerabilities do not directly align with the Common Vulnerability Scoring System (CVSS) baseline ratings provided by third parties. Therefore, we recommend that you use the RHSA OVAL definitions instead of those provided by third parties.

The RHSA OVAL definitions are available individually and as a complete package, and are updated within an hour of a new security advisory being made available on the Red Hat Customer Portal.

Each OVAL patch definition maps one-to-one to a Red Hat Security Advisory (RHSA). Because an RHSA can contain fixes for multiple vulnerabilities, each vulnerability is listed separately by its Common Vulnerabilities and Exposures (CVE) name and has a link to its entry in our public bug database.

The RHSA OVAL definitions are designed to check for vulnerable versions of RPM packages installed on a system. It is possible to extend these definitions to include further checks, for example, to find out if the packages are being used in a vulnerable configuration. These definitions are designed to cover software and updates shipped by Red Hat. Additional definitions are required to detect the patch status of third-party software.

NOTE

The Red Hat Insights for Red Hat Enterprise Linux compliance service helps IT security and compliance administrators to assess, monitor, and report on the security policy compliance of Red Hat Enterprise Linux systems. You can also create and manage your SCAP security policies entirely within the compliance service UI.

Additional resources

- Red Hat and OVAL compatibility
- Red Hat and CVE compatibility
- Notifications and Advisories in the Product Security Overview
8.2.2. Scanning the system for vulnerabilities

The oscap command-line utility enables you to scan local systems, validate configuration compliance content, and generate reports and guides based on these scans and evaluations. This utility serves as a front end to the OpenSCAP library and groups its functionalities to modules (sub-commands) based on the type of SCAP content it processes.

Prerequisites

- The openscap-scanner and bzip2 packages are installed.

Procedure

1. Download the latest RHSA OVAL definitions for your system:
   
   ```
   ```

2. Scan the system for vulnerabilities and save results to the vulnerability.html file:
   
   ```
   # oscap oval eval --report vulnerability.html rhel-9.oval.xml
   ```

Verification

- Check the results in a browser of your choice, for example:

  ```
  $ firefox vulnerability.html &
  ```

Additional resources

- oscap(8) man page
- Red Hat OVAL definitions

8.2.3. Scanning remote systems for vulnerabilities

You can check also remote systems for vulnerabilities with the OpenSCAP scanner using the oscap-ssh tool over the SSH protocol.

Prerequisites

- The openscap-utils and bzip2 packages are installed on the system you use for scanning.
- The openscap-scanner package is installed on the remote systems.
- The SSH server is running on the remote systems.

Procedure

1. Download the latest RHSA OVAL definitions for your system:
2. Scan a remote system with the `machine1` host name, SSH running on port 22, and the `joesec` user name for vulnerabilities and save results to the `remote-vulnerability.html` file:

```
# oscap-ssh joesec@machine1 22 oval eval --report remote-vulnerability.html rhel-9.oval.xml
```

**Additional resources**

- `oscap-ssh(8)`
- `Red Hat OVAL definitions`

### 8.3. CONFIGURATION COMPLIANCE SCANNING

#### 8.3.1. Configuration compliance in RHEL

You can use configuration compliance scanning to conform to a baseline defined by a specific organization. For example, if you work with the US government, you might have to align your systems with the Operating System Protection Profile (OSPP), and if you are a payment processor, you might have to align your systems with the Payment Card Industry Data Security Standard (PCI-DSS). You can also perform configuration compliance scanning to harden your system security.

Red Hat recommends you follow the Security Content Automation Protocol (SCAP) content provided in the SCAP Security Guide package because it is in line with Red Hat best practices for affected components.

The SCAP Security Guide package provides content which conforms to the SCAP 1.2 and SCAP 1.3 standards. The `openscap scanner` utility is compatible with both SCAP 1.2 and SCAP 1.3 content provided in the SCAP Security Guide package.

**IMPORTANT**

Performing a configuration compliance scanning does not guarantee the system is compliant.

The SCAP Security Guide suite provides profiles for several platforms in a form of data stream documents. A data stream is a file that contains definitions, benchmarks, profiles, and individual rules. Each rule specifies the applicability and requirements for compliance. RHEL provides several profiles for compliance with security policies. In addition to the industry standard, Red Hat data streams also contain information for remediation of failed rules.

**Structure of compliance scanning resources**

```
Data stream
├── xccdf
│   ├── benchmark
│   │   └── profile
│   │       └── rule reference
│   │           └── variable
│   └── rule
│       └── human readable data
```
A profile is a set of rules based on a security policy, such as OSPP, PCI-DSS, and Health Insurance Portability and Accountability Act (HIPAA). This enables you to audit the system in an automated way for compliance with security standards.

You can modify (tailor) a profile to customize certain rules, for example, password length. For more information on profile tailoring, see Customizing a security profile with SCAP Workbench.

### 8.3.2. Possible results of an OpenSCAP scan

Depending on various properties of your system and the data stream and profile applied to an OpenSCAP scan, each rule may produce a specific result. This is a list of possible results with brief explanations of what they mean.

<table>
<thead>
<tr>
<th>Result</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pass</td>
<td>The scan did not find any conflicts with this rule.</td>
</tr>
<tr>
<td>Fail</td>
<td>The scan found a conflict with this rule.</td>
</tr>
<tr>
<td>Not checked</td>
<td>OpenSCAP does not perform an automatic evaluation of this rule. Check whether your system conforms to this rule manually.</td>
</tr>
<tr>
<td>Not applicable</td>
<td>This rule does not apply to the current configuration.</td>
</tr>
<tr>
<td>Not selected</td>
<td>This rule is not part of the profile. OpenSCAP does not evaluate this rule and does not display these rules in the results.</td>
</tr>
<tr>
<td>Error</td>
<td>The scan encountered an error. For additional information, you can enter the oscap command with the <code>--verbose DEVEL</code> option. Consider opening a bug report.</td>
</tr>
<tr>
<td>Unknown</td>
<td>The scan encountered an unexpected situation. For additional information, you can enter the oscap command with the <code>--verbose DEVEL</code> option. Consider opening a bug report.</td>
</tr>
</tbody>
</table>

### 8.3.3. Viewing profiles for configuration compliance

Before you decide to use profiles for scanning or remediation, you can list them and check their detailed descriptions using the oscap info sub-command.
Prerequisites

- The openscap-scanner and scap-security-guide packages are installed.

Procedure

1. List all available files with security compliance profiles provided by the SCAP Security Guide project:

   ```
   $ ls /usr/share/xml/scap/ssg/content/
   ssg-rhel9-ds.xml
   ```

2. Display detailed information about a selected data stream using the oscap info sub-command. XML files containing data streams are indicated by the `-ds` string in their names. In the Profiles section, you can find a list of available profiles and their IDs:

   ```
   $ oscap info /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   Profiles:
   ...
   Title: Australian Cyber Security Centre (ACSC) Essential Eight
   Id: xccdf_org.ssgproject.content_profile_e8
   Title: Health Insurance Portability and Accountability Act (HIPAA)
   Id: xccdf_org.ssgproject.content_profile_hipaa
   Title: PCI-DSS v3.2.1 Control Baseline for Red Hat Enterprise Linux 9
   Id: xccdf_org.ssgproject.content_profile_pci-dss
   ...
   ```

3. Select a profile from the data-stream file and display additional details about the selected profile. To do so, use oscap info with the `--profile` option followed by the last section of the ID displayed in the output of the previous command. For example, the ID of the HIPPA profile is: `xccdf_org.ssgproject.content_profile_hipaa`, and the value for the `--profile` option is `hipaa`:

   ```
   $ oscap info --profile hipaa /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ...
   Profile
   Title: [RHEL9 DRAFT] Health Insurance Portability and Accountability Act (HIPAA)
   Id: xccdf_org.ssgproject.content_profile_hipaa
   Description: The HIPAA Security Rule establishes U.S. national standards to protect individuals' electronic personal health information that is created, received, used, or maintained by a covered entity. The Security Rule requires appropriate administrative, physical and technical safeguards to ensure the confidentiality, integrity, and security of electronic protected health information. This profile configures Red Hat Enterprise Linux 9 to the HIPAA Security Rule identified for securing of electronic protected health information. Use of this profile in no way guarantees or makes claims against legal compliance against the HIPAA Security Rule(s).
   ```

Additional resources

- scap-security-guide(8) man page

8.3.4. Assessing configuration compliance with a specific baseline

To determine whether your system conforms to a specific baseline, follow these steps.
Prerequisites

- The `openscap-scanner` and `scap-security-guide` packages are installed
- You know the ID of the profile within the baseline with which the system should comply. To find the ID, see Viewing Profiles for Configuration Compliance.

Procedure

1. Evaluate the compliance of the system with the selected profile and save the scan results in the `report.html` HTML file, for example:

   ```
   $ oscap xccdf eval --report report.html --profile hipaa /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ```

2. Optional: Scan a remote system with the `machine1` host name, SSH running on port 22, and the `joesec` user name for compliance and save results to the `remote-report.html` file:

   ```
   $ oscap-ssh joesec@machine1 22 xccdf eval --report remote_report.html --profile hipaa /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ```

Additional resources

- `scap-security-guide(8)` man page

8.4. REMEDIATING THE SYSTEM TO ALIGN WITH A SPECIFIC BASELINE

Use this procedure to remediate the RHEL system to align with a specific baseline. This example uses the Health Insurance Portability and Accountability Act (HIPAA) profile.

**WARNING**

If not used carefully, running the system evaluation with the Remediate option enabled might render the system non-functional. Red Hat does not provide any automated method to revert changes made by security-hardening remediations. Remediations are supported on RHEL systems in the default configuration. If your system has been altered after the installation, running remediation might not make it compliant with the required security profile.

Prerequisites

- The `scap-security-guide` package is installed on your RHEL system.
Procedure

1. Use the oscap command with the --remediate option:

   ```
   # oscap xccdf eval --profile hipaa --remediate /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ```

2. Restart your system.

Verification

1. Evaluate compliance of the system with the HIPAA profile, and save scan results in the hipaa_report.html file:

   ```
   $ oscap xccdf eval --report hipaa_report.html --profile hipaa /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ```

Additional resources

- scap-security-guide(8) and oscap(8) man pages

8.5. REMEDIATING THE SYSTEM TO ALIGN WITH A SPECIFIC BASELINE USING AN SSG ANSIBLE PLAYBOOK

Use this procedure to remediate your system with a specific baseline using an Ansible playbook file from the SCAP Security Guide project. This example uses the Health Insurance Portability and Accountability Act (HIPAA) profile.

WARNING

If not used carefully, running the system evaluation with the Remediate option enabled might render the system non-functional. Red Hat does not provide any automated method to revert changes made by security-hardening remediations. Remediations are supported on RHEL systems in the default configuration. If your system has been altered after the installation, running remediation might not make it compliant with the required security profile.

Prerequisites

- The scap-security-guide package is installed.
- The ansible-core package is installed. See the Ansible Installation Guide for more information.
NOTE

In RHEL 8.6 and later versions, Ansible Engine is replaced by the `ansible-core` package, which contains only built-in modules. Note that many Ansible remediations use modules from the community and Portable Operating System Interface (POSIX) collections, which are not included in the built-in modules. In this case, you can use Bash remediations as a substitute to Ansible remediations. The Red Hat Connector in RHEL 9 includes the necessary Ansible modules to enable the remediation playbooks to function with Ansible Core.

Procedure

1. Remediate your system to align with HIPAA using Ansible:

   ```
   # ansible-playbook -i localhost, -c local /usr/share/scap-security-guide/ansible/rhel9-playbook-hipaa.yml
   ```

2. Restart the system.

Verification

1. Evaluate compliance of the system with the HIPAA profile, and save scan results in the `hipaa_report.html` file:

   ```
   # oscap xccdf eval --profile hipaa --report hipaa_report.html /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ```

Additional resources

- `scap-security-guide(8)` and `oscap(8)` man pages
- Ansible Documentation

8.6. CREATING A REMEDIATION ANSIBLE PLAYBOOK TO ALIGN THE SYSTEM WITH A SPECIFIC BASELINE

You can create an Ansible playbook containing only the remediations that are required to align your system with a specific baseline. This example uses the Health Insurance Portability and Accountability Act (HIPAA) profile. With this procedure, you create a smaller playbook that does not cover already satisfied requirements. By following these steps, you do not modify your system in any way, you only prepare a file for later application.

NOTE

In RHEL 9, Ansible Engine is replaced by the `ansible-core` package, which contains only built-in modules. Note that many Ansible remediations use modules from the community and Portable Operating System Interface (POSIX) collections, which are not included in the built-in modules. In this case, you can use Bash remediations as a substitute for Ansible remediations. The Red Hat Connector in RHEL 9.0 includes the necessary Ansible modules to enable the remediation playbooks to function with Ansible Core.

Prerequisites
- The **scap-security-guide** package is installed.

**Procedure**

1. Scan the system and save the results:

   ```bash
   # oscap xccdf eval --profile hipaa --results hipaa-results.xml
   /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ```

2. Generate an Ansible playbook based on the file generated in the previous step:

   ```bash
   # oscap xccdf generate fix --fix-type ansible --profile hipaa --output hipaa-remediations.yml
   hipaa-results.xml
   ```

3. The **hipaa-remediations.yml** file contains Ansible remediations for rules that failed during the scan performed in step 1. After reviewing this generated file, you can apply it with the **ansible-playbook** `hipaa-remediations.yml` command.

**Verification**

- In a text editor of your choice, review that the **hipaa-remediations.yml** file contains rules that failed in the scan performed in step 1.

**Additional resources**

- **scap-security-guide(8)** and **oscap(8)** man pages
- **Ansible Documentation**

### 8.7. CREATING A REMEDIATION BASH SCRIPT FOR A LATER APPLICATION

Use this procedure to create a Bash script containing remediations that align your system with a security profile such as HIPAA. Using the following steps, you do not do any modifications to your system, you only prepare a file for later application.

**Prerequisites**

- The **scap-security-guide** package is installed on your RHEL system.

**Procedure**

1. Use the **oscap** command to scan the system and to save the results to an XML file. In the following example, **oscap** evaluates the system against the **hipaa** profile:

   ```bash
   # oscap xccdf eval --profile hipaa --results hipaa-results.xml
   /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ```

2. Generate a Bash script based on the results file generated in the previous step:

   ```bash
   # oscap xccdf generate fix --profile hipaa --fix-type bash --output hipaa-remediations.sh
   hipaa-results.xml
   ```
3. The **hipaa-remediations.sh** file contains remediations for rules that failed during the scan performed in step 1. After reviewing this generated file, you can apply it with the ./hipaa-remediations.sh command when you are in the same directory as this file.

**Verification**

- In a text editor of your choice, review that the **hipaa-remediations.sh** file contains rules that failed in the scan performed in step 1.

**Additional resources**

- scap-security-guide(8), oscap(8), and bash(1) man pages

### 8.8. SCANNING THE SYSTEM WITH A CUSTOMIZED PROFILE USING SCAP WORKBENCH

**SCAP Workbench**, which is contained in the **scap-workbench** package, is a graphical utility that enables users to perform configuration and vulnerability scans on a single local or a remote system, perform remediation of the system, and generate reports based on scan evaluations. Note that **SCAP Workbench** has limited functionality compared with the oscap command-line utility. **SCAP Workbench** processes security content in the form of data-stream files.

**8.8.1. Using SCAP Workbench to scan and remediate the system**

To evaluate your system against the selected security policy, use the following procedure.

**Prerequisites**

- The **scap-workbench** package is installed on your system.

**Procedure**

1. To run **SCAP Workbench** from the **GNOME Classic** desktop environment, press the **Super** key to enter the Activities Overview, type **scap-workbench**, and then press **Enter**. Alternatively, use:

   ```
   $ scap-workbench &
   ```

2. Select a security policy using either of the following options:

   - **Load Content** button on the starting window
   - **Open content from SCAP Security Guide**
   - **Open Other Content** in the **File** menu, and search the respective XCCDF, SCAP RPM, or data stream file.
3. You can allow automatic correction of the system configuration by selecting the **Remediate** check box. With this option enabled, **SCAP Workbench** attempts to change the system configuration in accordance with the security rules applied by the policy. This process should fix the related checks that fail during the system scan.

![SCAP Security Guide interface](image)

**WARNING**

If not used carefully, running the system evaluation with the **Remediate** option enabled might render the system non-functional. Red Hat does not provide any automated method to revert changes made by security-hardening remediations. Remediations are supported on RHEL systems in the default configuration. If your system has been altered after the installation, running remediation might not make it compliant with the required security profile.

4. Scan your system with the selected profile by clicking the **Scan** button.
5. To store the scan results in form of an XCCDF, ARF, or HTML file, click the **Save Results** combo box. Choose the **HTML Report** option to generate the scan report in human-readable format. The XCCDF and ARF (data stream) formats are suitable for further automatic processing. You can repeatedly choose all three options.

6. To export results-based remediations to a file, use the **Generate remediation role** pop-up menu.

### 8.8.2. Customizing a security profile with SCAP Workbench

You can customize a security profile by changing parameters in certain rules (for example, minimum password length), removing rules that you cover in a different way, and selecting additional rules, to implement internal policies. You cannot define new rules by customizing a profile.

The following procedure demonstrates the use of **SCAP Workbench** for customizing (tailoring) a profile. You can also save the tailored profile for use with the **oscap** command-line utility.

**Prerequisites**

- The **scap-workbench** package is installed on your system.

**Procedure**
1. Run SCAP Workbench, and select the profile to customize by using either Open content from SCAP Security Guide or Open Other Content in the File menu.

2. To adjust the selected security profile according to your needs, click the Customize button. This opens the new Customization window that enables you to modify the currently selected profile without changing the original data stream file. Choose a new profile ID.

   ![Customize Profile](image)

   **Warning:** Choose it wisely. It cannot be changed later and may be required if you choose to use command line tools or various integrations of OpenSCAP.

   The ID has to have a format of "xccdf_{reverse DNS}_profile_{rest of the ID}." For example "xccdf_org.mycorporation_profile_server".

   **New Profile ID:** xccdf_org.ssgproject.content_profile_ospp_customized

3. Find a rule to modify using either the tree structure with rules organized into logical groups or the Search field.

4. Include or exclude rules using check boxes in the tree structure, or modify values in rules where applicable.

5. Confirm the changes by clicking the OK button.

6. To store your changes permanently, use one of the following options:
   - Save a customization file separately by using Save Customization Only in the File menu.
• Save all security content at once by **Save All** in the **File** menu. If you select the **Into a directory** option, **SCAP Workbench** saves both the data stream file and the customization file to the specified location. You can use this as a backup solution.

By selecting the **As RPM** option, you can instruct **SCAP Workbench** to create an RPM package containing the data stream file and the customization file. This is useful for distributing the security content to systems that cannot be scanned remotely, and for delivering the content for further processing.

**NOTE**

Because **SCAP Workbench** does not support results-based remediations for tailored profiles, use the exported remediations with the **oscap** command-line utility.

### 8.8.3. Additional resources

- **scap-workbench**(8) man page
- */usr/share/doc/scap-workbench/user_manual.html* file provided by the **scap-workbench** package
- Deploy customized SCAP policies with Satellite 6.x  KCS article

### 8.9. DEPLOYING SYSTEMS THAT ARE COMPLIANT WITH A SECURITY PROFILE IMMEDIATELY AFTER AN INSTALLATION

You can use the OpenSCAP suite to deploy RHEL systems that are compliant with a security profile, such as OSPP, PCI-DSS, and HIPAA profile, immediately after the installation process. Using this deployment method, you can apply specific rules that cannot be applied later using remediation scripts, for example, a rule for password strength and partitioning.

#### 8.9.1. Profiles not compatible with Server with GUI

Certain security profiles provided as part of the **SCAP Security Guide** are not compatible with the extended package set included in the **Server with GUI** base environment. Therefore, do not select **Server with GUI** when installing systems compliant with one of the following profiles:

<table>
<thead>
<tr>
<th>Profile name</th>
<th>Profile ID</th>
<th>Justification</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>[DRAFT] CIS Red Hat Enterprise Linux 9 Benchmark for Level 2 - Server</td>
<td>xccdf_org.ssgproject.content_profile_cis</td>
<td>Packages <strong>xorg-x11-server-Xorg</strong>, <strong>xorg-x11-server-common</strong>, <strong>xorg-x11-server-utils</strong>, and <strong>xorg-x11-server-Xwayland</strong> are part of the <strong>Server with GUI</strong> package set, but the policy requires their removal.</td>
<td></td>
</tr>
</tbody>
</table>
### 8.9.2. Deploying baseline-compliant RHEL systems using the graphical installation

Use this procedure to deploy a RHEL system that is aligned with a specific baseline. This example uses Protection Profile for General Purpose Operating System (OSPP).

<table>
<thead>
<tr>
<th>Profile name</th>
<th>Profile ID</th>
<th>Justification</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>[DRAFT] CIS Red Hat Enterprise Linux 9 Benchmark for Level 1 - Server</td>
<td>xccdf_org.ssgproject.content_profile_cis_server_l1</td>
<td>Packages xorg-x11-server-Xorg, xorg-x11-server-common, xorg-x11-server-utils, and xorg-x11-server-Xwayland are part of the Server with GUI package set, but the policy requires their removal.</td>
<td></td>
</tr>
<tr>
<td>Unclassified Information in Non-federal Information Systems and Organizations (NIST 800-171)</td>
<td>xccdf_org.ssgproject.content_profile_cui</td>
<td>The nfs-utils package is part of the Server with GUI package set, but the policy requires its removal.</td>
<td></td>
</tr>
<tr>
<td>[RHEL9 DRAFT] Protection Profile for General Purpose Operating Systems</td>
<td>xccdf_org.ssgproject.content_profile_ospp</td>
<td>The nfs-utils package is part of the Server with GUI package set, but the policy requires its removal.</td>
<td>BZ#1787156</td>
</tr>
<tr>
<td>[DRAFT] DISA STIG for Red Hat Enterprise Linux 9</td>
<td>xccdf_org.ssgproject.content_profile_stig</td>
<td>Packages xorg-x11-server-Xorg, xorg-x11-server-common, xorg-x11-server-utils, and xorg-x11-server-Xwayland are part of the Server with GUI package set, but the policy requires their removal.</td>
<td>BZ#1648162</td>
</tr>
</tbody>
</table>

---

Red Hat Enterprise Linux 9 Security hardening

54
**WARNING**

Certain security profiles provided as part of the **SCAP Security Guide** are not compatible with the extended package set included in the **Server with GUI** base environment. For additional details, see [Profiles not compatible with a GUI server](#).

**Prerequisites**

- You have booted into the **graphical** installation program. Note that the **OSCAP Anaconda Add-on** does not support interactive text-only installation.
- You have accessed the **Installation Summary** window.

**Procedure**

1. From the **Installation Summary** window, click **Software Selection**. The **Software Selection** window opens.
2. From the **Base Environment** pane, select the **Server** environment. You can select only one base environment.
3. Click **Done** to apply the setting and return to the **Installation Summary** window.
4. Click **Security Policy**. The **Security Policy** window opens.
5. To enable security policies on the system, toggle the **Apply security policy** switch to **ON**.
6. Select **Protection Profile for General Purpose Operating Systems** from the profile pane.
7. Click **Select Profile** to confirm the selection.
8. Confirm the changes in the **Changes that were done or need to be done** pane that is displayed at the bottom of the window. Complete any remaining manual changes.
9. Because OSPP has strict partitioning requirements that must be met, create separate partitions for `/boot`, `/home`, `/var`, `/var/log`, `/var/tmp`, and `/var/log/audit`.
10. Complete the graphical installation process.

**NOTE**

The graphical installation program automatically creates a corresponding Kickstart file after a successful installation. You can use the `/root/anaconda-ks.cfg` file to automatically install OSPP-compliant systems.

**Verification**

- To check the current status of the system after installation is complete, reboot the system and start a new scan:
8.9.3. Deploying baseline-compliant RHEL systems using Kickstart

Use this procedure to deploy RHEL systems that are aligned with a specific baseline. This example uses Protection Profile for General Purpose Operating System (OSPP).

**Prerequisites**

- The `scap-security-guide` package is installed on your RHEL 9 system.

**Procedure**

2. Update the partitioning scheme to fit your configuration requirements. For OSPP compliance, the separate partitions for `/boot`, `/home`, `/var`, `/var/log`, `/var/tmp`, and `/var/log/audit` must be preserved, and you can only change the size of the partitions.

3. Start a Kickstart installation as described in [Performing an automated installation using Kickstart](#).

   **IMPORTANT**

   Passwords in Kickstart files are not checked for OSPP requirements.

**Verification**

1. To check the current status of the system after installation is complete, reboot the system and start a new scan:

   ```
   # oscap xccdf eval --profile ospp --report eval_postinstall_report.html
   /usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml
   ```

**Additional resources**

- [OSCAP Anaconda Add-on](#)

8.10. SCANNING CONTAINER AND CONTAINER IMAGES FOR VULNERABILITIES

Use this procedure to find security vulnerabilities in a container or a container image.

**Prerequisites**

- The `openscap-utils` and `bzip2` packages are installed.
CHAPTER 8. SCANNING THE SYSTEM FOR CONFIGURATION COMPLIANCE AND VULNERABILITIES

Procedure

1. Download the latest RHSA OVAL definitions for your system:

```
```

2. Get the ID of a container or a container image, for example:

```
# podman images
REPOSITORY                      TAG      IMAGE ID       CREATED       SIZE
registry.access.redhat.com/ubi9/ubi latest 096cae65a207 7 weeks ago 239 MB
```

3. Scan the container or the container image for vulnerabilities and save results to the `vulnerability.html` file:

```
# oscap-podman 096cae65a207 oval eval --report vulnerability.html rhel-9.oval.xml
```

Note that the `oscap-podman` command requires root privileges, and the ID of a container is the first argument.

Verification

- Check the results in a browser of your choice, for example:

```
$ firefox vulnerability.html &
```

Additional resources

- For more information, see the `oscap-podman(8)` and `oscap(8)` man pages.

8.11. ASSESSING SECURITY COMPLIANCE OF A CONTAINER OR A CONTAINER IMAGE WITH A SPECIFIC BASELINE

Follow these steps to assess compliance of your container or a container image with a specific security baseline, such as Operating System Protection Profile (OSPP), Payment Card Industry Data Security Standard (PCI-DSS), and Health Insurance Portability and Accountability Act (HIPAA).

Prerequisites

- The `openscap-utils` and `scap-security-guide` packages are installed.

Procedure

1. Get the ID of a container or a container image, for example:

```
# podman images
REPOSITORY                      TAG      IMAGE ID       CREATED       SIZE
registry.access.redhat.com/ubi9/ubi latest 096cae65a207 7 weeks ago 239 MB
```

2. Evaluate the compliance of the container image with the HIPAA profile and save scan results into the `report.html` HTML file.
# oscap-podman 096cae65a207 xccdf eval --report report.html --profile hipaa
/usr/share/xml/scap/ssg/content/ssg-rhel9-ds.xml

Replace 096cae65a207 with the ID of your container image and the hipaa value with ospp or pci-dss if you assess security compliance with the OSPP or PCI-DSS baseline. Note that the oscap-podman command requires root privileges.

**Verification**

- Check the results in a browser of your choice, for example:

```
$ firefox report.html
```

**NOTE**

The rules marked as notapplicable are rules that do not apply to containerized systems. These rules apply only to bare-metal and virtualized systems.

**Additional resources**

- oscap-podman(8) and scap-security-guide(8) man pages.

### 8.12. SCAP SECURITY GUIDE PROFILES SUPPORTED IN RHEL 9

Use only the SCAP content provided in the particular minor release of RHEL. This is because components that participate in hardening are sometimes updated with new capabilities. SCAP content changes to reflect these updates, but it is not always backward compatible.

In the following tables, you can find the profiles provided in RHEL 9, together with the version of the policy with which the profile aligns.

**Table 8.3. SCAP Security Guide profiles supported in RHEL 9.1**

<table>
<thead>
<tr>

8.13. ADDITIONAL RESOURCES

- **Supported versions of the SCAP Security Guide in RHEL**

- **The OpenSCAP project page** - The home page of the OpenSCAP project provides detailed information about the oscap utility and other components and projects related to SCAP.

- **The SCAP Workbench project page** - The home page of the SCAP Workbench project provides detailed information about the scap-workbench application.

- **The SCAP Security Guide (SSG) project page** - The home page of the SSG project that provides the latest security content for Red Hat Enterprise Linux.

- **Red Hat Security Demos: Creating Customized Security Policy Content to Automate Security Compliance** - A hands-on lab to get initial experience in automating security compliance using the tools that are included in Red Hat Enterprise Linux to comply with both industry standard security policies and custom security policies. If you want training or access to these lab exercises for your team, contact your Red Hat account team for additional details.

- **Red Hat Security Demos: Defend Yourself with RHEL Security Technologies** - A hands-on lab to learn how to implement security at all levels of your RHEL system, using the key security technologies available to you in Red Hat Enterprise Linux, including OpenSCAP. If you want training or access to these lab exercises for your team, contact your Red Hat account team for additional details.

- **National Institute of Standards and Technology (NIST) SCAP page** - This page represents a vast collection of SCAP-related materials, including SCAP publications, specifications, and the SCAP Validation Program.
- National Vulnerability Database (NVD) - This page represents the largest repository of SCAP content and other SCAP standards-based vulnerability management data.

- Red Hat OVAL content repository - This is a repository containing OVAL definitions for vulnerabilities of Red Hat Enterprise Linux systems. This is the recommended source of vulnerability content.

- MITRE CVE - This is a database of publicly known security vulnerabilities provided by the MITRE corporation. For RHEL, using OVAL CVE content provided by Red Hat is recommended.

- MITRE OVAL - This is an OVAL-related project provided by the MITRE corporation. Among other OVAL-related information, these pages contain the OVAL language and a repository of OVAL content with thousands of OVAL definitions. Note that for scanning RHEL, using OVAL CVE content provided by Red Hat is recommended.

- Managing security compliance in Red Hat Satellite - This set of guides describes, among other topics, how to maintain system security on multiple systems by using OpenSCAP.
CHAPTER 9. CHECKING INTEGRITY WITH AIDE

Advanced Intrusion Detection Environment (AIDE) is a utility that creates a database of files on the system, and then uses that database to ensure file integrity and detect system intrusions.

9.1. INSTALLING AIDE

The following steps are necessary to install AIDE and to initiate its database.

Prerequisites

- The AppStream repository is enabled.

Procedure

1. To install the aide package:

   # dnf install aide

2. To generate an initial database:

   # aide --init

   **NOTE**
   
   In the default configuration, the `aide --init` command checks just a set of directories and files defined in the `/etc/aide.conf` file. To include additional directories or files in the AIDE database, and to change their watched parameters, edit `/etc/aide.conf` accordingly.

3. To start using the database, remove the `.new` substring from the initial database file name:

   # mv /var/lib/aide/aide.db.new.gz /var/lib/aide/aide.db.gz

4. To change the location of the AIDE database, edit the `/etc/aide.conf` file and modify the `DBDIR` value. For additional security, store the database, configuration, and the `/usr/sbin/aide` binary file in a secure location such as a read-only media.

9.2. PERFORMING INTEGRITY CHECKS WITH AIDE

Prerequisites

- AIDE is properly installed and its database is initialized. See Installing AIDE

Procedure

1. To initiate a manual check:

   # aide --check
   
   Start timestamp: 2018-07-11 12:41:20 +0200 (AIDE 0.16)
   
   AIDE found differences between database and filesystem!!
2. At a minimum, configure the system to run **AIDE** weekly. Optimally, run **AIDE** daily. For example, to schedule a daily execution of **AIDE** at 04:05 a.m. using the **cron** command, add the following line to the `/etc/crontab` file:

```
05 4 * * * root /usr/sbin/aide --check
```

### 9.3. UPDATING AN AIDE DATABASE

After verifying the changes of your system such as, package updates or configuration files adjustments, Red Hat recommends updating your baseline **AIDE** database.

**Prerequisites**

- **AIDE** is properly installed and its database is initialized. See [Installing AIDE](#).

**Procedure**

1. Update your baseline **AIDE** database:

   ```
   # aide --update
   ```

   The **aide --update** command creates the `/var/lib/aide/aide.db.new.gz` database file.

2. To start using the updated database for integrity checks, remove the `.new` substring from the file name.

### 9.4. FILE-INTEGRITY TOOLS: AIDE AND IMA

Red Hat Enterprise Linux provides several tools for checking and preserving the integrity of files and directories on your system. The following table helps you decide which tool better fits your scenario.

<table>
<thead>
<tr>
<th>Question</th>
<th>Advanced Intrusion Detection Environment (AIDE)</th>
<th>Integrity Measurement Architecture (IMA)</th>
</tr>
</thead>
<tbody>
<tr>
<td>What</td>
<td>AIDE is a utility that creates a database of files and directories on the system. This database serves for checking file integrity and detect intrusion detection.</td>
<td>IMA detects if a file is altered by checking file measurement (hash values) compared to previously stored extended attributes.</td>
</tr>
<tr>
<td>How</td>
<td>AIDE uses rules to compare the integrity state of the files and directories.</td>
<td>IMA uses file hash values to detect the intrusion.</td>
</tr>
<tr>
<td>Question</td>
<td>Advanced Intrusion Detection Environment (AIDE)</td>
<td>Integrity Measurement Architecture (IMA)</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Why</td>
<td>Detection - AIDE detects if a file is modified by verifying the rules.</td>
<td>Detection and Prevention - IMA detects and prevents an attack by replacing the extended attribute of a file.</td>
</tr>
<tr>
<td>Usage</td>
<td>AIDE detects a threat when the file or directory is modified.</td>
<td>IMA detects a threat when someone tries to alter the entire file.</td>
</tr>
<tr>
<td>Extension</td>
<td>AIDE checks the integrity of files and directories on the local system.</td>
<td>IMA ensures security on the local and remote systems.</td>
</tr>
</tbody>
</table>

### 9.5. ADDITIONAL RESOURCES

- [aide(1) man page](#)
- [Kernel integrity subsystem](#)
CHAPTER 10. ENCRYPTING BLOCK DEVICES USING LUKS

Disk encryption protects the data on a block device by encrypting it. To access the device’s decrypted contents, a user must provide a passphrase or key as authentication. This is particularly important when it comes to mobile computers and removable media: it helps to protect the device’s contents even if it has been physically removed from the system. The LUKS format is a default implementation of block device encryption in RHEL.

10.1. LUKS DISK ENCRYPTION

The Linux Unified Key Setup-on-disk-format (LUKS) enables you to encrypt block devices and it provides a set of tools that simplifies managing the encrypted devices. LUKS allows multiple user keys to decrypt a master key, which is used for the bulk encryption of the partition.

RHEL uses LUKS to perform block device encryption. By default, the option to encrypt the block device is unchecked during the installation. If you select the option to encrypt your disk, the system prompts you for a passphrase every time you boot the computer. This passphrase “unlocks” the bulk encryption key that decrypts your partition. If you choose to modify the default partition table, you can choose which partitions you want to encrypt. This is set in the partition table settings.

What LUKS does

- LUKS encrypts entire block devices and is therefore well-suited for protecting contents of mobile devices such as removable storage media or laptop disk drives.
- The underlying contents of the encrypted block device are arbitrary, which makes it useful for encrypting swap devices. This can also be useful with certain databases that use specially formatted block devices for data storage.
- LUKS uses the existing device mapper kernel subsystem.
- LUKS provides passphrase strengthening, which protects against dictionary attacks.
- LUKS devices contain multiple key slots, allowing users to add backup keys or passphrases.

What LUKS does not do

- Disk-encryption solutions like LUKS protect the data only when your system is off. Once the system is on and LUKS has decrypted the disk, the files on that disk are available to anyone who would normally have access to them.
- LUKS is not well-suited for scenarios that require many users to have distinct access keys to the same device. The LUKS1 format provides eight key slots, LUKS2 up to 32 key slots.
- LUKS is not well-suited for applications requiring file-level encryption.

Ciphers

The default cipher used for LUKS is `aes-xts-plain64`. The default key size for LUKS is 512 bits. The default key size for LUKS with Anaconda (XTS mode) is 512 bits. Ciphers that are available are:

- AES - Advanced Encryption Standard
- Twofish (a 128-bit block cipher)
- Serpent
10.2. LUKS VERSIONS IN RHEL

In RHEL, the default format for LUKS encryption is LUKS2. The legacy LUKS1 format remains fully supported and it is provided as a format compatible with earlier RHEL releases.

The LUKS2 format is designed to enable future updates of various parts without a need to modify binary structures. LUKS2 internally uses JSON text format for metadata, provides redundancy of metadata, detects metadata corruption and allows automatic repairs from a metadata copy.

**IMPORTANT**

Do not use LUKS2 in systems that must be compatible with legacy systems that support only LUKS1. Note that RHEL 7 supports the LUKS2 format since version 7.6.

**WARNING**

LUKS2 and LUKS1 use different commands to encrypt the disk. Using the wrong command for a LUKS version might cause data loss.

<table>
<thead>
<tr>
<th>LUKS version</th>
<th>Encryption command</th>
</tr>
</thead>
<tbody>
<tr>
<td>LUKS2</td>
<td>cryptsetup reencrypt</td>
</tr>
<tr>
<td>LUKS1</td>
<td>cryptsetup-reencrypt</td>
</tr>
</tbody>
</table>

**Online re-encryption**

The LUKS2 format supports re-encrypting encrypted devices while the devices are in use. For example, you do not have to unmount the file system on the device to perform the following tasks:

- Change the volume key
- Change the encryption algorithm

When encrypting a non-encrypted device, you must still unmount the file system. You can remount the file system after a short initialization of the encryption.

The LUKS1 format does not support online re-encryption.

**Conversion**
The LUKS2 format is inspired by LUKS1. In certain situations, you can convert LUKS1 to LUKS2. The conversion is not possible specifically in the following scenarios:

- A LUKS1 device is marked as being used by a Policy-Based Decryption (PBD - Clevis) solution. The cryptsetup tool refuses to convert the device when some luksmeta metadata are detected.
- A device is active. The device must be in the inactive state before any conversion is possible.

### 10.3. OPTIONS FOR DATA PROTECTION DURING LUKS2 RE-ENCRYPTION

LUKS2 provides several options that prioritize performance or data protection during the re-encryption process:

**checksum**

This is the default mode. It balances data protection and performance. This mode stores individual checksums of the sectors in the re-encryption area, so the recovery process can detect which sectors LUKS2 already re-encrypted. The mode requires that the block device sector write is atomic.

**journal**

That is the safest mode but also the slowest. This mode journals the re-encryption area in the binary area, so LUKS2 writes the data twice.

**none**

This mode prioritizes performance and provides no data protection. It protects the data only against safe process termination, such as the SIGTERM signal or the user pressing Ctrl+C. Any unexpected system crash or application crash might result in data corruption.

You can select the mode using the `--resilience` option of cryptsetup.

If a LUKS2 re-encryption process terminates unexpectedly by force, LUKS2 can perform the recovery in one of the following ways:

- Automatically, during the next LUKS2 device open action. This action is triggered either by the cryptsetup open command or by attaching the device with systemd-cryptsetup.
- Manually, by using the cryptsetup repair command on the LUKS2 device.

### 10.4. ENCRYPTING EXISTING DATA ON A BLOCK DEVICE USING LUKS2

This procedure encrypts existing data on a not yet encrypted device using the LUKS2 format. A new LUKS header is stored in the head of the device.

**Prerequisites**

- The block device contains a file system.
- You have backed up your data.
WARNING

You might lose your data during the encryption process: due to a hardware, kernel, or human failure. Ensure that you have a reliable backup before you start encrypting the data.

Procedure

1. Unmount all file systems on the device that you plan to encrypt. For example:

```
# umount /dev/sdb1
```

2. Make free space for storing a LUKS header. Choose one of the following options that suits your scenario:

- In the case of encrypting a logical volume, you can extend the logical volume without resizing the file system. For example:

```
# lvextend -L+32M vg00/lv00
```

- Extend the partition using partition management tools, such as `parted`.

- Shrink the file system on the device. You can use the `resize2fs` utility for the ext2, ext3, or ext4 file systems. Note that you cannot shrink the XFS file system.

3. Initialize the encryption. For example:

```
# cryptsetup reencrypt \
   --encrypt \n   --init-only \n   --reduce-device-size 32M \n   /dev/sdb1 sdb1_encrypted
```

The command asks you for a passphrase and starts the encryption process.

4. Mount the device:

```
# mount /dev/mapper/sdb1_encrypted /mnt/sdb1_encrypted
```

5. Start the online encryption:

```
# cryptsetup reencrypt --resume-only /dev/sdb1
```

Additional resources

- `cryptsetup(8)`, `lvextend(8)`, `resize2fs(8)`, and `parted(8)` man pages

10.5. ENCRYPTING EXISTING DATA ON A BLOCK DEVICE USING LUKS2 WITH A DETACHED HEADER
This procedure encrypts existing data on a block device without creating free space for storing a LUKS header. The header is stored in a detached location, which also serves as an additional layer of security. The procedure uses the LUKS2 encryption format.

**Prerequisites**

- The block device contains a file system.
- You have backed up your data.

**WARNING**

You might lose your data during the encryption process: due to a hardware, kernel, or human failure. Ensure that you have a reliable backup before you start encrypting the data.

**Procedure**

1. Unmount all file systems on the device. For example:

```bash
# umount /dev/sdb1
```

2. Initialize the encryption:

```bash
# cryptsetup reencrypt --encrypt --init-only --header /path/to/header /dev/sdb1 sdb1_encrypted
```

Replace `/path/to/header` with a path to the file with a detached LUKS header. The detached LUKS header has to be accessible so that the encrypted device can be unlocked later.

The command asks you for a passphrase and starts the encryption process.

3. Mount the device:

```bash
# mount /dev/mapper/sdb1_encrypted /mnt/sdb1_encrypted
```

4. Start the online encryption:

```bash
# cryptsetup reencrypt --resume-only --header /path/to/header /dev/sdb1
```

**Additional resources**

- `cryptsetup(8)` man page

**10.6. Encrypting a Blank Block Device Using LUKS2**
This procedure provides information about encrypting a blank block device using the LUKS2 format.

Prerequisites

- A blank block device.

Procedure

1. Setup a partition as an encrypted LUKS partition:

   ```
   # cryptsetup luksFormat /dev/sdb1
   ```

2. Open an encrypted LUKS partition:

   ```
   # cryptsetup open /dev/sdb1 sdb1_encrypted
   ```

   This unlocks the partition and maps it to a new device using the device mapper. This alerts the kernel that the device is an encrypted device and should be addressed through LUKS using the `/dev/mapper/device_mapped_name` so as not to overwrite the encrypted data.

3. To write encrypted data to the partition, it must be accessed through the device mapped name. To do this, you must create a file system. For example:

   ```
   # mkfs -t ext4 /dev/mapper/sdb1_encrypted
   ```

4. Mount the device:

   ```
   # mount /dev/mapper/sdb1_encrypted mount-point
   ```

Additional resources

- `cryptsetup(8)` man page

10.7. CREATING A LUKS ENCRYPTED VOLUME USING THE STORAGE SYSTEM ROLE

You can use the Storage role to create and configure a volume encrypted with LUKS by running an Ansible playbook.

Prerequisites

- Access and permissions to one or more managed nodes, which are systems you want to configure with the Crypto Policies System Role.

- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems. On the control node:

  - The `ansible-core` and `rhel-system-roles` packages are installed.
IMPORTANT

RHEL 8.0-8.5 provided access to a separate Ansible repository that contains Ansible Engine 2.9 for automation based on Ansible. Ansible Engine contains command-line utilities such as `ansible`, `ansible-playbook`, connectors such as `docker` and `podman`, and many plugins and modules. For information on how to obtain and install Ansible Engine, see the How to download and install Red Hat Ansible Engine Knowledgebase article.

RHEL 8.6 and 9.0 have introduced Ansible Core (provided as the `ansible-core` package), which contains the Ansible command-line utilities, commands, and a small set of built-in Ansible plugins. RHEL provides this package through the AppStream repository, and it has a limited scope of support. For more information, see the Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories Knowledgebase article.

- An inventory file which lists the managed nodes.

Procedure

1. Create a new `playbook.yml` file with the following content:

```yaml
- hosts: all
  vars:
    storage_volumes:
      - name: barefs
        type: disk
        disks:
          - sdb
        fs_type: xfs
        fs_label: label-name
        mount_point: /mnt/data
        encryption: true
        encryption_password: your-password
  roles:
    - rhel-system-roles.storage
```

2. Optional: Verify playbook syntax:

```
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```
# ansible-playbook -i inventory.file /path/to/file/playbook.yml
```

Additional resources

- `/usr/share/ansible/roles/rhel-system-roles.storage/README.md` file
CHAPTER 11. CONFIGURING AUTOMATED UNLOCKING OF ENCRYPTED VOLUMES USING POLICY-BASED DECRYPTION

Policy-Based Decryption (PBD) is a collection of technologies that enable unlocking encrypted root and secondary volumes of hard drives on physical and virtual machines. PBD uses a variety of unlocking methods, such as user passwords, a Trusted Platform Module (TPM) device, a PKCS #11 device connected to a system, for example, a smart card, or a special network server.

PBD allows combining different unlocking methods into a policy, which makes it possible to unlock the same volume in different ways. The current implementation of the PBD in RHEL consists of the Clevis framework and plug-ins called pins. Each pin provides a separate unlocking capability. Currently, the following pins are available:

- **tang** - allows unlocking volumes using a network server
- **tpm2** - allows unlocking volumes using a TPM2 policy
- **sss** - allows deploying high-availability systems using the Shamir’s Secret Sharing (SSS) cryptographic scheme

The Network Bound Disc Encryption (NBDE) is a subcategory of PBD that allows binding encrypted volumes to a special network server. The current implementation of the NBDE includes a Clevis pin for the Tang server and the Tang server itself.

11.1. NETWORK-BOUND DISK ENCRYPTION

In Red Hat Enterprise Linux, NBDE is implemented through the following components and technologies:

**Figure 11.1. NBDE scheme when using a LUKS1-encrypted volume. The luksmeta package is not used for LUKS2 volumes.**

**Tang** is a server for binding data to network presence. It makes a system containing your data available when the system is bound to a certain secure network. Tang is stateless and does not require TLS or authentication. Unlike escrow-based solutions, where the server stores all encryption keys and has knowledge of every key ever used, Tang never interacts with any client keys, so it never gains any identifying information from the client.
Clevis is a pluggable framework for automated decryption. In NBDE, Clevis provides automated unlocking of LUKS volumes. The clevis package provides the client side of the feature.

A Clevis pin is a plug-in into the Clevis framework. One of such pins is a plug-in that implements interactions with the NBDE server — Tang.

Clevis and Tang are generic client and server components that provide network-bound encryption. In Red Hat Enterprise Linux, they are used in conjunction with LUKS to encrypt and decrypt root and non-root storage volumes to accomplish Network-Bound Disk Encryption.

Both client- and server-side components use the José library to perform encryption and decryption operations.

When you begin provisioning NBDE, the Clevis pin for Tang server gets a list of the Tang server’s advertised asymmetric keys. Alternatively, since the keys are asymmetric, a list of Tang’s public keys can be distributed out of band so that clients can operate without access to the Tang server. This mode is called offline provisioning.

The Clevis pin for Tang uses one of the public keys to generate a unique, cryptographically-strong encryption key. Once the data is encrypted using this key, the key is discarded. The Clevis client should store the state produced by this provisioning operation in a convenient location. This process of encrypting data is the provisioning step.

The LUKS version 2 (LUKS2) is the default disk-encryption format in RHEL, hence, the provisioning state for NBDE is stored as a token in a LUKS2 header. The leveraging of provisioning state for NBDE by the luksmeta package is used only for volumes encrypted with LUKS1.

The Clevis pin for Tang supports both LUKS1 and LUKS2 without specification need. Clevis can encrypt plain-text files but you have to use the cryptsetup tool for encrypting block devices. See the Encrypting block devices using LUKS for more information.

When the client is ready to access its data, it loads the metadata produced in the provisioning step and it responds to recover the encryption key. This process is the recovery step.

In NBDE, Clevis binds a LUKS volume using a pin so that it can be automatically unlocked. After successful completion of the binding process, the disk can be unlocked using the provided Dracut unlocker.

NOTE

If the kdump kernel crash dumping mechanism is set to save the content of the system memory to a LUKS-encrypted device, you are prompted for entering a password during the second kernel boot.

11.2. INSTALLING AN ENCRYPTION CLIENT - CLEVIS

Use this procedure to deploy and start using the Clevis pluggable framework on your system.

Procedure

1. To install Clevis and its pins on a system with an encrypted volume:

   # dnf install clevis
2. To decrypt data, use a `clevis decrypt` command and provide a cipher text in the JSON Web Encryption (JWE) format, for example:

```
$ clevis decrypt < secret.jwe
```

Additional resources

- `clevis(1)` man page
- Built-in CLI help after entering the `clevis` command without any argument:

```
$ clevis
Usage: clevis COMMAND [OPTIONS]
```

11.3. DEPLOYING A TANG SERVER WITH SELINUX IN ENFORCING MODE

Use this procedure to deploy a Tang server running on a custom port as a confined service in SELinux enforcing mode.

Prerequisites

- The `policycoreutils-python-utils` package and its dependencies are installed.
- The `firewalld` service is running.

Procedure

1. To install the `tang` package and its dependencies, enter the following command as `root`:

```
# dnf install tang
```

2. Pick an unoccupied port, for example, `7500/tcp`, and allow the `tangd` service to bind to that port:

```
# semanage port -a -t tangd_port_t -p tcp 7500
```

Note that a port can be used only by one service at a time, and thus an attempt to use an already occupied port implies the `ValueError: Port already defined` error message.
3. Open the port in the firewall:

```bash
# firewall-cmd --add-port=7500/tcp
# firewall-cmd --runtime-to-permanent
```

4. Enable the `tangd` service:

```bash
# systemctl enable tangd.socket
```

5. Create an override file:

```bash
# systemctl edit tangd.socket
```

6. In the following editor screen, which opens an empty `override.conf` file located in the `/etc/systemd/system/tangd.socket.d/` directory, change the default port for the Tang server from 80 to the previously picked number by adding the following lines:

```plaintext
[Socket]
ListenStream=
ListenStream=7500
```

Save the file and exit the editor.

7. Reload the changed configuration:

```bash
# systemctl daemon-reload
```

8. Check that your configuration is working:

```bash
# systemctl show tangd.socket -p Listen
Listen=[::]:7500 (Stream)
```

9. Start the `tangd` service:

```bash
# systemctl restart tangd.socket
```

Because `tangd` uses the `systemd` socket activation mechanism, the server starts as soon as the first connection comes in. A new set of cryptographic keys is automatically generated at the first start. To perform cryptographic operations such as manual key generation, use the `jose` utility.

Additional resources

- `tang(8)`, `semanage(8)`, `firewall-cmd(1)`, `jose(1)`, `systemd.unit(5)`, and `systemd.socket(5)` man pages

11.4. ROTATING TANG SERVER KEYS AND UPDATING BINDINGS ON CLIENTS

Use the following steps to rotate your Tang server keys and update existing bindings on clients. The precise interval at which you should rotate them depends on your application, key sizes, and institutional policy.
Alternatively, you can rotate Tang keys by using the `nbde_server` RHEL system role. See Using the `nbde_server` system role for setting up multiple Tang servers for more information.

Prerequisites

- A Tang server is running.
- The `clevis` and `clevis-luks` packages are installed on your clients.

Procedure

1. Rename all keys in the `/var/db/tang` key database directory to have a leading `.` to hide them from advertisement. Note that the file names in the following example differs from unique file names in the key database directory of your Tang server:

   ```bash
   # cd /var/db/tang
   # ls -l
   -rw-r--r--. 1 root root 349 Feb  7 14:55 UV6dqXSwe1bRKG3KbJmdR020hY.jwk
   -rw-r--r--. 1 root root 354 Feb  7 14:55 y9hxLTQSiSB5jSEGWnjhY8fDTJU.jwk
   # mv UV6dqXSwe1bRKG3KbJmdR020hY.jwk .UV6dqXSwe1bRKG3KbJmdR020hY.jwk
   # mv y9hxLTQSiSB5jSEGWnjhY8fDTJU.jwk .y9hxLTQSiSB5jSEGWnjhY8fDTJU.jwk
   ```

2. Check that you renamed and therefore hid all keys from the Tang server advertisement:

   ```bash
   # ls -l
   total 0
   ```

3. Generate new keys using the `/usr/libexec/tangd-keygen` command in `/var/db/tang` on the Tang server:

   ```bash
   # /usr/libexec/tangd-keygen /var/db/tang
   # ls /var/db/tang
   3ZWS6-cDrCG61UPJS2BMmPU4I54.jwk zyLuX6hijUy_PSeUEFDi7hi38.jwk
   ```

4. Check that your Tang server advertises the signing key from the new key pair, for example:

   ```bash
   # tang-show-keys 7500
   3ZWS6-cDrCG61UPJS2BMmPU4I54
   ```

5. On your NBDE clients, use the `clevis luks report` command to check if the keys advertised by the Tang server remains the same. You can identify slots with the relevant binding using the `clevis luks list` command, for example:

   ```bash
   # clevis luks list -d /dev/sda2
   1: tang ["url":"http://tang.srv"]
   # clevis luks report -d /dev/sda2 -s 1
   ...
   Report detected that some keys were rotated.
   Do you want to regenerate luks metadata with "clevis luks regen -d /dev/sda2 -s 1"? [ynYN]
   ```

6. To regenerate LUKS metadata for the new keys either press `y` to the prompt of the previous command, or use the `clevis luks regen` command:

   ```bash
   # clevis luks regen -d /dev/sda2 -s 1
   ```
When you are sure that all old clients use the new keys, you can remove the old keys from the Tang server, for example:

```
# cd /var/db/tang
# rm *.jwk
```

**WARNING**
Removing the old keys while clients are still using them can result in data loss. If you accidentally remove such keys, use the `clevis luks regen` command on the clients, and provide your LUKS password manually.

Additional resources
- `tang-show-keys(1)`, `clevis-luks-list(1)`, `clevis-luks-report(1)`, and `clevis-luks-regen(1)` man pages

### 11.5. CONFIGURING AUTOMATED UNLOCKING USING A TANG KEY IN THE WEB CONSOLE

Configure automated unlocking of a LUKS-encrypted storage device using a key provided by a Tang server.

**Prerequisites**
- The RHEL 9 web console has been installed. For details, see [Installing the web console](#).
- The `cockpit-storaged` package is installed on your system.
- The `cockpit.socket` service is running at port 9090.
- The `clevis`, `tang`, and `clevis-dracut` packages are installed.
- A Tang server is running.

**Procedure**
1. Open the RHEL web console by entering the following address in a web browser:

   ```
   https://localhost:9090
   ```

   Replace the `localhost` part by the remote server’s host name or IP address when you connect to a remote system.

2. Provide your credentials and click **Storage**. Click `>` to expand details of the encrypted device you want to unlock using the Tang server, and click **Encryption**.
3. Click + in the Keys section to add a Tang key:

4. Provide the address of your Tang server and a password that unlocks the LUKS-encrypted device. Click Add to confirm:

   **Add Key**

   Key source
   - Passphrase
   - Tang keyservers

   Keyserver address
   example.com:80

   Disk passphrase
   ***************

   Saving a new passphrase requires unlocking the disk. Please provide a current disk passphrase.

   The following dialog window provides a command to verify that the key hash matches.

5. In a terminal on the Tang server, use the `tang-show-keys` command to display the key hash for comparison. In this example, the Tang server is running on the port 7500:

   ```bash
   # tang-show-keys 7500
   fM-EwYeiTxS66X3s1UAywGKnxnll8ig0KOQmr9CM
   ```
6. Click **Trust key** when the key hashes in the web console and in the output of previously listed commands are the same:

**Verify key**

Make sure the key hash from the Tang server matches:

3ZWS6-cDrCG61UPJS2BMmPU4I54

Manually check with SSH: `ssh localhost tang-show-keys 7500`

If `tang-show-keys` is not available, run the following:

```
ssh localhost "curl -s localhost:7500/adv |
    jose fmt -j -g payload -y -o - |
    jose jwk use -i -r -u verify -o - |
    jose jwk thp -i -"
```

7. To enable the early boot system to process the disk binding, click **Terminal** at the bottom of the left navigation bar and enter the following commands:

```
# dnf install clevis-dracut
# grubby --update-kernel=ALL --args="rd.neednet=1"
# dracut -fv --regenerate-all
```

8. To enable Clevis to unlock also volumes that mount late in the boot process, use the following command on the client before restarting the system:

```
# systemctl enable clevis-luks-askpass.path
```

**Verification**

1. Check that the newly added Tang key is now listed in the **Keys** section with the **Keyserver** type:

```
Partition  Encryption

Stored passphrase  Edit

Options  (none)

Keys

<table>
<thead>
<tr>
<th>Passphrase</th>
<th>Slot 0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Keyserver</th>
<th>localhost:7500</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Slot 1</td>
</tr>
</tbody>
</table>
```

Red Hat Enterprise Linux 9 Security hardening
2. Verify that the bindings are available for the early boot, for example:

```bash
# lsinitrd | grep clevis
clevis
clevis-pin-sss
clevis-pin-tang
clevis-pin-tpm2
-rwxr-xr-x   1 root     root         1600 Feb 11 16:30 usr/bin/clevis
-rwxr-xr-x   1 root     root         1654 Feb 11 16:30 usr/bin/clevis-decrypt
...  
-rwxr-xr-x   2 root     root           45 Feb 11 16:30 usr/lib/dracut/hooks/initqueue/settled/60-clevis-hook.sh
-rwxr-xr-x   1 root     root         2257 Feb 11 16:30 usr/libexec/clevis-luks-askpass
```

## 11.6. BASIC NBDE AND TPM2 ENCRYPTION-CLIENT OPERATIONS

The Clevis framework can encrypt plain-text files and decrypt both ciphertexts in the JSON Web Encryption (JWE) format and LUKS-encrypted block devices. Clevis clients can use either Tang network servers or Trusted Platform Module 2.0 (TPM 2.0) chips for cryptographic operations.

The following commands demonstrate the basic functionality provided by Clevis on examples containing plain-text files. You can also use them for troubleshooting your NBDE or Clevis+TPM deployments.

### Encryption client bound to a Tang server

- To check that a Clevis encryption client binds to a Tang server, use the `clevis encrypt tang` sub-command:

  ```bash
  $ clevis encrypt tang 'curl:"http://tang.srv:port"' < input-plain.txt > secret.jwe
  The advertisement contains the following signing keys:
  _OsIk0T-E2l6qjfdDiwVmidoZjA
  Do you wish to trust these keys? [ynYN] y
  ```

  Change the `http://tang.srv:port` URL in the previous example to match the URL of the server where `tang` is installed. The `secret.jwe` output file contains your encrypted cipher text in the JWE format. This cipher text is read from the `input-plain.txt` input file.

  Alternatively, if your configuration requires a non-interactive communication with a Tang server without SSH access, you can download an advertisement and save it to a file:

  ```bash
  $ curl -sf http://tang.srv:port/adv -o adv.jws
  ```

  Use the advertisement in the `adv.jws` file for any following tasks, such as encryption of files or messages:

  ```bash
  $ echo 'hello' | clevis encrypt tang 'curl:"http://tang.srv:port"',"adv":"adv.jws"'
  ```
To decrypt data, use the `clevis decrypt` command and provide the cipher text (JWE):

```
$ clevis decrypt < secret.jwe > output-plain.txt
```

**Encryption client using TPM 2.0**

- To encrypt using a TPM 2.0 chip, use the `clevis encrypt tpm2` sub-command with the only argument in form of the JSON configuration object:

```
$ clevis encrypt tpm2 '{}' < input-plain.txt > secret.jwe
```

To choose a different hierarchy, hash, and key algorithms, specify configuration properties, for example:

```
$ clevis encrypt tpm2 '{"hash":"sha256","key":"rsa"}' < input-plain.txt > secret.jwe
```

- To decrypt the data, provide the ciphertext in the JSON Web Encryption (JWE) format:

```
$ clevis decrypt < secret.jwe > output-plain.txt
```

The pin also supports sealing data to a Platform Configuration Registers (PCR) state. That way, the data can only be unsealed if the PCR hashes values match the policy used when sealing.

For example, to seal the data to the PCR with index 0 and 7 for the SHA-256 bank:

```
$ clevis encrypt tpm2 '{"pcr_bank":"sha256","pcr_ids":"0,7"}' < input-plain.txt > secret.jwe
```

**WARNING**

Hashes in PCRs can be rewritten, and you no longer can unlock your encrypted volume. For this reason, add a strong passphrase that enable you to unlock the encrypted volume manually even when a value in a PCR changes.

If the system cannot automatically unlock your encrypted volume after an upgrade of the `shim-x64` package, follow the steps in the [Clevis TPM2 no longer decrypts LUKS devices after a restart](https://www.redhat.com/support/knowledgecenter) KCS article.

**Additional resources**

- `clevis-encrypt-tang(1)`, `clevis-luks-unlockers(7)`, `clevis(1)`, and `clevis-encrypt-tpm2(1)` man pages

- `clevis`, `clevis decrypt`, and `clevis encrypt tang` commands without any arguments show the built-in CLI help, for example:

```
$ clevis encrypt tang
Usage: clevis encrypt tang CONFIG < PLAINTEXT > JWE
...
11.7. CONFIGURING MANUAL ENROLLMENT OF LUKS-ENCRYPTED VOLUMES

Use the following steps to configure unlocking of LUKS-encrypted volumes with NBDE.

Prerequisites

- A Tang server is running and available.

Procedure

1. To automatically unlock an existing LUKS-encrypted volume, install the `clevis-luks` subpackage:

   ```bash
   # dnf install clevis-luks
   ```

2. Identify the LUKS-encrypted volume for PBD. In the following example, the block device is referred as `/dev/sda2`:

   ```bash
   # lsblk
   NAME          MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
   sda            8:0  0    12G  0 disk
     └─sda1       8:1  0     1G  0 part /boot
     └─sda2       8:2  0    11G  0 part
       └─luks-40e20552-2ade-4954-9d56-565aa7994fb6 253:0  0    11G  0 crypt
         └─rhel-root  253:0  0   9.8G  0 lvm /
             └─rhel-swap  253:1  0   1.2G  0 lvm [SWAP]
   ```

3. Bind the volume to a Tang server using the `clevis luks bind` command:

   ```bash
   # clevis luks bind -d /dev/sda2 tang '{"url":"http://tang.srv"}"
   ```

   The advertisement contains the following signing keys:

   ```
   _OsIk0T-E2l6qjfdDiwVmidoZjA
   ```

   Do you wish to trust these keys? [ynYN] y

   You are about to initialize a LUKS device for metadata storage.
   Attempting to initialize it may result in data loss if data was already written into the LUKS header gap in a different format.
   A backup is advised before initialization is performed.

   ```
   Do you wish to initialize /dev/sda2? [yn] y
   ```

   Enter existing LUKS password:

   This command performs four steps:

   a. Creates a new key with the same entropy as the LUKS master key.
   b. Encrypts the new key with Clevis.
   c. Stores the Clevis JWE object in the LUKS2 header token or uses LUKSMeta if the non-default LUKS1 header is used.
   d. Enables the new key for use with LUKS.
The binding procedure assumes that there is at least one free LUKS password slot. The `clevis luks bind` command takes one of the slots.

The volume can now be unlocked with your existing password as well as with the Clevis policy.

4. To enable Clevis to unlock also volumes that mount late in the boot process, use the following command on the client before restarting the system:

   ```bash
   # systemctl enable clevis-luks-askpass.path
   ```

5. To enable the early boot system to process the disk binding, use the `dracut` tool on an already installed system:

   ```bash
   # dnf install clevis-dracut
   ```

   In RHEL, Clevis produces a generic `initrd` (initial ramdisk) without host-specific configuration options and does not automatically add parameters such as `rd.neednet=1` to the kernel command line. If your configuration relies on a Tang pin that requires network during early boot, use the `--hostonly-cmdline` argument and `dracut` adds `rd.neednet=1` when it detects a Tang binding:

   ```bash
   # dracut -fv --regenerate-all --hostonly-cmdline
   ```

   Alternatively, create a `.conf` file in the `/etc/dracut.conf.d/`, and add the `hostonly_cmdline=yes` option to the file, for example:

   ```bash
   # echo "hostonly_cmdline=yes" > /etc/dracut.conf.d/clevis.conf
   ```

   You can also ensure that networking for a Tang pin is available during early boot by using the `grubby` tool on the system where Clevis is installed:

   ```bash
   # grubby --update-kernel=ALL --args="rd.neednet=1"
   ```

   Then you can use `dracut` without `--hostonly-cmdline`:

   ```bash
   # dracut -fv --regenerate-all
   ```

   **Verification**

   1. To verify that the Clevis JWE object is successfully placed in a LUKS header, use the `clevis luks list` command:

   ```bash
   # clevis luks list -d /dev/sda2
   1: tang 
   ```
IMPORTANT

To use NBDE for clients with static IP configuration (without DHCP), pass your network configuration to the `dracut` tool manually, for example:

```
# dracut -fv --regenerate-all --kernel-cmdline "ip=192.0.2.10::192.0.2.1:255.255.255.0::ens3:none"
```

Alternatively, create a .conf file in the `/etc/dracut.conf.d/` directory with the static network information. For example:

```
# cat /etc/dracut.conf.d/static_ip.conf
kernel_cmdline="ip=192.0.2.10::192.0.2.1:255.255.255.0::ens3:none"
```

Regenerate the initial RAM disk image:

```
# dracut -fv --regenerate-all
```

Additional resources

- `clevis-luks-bind(1)` and `dracut.cmdline(7)` man pages.
- RHEL Network boot options

11.8. CONFIGURING MANUAL ENROLLMENT OF LUKS-ENCRYPTED VOLUMES USING A TPM 2.0 POLICY

Use the following steps to configure unlocking of LUKS-encrypted volumes by using a Trusted Platform Module 2.0 (TPM 2.0) policy.

Prerequisites

- An accessible TPM 2.0-compatible device.
- A system with the 64-bit Intel or 64-bit AMD architecture.

Procedure

1. To automatically unlock an existing LUKS-encrypted volume, install the `clevis-luks` subpackage:

   ```
   # dnf install clevis-luks
   ```

2. Identify the LUKS-encrypted volume for PBD. In the following example, the block device is referred as `/dev/sda2`:

   ```
   # lsblk
   NAME          MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
   sda          8:0      0  12G 0 disk          
   └─sda1       8:1      0  1G  0 part /boot
   └─sda2       8:2      0  11G 0 part
   └─luks-40e20552-2ade-4954-9d56-565aa7994fb6 253:0  0 11G 0 crypt
   └─rhel-root  253:0  0  9.8G 0 lvm  /
   └─rhel-swap  253:1  0  1.2G 0 lvm  [SWAP]
   ```
3. Bind the volume to a TPM 2.0 device using the `clevis luks bind` command, for example:

```
# clevis luks bind -d /dev/sda2 tpm2 '{"hash":"sha256","key":"rsa"}'
...
Do you wish to initialize /dev/sda2? [yn] y
Enter existing LUKS password:
```

This command performs four steps:

a. Creates a new key with the same entropy as the LUKS master key.

b. Encrypts the new key with Clevis.

c. Stores the Clevis JWE object in the LUKS2 header token or uses LUKSMeta if the non-default LUKS1 header is used.

d. Enables the new key for use with LUKS.

**NOTE**
The binding procedure assumes that there is at least one free LUKS password slot. The `clevis luks bind` command takes one of the slots.

Alternatively, if you want to seal data to specific Platform Configuration Registers (PCR) states, add the `pcr_bank` and `pcr_ids` values to the `clevis luks bind` command, for example:

```
# clevis luks bind -d /dev/sda2 tpm2 '{"hash":"sha256","key":"rsa","pcr_bank":"sha256","pcr_ids":"0,1"}'
```

**WARNING**
Because the data can only be unsealed if PCR hashes values match the policy used when sealing and the hashes can be rewritten, add a strong passphrase that enable you to unlock the encrypted volume manually when a value in a PCR changes.

If the system cannot automatically unlock your encrypted volume after an upgrade of the `shim-x64` package, follow the steps in the Clevis **TPM2 no longer decrypts LUKS devices after a restart** KCS article.

4. The volume can now be unlocked with your existing password as well as with the Clevis policy.

5. To enable the early boot system to process the disk binding, use the `dracut` tool on an already installed system:

```
# dnf install clevis-dracut
# dracut -fv --regenerate-all
```
Verification

1. To verify that the Clevis JWE object is successfully placed in a LUKS header, use the `clevis luks list` command:

```
# clevis luks list -d /dev/sda2
1: tpm2 {"hash":"sha256","key":"rsa"}
```

Additional resources

- `clevis-luks-bind(1)`, `clevis-encrypt-tpm2(1)`, and `dracut.cmdline(7)` man pages

11.9. REMOVING A CLEVIS PIN FROM A LUKS-ENCRYPTED VOLUME MANUALLY

Use the following procedure for manual removing the metadata created by the `clevis luks bind` command and also for wiping a key slot that contains passphrase added by Clevis.

**IMPORTANT**

The recommended way to remove a Clevis pin from a LUKS-encrypted volume is through the `clevis luks unbind` command. The removal procedure using `clevis luks unbind` consists of only one step and works for both LUKS1 and LUKS2 volumes. The following example command removes the metadata created by the binding step and wipe the key slot 1 on the `/dev/sda2` device:

```
# clevis luks unbind -d /dev/sda2 -s 1
```

Prerequisites

- A LUKS-encrypted volume with a Clevis binding.

Procedure

1. Check which LUKS version the volume, for example `/dev/sda2`, is encrypted by and identify a slot and a token that is bound to Clevis:

```
# cryptsetup luksDump /dev/sda2
LUKS header information
Version: 2
...
Keyslots:
0: luks2
...
1: luks2
  Key: 512 bits
  Priority: normal
  Cipher: aes-xts-plain64
...
Tokens:
0: clevis
    Keyslot: 1
...
In the previous example, the Clevis token is identified by 0 and the associated key slot is 1.

2. In case of LUKS2 encryption, remove the token:

```
# cryptsetup token remove --token-id 0 /dev/sda2
```

3. If your device is encrypted by LUKS1, which is indicated by the Version: 1 string in the output of the cryptsetup luksDump command, perform this additional step with the luksmeta wipe command:

```
# luksmeta wipe -d /dev/sda2 -s 1
```

4. Wipe the key slot containing the Clevis passphrase:

```
# cryptsetup luksKillSlot /dev/sda2 1
```

Additional resources

- clevis-luks-unbind(1), cryptsetup(8), and luksmeta(8) man pages

11.10. CONFIGURING AUTOMATED ENROLLMENT OF LUKS-ENCRYPTED VOLUMES USING KICKSTART

Follow the steps in this procedure to configure an automated installation process that uses Clevis for the enrollment of LUKS-encrypted volumes.

Procedure

1. Instruct Kickstart to partition the disk such that LUKS encryption has enabled for all mount points, other than /boot, with a temporary password. The password is temporary for this step of the enrollment process.

```
part /boot --fstype="xfs" --ondisk=vda --size=256
part / --fstype="xfs" --ondisk=vda --grow --encrypted --passphrase=temppass
```

Note that OSPP-compliant systems require a more complex configuration, for example:

```
part /boot --fstype="xfs" --ondisk=vda --size=256
part / --fstype="xfs" --ondisk=vda --size=2048 --encrypted --passphrase=temppass
part /var --fstype="xfs" --ondisk=vda --size=1024 --encrypted --passphrase=temppass
part /tmp --fstype="xfs" --ondisk=vda --size=1024 --encrypted --passphrase=temppass
part /home --fstype="xfs" --ondisk=vda --size=2048 --grow --encrypted --passphrase=temppass
part /var/log --fstype="xfs" --ondisk=vda --size=1024 --encrypted --passphrase=temppass
part /var/log/audit --fstype="xfs" --ondisk=vda --size=1024 --encrypted --passphrase=temppass
```

2. Install the related Clevis packages by listing them in the %packages section:

```
%packages
  clevis-dracut
clevis-luks
```
3. Optionally, to ensure that you can unlock the encrypted volume manually when required, add a strong passphrase before you remove the temporary passphrase. See the How to add a passphrase, key, or keyfile to an existing LUKS device article for more information.

4. Call clevis luks bind to perform binding in the %post section. Afterward, remove the temporary password:

   %post
   clevis luks bind -y -k - -d /dev/vda2 \
   tang '{"url":"http://tang.srv"}' <<< "temppass"
   cryptsetup luksRemoveKey /dev/vda2 <<< "temppass"
   dracut -f --regenerate-all
   %end

   If your configuration relies on a Tang pin that requires network during early boot or you use NBDE clients with static IP configurations, you have to modify the dracut command as described in Configuring manual enrollment of LUKS-encrypted volumes.

   Note that the -y option for the clevis luks bind command is available from RHEL 8.3. In RHEL 8.2 and older, replace -y by -f in the clevis luks bind command and download the advertisement from the Tang server:

   %post
   curl -sf http://tang.srv/adv -o adv.jws
   clevis luks bind -f -k - -d /dev/vda2 \
   tang '{"url":"http://tang.srv","adv":"adv.jws"}' <<< "temppass"
   cryptsetup luksRemoveKey /dev/vda2 <<< "temppass"
   dracut -f --regenerate-all
   %end

   ! WARNING
   The cryptsetup luksRemoveKey command prevents any further administration of a LUKS2 device on which you apply it. You can recover a removed master key using the dmsetup command only for LUKS1 devices.

   You can use an analogous procedure when using a TPM 2.0 policy instead of a Tang server.

   Additional resources
   - clevis(1), clevis-luks-bind(1), cryptsetup(8), and dmsetup(8) man pages
   - Installing Red Hat Enterprise Linux 9 using Kickstart

11.11. CONFIGURING AUTOMATED UNLOCKING OF A LUKS-ENCRYPTED REMOVABLE STORAGE DEVICE
Use this procedure to set up an automated unlocking process of a LUKS-encrypted USB storage device.

Procedure

1. To automatically unlock a LUKS-encrypted removable storage device, such as a USB drive, install the clevis-udisks2 package:

```
# dnf install clevis-udisks2
```

2. Reboot the system, and then perform the binding step using the clevis luks bind command as described in Configuring manual enrollment of LUKS-encrypted volumes, for example:

```
# clevis luks bind -d /dev/sdb1 tang '{"url":"http://tang.srv"}'
```

3. The LUKS-encrypted removable device can be now unlocked automatically in your GNOME desktop session. The device bound to a Clevis policy can be also unlocked by the clevis luks unlock command:

```
# clevis luks unlock -d /dev/sdb1
```

You can use an analogous procedure when using a TPM 2.0 policy instead of a Tang server.

Additional resources

- clevis-luks-unlockers(7) man page

11.12. DEPLOYING HIGH-AVAILABILITY NBDE SYSTEMS

Tang provides two methods for building a high-availability deployment:

Client redundancy (recommended)

Clients should be configured with the ability to bind to multiple Tang servers. In this setup, each Tang server has its own keys and clients can decrypt by contacting a subset of these servers. Clevis already supports this workflow through its sss plug-in. Red Hat recommends this method for a high-availability deployment.

Key sharing

For redundancy purposes, more than one instance of Tang can be deployed. To set up a second or any subsequent instance, install the tang packages and copy the key directory to the new host using rsync over SSH. Note that Red Hat does not recommend this method because sharing keys increases the risk of key compromise and requires additional automation infrastructure.

11.12.1. High-available NBDE using Shamir’s Secret Sharing

Shamir’s Secret Sharing (SSS) is a cryptographic scheme that divides a secret into several unique parts. To reconstruct the secret, a number of parts is required. The number is called threshold and SSS is also referred to as a thresholding scheme.

Clevis provides an implementation of SSS. It creates a key and divides it into a number of pieces. Each piece is encrypted using another pin including even SSS recursively. Additionally, you define the threshold \( t \). If an NBDE deployment decrypts at least \( t \) pieces, then it recovers the encryption key and the decryption process succeeds. When Clevis detects a smaller number of parts than specified in the threshold, it prints an error message.
11.12.1.1. Example 1: Redundancy with two Tang servers

The following command decrypts a LUKS-encrypted device when at least one of two Tang servers is available:

```
# clevis luks bind -d /dev/sda1 sss '{"t":1,"pins":{"tang":{"url":"http://tang1.srv"},
{"url":"http://tang2.srv"}}}''
```

The previous command used the following configuration scheme:

```
{
  "t":1,
  "pins":{
    "tang":[
      {
        "url":"http://tang1.srv"
      },
      {
        "url":"http://tang2.srv"
      }
    ]
  }
}
```

In this configuration, the SSS threshold \texttt{t} is set to 1 and the \texttt{clevis luks bind} command successfully reconstructs the secret if at least one from two listed \texttt{tang} servers is available.

11.12.1.2. Example 2: Shared secret on a Tang server and a TPM device

The following command successfully decrypts a LUKS-encrypted device when both the \texttt{tang} server and the \texttt{tpm2} device are available:

```
# clevis luks bind -d /dev/sda1 sss '{"t":2,"pins":{"tang":{"url":"http://tang1.srv"},
"tpm2":{"pcr_ids":"0,7"}}}'
```

The configuration scheme with the SSS threshold \texttt{t} set to 2 is now:

```
{
  "t":2,
  "pins":{
    "tang":[
      {
        "url":"http://tang1.srv"
      }
    ],
    "tpm2":{
      "pcr_ids":"0,7"
    }
  }
}
```

Additional resources

- \texttt{tang}(8)
- \texttt{clevis}(1)
- \texttt{clevis-}
11.13. DEPLOYMENT OF VIRTUAL MACHINES IN A NBDE NETWORK

The `clevis luks bind` command does not change the LUKS master key. This implies that if you create a LUKS-encrypted image for use in a virtual machine or cloud environment, all the instances that run this image share a master key. This is extremely insecure and should be avoided at all times.

This is not a limitation of Clevis but a design principle of LUKS. If your scenario requires having encrypted root volumes in a cloud, perform the installation process (usually using Kickstart) for each instance of Red Hat Enterprise Linux in the cloud as well. The images cannot be shared without also sharing a LUKS master key.

To deploy automated unlocking in a virtualized environment, use systems such as `lorax` or `virt-install` together with a Kickstart file (see Configuring automated enrollment of LUKS-encrypted volumes using Kickstart) or another automated provisioning tool to ensure that each encrypted VM has a unique master key.

Additional resources

- `clevis-luks-bind(1)` man page

11.14. BUILDING AUTOMATICALLY-ENROLLABLE VM IMAGES FOR CLOUD ENVIRONMENTS USING NBDE

Deploying automatically-enrollable encrypted images in a cloud environment can provide a unique set of challenges. Like other virtualization environments, it is recommended to reduce the number of instances started from a single image to avoid sharing the LUKS master key.

Therefore, the best practice is to create customized images that are not shared in any public repository and that provide a base for the deployment of a limited amount of instances. The exact number of instances to create should be defined by deployment’s security policies and based on the risk tolerance associated with the LUKS master key attack vector.

To build LUKS-enabled automated deployments, systems such as Lorax or virt-install together with a Kickstart file should be used to ensure master key uniqueness during the image building process.

Cloud environments enable two Tang server deployment options which we consider here. First, the Tang server can be deployed within the cloud environment itself. Second, the Tang server can be deployed outside of the cloud on independent infrastructure with a VPN link between the two infrastructures.

Deploying Tang natively in the cloud does allow for easy deployment. However, given that it shares infrastructure with the data persistence layer of ciphertext of other systems, it may be possible for both the Tang server’s private key and the Clevis metadata to be stored on the same physical disk. Access to this physical disk permits a full compromise of the ciphertext data.

**IMPORTANT**

For this reason, Red Hat strongly recommends maintaining a physical separation between the location where the data is stored and the system where Tang is running. This separation between the cloud and the Tang server ensures that the Tang server’s private key cannot be accidentally combined with the Clevis metadata. It also provides local control of the Tang server if the cloud infrastructure is at risk.
11.15. DEPLOYING TANG AS A CONTAINER

The **tang** container image provides Tang-server decryption capabilities for Clevis clients that run either in OpenShift Container Platform (OCP) clusters or in separate virtual machines.

**Prerequisites**

- The **podman** package and its dependencies are installed on the system.
- You have logged in on the **registry.redhat.io** container catalog using the **podman login registry.redhat.io** command. See [Red Hat Container Registry Authentication](#) for more information.
- The Clevis client is installed on systems containing LUKS-encrypted volumes that you want to automatically unlock by using a Tang server.

**Procedure**

1. Pull the **tang** container image from the **registry.redhat.io** registry:
   ```bash
   # podman pull registry.redhat.io/rhel9/tang
   ```

2. Run the container, specify its port, and specify the path to the Tang keys. The previous example runs the **tang** container, specifies the port **7500**, and indicates a path to the Tang keys of the **/var/db/tang** directory:
   ```bash
   # podman run -d -p 7500:7500 -v tang-keys:/var/db/tang --name tang registry.redhat.io/rhel9/tang
   ```
   Note that Tang uses port 80 by default but this may collide with other services such as the Apache HTTP server.

3. [Optional] For increased security, rotate the Tang keys periodically. You can use the **tangd-rotate-keys** script, for example:
   ```bash
   # podman run --rm -v tang-keys:/var/db/tang registry.redhat.io/rhel9/tang tangd-rotate-keys -v -d /var/db/tang
   Rotated key 'rZAMKaseaXBe0rcKXL1hCClq-DY.jwk' -> 'rZAMKaseaXBe0rcKXL1hCClq-DY.jwk'
   Rotated key 'x1AIpc6WmnCU-CabD8_4q18vDuw.jwk' -> 'x1Alpc6WmnCU-CabD8_4q18vDuw.jwk'
   Created new key GrMMX_WfdqomIU_4RyjpcdlXb0E.jwk
   Created new key _dTTfn17szZqVAp80u3ygFDHtjk.jwk
   Keys rotated successfully.
   ```

**Verification**

- On a system that contains LUKS-encrypted volumes for automated unlocking by the presence of the Tang server, check that the Clevis client can encrypt and decrypt a plain-text message using Tang:
  ```bash
  # echo test | clevis encrypt tang '{"url":"http://localhost:7500"}' | clevis decrypt
  ```
  The advertisement contains the following signing keys:
Do you wish to trust these keys? [ynYN] y

test

The previous example command shows the **test** string at the end of its output when a Tang server is available on the *localhost* URL and communicates through port *7500*.

**Additional resources**

- **podman**(1), **clevis**(1), and **tang**(8) man pages

### 11.16. INTRODUCTION TO THE CLEVIS AND TANG SYSTEM ROLES

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems.

You can use Ansible roles for automated deployments of Policy-Based Decryption (PBD) solutions using Clevis and Tang. The **rhel-system-roles** package contains these system roles, the related examples, and also the reference documentation.

The Network Bound Disk Encryption Client System Role enables you to deploy multiple Clevis clients in an automated way. Note that the Network Bound Disk Encryption Client role supports only Tang bindings, and you cannot use it for TPM2 bindings at the moment.

The Network Bound Disk Encryption Client role requires volumes that are already encrypted using LUKS. This role supports to bind a LUKS-encrypted volume to one or more Network-Bound (NBDE) servers - Tang servers. You can either preserve the existing volume encryption with a passphrase or remove it. After removing the passphrase, you can unlock the volume only using NBDE. This is useful when a volume is initially encrypted using a temporary key or password that you should remove after you provision the system.

If you provide both a passphrase and a key file, the role uses what you have provided first. If it does not find any of these valid, it attempts to retrieve a passphrase from an existing binding.

PBD defines a binding as a mapping of a device to a slot. This means that you can have multiple bindings for the same device. The default slot is slot 1.

The Network Bound Disk Encryption Client role provides also the **state** variable. Use the **present** value for either creating a new binding or updating an existing one. Contrary to a **clevis luks bind** command, you can use **state: present** also for overwriting an existing binding in its device slot. The **absent** value removes a specified binding.

Using the Network Bound Disk Encryption Server System Role, you can deploy and manage a Tang server as part of an automated disk encryption solution. This role supports the following features:

- Rotating Tang keys
- Deploying and backing up Tang keys

**Additional resources**

- For a detailed reference on Network-Bound Disk Encryption (NBDE) role variables, install the **rhel-system-roles** package, and see the **README.md** and **README.html** files in the `/usr/share/doc/rhel-system-roles/nbde_client/` and `/usr/share/doc/rhel-system-roles/nbde_server/` directories.
For example system-roles playbooks, install the `rhel-system-roles` package, and see the `/usr/share/ansible/roles/rhel-system-roles.nbde_server/examples/` directories.

For more information on RHEL System Roles, see Introduction to RHEL System Roles

### 11.17. USING THE NBDE SERVER SYSTEM ROLE FOR SETTING UP MULTIPLE TANG SERVERS

Follow the steps to prepare and apply an Ansible playbook containing your Tang server settings.

### Prerequisites

- Access and permissions to one or more managed nodes, which are systems you want to configure with the NBDE Server System Role.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems.

On the control node:

- The `ansible-core` and `rhel-system-roles` packages are installed.

**IMPORTANT**

RHEL 8.0-8.5 provided access to a separate Ansible repository that contains Ansible Engine 2.9 for automation based on Ansible. Ansible Engine contains command-line utilities such as `ansible`, `ansible-playbook`, connectors such as `docker` and `podman`, and many plugins and modules. For information on how to obtain and install Ansible Engine, see the How to download and install Red Hat Ansible Engine Knowledgebase article.

RHEL 8.6 and 9.0 have introduced Ansible Core (provided as the `ansible-core` package), which contains the Ansible command-line utilities, commands, and a small set of built-in Ansible plugins. RHEL provides this package through the AppStream repository, and it has a limited scope of support. For more information, see the Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories Knowledgebase article.

- An inventory file which lists the managed nodes.

### Procedure

1. Prepare your playbook containing settings for Tang servers. You can either start from the scratch, or use one of the example playbooks from the `/usr/share/ansible/roles/rhel-system-roles.nbde_server/examples/` directory.

   ```bash
   # cp /usr/share/ansible/roles/rhel-system-roles.nbde_server/examples/simple_deploy.yml .my-tang-playbook.yml
   ```

2. Edit the playbook in a text editor of your choice, for example:

   ```bash
   # vi my-tang-playbook.yml
   ```

3. Add the required parameters. The following example playbook ensures deploying of your Tang server and a key rotation:

   ```yaml
   ```
---
- hosts: all
  vars:
    nbde_server_rotate_keys: yes
  roles:
    - rhel-system-roles.nbde_server

4. Apply the finished playbook:

```yaml
# ansible-playbook -i inventory-file my-tang-playbook.yml
```

Where: *inventory-file* is the inventory file. *logging-playbook.yml* is the playbook you use.

**IMPORTANT**

To ensure that networking for a Tang pin is available during early boot by using the `grubby` tool on the systems where Clevis is installed:

```
# grubby --update-kernel=ALL --args="rd.neednet=1"
```

**Additional resources**

- For more information, install the `rhel-system-roles` package, and see the `/usr/share/doc/rhel-system-roles/nbde_server/` and `/usr/share/ansible/roles/rhel-system-roles.nbde_server/` directories.

### 11.18. USING THE NBDE CLIENT SYSTEM ROLE FOR SETTING UP MULTIPLE CLEVIS CLIENTS

Follow the steps to prepare and apply an Ansible playbook containing your Clevis client settings.

**NOTE**

The NBDE Client System Role supports only Tang bindings. This means that you cannot use it for TPM2 bindings at the moment.

**Prerequisites**

- Access and permissions to one or more *managed nodes*, which are systems you want to configure with the NBDE Client System Role.

- Access and permissions to a *control node*, which is a system from which Red Hat Ansible Core configures other systems.

- The Ansible Core package is installed on the control machine.

- The `rhel-system-roles` package is installed on the system from which you want to run the playbook.

**Procedure**
1. Prepare your playbook containing settings for Clevis clients. You can either start from the scratch, or use one of the example playbooks from the `/usr/share/ansible/roles/rhel-system-roles.nbde_client/examples/` directory.

```bash
# cp /usr/share/ansible/roles/rhel-system-roles.nbde_client/examples/high_availability.yml ./my-clevis-playbook.yml
```

2. Edit the playbook in a text editor of your choice, for example:

```bash
# vi my-clevis-playbook.yml
```

3. Add the required parameters. The following example playbook configures Clevis clients for automated unlocking of two LUKS-encrypted volumes by when at least one of two Tang servers is available:

```yaml
---
- hosts: all
  vars:
    nbde_client_bindings:
      - device: /dev/rhel/root
        encryption_key_src: /etc/luks/keyfile
        servers:
          - http://server1.example.com
          - http://server2.example.com
      - device: /dev/rhel/swap
        encryption_key_src: /etc/luks/keyfile
        servers:
          - http://server1.example.com
          - http://server2.example.com

  roles:
    - rhel-system-roles.nbde_client
```

4. Apply the finished playbook:

```bash
# ansible-playbook -i host1,host2,host3 my-clevis-playbook.yml
```

**IMPORTANT**

To ensure that networking for a Tang pin is available during early boot by using the `grubby` tool on the system where Clevis is installed:

```bash
# grubby --update-kernel=ALL --args="rd.neednet=1"
```

**Additional resources**

- For details about the parameters and additional information about the NBDE Client System Role, install the `rhel-system-roles` package, and see the `/usr/share/doc/rhel-system-roles/nbde_client/` and `/usr/share/ansible/roles/rhel-system-roles.nbde_client/` directories.
- `tang(8)`, `clevis(1)`, `jose(1)`, and `clevis-luks-unlockers(7)` man pages
- How to set up Network-Bound Disk Encryption with multiple LUKS devices (Clevis + Tang unlocking) Knowledgebase article
CHAPTER 12. AUDITING THE SYSTEM

Audit does not provide additional security to your system; rather, it can be used to discover violations of security policies used on your system. These violations can further be prevented by additional security measures such as SELinux.

12.1. LINUX AUDIT

The Linux Audit system provides a way to track security-relevant information on your system. Based on pre-configured rules, Audit generates log entries to record as much information about the events that are happening on your system as possible. This information is crucial for mission-critical environments to determine the violator of the security policy and the actions they performed.

The following list summarizes some of the information that Audit is capable of recording in its log files:

- Date and time, type, and outcome of an event.
- Sensitivity labels of subjects and objects.
- Association of an event with the identity of the user who triggered the event.
- All modifications to Audit configuration and attempts to access Audit log files.
- All uses of authentication mechanisms, such as SSH, Kerberos, and others.
- Changes to any trusted database, such as `/etc/passwd`.
- Attempts to import or export information into or from the system.
- Include or exclude events based on user identity, subject and object labels, and other attributes.

The use of the Audit system is also a requirement for a number of security-related certifications. Audit is designed to meet or exceed the requirements of the following certifications or compliance guides:

- Controlled Access Protection Profile (CAPP)
- Labeled Security Protection Profile (LSPP)
- Rule Set Base Access Control (RSBAC)
- National Industrial Security Program Operating Manual (NISPOM)
- Federal Information Security Management Act (FISMA)
- Payment Card Industry – Data Security Standard (PCI-DSS)
- Security Technical Implementation Guides (STIG)

Audit has also been:

- Evaluated by National Information Assurance Partnership (NIAP) and Best Security Industries (BSI).
- Certified to LSPP/CAPP/RSBAC/EAL4+ on Red Hat Enterprise Linux 5.
Use Cases

Watching file access

Audit can track whether a file or a directory has been accessed, modified, executed, or the file’s attributes have been changed. This is useful, for example, to detect access to important files and have an Audit trail available in case one of these files is corrupted.

Monitoring system calls

Audit can be configured to generate a log entry every time a particular system call is used. This can be used, for example, to track changes to the system time by monitoring the `settimeofday`, `clock_adjtime`, and other time-related system calls.

Recording commands run by a user

Audit can track whether a file has been executed, so rules can be defined to record every execution of a particular command. For example, a rule can be defined for every executable in the `/bin` directory. The resulting log entries can then be searched by user ID to generate an audit trail of executed commands per user.

Recording execution of system pathnames

Aside from watching file access which translates a path to an inode at rule invocation, Audit can now watch the execution of a path even if it does not exist at rule invocation, or if the file is replaced after rule invocation. This allows rules to continue to work after upgrading a program executable or before it is even installed.

Recording security events

The `pam_faillock` authentication module is capable of recording failed login attempts. Audit can be set up to record failed login attempts as well and provides additional information about the user who attempted to log in.

Searching for events

Audit provides the `ausearch` utility, which can be used to filter the log entries and provide a complete audit trail based on several conditions.

Running summary reports

The `aureport` utility can be used to generate, among other things, daily reports of recorded events. A system administrator can then analyze these reports and investigate suspicious activity further.

Monitoring network access

The `nftables`, `iptables`, and `ebtables` utilities can be configured to trigger Audit events, allowing system administrators to monitor network access.

NOTE

System performance may be affected depending on the amount of information that is collected by Audit.

12.2. AUDIT SYSTEM ARCHITECTURE

The Audit system consists of two main parts: the user-space applications and utilities, and the kernel-side system call processing. The kernel component receives system calls from user-space applications and filters them through one of the following filters: `user`, `task`, `fstype`, or `exit`.

Once a system call passes the `exclude` filter, it is sent through one of the aforementioned filters, which, based on the Audit rule configuration, sends it to the Audit daemon for further processing.
The user-space Audit daemon collects the information from the kernel and creates entries in a log file. Other Audit user-space utilities interact with the Audit daemon, the kernel Audit component, or the Audit log files:

- \texttt{auditctl} — the Audit control utility interacts with the kernel Audit component to manage rules and to control many settings and parameters of the event generation process.

- The remaining Audit utilities take the contents of the Audit log files as input and generate output based on user’s requirements. For example, the \texttt{aureport} utility generates a report of all recorded events.

In RHEL 9, the Audit dispatcher daemon (\texttt{audisp}) functionality is integrated in the Audit daemon (\texttt{auditd}). Configuration files of plugins for the interaction of real-time analytical programs with Audit events are located in the \texttt{/etc/audit/plugins.d/} directory by default.

### 12.3. Configuring Auditd for a Secure Environment

The default \texttt{auditd} configuration should be suitable for most environments. However, if your environment has to meet strict security policies, the following settings are suggested for the Audit daemon configuration in the \texttt{/etc/audit/auditd.conf} file:

- \texttt{log_file}
  - The directory that holds the Audit log files (usually \texttt{/var/log/audit/}) should reside on a separate mount point. This prevents other processes from consuming space in this directory and provides accurate detection of the remaining space for the Audit daemon.

- \texttt{max_log_file}
  - Specifies the maximum size of a single Audit log file, must be set to make full use of the available space on the partition that holds the Audit log files.

- \texttt{max_log_file_action}
  - Decides what action is taken once the limit set in \texttt{max_log_file} is reached, should be set to \texttt{keep_logs} to prevent Audit log files from being overwritten.

- \texttt{space_left}
  - Specifies the amount of free space left on the disk for which an action that is set in the \texttt{space_left_action} parameter is triggered. Must be set to a number that gives the administrator enough time to respond and free up disk space. The \texttt{space_left} value depends on the rate at which the Audit log files are generated.

- \texttt{space_left_action}
  - It is recommended to set the \texttt{space_left_action} parameter to \texttt{email} or \texttt{exec} with an appropriate notification method.

- \texttt{admin_space_left}
  - Specifies the absolute minimum amount of free space for which an action that is set in the \texttt{admin_space_left_action} parameter is triggered, must be set to a value that leaves enough space to log actions performed by the administrator.

- \texttt{admin_space_left_action}
  - Should be set to \texttt{single} to put the system into single-user mode and allow the administrator to free up some disk space.

- \texttt{disk_full_action}
  - Specifies an action that is triggered when no free space is available on the partition that holds the Audit log files, must be set to \texttt{halt} or \texttt{single}. This ensures that the system is either shut down or operating in single-user mode when Audit can no longer log events.
disk_error_action

Specifies an action that is triggered in case an error is detected on the partition that holds the Audit log files, must be set to syslog, single, or halt, depending on your local security policies regarding the handling of hardware malfunctions.

flush

Should be set to incremental_async. It works in combination with the freq parameter, which determines how many records can be sent to the disk before forcing a hard synchronization with the hard drive. The freq parameter should be set to 100. These parameters assure that Audit event data is synchronized with the log files on the disk while keeping good performance for bursts of activity.

The remaining configuration options should be set according to your local security policy.

12.4. STARTING AND CONTROLLING AUDITD

After auditd is configured, start the service to collect Audit information and store it in the log files. Use the following command as the root user to start auditd:

```
# service auditd start
```

To configure auditd to start at boot time:

```
# systemctl enable auditd
```

You can temporarily disable auditd with the # auditctl -e 0 command and re-enable it with # auditctl -e 1.

A number of other actions can be performed on auditd using the service auditd action command, where action can be one of the following:

**stop**

Stops auditd.

**restart**

Restarts auditd.

**reload** or **force-reload**

Reloads the configuration of auditd from the /etc/audit/auditd.conf file.

**rotate**

Rotates the log files in the /var/log/audit/ directory.

**resume**

Resumes logging of Audit events after it has been previously suspended, for example, when there is not enough free space on the disk partition that holds the Audit log files.

**condrestart** or **try-restart**

Restarts auditd only if it is already running.

**status**

Displays the running status of auditd.
### 12.5. UNDERSTANDING AUDIT LOG FILES

By default, the Audit system stores log entries in the `/var/log/audit/audit.log` file; if log rotation is enabled, rotated `audit.log` files are stored in the same directory.

Add the following Audit rule to log every attempt to read or modify the `/etc/ssh/sshd_config` file:

```bash
# auditctl -w /etc/ssh/sshd_config -p warx -k sshd_config
```

If the `auditd` daemon is running, for example, using the following command creates a new event in the Audit log file:

```bash
$ cat /etc/ssh/sshd_config
```

This event in the `audit.log` file looks as follows:

```
type=SYSCALL msg=audit(1364481363.243:24287): arch=c000003e syscall=2 success=no exit=-13 a0=7fffd19c5592 a1=0 a2=7fffd19c4b50 a3=a items=1 ppid=2686 pid=3538 auid=1000 uid=1000 gid=1000 euid=1000 suid=1000 sgid=1000 fsuid=1000 fsgid=1000 tty=pts0 ses=1 comm="cat" exe="/bin/cat" subj=unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023 key="sshd_config"
type=CWD msg=audit(1364481363.243:24287) : cwd="/home/shadowman"
type=PATH msg=audit(1364481363.243:24287): item=0 name="/etc/ssh/sshd_config" ino=409248 dev=fd:00 mode=0100600 ouid=0 ogid=0 rdev=00:00 obj=system_u:object_r:etc_t:s0 nametype=NORMAL cap_fp=none cap_fi=none cap_fe=0 cap_fver=0 type=PROCTITLE msg=audit(1364481363.243:24287) :
proctitle=636174002F6574632F7373682F737368645F636F6E66696765
```

The above event consists of four records, which share the same time stamp and serial number. Records always start with the `type=` keyword. Each record consists of several `name=value` pairs separated by a white space or a comma. A detailed analysis of the above event follows:

#### First Record

**type=SYSCALL**

The `type` field contains the type of the record. In this example, the `SYSCALL` value specifies that this record was triggered by a system call to the kernel.

**msg=audit(1364481363.243:24287):**

The `msg` field records:

- a time stamp and a unique ID of the record in the form `audit(time_stamp:ID)`. Multiple records can share the same time stamp and ID if they were generated as part of the same Audit event. The time stamp is using the Unix time format - seconds since 00:00:00 UTC on 1 January 1970.

- various event-specific `name=value` pairs provided by the kernel or user-space applications.
The `arch` field contains information about the CPU architecture of the system. The value, `c000003e`, is encoded in hexadecimal notation. When searching Audit records with the `ausearch` command, use the `-i` or `--interpret` option to automatically convert hexadecimal values into their human-readable equivalents. The `c000003e` value is interpreted as  `x86_64`.

The `syscall` field records the type of the system call that was sent to the kernel. The value, `2`, can be matched with its human-readable equivalent in the `/usr/include/asm/unistd_64.h` file. In this case, `2` is the `open` system call. Note that the `ausyscall` utility allows you to convert system call numbers to their human-readable equivalents. Use the `ausyscall --dump` command to display a listing of all system calls along with their numbers. For more information, see the `ausyscall(8)` man page.

The `success` field records whether the system call recorded in that particular event succeeded or failed. In this case, the call did not succeed.

The `exit` field contains a value that specifies the exit code returned by the system call. This value varies for a different system call. You can interpret the value to its human-readable equivalent with the following command:

```
# ausearch --interpret --exit -13
```

Note that the previous example assumes that your Audit log contains an event that failed with exit code `-13`.

The `a0` to `a3` fields record the first four arguments, encoded in hexadecimal notation, of the system call in this event. These arguments depend on the system call that is used; they can be interpreted by the `ausearch` utility.

The `items` field contains the number of PATH auxiliary records that follow the syscall record.

The `ppid` field records the Parent Process ID (PPID). In this case, `2686` was the PPID of the parent process such as `bash`.

The `pid` field records the Process ID (PID). In this case, `3538` was the PID of the `cat` process.

The `auid` field records the Audit user ID, that is the loginuid. This ID is assigned to a user upon login and is inherited by every process even when the user’s identity changes, for example, by switching user accounts with the `su - john` command.

The `uid` field records the user ID of the user who started the analyzed process. The user ID can be interpreted into user names with the following command: `ausearch -i --uid UID`.

The `gid` field records the group ID of the user who started the analyzed process.

The `euid` field records the effective user ID of the user who started the analyzed process.

The `suid` field records the effective user ID of the user who started the analyzed process.
The **suid** field records the set user ID of the user who started the analyzed process.

```bash
fsuid=1000
```

The **fsuid** field records the file system user ID of the user who started the analyzed process.

```bash
egid=1000
```

The **egid** field records the effective group ID of the user who started the analyzed process.

```bash
sgid=1000
```

The **sgid** field records the set group ID of the user who started the analyzed process.

```bash
fsgid=1000
```

The **fsgid** field records the file system group ID of the user who started the analyzed process.

```bash
tty=pts0
```

The **tty** field records the terminal from which the analyzed process was invoked.

```bash
ses=1
```

The **ses** field records the session ID of the session from which the analyzed process was invoked.

```bash
comm="cat"
```

The **comm** field records the command-line name of the command that was used to invoke the analyzed process. In this case, the **cat** command was used to trigger this Audit event.

```bash
exe="/bin/cat"
```

The **exe** field records the path to the executable that was used to invoke the analyzed process.

```bash
subj=unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

The **subj** field records the SELinux context with which the analyzed process was labeled at the time of execution.

```bash
key="sshd_config"
```

The **key** field records the administrator-defined string associated with the rule that generated this event in the Audit log.

**Second Record**

`type=CWD`

In the second record, the **type** field value is **CWD** — current working directory. This type is used to record the working directory from which the process that invoked the system call specified in the first record was executed.

The purpose of this record is to record the current process’s location in case a relative path winds up being captured in the associated PATH record. This way the absolute path can be reconstructed.

```bash
msg=audit(1364481363.243:24287)
```

The **msg** field holds the same time stamp and ID value as the value in the first record. The time stamp is using the Unix time format – seconds since 00:00:00 UTC on 1 January 1970.

```bash
cwd="/home/user_name"
```

The **cwd** field contains the path to the directory in which the system call was invoked.

**Third Record**

`type=PATH`

In the third record, the **type** field value is **PATH**. An Audit event contains a **PATH**-type record for every path that is passed to the system call as an argument. In this Audit event, only one path (/etc/ssh/sshd_config) was used as an argument.
msg=audit(1364481363.243:24287):

The msg field holds the same time stamp and ID value as the value in the first and second record.

item=0

The item field indicates which item, of the total number of items referenced in the SYSCALL type record, the current record is. This number is zero-based; a value of 0 means it is the first item.

name="/etc/ssh/sshd_config"

The name field records the path of the file or directory that was passed to the system call as an argument. In this case, it was the /etc/ssh/sshd_config file.

inode=409248

The inode field contains the inode number associated with the file or directory recorded in this event. The following command displays the file or directory that is associated with the 409248 inode number:

```
# find / -inum 409248 -print
/etc/ssh/sshd_config
```

dev=fd:00

The dev field specifies the minor and major ID of the device that contains the file or directory recorded in this event. In this case, the value represents the /dev/fd/0 device.

mode=0100600

The mode field records the file or directory permissions, encoded in numerical notation as returned by the stat command in the st_mode field. See the stat(2) man page for more information. In this case, 0100600 can be interpreted as -rw-------, meaning that only the root user has read and write permissions to the /etc/ssh/sshd_config file.

ouid=0

The ouid field records the object owner’s user ID.

ogid=0

The ogid field records the object owner’s group ID.

rdev=00:00

The rdev field contains a recorded device identifier for special files only. In this case, it is not used as the recorded file is a regular file.

obj=system_u:object_r:etc_t:s0

The obj field records the SELinux context with which the recorded file or directory was labeled at the time of execution.

nametype=NORMAL

The nametype field records the intent of each path record’s operation in the context of a given syscall.

cap_fp=none

The cap_fp field records data related to the setting of a permitted file system-based capability of the file or directory object.

cap-fi=none

The cap-fi field records data related to the setting of an inherited file system-based capability of the file or directory object.

cap_fe=0

The cap_fe field records the setting of the effective bit of the file system-based capability of the file or directory object.
The `cap_fver` field records the version of the file system-based capability of the file or directory object.

**Fourth Record**

**type=PROCTITLE**

The `type` field contains the type of the record. In this example, the `PROCTITLE` value specifies that this record gives the full command-line that triggered this Audit event, triggered by a system call to the kernel.

**proctitle=636174002F6574632F7373682F737368645F636F6E666967**

The `proctitle` field records the full command-line of the command that was used to invoke the analyzed process. The field is encoded in hexadecimal notation to not allow the user to influence the Audit log parser. The text decodes to the command that triggered this Audit event. When searching Audit records with the `ausearch` command, use the `-i` or `--interpret` option to automatically convert hexadecimal values into their human-readable equivalents. The `636174002F6574632F7373682F737368645F636F6E666967` value is interpreted as `cat /etc/ssh/sshd_config`.

### 12.6. USING AUDITCTL FOR DEFINING AND EXECUTING AUDIT RULES

The Audit system operates on a set of rules that define what is captured in the log files. Audit rules can be set either on the command line using the `auditctl` utility or in the `/etc/audit/rules.d/` directory.

The `auditctl` command enables you to control the basic functionality of the Audit system and to define rules that decide which Audit events are logged.

#### File-system rules examples

1. To define a rule that logs all write access to, and every attribute change of, the `/etc/passwd` file:

   ```
   # auditctl -w /etc/passwd -p wa -k passwd_changes
   ```

2. To define a rule that logs all write access to, and every attribute change of, all the files in the `/etc/selinux/` directory:

   ```
   # auditctl -w /etc/selinux/ -p wa -k selinux_changes
   ```

#### System-call rules examples

1. To define a rule that creates a log entry every time the `adjtimex` or `settimeofday` system calls are used by a program, and the system uses the 64-bit architecture:

   ```
   # auditctl -a always,exit -F arch=b64 -S adjtimex -S settimeofday -k time_change
   ```

2. To define a rule that creates a log entry every time a file is deleted or renamed by a system user whose ID is 1000 or larger:

   ```
   # auditctl -a always,exit -S unlink -S unlinkat -S rename -S renameat -F auid>=1000 -F auid!=4294967295 -k delete
   ```

   Note that the `--F auid!=4294967295` option is used to exclude users whose login UID is not set.
Executable-file rules

To define a rule that logs all execution of the /bin/id program, execute the following command:

```
# auditctl -a always,exit -F exe=/bin/id -F arch=b64 -S execve -k execution_bin_id
```

Additional resources

- **auditctl(8)** man page.

12.7. DEFINING PERSISTENT AUDIT RULES

To define Audit rules that are persistent across reboots, you must either directly include them in the /etc/audit/rules.d/audit.rules file or use the **augenrules** program that reads rules located in the /etc/audit/rules.d/ directory.

Note that the /etc/audit/audit.rules file is generated whenever the **auditd** service starts. Files in /etc/audit/rules.d/ use the same auditctl command-line syntax to specify the rules. Empty lines and text following a hash sign (#) are ignored.

Furthermore, you can use the **auditctl** command to read rules from a specified file using the **-R** option, for example:

```
# auditctl -R /usr/share/audit/sample-rules/30-stig.rules
```

12.8. USING PRE-CONFIGURED RULES FILES

In the /usr/share/audit/sample-rules directory, the **audit** package provides a set of pre-configured rules files according to various certification standards:

- **30-nispom.rules**
  Audit rule configuration that meets the requirements specified in the Information System Security chapter of the National Industrial Security Program Operating Manual.

- **30-ospp-v42*.rules**
  Audit rule configuration that meets the requirements defined in the OSPP (Protection Profile for General Purpose Operating Systems) profile version 4.2.

- **30-pci-dss-v31.rules**
  Audit rule configuration that meets the requirements set by Payment Card Industry Data Security Standard (PCI DSS) v3.1.

- **30-stig.rules**
  Audit rule configuration that meets the requirements set by Security Technical Implementation Guides (STIG).

To use these configuration files, copy them to the /etc/audit/rules.d/ directory and use the **augenrules --load** command, for example:

```
# cd /usr/share/audit/sample-rules/
# cp 10-base-config.rules 30-stig.rules 31-privileged.rules 99-finalize.rules /etc/audit/rules.d/
# augenrules --load
```
You can order Audit rules using a numbering scheme. See the `/usr/share/audit/sample-rules/README-rules` file for more information.

Additional resources

- `audit.rules(7)` man page.

### 12.9. USING AUGENRULES TO DEFINE PERSISTENT RULES

The `augenrules` script reads rules located in the `/etc/audit/rules.d/` directory and compiles them into an `audit.rules` file. This script processes all files that end with `.rules` in a specific order based on their natural sort order. The files in this directory are organized into groups with the following meanings:

- **10** - Kernel and auditctl configuration
- **20** - Rules that could match general rules but you want a different match
- **30** - Main rules
- **40** - Optional rules
- **50** - Server-specific rules
- **70** - System local rules
- **90** - Finalize (immutable)

The rules are not meant to be used all at once. They are pieces of a policy that should be thought out and individual files copied to `/etc/audit/rules.d/`. For example, to set a system up in the STIG configuration, copy rules `10-base-config`, `30-stig`, `31-privileged`, and `99-finalize`.

Once you have the rules in the `/etc/audit/rules.d/` directory, load them by running the `augenrules` script with the `--load` directive:

```
# augenrules --load
/sbin/augenrules: No change
No rules
enabled 1
failure 1
pid 742
rate_limit 0
...
```

Additional resources

- `audit.rules(8)` and `augenrules(8)` man pages.

### 12.10. DISABLING AUGENRULES

Use the following steps to disable the `augenrules` utility. This switches Audit to use rules defined in the `/etc/audit/audit.rules` file.

**Procedure**
1. Copy the `/usr/lib/systemd/system/auditd.service` file to the `/etc/systemd/system/` directory:

   ```
   # cp -f /usr/lib/systemd/system/auditd.service /etc/systemd/system/
   ```

2. Edit the `/etc/systemd/system/auditd.service` file in a text editor of your choice, for example:

   ```
   # vi /etc/systemd/system/auditd.service
   ```

3. Comment out the line containing `augenrules`, and uncomment the line containing the `auditctl -R` command:

   ```
   #ExecStartPost=-/sbin/augenrules --load
   ExecStartPost=-/sbin/auditctl -R /etc/audit/audit.rules
   ```

4. Reload the `systemd` daemon to fetch changes in the `auditd.service` file:

   ```
   # systemctl daemon-reload
   ```

5. Restart the `auditd` service:

   ```
   # service auditd restart
   ```

Additional resources

- `augenrules(8)` and `audit.rules(8)` man pages.
- `Auditd service restart overrides changes made to /etc/audit/audit.rules`.

12.11. SETTING UP AUDIT TO MONITOR SOFTWARE UPDATES

You can use the pre-configured rule `44-installer.rules` to configure Audit to monitor the following utilities that install software:

- `dnf` [2]
- `yum`
- `pip`
- `npm`
- `cpan`
- `gem`
- `luarocks`

To monitor the `rpm` utility, install the `rpm-plugin-audit` package. Audit will then generate `SOFTWARE_UPDATE` events when it installs or updates a package. You can list these events by entering `ausearch -m SOFTWARE_UPDATE` on the command line.
NOTE

Pre-configured rule files cannot be used on systems with the ppc64le and aarch64 architectures.

Prerequisites

- **auditd** is configured in accordance with the settings provided in Configuring auditd for a secure environment.

Procedure

1. Copy the pre-configured rule file `44-installers.rules` from the `/usr/share/audit/sample-rules/` directory to the `/etc/audit/rules.d/` directory:

   ```
   # cp /usr/share/audit/sample-rules/44-installers.rules /etc/audit/rules.d/
   ```

2. Load the audit rules:

   ```
   # augenrules --load
   ```

Verification

1. List the loaded rules:

   ```
   # auditctl -I
   -p x-w /usr/bin/dnf-3 -k software-installer
   -p x-w /usr/bin/yum -k software-installer
   -p x-w /usr/bin/pip -k software-installer
   -p x-w /usr/bin/npm -k software-installer
   -p x-w /usr/bin/cpan -k software-installer
   -p x-w /usr/bin/gem -k software-installer
   -p x-w /usr/bin/luarocks -k software-installer
   ```

2. Perform an installation, for example:

   ```
   # dnf reinstall -y vim-enhanced
   ```

3. Search the Audit log for recent installation events, for example:

   ```
   # ausearch -ts recent -k software-installer
   ```
type=PATH msg=audit(1639668826.074:298): item=0 name="/usr/bin/dnf" inode=6886099 dev=fd:01 mode=0100755 ouid=0 ogid=0 rdev=00:00 obj=system_u:object_r:rpm_exec_t:s0 nametype=NORMAL cap_fp=0 cap_fl=0 cap_fe=0 cap_fver=0 cap_frootid=0
type=CWD msg=audit(1639668826.074:298): cwd="/root"
type=EXECVE msg=audit(1639668826.074:298): argc=5 a0="/usr/libexec/platform-python" a1="/usr/bin/dnf" a2="reinstall" a3="-y" a4="vim-enhanced"
type=SYSCALL msg=audit(1639668826.074:298): arch=c000003e syscall=59 success=yes exit=0 a0=55c437f22b20 a1=55c437f2c9d0 a2=55c437f2aeb0 a3=8 items=3 ppid=5256 pid=5375 auid=0 uid=0 gid=0 euid=0 suid=0 fsuid=0 egid=0 sgid=0 fsgid=0 tty=pts0 ses=3 comm="dnf" exe="/usr/libexec/platform-python3.6" subj=unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023 key="software-installer"

12.12. MONITORING USER LOGIN TIMES WITH AUDIT

To monitor which users logged in at specific times, you do not need to configure Audit in any special way. You can use the ausearch or aureport tools, which provide different ways of presenting the same information.

Prerequisites

- audid is configured in accordance with the settings provided in Configuring auditd for a secure environment.

Procedure

To display user log in times, use any one of the following commands:

- Search the audit log for the USER_LOGIN message type:

  # ausearch -m USER_LOGIN -ts '12/02/2020' '18:00:00' -sv no
time->Mon Nov 22 07:33:22 2021
type=USER_LOGIN msg=audit(1637584402.416:92): pid=1939 uid=0 auid=4294967295 ses=4294967295 subj=system_u:system_r:sshd_t:s0-s0:c0.c1023 msg='op=login acct="(unknown)" exe="/usr/sbin/sshd" hostname=? addr=10.37.128.108 terminal=ssh res=failed'

- You can specify the date and time with the -ts option. If you do not use this option, ausearch provides results from today, and if you omit time, ausearch provides results from midnight.

- You can use the -sv yes option to filter out successful login attempts and -sv no for unsuccessful login attempts.

- Pipe the raw output of the ausearch command into the aulast utility, which displays the output in a format similar to the output of the last command. For example:

  # ausearch --raw | aulast --stdin
  root  ssh  10.37.128.108  Mon Nov 22 07:33 - 07:33  (00:00)
  root  ssh  10.37.128.108  Mon Nov 22 07:33 - 07:33  (00:00)
  root  ssh  10.22.16.106   Mon Nov 22 07:40 - 07:40  (00:00)
  reboot system boot 4.18.0-348.6.el8 Mon Nov 22 07:33

- Display the list of login events by using the aureport command with the --login -i options.

  # aureport --login -i
### Login Report

<table>
<thead>
<tr>
<th>Date</th>
<th>Time</th>
<th>User</th>
<th>IP Address</th>
<th>Command</th>
<th>Success</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>11/16/2021</td>
<td>13:11:30</td>
<td>root</td>
<td>10.40.192.190</td>
<td>ssh /usr/sbin/sshd</td>
<td>yes</td>
<td>6920</td>
</tr>
<tr>
<td>11/16/2021</td>
<td>13:11:33</td>
<td>root</td>
<td>10.40.192.190</td>
<td>/dev/pts/0 /usr/sbin/sshd</td>
<td>yes</td>
<td>6945</td>
</tr>
</tbody>
</table>

Additional resources

- The `ausearch(8)` man page.
- The `aulast(8)` man page.
- The `aureport(8)` man page.

### 12.13. ADDITIONAL RESOURCES

- The RHEL Audit System Reference Knowledgebase article.
- The Audid execution options in a container Knowledgebase article.
- The Linux Audit Documentation Project page.
- The `audit` package provides documentation in the `/usr/share/doc/audit/` directory.
- `auditd(8), auditctl(8), ausearch(8), audit.rules(7), audispd.conf(5), audispd(8), auditd.conf(5), ausearch-expression(5), aulast(8), aulastlog(8), aureport(8), ausyscall(8), autrace(8), and auvirt(8)` man pages.

---

[2] Because `dnf` is a symlink in RHEL, the path in the `dnf` Audit rule must include the target of the symlink. To receive correct Audit events, modify the `44-installers.rules` file by changing the `path=/usr/bin/dnf` path to `/usr/bin/dnf-3`. 

---
CHAPTER 13. BLOCKING AND ALLOWING APPLICATIONS USING FAPOLICYD

Setting and enforcing a policy that either allows or denies application execution based on a rule set efficiently prevents the execution of unknown and potentially malicious software.

13.1. INTRODUCTION TO FAPOLICYD

The fapolicyd software framework controls the execution of applications based on a user-defined policy. This is one of the most efficient ways to prevent running untrusted and possibly malicious applications on the system.

The fapolicyd framework provides the following components:

- fapolicyd service
- fapolicyd command-line utilities
- fapolicyd RPM plugin
- fapolicyd rule language
- fagenrules script

The administrator can define the allow and deny execution rules for any application with the possibility of auditing based on a path, hash, MIME type, or trust.

The fapolicyd framework introduces the concept of trust. An application is trusted when it is properly installed by the system package manager, and therefore it is registered in the system RPM database. The fapolicyd daemon uses the RPM database as a list of trusted binaries and scripts. The fapolicyd RPM plugin registers any system update that is handled by either the DNF package manager or the RPM Package Manager. The plugin notifies the fapolicyd daemon about changes in this database. Other ways of adding applications require the creation of custom rules and restarting the fapolicyd service.

The fapolicyd service configuration is located in the /etc/fapolicyd/ directory with the following structure:

- The /etc/fapolicyd/fapolicyd.trust file contains a list of trusted files. You can also use multiple trust files in the /etc/fapolicyd/trust.d/ directory.
- The /etc/fapolicyd/rules.d/ directory for files containing allow and deny execution rules. The fagenrules script merges these component rules files to the /etc/fapolicyd/compiled.rules file.
- The fapolicyd.conf file contains the daemon’s configuration options. This file is useful primarily for performance-tuning purposes.

Rules in /etc/fapolicyd/rules.d/ are organized in several files, each representing a different policy goal. The numbers at the beginning of the corresponding file names determine the order in /etc/fapolicyd/compiled.rules:

- 10 - language rules
- 20 - Dracut-related Rules
- 21 - rules for updaters
You can use one of the ways for fapolicyd integrity checking:

- file-size checking
- comparing SHA-256 hashes
- Integrity Measurement Architecture (IMA) subsystem

By default, fapolicyd does no integrity checking. Integrity checking based on the file size is fast, but an attacker can replace the content of the file and preserve its byte size. Computing and checking SHA-256 checksums is more secure, but it affects the performance of the system. The `integrity = ima` option in `fapolicyd.conf` requires support for files extended attributes (also known as `xattr`) on all file systems containing executable files.

Additional resources

- `fapolicyd(8), fapolicyd.rules(5), fapolicyd.conf(5), fapolicyd.trust(13), fagenrules(8), and fapolicyd-cli(1)` man pages.
- The Enhancing security with the kernel integrity subsystem chapter in the Managing, monitoring, and updating the kernel document.

### 13.2. DEPLOYING FAPOLICYD

To deploy the fapolicyd framework in RHEL:

**Procedure**

1. Install the fapolicyd package:

   ```
   # dnf install fapolicyd
   ```

2. Enable and start the fapolicyd service:

   ```
   # systemctl enable --now fapolicyd
   ```
Verification

1. Verify that the fapolicyd service is running correctly:

```bash
# systemctl status fapolicyd
● fapolicyd.service - File Access Policy Daemon
Loaded: loaded (/usr/lib/systemd/system/fapolicyd.service; enabled; vendor provided)
Active: active (running) since Tue 2019-10-15 18:02:35 CEST; 55s ago
Process: 8818 ExecStart=/usr/sbin/fapolicyd (code=exited, status=0/SUCCESS)
Main PID: 8819 (fapolicyd)
Tasks: 4 (limit: 11500)
Memory: 78.2M
CGROUP: /system.slice/fapolicyd.service
└─ 8819 /usr/sbin/fapolicyd

Oct 15 18:02:35 localhost.localdomain systemd[1]: Starting File Access Policy Daemon
Oct 15 18:02:35 localhost.localdomain fapolicyd[8819]: Initialization of the database
Oct 15 18:02:35 localhost.localdomain fapolicyd[8819]: Reading RPMDB into memory
Oct 15 18:02:36 localhost.localdomain systemd[1]: Started File Access Policy Daemon
Oct 15 18:02:36 localhost.localdomain fapolicyd[8819]: Creating database
```

2. Log in as a user without root privileges, and check that fapolicyd is working, for example:

```bash
$ cp /bin/ls /tmp
$ /tmp/ls
bash: /tmp/ls: Operation not permitted
```

13.3. MARKING FILES AS TRUSTED USING AN ADDITIONAL SOURCE OF TRUST

The fapolicyd framework trusts files contained in the RPM database. You can mark additional files as trusted by adding the corresponding entries to the /etc/fapolicyd/fapolicyd.trust plain-text file or the /etc/fapolicyd/trust.d/ directory, which supports separating a list of trusted files into more files. You can modify fapolicyd.trust or the files in /etc/fapolicyd/trust.d either directly using a text editor or through fapolicyd-cli commands.

```
NOTE
Marking files as trusted using fapolicyd.trust or trust.d/ is better than writing custom fapolicyd rules due to performance reasons.
```

Prerequisites

- The fapolicyd framework is deployed on your system.

Procedure

1. Copy your custom binary to the required directory, for example:

```bash
$ cp /bin/ls /tmp
$ /tmp/ls
bash: /tmp/ls: Operation not permitted
```
2. Mark your custom binary as trusted, and store the corresponding entry to the `myapp` file in 
`/etc/fapolicyd/trust.d/`:

```bash
# fapolicyd-cli --file add /tmp/ls --trust-file myapp
```

- If you skip the `--trust-file` option, then the previous command adds the corresponding line to `/etc/fapolicyd/fapolicyd.trust`.

- To mark all existing files in a directory as trusted, provide the directory path as an argument of the `--file` option, for example: `fapolicyd-cli --file add /tmp/my_bin_dir/ --trust-file myapp`.

3. Update the `fapolicyd` database:

```bash
# fapolicyd-cli --update
```

**NOTE**

Changing the content of a trusted file or directory changes their checksum, and therefore `fapolicyd` no longer considers them trusted.

To make the new content trusted again, refresh the file trust database by using the `fapolicyd-cli --file update` command. If you do not provide any argument, the entire database refreshes. Alternatively, you can specify a path to a specific file or directory. Then, update the database by using `fapolicyd-cli --update`.

**Verification**

1. Check that your custom binary can be now executed, for example:

```bash
$ /tmp/ls
ls
```

**Additional resources**

- `fapolicyd.trust(13)` man page.

**13.4. ADDING CUSTOM ALLOW AND DENY RULES FOR FAPOLICYD**

The default set of rules in the `fapolicyd` package does not affect system functions. For custom scenarios, such as storing binaries and scripts in a non-standard directory or adding applications without the `dnf` or `rpm` installers, you must either mark additional files as trusted or add new custom rules.

For basic scenarios, prefer **Marking files as trusted using an additional source of trust**. In more advanced scenarios such as allowing to execute a custom binary only for specific user and group identifiers, add new custom rules to the `/etc/fapolicyd/rules.d/` directory.

The following steps demonstrate adding a new rule to allow a custom binary.

**Prerequisites**

- The `fapolicyd` framework is deployed on your system.
Procedure

1. Copy your custom binary to the required directory, for example:

   ```
   $ cp /bin/ls /tmp
   $ /tmp/ls
   bash: /tmp/ls: Operation not permitted
   ```

2. Stop the `fapolicyd` service:

   ```
   # systemctl stop fapolicyd
   ```

3. Use debug mode to identify a corresponding rule. Because the output of the `fapolicyd --debug` command is verbose and you can stop it only by pressing Ctrl+C or killing the corresponding process, redirect the error output to a file. In this case, you can limit the output only to access denials by using the `--debug-deny` option instead of `--debug`:

   ```
   # fapolicyd --debug-deny 2> fapolicy.output &
   [1] 51341
   ```

   Alternatively, you can run `fapolicyd` debug mode in another terminal.

4. Repeat the command that `fapolicyd` denied:

   ```
   $ /tmp/ls
   bash: /tmp/ls: Operation not permitted
   ```

5. Stop debug mode by resuming it in the foreground and pressing Ctrl+C:

   ```
   # fg
   fapolicyd --debug 2> fapolicy.output
   ^C
   ```

   Alternatively, kill the process of `fapolicyd` debug mode:

   ```
   # kill 51341
   ```

6. Find a rule that denies the execution of your application:

   ```
   # cat fapolicy.output | grep 'deny_audit'
   ...
   rule=13 dec=deny_audit perm=execute auid=0 pid=6855 exe=/usr/bin/bash : path=/tmp/ls ftype=application/x-executable trust=0
   ```

7. Locate the file that contains a rule that prevented the execution of your custom binary. In this case, the `deny_audit perm=execute` rule belongs to the `90-deny-execute.rules` file:

   ```
   # ls /etc/fapolicyd/rules.d/
   10-languages.rules 40-bad-elf.rules 72-shell.rules
   20-dracut.rules 41-shared-obj.rules 90-deny-execute.rules
   21-updaters.rules 42-trusted-elf.rules 95-allow-open.rules
   30-patterns.rules 70-trusted-lang.rules
   ```
# cat /etc/fapolicyd/rules.d/90-deny-execute.rules
# Deny execution for anything untrusted
deny_audt perm=execute all : all

8. Add a new **allow** rule to the file that lexically **precedes** the rule file that contains the rule that denied the execution of your custom binary in the `/etc/fapolicyd/rules.d/` directory:

```bash
# touch /etc/fapolicyd/rules.d/80-myapps.rules
# vi /etc/fapolicyd/rules.d/80-myapps.rules
```

Insert the following rule to the **80-myapps.rules** file:

```bash
allow perm=execute exe=/usr/bin/bash trust=1 : path=/tmp/ls ftype=application/x-executable trust=0
```

Alternatively, you can allow executions of all binaries in the `/tmp` directory by adding the following rule to the rule file in `/etc/fapolicyd/rules.d/`:

```bash
allow perm=execute exe=/usr/bin/bash trust=1 : dir=/tmp/ all trust=0
```

9. To prevent changes in the content of your custom binary, define the required rule using an SHA-256 checksum:

```bash
$ sha256sum /tmp/ls
780b75c90b2d41ea41679fcb358c892b1251b68d1927c80fbc0d9d148b25e836  ls
```

Change the rule to the following definition:

```bash
allow perm=execute exe=/usr/bin/bash trust=1 :
sha256hash=780b75c90b2d41ea41679fcb358c892b1251b68d1927c80fbc0d9d148b25e836
```

10. Check that the list of compiled differs from the rule set in `/etc/fapolicyd/rules.d/`, and update the list, which is stored in the `/etc/fapolicyd/compiled.rules` file:

```bash
# fagenrules --check
/usr/sbin/fagenrules: Rules have changed and should be updated
# fagenrules --load
```

11. Check that your custom rule is in the list of **fapolicyd** rules before the rule that prevented the execution:

```bash
# fapolicyd-cli --list
... 13. allow perm=execute exe=/usr/bin/bash trust=1 : path=/tmp/ls ftype=application/x-executable trust=0
14. deny_audt perm=execute all : all
...```

12. Start the **fapolicyd** service:
# systemctl start fapolicyd

Verification

1. Check that your custom binary can be now executed, for example:

```bash
$ /tmp/ls
ls
```

Additional resources

- `fapolicyd.rules(5)` and `fapolicyd-cli(1)` man pages.
- The documentation installed with the `fapolicyd` package in the `/usr/share/fapolicyd/sample-rules/README-rules` file.

13.5. ENABLING FAPOLICYD INTEGRITY CHECKS

By default, `fapolicyd` does not perform integrity checking. You can configure `fapolicyd` to perform integrity checks by comparing either file sizes or SHA-256 hashes. You can also set integrity checks by using the Integrity Measurement Architecture (IMA) subsystem.

Prerequisites

- The `fapolicyd` framework is deployed on your system.

Procedure

1. Open the `/etc/fapolicyd/fapolicyd.conf` file in a text editor of your choice, for example:

```bash
# vi /etc/fapolicyd/fapolicyd.conf
```

2. Change the value of the `integrity` option from `none` to `sha256`, save the file, and exit the editor:

```bash
integrity = sha256
```

3. Restart the `fapolicyd` service:

```bash
# systemctl restart fapolicyd
```

Verification

1. Back up the file used for the verification:

```bash
# cp /bin/more /bin/more.bak
```

2. Change the content of the `/bin/more` binary:

```bash
# cat /bin/less > /bin/more
```

3. Use the changed binary as a regular user:
4. Revert the changes:

   # mv -f /bin/more.bak /bin/more

13.6. TROUBLESHOOTING PROBLEMS RELATED TO FAPOLICYD

The following section provides tips for basic troubleshooting of the fapolicyd application framework and guidance for adding applications using the rpm command.

**Installing applications using rpm**

- If you install an application using the **rpm** command, you have to perform a manual refresh of the fapolicyd RPM database:
  1. Install your application:
     
     ```
     # rpm -i application.rpm
     ```
  2. Refresh the database:
     
     ```
     # fapolicyd-cli --update
     ```

     If you skip this step, the system can freeze and must be restarted.

**Service status**

- If **fapolicyd** does not work correctly, check the service status:

  ```
  # systemctl status fapolicyd
  ```

**fapolicyd-cli checks and listings**

- The **--check-config**, **--check-watch_fs**, and **--check-trustdb** options help you find syntax errors, not-yet-watched file systems, and file mismatches, for example:

  ```
  # fapolicyd-cli --check-config
  Daemon config is OK
  ```

  ```
  # fapolicyd-cli --check-trustdb
  /etc/selinux/targeted/contexts/files/file_contexts miscompares: size sha256
  /etc/selinux/targeted/policy/policy.31 miscompares: size sha256
  ```

- Use the **--list** option to check the current list of rules and their order:

  ```
  # fapolicyd-cli --list
  ... 9. allow perm=execute all : trust=1
  10. allow perm=open all : ftype=%languages trust=1
  ```
Debug mode

- Debug mode provides detailed information about matched rules, database status, and more. To switch fapolicyd to debug mode:

  1. Stop the fapolicyd service:

     ```
     # systemctl stop fapolicyd
     ```

  2. Use debug mode to identify a corresponding rule:

     ```
     # fapolicyd --debug
     ```

     Because the output of the `fapolicyd --debug` command is verbose, you can redirect the error output to a file:

     ```
     # fapolicyd --debug 2> fapolicy.output
     ```

     Alternatively, to limit the output only to entries when `fapolicyd` denies access, use the ```-debug-deny``` option:

     ```
     # fapolicyd --debug-deny
     ```

Removing the fapolicyd database

- To solve problems related to the fapolicyd database, try to remove the database file:

  ```
  # systemctl stop fapolicyd
  # fapolicyd-cli --delete-db
  ```

WARNING

Do not remove the /var/lib/fapolicyd/ directory. The fapolicyd framework automatically restores only the database file in this directory.

Dumping the fapolicyd database

- The fapolicyd contains entries from all enabled trust sources. You can check the entries after dumping the database:

  ```
  # fapolicyd-cli --dump-db
  ```
Application pipe

- In rare cases, removing the **fapolicyd** pipe file can solve a lockup:

  ```bash
  # rm -f /var/run/fapolicyd/fapolicyd.fifo
  ```

Additional resources

- **fapolicyd-cli(1)** man page.

13.7. ADDITIONAL RESOURCES

- **fapolicyd**-related man pages listed by using the **man -k fapolicyd** command.

- The **FOSDEM 2020 fapolicyd** presentation.
CHAPTER 14. PROTECTING SYSTEMS AGAINST INTRUSIVE USB DEVICES

USB devices can be loaded with spyware, malware, or trojans, which can steal your data or damage your system. As a Red Hat Enterprise Linux administrator, you can prevent such USB attacks with **USBGuard**.

14.1. USBGUARD

With the USBGuard software framework, you can protect your systems against intrusive USB devices by using basic lists of permitted and forbidden devices based on the USB device authorization feature in the kernel.

The USBGuard framework provides the following components:

- The system service component with an inter-process communication (IPC) interface for dynamic interaction and policy enforcement
- The command-line interface to interact with a running `usbguard` system service
- The rule language for writing USB device authorization policies
- The C++ API for interacting with the system service component implemented in a shared library

The `usbguard` system service configuration file (`/etc/usbguard/usbguard-daemon.conf`) includes the options to authorize the users and groups to use the IPC interface.

**IMPORTANT**

The system service provides the USBGuard public IPC interface. In Red Hat Enterprise Linux, the access to this interface is limited to the root user only by default.

Consider setting either the `IPCAccessControlFiles` option (recommended) or the `IPCAllowedUsers` and `IPCAllowedGroups` options to limit access to the IPC interface.

Ensure that you do not leave the Access Control List (ACL) unconfigured as this exposes the IPC interface to all local users and allows them to manipulate the authorization state of USB devices and modify the USBGuard policy.

14.2. INSTALLING USBGUARD

Use this procedure to install and initiate the **USBGuard** framework.

**Procedure**

1. Install the `usbguard` package:

   ```
   # dnf install usbguard
   ```

2. Create an initial rule set:

   ```
   # usbguard generate-policy > /etc/usbguard/rules.conf
   ```

3. Start the `usbguard` daemon and ensure that it starts automatically on boot:
Verification

1. Verify that the **usbguard** service is running:

```
# systemctl status usbguard
● usbguard.service - USBGuard daemon
 Loaded: loaded (/usr/lib/systemd/system/usbguard.service; enabled; vendor preset: disabled)
 Active: active (running) since Thu 2019-11-07 09:44:07 CET; 3min 16s ago
 Docs: man:usbguard-daemon(8)
 Main PID: 6122 (usbguard-daemon)
 Tasks: 3 (limit: 11493)
 Memory: 1.2M
 CGroup: /system.slice/usbguard.service
 └─ 6122 /usr/sbin/usbguard-daemon -f -s -c /etc/usbguard/usbguard-daemon.conf
```

Nov 07 09:44:06 localhost.localdomain systemd[1]: Starting USBGuard daemon...
Nov 07 09:44:07 localhost.localdomain systemd[1]: Started USBGuard daemon.

2. List USB devices recognized by **USBGuard**:

```
# usbguard list-devices
4: allow id 1d6b:0002 serial "0000:02:00.0" name "xHCI Host Controller" hash...
```

Additional resources

- **usbguard(1)** and **usbguard-daemon.conf(5)** man pages.

### 14.3. BLOCKING AND AUTHORIZING A USB DEVICE USING CLI

This procedure outlines how to authorize and block a USB device using the **usbguard** command.

**Prerequisites**

- The **usbguard** service is installed and running.

**Procedure**

1. List USB devices recognized by **USBGuard**:

```
# usbguard list-devices
1: allow id 1d6b:0002 serial "0000:00:06.7" name "EHCI Host Controller" hash
 "JDOb0BiktYs2ct3mSQKopnOOV2h9MGYADwhT+oUtF2s=" parent-hash
 "4PHGcaDKWiPjKDWyplRG722cB9SI/G29l91lea93+Gt9c=" via-port "usb1" with-interface 09:00:00
 ...
 6: block id 1b1c:1ab1 serial "000024937962" name "Voyager" hash
 "CrXgiaWIf2bZAU+5WkzOE7y0rdSO82XMzubn7HDb95Q=" parent-hash
 "JDOb0BiktYs2ct3mSQKopnOOV2h9MGYADwhT+oUtF2s=" via-port "1-3" with-interface 08:06:50
```
2. Authorize the device 6 to interact with the system:

```
# usbguard allow-device 6
```

3. Deauthorize and remove the device 6:

```
# usbguard reject-device 6
```

4. Deauthorize and retain the device 6:

```
# usbguard block-device 6
```

**NOTE**

**USBGuard** uses the *block* and *reject* terms with the following meanings:

- **block**: do not interact with this device for now.
- **reject**: ignore this device as if it does not exist.

**Additional resources**

- [usbguard(1) man page](#).
- Built-in help listed by using the `usbguard --help` command.

**14.4. PERMANENTLY BLOCKING AND AUTHORIZING A USB DEVICE**

You can permanently block and authorize a USB device using the `-p` option. This adds a device-specific rule to the current policy.

**Prerequisites**

- The **usbguard** service is installed and running.

**Procedure**

1. Configure SELinux to allow the **usbguard** daemon to write rules.
   
   a. Display the **semanage** Booleans relevant to **usbguard**.

   ```
   # semanage boolean -l | grep usbguard
   usbguard_daemon_write_conf   (off , off)  Allow usbguard to daemon write conf
   usbguard_daemon_write_rules  (on , on)  Allow usbguard to daemon write rules
   ```
   
   b. Optional: If the **usbguard_daemon_write_rules** Boolean is turned off, turn it on.

   ```
   # semanage boolean -m --on usbguard_daemon_write_rules
   ```

2. List USB devices recognized by **USBGuard**:

   ```
   # usbguard list-devices
   1: allow id 1d6b:0002 serial "0000:00:06.7" name "EHCI Host Controller" hash
   ```
3. Permanently authorize the device 6 to interact with the system:

   # usbguard allow-device 6 -p

4. Permanently deauthorize and remove the device 6:

   # usbguard reject-device 6 -p

5. Permanently deauthorize and retain the device 6:

   # usbguard block-device 6 -p

**NOTE**

USBGuard uses the terms *block* and *reject* with the following meanings:

- *block*: do not interact with this device for now.
- *reject*: ignore this device as if it does not exist.

**Verification**

1. Check that USBGuard rules include the changes you made.

   # usbguard list-rules

**Additional resources**

- *usbguard(1)* man page.
- Built-in help listed by using the `usbguard --help` command.

**14.5. CREATING A CUSTOM POLICY FOR USB DEVICES**

The following procedure contains steps for creating a rule set for USB devices that reflects the requirements of your scenario.

**Prerequisites**

- The `usbguard` service is installed and running.
- The `/etc/usbguard/rules.conf` file contains an initial rule set generated by the `usbguard generate-policy` command.
Procedure

1. Create a policy which authorizes the currently connected USB devices, and store the generated rules to the `rules.conf` file:

   ```
   # usbguard generate-policy --no-hashes > ./rules.conf
   ```

   The `--no-hashes` option does not generate hash attributes for devices. Avoid hash attributes in your configuration settings because they might not be persistent.

2. Edit the `rules.conf` file with a text editor of your choice, for example:

   ```
   # vi ./rules.conf
   ```

3. Add, remove, or edit the rules as required. For example, the following rule allows only devices with a single mass storage interface to interact with the system:

   ```
   allow with-interface equals { 08:*:* }
   ```

   See the `usbguard-rules.conf(5)` man page for a detailed rule-language description and more examples.

4. Install the updated policy:

   ```
   # install -m 0600 -o root -g root rules.conf /etc/usbguard/rules.conf
   ```

5. Restart the `usbguard` daemon to apply your changes:

   ```
   # systemctl restart usbguard
   ```

Verification

1. Check that your custom rules are in the active policy, for example:

   ```
   # usbguard list-rules
   ...
   4: allow with-interface 08:*:*
   ...
   ```

Additional resources

- `usbguard-rules.conf(5)` man page.

14.6. CREATING A STRUCTURED CUSTOM POLICY FOR USB DEVICES

You can organize your custom USBGuard policy in several `.conf` files within the `/etc/usbguard/rules.d/` directory. The `usbguard-daemon` then combines the main `rules.conf` file with the `.conf` files within the directory in alphabetical order.

Prerequisites

- The `usbguard` service is installed and running.
Procedure

1. Create a policy which authorizes the currently connected USB devices, and store the generated rules to a new `.conf` file, for example, `policy.conf`.

```
# usbguard generate-policy --no-hashes > ./policy.conf
```

The `--no-hashes` option does not generate hash attributes for devices. Avoid hash attributes in your configuration settings because they might not be persistent.

2. Display the `policy.conf` file with a text editor of your choice, for example:

```
# vi ./policy.conf
...
allow id 04f2:0833 serial "" name "USB Keyboard" via-port "7-2" with-interface { 03:01:01 03:00:00 } with-connect-type "unknown"
...
```

3. Move selected lines into a separate `.conf` file.

   **NOTE**

   The two digits at the beginning of the file name specify the order in which the daemon reads the configuration files.

   For example, copy the rules for your keyboards into a new `.conf` file.

```
# grep "USB Keyboard" ./policy.conf > ./10keyboards.conf
```

4. Install the new policy to the `/etc/usbguard/rules.d/` directory.

```
# install -m 0600 -o root -g root 10keyboards.conf /etc/usbguard/rules.d/10keyboards.conf
```

5. Move the rest of the lines to a main `rules.conf` file.

```
# grep -v "USB Keyboard" ./policy.conf > ./rules.conf
```

6. Install the remaining rules.

```
# install -m 0600 -o root -g root rules.conf /etc/usbguard/rules.conf
```

7. Restart the `usbguard` daemon to apply your changes.

```
# systemctl restart usbguard
```

Verification

1. Display all active USBGuard rules.

```
# usbguard list-rules
...
15: allow id 04f2:0833 serial "" name "USB Keyboard" hash
```
2. Display the contents of the `rules.conf` file and all the `.conf` files in the `/etc/usbguard/rules.d/` directory.

```bash
# cat /etc/usbguard/rules.conf /etc/usbguard/rules.d/*.conf
```

3. Verify that the active rules contain all the rules from the files and are in the correct order.

Additional resources

- [usbguard-rules.conf(5)](man) man page.

### 14.7. AUTHORIZING USERS AND GROUPS TO USE THE USBGUARD IPC INTERFACE

Use this procedure to authorize a specific user or a group to use the USBGuard public IPC interface. By default, only the root user can use this interface.

**Prerequisites**

- The `usbguard` service is installed and running.
- The `/etc/usbguard/rules.conf` file contains an initial rule set generated by the `usbguard generate-policy` command.

**Procedure**

1. Edit the `/etc/usbguard/usbguard-daemon.conf` file with a text editor of your choice:

   ```bash
   # vi /etc/usbguard/usbguard-daemon.conf
   ```

2. For example, add a line with a rule that allows all users in the `wheel` group to use the IPC interface, and save the file:

   ```
   IPCAllowGroups=wheel
   ```

3. You can add users or groups also with the `usbguard` command. For example, the following command enables the `joesec` user to have full access to the Devices and Exceptions sections. Furthermore, `joesec` can list and modify the current policy:

   ```bash
   # usbguard add-user joesec --devices ALL --policy modify,list --exceptions ALL
   ```

   To remove the granted permissions for the `joesec` user, use the `usbguard remove-user joesec` command.

4. Restart the `usbguard` daemon to apply your changes:

   ```bash
   # systemctl restart usbguard
   ```
14.8. LOGGING USBGUARD AUTHORIZATION EVENTS TO THE LINUX AUDIT LOG

Use the following steps to integrate logging of USBguard authorization events to the standard Linux Audit log. By default, the `usbguard` daemon logs events to the `/var/log/usbguard/usbguard-audit.log` file.

**Prerequisites**

- The `usbguard` service is installed and running.
- The `auditd` service is running.

**Procedure**

1. Edit the `usbguard-daemon.conf` file with a text editor of your choice:

   ```
   # vi /etc/usbguard/usbguard-daemon.conf
   ```

2. Change the `AuditBackend` option from `FileAudit` to `LinuxAudit`:

   ```
   AuditBackend=LinuxAudit
   ```

3. Restart the `usbguard` daemon to apply the configuration change:

   ```
   # systemctl restart usbguard
   ```

**Verification**

1. Query the `audit` daemon log for a USB authorization event, for example:

   ```
   # ausearch -ts recent -m USER_DEVICE
   ```

**Additional resources**

- `usbguard(1)` and `usbguard-rules.conf(5)` man pages.

14.9. ADDITIONAL RESOURCES

- `usbguard(1), usbguard-rules.conf(5), usbguard-daemon(8), and usbguard-daemon.conf(5)` man pages.
- [USBGuard Homepage](#).
CHAPTER 15. CONFIGURING A REMOTE LOGGING SOLUTION

To ensure that logs from various machines in your environment are recorded centrally on a logging server, you can configure the Rsyslog application to record logs that fit specific criteria from the client system to the server.

15.1. THE RSYSLOG LOGGING SERVICE

The Rsyslog application, in combination with the systemd-journald service, provides local and remote logging support in Red Hat Enterprise Linux. The rsyslogd daemon continuously reads syslog messages received by the systemd-journald service from the Journal. rsyslogd then filters and processes these syslog events and records them to rsyslog log files or forwards them to other services according to its configuration.

The rsyslogd daemon also provides extended filtering, encryption protected relaying of messages, input and output modules, and support for transportation using the TCP and UDP protocols.

In /etc/rsyslog.conf, which is the main configuration file for rsyslog, you can specify the rules according to which rsyslogd handles the messages. Generally, you can classify messages by their source and topic (facility) and urgency (priority), and then assign an action that should be performed when a message fits these criteria.

In /etc/rsyslog.conf, you can also see a list of log files maintained by rsyslogd. Most log files are located in the /var/log/ directory. Some applications, such as httpd and samba, store their log files in a subdirectory within /var/log/.

Additional resources

- The rsyslogd(8) and rsyslog.conf(5) man pages.

15.2. INSTALLING RSYSLOG DOCUMENTATION

The Rsyslog application has extensive online documentation that is available at https://www.rsyslog.com/doc/, but you can also install the rsyslog-doc documentation package locally.

Prerequisites

- You have activated the AppStream repository on your system.
- You are authorized to install new packages using sudo.

Procedure

- Install the rsyslog-doc package:

```
# dnf install rsyslog-doc
```

Verification

- Open the /usr/share/doc/rsyslog/html/index.html file in a browser of your choice, for example:
15.3. CONFIGURING A SERVER FOR REMOTE LOGGING OVER TCP

The Rsyslog application enables you to both run a logging server and configure individual systems to send their log files to the logging server. To use remote logging through TCP, configure both the server and the client. The server collects and analyzes the logs sent by one or more client systems.

With the Rsyslog application, you can maintain a centralized logging system where log messages are forwarded to a server over the network. To avoid message loss when the server is not available, you can configure an action queue for the forwarding action. This way, messages that failed to be sent are stored locally until the server is reachable again. Note that such queues cannot be configured for connections using the UDP protocol.

The `omfwd` plug-in provides forwarding over UDP or TCP. The default protocol is UDP. Because the plug-in is built in, it does not have to be loaded.

By default, `rsyslog` uses TCP on port 514.

Prerequisites

- Rsyslog is installed on the server system.
- You are logged in as root on the server.
- The `policycoreutils-python-utils` package is installed for the optional step using the `semanage` command.
- The `firewalld` service is running.

Procedure

1. Optional: To use a different port for `rsyslog` traffic, add the `syslogd_port_t` SELinux type to port. For example, enable port 30514:

   ```bash
   # semanage port -a -t syslogd_port_t -p tcp 30514
   ``

2. Optional: To use a different port for `rsyslog` traffic, configure `firewalld` to allow incoming `rsyslog` traffic on that port. For example, allow TCP traffic on port 30514:

   ```bash
   # firewall-cmd --zone=<zone-name> --permanent --add-port=30514/tcp
   # firewall-cmd --reload
   ``

3. Create a new file in the `/etc/rsyslog.d/` directory named, for example, `remotelog.conf`, and insert the following content:

   ```bash
   # Define templates before the rules that use them
   # Per-Host templates for remote systems
   template(name="TmplAuthpriv" type="list") {
     constant(value="/var/log/remote/auth")
     property(name="hostname")
     constant(value="/")
     property(name="programname" SecurePath="replace")
   }
   ```
constant(value=".log")
}

template(name="TmplMsg" type="list") {
  constant(value="/var/log/remote/msg/")
  property(name="hostname")
  constant(value="")
  property(name="programname" SecurePath="replace")
  constant(value=".log")
}

# Provides TCP syslog reception
module(load="imtcp")

# Adding this ruleset to process remote messages
ruleset(name="remote1"){
  authpriv.*   action(type="omfile" DynaFile="TmplAuthpriv")
  *.info;mail.none;authpriv.none;cron.none
  action(type="omfile" DynaFile="TmplMsg")
}

input(type="imtcp" port="30514" ruleset="remote1")

4. Save the changes to the /etc/rsyslog.d/remotelog.conf file.

5. Test the syntax of the /etc/rsyslog.conf file:

   # rsyslogd -N 1
   rsyslogd: version 8.1911.0-2.el8, config validation run (level 1), master config
   /etc/rsyslog.conf

6. Make sure the rsyslog service is running and enabled on the logging server:

   # systemctl status rsyslog

7. Restart the rsyslog service.

   # systemctl restart rsyslog

8. Optional: If rsyslog is not enabled, ensure the rsyslog service starts automatically after reboot:

   # systemctl enable rsyslog

Your log server is now configured to receive and store log files from the other systems in your environment.

Additional resources

- rsyslogd(8), rsyslog.conf(5), semanage(8), and firewall-cmd(1) man pages.
- Documentation installed with the rsyslog-doc package in the
15.4. CONFIGURING REMOTE LOGGING TO A SERVER OVER TCP

Follow this procedure to configure a system for forwarding log messages to a server over the TCP protocol. The omfwd plug-in provides forwarding over UDP or TCP. The default protocol is UDP. Because the plug-in is built in, you do not have to load it.

Prerequisites

- The rsyslog package is installed on the client systems that should report to the server.
- You have configured the server for remote logging.
- The specified port is permitted in SELinux and open in firewall.
- The system contains the policycoreutils-python-utils package, which provides the semanage command for adding a non-standard port to the SELinux configuration.

Procedure

1. Create a new file in the /etc/rsyslog.d/ directory named, for example, 10-remotelog.conf, and insert the following content:

   ```
   *. action(type="omfwd"
       queue.type="linkedlist"
       queue.filename="example_fwd"
       action.resumeRetryCount="-1"
       queue.saveOnShutdown="on"
       target="example.com" port="30514" protocol="tcp"
   )
   ```

   Where:

   - `queue.type="linkedlist"` enables a LinkedList in-memory queue,
   - `queue.filename` defines a disk storage. The backup files are created with the example_fwd prefix in the working directory specified by the preceding global workDirectory directive,
   - the `action.resumeRetryCount -1` setting prevents rsyslog from dropping messages when retrying to connect if server is not responding,
   - enabled `queue.saveOnShutdown="on"` saves in-memory data if rsyslog shuts down,
   - the last line forwards all received messages to the logging server, port specification is optional.
   
   With this configuration, rsyslog sends messages to the server but keeps messages in memory if the remote server is not reachable. A file on disk is created only if rsyslog runs out of the configured memory queue space or needs to shut down, which benefits the system performance.

   **NOTE**
   
   Rsyslog processes configuration files /etc/rsyslog.d/ in the lexical order.

2. Restart the rsyslog service.
Verification

To verify that the client system sends messages to the server, follow these steps:

1. On the client system, send a test message:
   
   ```
   # logger test
   ```

2. On the server system, view the `/var/log/messages` log, for example:
   
   ```
   # cat /var/log/remote/msg/hostname/root.log
   Feb 25 03:53:17 hostname root[6064]: test
   ```

   Where `hostname` is the host name of the client system. Note that the log contains the user name of the user that entered the `logger` command, in this case `root`.

Additional resources

- `rsyslogd(8)` and `rsyslog.conf(5)` man pages.

15.5. CONFIGURING TLS-ENCRYPTED REMOTE LOGGING

By default, Rsyslog sends remote-logging communication in the plain text format. If your scenario requires to secure this communication channel, you can encrypt it using TLS.

To use encrypted transport through TLS, configure both the server and the client. The server collects and analyzes the logs sent by one or more client systems.

You can use either the `ossl` network stream driver (OpenSSL) or the `gtls` stream driver (GnuTLS).

**NOTE**

If you have a separate system with higher security, for example, a system that is not connected to any network or has stricter authorizations, use the separate system as the certifying authority (CA).

Prerequisites

- You have `root` access to both the client and server systems.
- The `rsyslog` and `rsyslog-openssl` packages are installed on the server and the client systems.
- If you use the `gtls` network stream driver, install the `rsyslog-gnutls` package instead of `rsyslog-openssl`.
- If you generate certificates using the `certtool` command, install the `gnutls-utils` package.
- On your logging server, the following certificates are in the `/etc/pki/ca-trust/source/anchors/` directory and your system configuration is updated by using the `update-ca-trust` command:
- **ca-cert.pem** - a CA certificate that can verify keys and certificates on logging servers and clients.

- **server-cert.pem** - a public key of the logging server.

- **server-key.pem** - a private key of the logging server.

- On your logging clients, the following certificates are in the `/etc/pki/ca-trust/source/anchors/` directory and your system configuration is updated by using `update-ca-trust`:

  - **ca-cert.pem** - a CA certificate that can verify keys and certificates on logging servers and clients.

  - **client-cert.pem** - a public key of a client.

  - **client-key.pem** - a private key of a client.

**Procedure**

1. Configure the server for receiving encrypted logs from your client systems:
   
   a. Create a new file in the `/etc/rsyslog.d/` directory named, for example, `securelogser.conf`.

   b. To encrypt the communication, the configuration file must contain paths to certificate files on your server, a selected authentication method, and a stream driver that supports TLS encryption. Add the following lines to the `/etc/rsyslog.d/securelogser.conf` file:

   ```
   # Set certificate files
   global(
       DefaultNetstreamDriverCAFile="/etc/pki/ca-trust/source/anchors/ca-cert.pem"
       DefaultNetstreamDriverCertFile="/etc/pki/ca-trust/source/anchors/server-cert.pem"
       DefaultNetstreamDriverKeyFile="/etc/pki/ca-trust/source/anchors/server-key.pem"
   )

   # TCP listener
   module(
       load="imtcp"
       PermittedPeer=['client1.example.com', 'client2.example.com']
       StreamDriver.AuthMode="x509/name"
       StreamDriver.Mode="1"
       StreamDriver.Name="ossl"
   )

   # Start up listener at port 514
   input(
       type="imtcp"
       port="514"
   )
   ```

   **NOTE**

   If you prefer the GnuTLS driver, use the `StreamDriver.Name=\"gtls\"` configuration option. See the documentation installed with the `rsyslog-doc` package for more information about less strict authentication modes than `x509/name`. 

c. Save the changes to the `/etc/rsyslog.d/securelogser.conf` file.

d. Verify the syntax of the `/etc/rsyslog.conf` file and any files in the `/etc/rsyslog.d/` directory:

```
# rsyslogd -N 1
rsyslogd: version 8.1911.0-2.el8, config validation run (level 1), master config
/etc/rsyslog.conf
```

e. Make sure the `rsyslog` service is running and enabled on the logging server:

```
# systemctl status rsyslog
```

f. Restart the `rsyslog` service:

```
# systemctl restart rsyslog
```

g. Optional: If Rsyslog is not enabled, ensure the `rsyslog` service starts automatically after reboot:

```
# systemctl enable rsyslog
```

2. Configure clients for sending encrypted logs to the server:

a. On a client system, create a new file in the `/etc/rsyslog.d/` directory named, for example, `securelogcli.conf`.

b. Add the following lines to the `/etc/rsyslog.d/securelogcli.conf` file:

```
# Set certificate files
global(
   DefaultNetstreamDriverCAFile="/etc/pki/ca-trust/source/anchors/ca-cert.pem"
   DefaultNetstreamDriverCertFile="/etc/pki/ca-trust/source/anchors/client-cert.pem"
   DefaultNetstreamDriverKeyFile="/etc/pki/ca-trust/source/anchors/client-key.pem"
)

# Set up the action for all messages
*.* action(
   type="omfwd"
   StreamDriver="ossl"
   StreamDriverMode="1"
   StreamDriverPermittedPeers="server.example.com"
   StreamDriverAuthMode="x509/name"
   target="server.example.com" port="514" protocol="tcp"
)
```

**NOTE**

If you prefer the GnuTLS driver, use the `StreamDriver.Name="gtls"` configuration option.

c. Save the changes to the `/etc/rsyslog.d/securelogser.conf` file.
d. Verify the syntax of the `/etc/rsyslog.conf` file and other files in the `/etc/rsyslog.d/` directory:

```
# rsyslogd -N 1
rsyslogd: version 8.1911.0-2.el8, config validation run (level 1), master config /etc/rsyslog.conf
```

e. Make sure the `rsyslog` service is running and enabled on the logging server:

```
# systemctl status rsyslog
```

f. Restart the `rsyslog` service:

```
# systemctl restart rsyslog
```

g. Optional: If Rsyslog is not enabled, ensure the `rsyslog` service starts automatically after reboot:

```
# systemctl enable rsyslog
```

Verification

To verify that the client system sends messages to the server, follow these steps:

1. On the client system, send a test message:

```
# logger test
```

2. On the server system, view the `/var/log/messages` log, for example:

```
# cat /var/log/remote/msg/hostname/root.log
Feb 25 03:53:17 hostname root[6064]: test
```

Where `hostname` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

Additional resources

- The `certtool(1), openssl(1), update-ca-trust(8), rsyslogd(8),` and `rsyslog.conf(5)` man pages.
- Documentation installed with the `rsyslog-doc` package at `/usr/share/doc/rsyslog/html/index.html`.
- The Using the Logging System Role article.

15.6. CONFIGURING A SERVER FOR RECEIVING REMOTE LOGGING INFORMATION OVER UDP

The Rsyslog application enables you to configure a system to receive logging information from remote systems. To use remote logging through UDP, configure both the server and the client. The receiving server collects and analyzes the logs sent by one or more client systems. By default, `rsyslog` uses UDP on port `514` to receive log information from remote systems.
Follow this procedure to configure a server for collecting and analyzing logs sent by one or more client systems over the UDP protocol.

**Prerequisites**

- Rsyslog is installed on the server system.
- You are logged in as **root** on the server.
- The **policycoreutils-python-utils** package is installed for the optional step using the **semanage** command.
- The **firewalld** service is running.

**Procedure**

1. Optional: To use a different port for **rsyslog** traffic than the default port **514**:
   a. Add the **syslogd_port_t** SELinux type to the SELinux policy configuration, replacing **portno** with the port number you want **rsyslog** to use:
      ```
      # semanage port -a -t syslogd_port_t -p udp portno
      ```
   b. Configure **firewalld** to allow incoming **rsyslog** traffic, replacing **portno** with the port number and **zone** with the zone you want **rsyslog** to use:
      ```
      # firewall-cmd --zone=zone --permanent --add-port=portno/udp
      success
      # firewall-cmd --reload
      ```
   c. Reload the firewall rules:
      ```
      # firewall-cmd --reload
      ```

2. Create a new **.conf** file in the **/etc/rsyslog.d/** directory, for example, **remotelogserv.conf**, and insert the following content:

```
# Define templates before the rules that use them
# Per-Host templates for remote systems
template(name="TmpAuthpriv" type="list") {
    constant(value="/var/log/remote/auth/")
    property(name="hostname")
    constant(value="/")
    property(name="programname" SecurePath="replace")
    constant(value=".log")
}

template(name="TmpMsg" type="list") {
    constant(value="/var/log/remote/msg/")
    property(name="hostname")
    constant(value="/")
    property(name="programname" SecurePath="replace")
    constant(value=".log")
}
```
15.7. CONFIGURING REMOTE LOGGING TO A SERVER OVER UDP

Follow this procedure to configure a system for forwarding log messages to a server over the UDP protocol. The omfwd plug-in provides forwarding over UDP or TCP. The default protocol is UDP. Because the plug-in is built in, you do not have to load it.

Prerequisites

- The rsyslog package is installed on the client systems that should report to the server.
- You have configured the server for remote logging as described in Configuring a server for receiving remote logging information over UDP.

Procedure

1. Create a new .conf file in the /etc/rsyslog.d/ directory, for example, 10-remotelogcli.conf, and insert the following content:

```plaintext
# Provides UDP syslog reception
module(load="imudp")

# This ruleset processes remote messages
ruleset(name="remote1"){
    authpriv.* action(type="omfile" DynaFile="TmplAuthpriv")
    *.info;mail.none;authpriv.none;cron.none
    action(type="omfile" DynaFile="TmplMsg")
}

input(type="imudp" port="514" ruleset="remote1")
```

Where 514 is the port number rsyslog uses by default. You can specify a different port instead.

3. Verify the syntax of the /etc/rsyslog.conf file and all .conf files in the /etc/rsyslog.d/ directory:

```
# rsyslogd -N 1
rsyslogd: version 8.1911.0-2.el8, config validation run (level 1), master config /etc/rsyslog.conf
```

4. Restart the rsyslog service.

```
# systemctl restart rsyslog
```

5. Optional: If rsyslog is not enabled, ensure the rsyslog service starts automatically after reboot:

```
# systemctl enable rsyslog
```

Additional resources

- rsyslogd(8), rsyslog.conf(5), semanage(8), and firewall-cmd(1) man pages.
.* action(type="omfwd"
  queue.type="linkedlist"
  queue.filename="example_fwd"
  action.resumeRetryCount="-1"
  queue.saveOnShutdown="on"
  target="example.com" port="portno" protocol="udp"
)

Where:

- **queue.type="linkedlist"** enables a LinkedList in-memory queue.
- **queue.filename** defines a disk storage. The backup files are created with the `example_fwd` prefix in the working directory specified by the preceding global `workDirectory` directive.
- The **action.resumeRetryCount -1** setting prevents `rsyslog` from dropping messages when retrying to connect if the server is not responding.
- **enabled queue.saveOnShutdown="on"** saves in-memory data if `rsyslog` shuts down.
- **portno** is the port number you want `rsyslog` to use. The default value is **514**.
- The last line forwards all received messages to the logging server, port specification is optional.

With this configuration, `rsyslog` sends messages to the server but keeps messages in memory if the remote server is not reachable. A file on disk is created only if `rsyslog` runs out of the configured memory queue space or needs to shut down, which benefits the system performance.

**NOTE**

Rsyslog processes configuration files `/etc/rsyslog.d/` in the lexical order.

2. Restart the `rsyslog` service.

```bash
# systemctl restart rsyslog
```

3. Optional: If `rsyslog` is not enabled, ensure the `rsyslog` service starts automatically after reboot:

```bash
# systemctl enable rsyslog
```

**Verification**

To verify that the client system sends messages to the server, follow these steps:

1. On the client system, send a test message:

```bash
# logger test
```

2. On the server system, view the `/var/log/remote/msg/hostname/root.log` log, for example:

```bash
# cat /var/log/remote/msg/hostname/root.log
```

Feb 25 03:53:17 hostname root[6064]: test
Where `hostname` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

**Additional resources**

- `rsyslogd(8)` and `rsyslog.conf(5)` man pages.
- Documentation installed with the `rsyslog-doc` package at `/usr/share/doc/rsyslog/html/index.html`.

**15.8. LOAD BALANCING HELPER IN R SYSLOG**

The `RebindInterval` setting specifies an interval at which the current connection is broken and is re-established. This setting applies to TCP, UDP, and RELP traffic. The load balancers perceive it as a new connection and forward the messages to another physical target system.

The `RebindInterval` setting proves to be helpful in scenarios when a target system has changed its IP address. The Rsyslog application caches the IP address when the connection establishes, therefore, the messages are sent to the same server. If the IP address changes, the UDP packets will be lost until the Rsyslog service restarts. Re-establishing the connection will ensure the IP to be resolved by DNS again.

```plaintext
action(type="omfwd" protocol="tcp" RebindInterval="250" target="example.com" port="514" ...)
action(type="omfwd" protocol="udp" RebindInterval="250" target="example.com" port="514" ...)
action(type="omrelp" RebindInterval="250" target="example.com" port="6514" ...)
```

**15.9. CONFIGURING RELIABLE REMOTE LOGGING**

With the Reliable Event Logging Protocol (RELP), you can send and receive `syslog` messages over TCP with a much reduced risk of message loss. RELP provides reliable delivery of event messages, which makes it useful in environments where message loss is not acceptable. To use RELP, configure the `imrelp` input module, which runs on the server and receives the logs, and the `omrelp` output module, which runs on the client and sends logs to the logging server.

**Prerequisites**

- You have installed the `rsyslog`, `librelp`, and `rsyslog-relp` packages on the server and the client systems.
- The specified port is permitted in SELinux and open in the firewall.

**Procedure**

1. Configure the client system for reliable remote logging:
   a. On the client system, create a new `.conf` file in the `/etc/rsyslog.d/` directory named, for example, `relopclient.conf`, and insert the following content:

   ```plaintext
   module(load="omrelp")
   *.*  action(type="omrelp" target="_target_IP_" port="_target_port_")
   ```

   Where:
• **target_IP** is the IP address of the logging server.

• **target_port** is the port of the logging server.

b. Save the changes to the `/etc/rsyslog.d/relpclient.conf` file.

c. Restart the **rsyslog** service.

```
# systemctl restart rsyslog
```

d. Optional: If **rsyslog** is not enabled, ensure the **rsyslog** service starts automatically after reboot:

```
# systemctl enable rsyslog
```

2. Configure the server system for reliable remote logging:

a. On the server system, create a new `.conf` file in the `/etc/rsyslog.d/` directory named, for example, `repserv.conf`, and insert the following content:

```
ruleset(name="relp"){
   *. action(type="omfile" file="_log_path_")
}
```

```
module(load="imrelp")
   input(type="imrelp" port="_target_port_" ruleset="relp")
```

Where:

• **log_path** specifies the path for storing messages.

• **target_port** is the port of the logging server. Use the same value as in the client configuration file.

b. Save the changes to the `/etc/rsyslog.d/repserv.conf` file.

c. Restart the **rsyslog** service.

```
# systemctl restart rsyslog
```

d. Optional: If **rsyslog** is not enabled, ensure the **rsyslog** service starts automatically after reboot:

```
# systemctl enable rsyslog
```

**Verification**

To verify that the client system sends messages to the server, follow these steps:

1. On the client system, send a test message:

```
# logger test
```

2. On the server system, view the log at the specified **log_path**, for example:
# cat /var/log/remote/msg/hostname/root.log
Feb 25 03:53:17 hostname root[6064]: test

Where hostname is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case root.

Additional resources

- rsyslogd(8) and rsyslog.conf(5) man pages.

15.10. SUPPORTED RSYSLOG MODULES

To expand the functionality of the Rsyslog application, you can use specific modules. Modules provide additional inputs (Input Modules), outputs (Output Modules), and other functionalities. A module can also provide additional configuration directives that become available after you load the module.

You can list the input and output modules installed on your system by entering the following command:

```
# ls /usr/lib64/rsyslog/{i,o}m*
```

You can view the list of all available rsyslog modules in the /usr/share/doc/rsyslog/html/configuration/modules/idx_output.html file after you install the rsyslog-doc package.

15.11. ADDITIONAL RESOURCES

- The rsyslog.conf(5) and rsyslogd(8) man pages.
- The Configuring system logging without journald or with minimized journald usage Knowledgebase article.
- The Negative effects of the RHEL default logging setup on performance and their mitigations article.
- The Using the Logging System Role article.
CHAPTER 16. USING THE LOGGING SYSTEM ROLE

As a system administrator, you can use the Logging System Role to configure a RHEL host as a logging server to collect logs from many client systems.

16.1. THE LOGGING SYSTEM ROLE

With the Logging System Role, you can deploy logging configurations on local and remote hosts.

To apply a Logging System Role on one or more systems, you define the logging configuration in a playbook. A playbook is a list of one or more plays. Playbooks are human-readable, and they are written in the YAML format. For more information about playbooks, see Working with playbooks in Ansible documentation.

The set of systems that you want to configure according to the playbook is defined in an inventory file. For more information on creating and using inventories, see How to build your inventory in Ansible documentation.

Logging solutions provide multiple ways of reading logs and multiple logging outputs.

For example, a logging system can receive the following inputs:

- local files,
- systemd/journal,
- another logging system over the network.

In addition, a logging system can have the following outputs:

- logs stored in the local files in the /var/log directory,
- logs sent to Elasticsearch,
- logs forwarded to another logging system.

With the Logging System Role, you can combine the inputs and outputs to fit your scenario. For example, you can configure a logging solution that stores inputs from journal in a local file, whereas inputs read from files are both forwarded to another logging system and stored in the local log files.

16.2. LOGGING SYSTEM ROLE PARAMETERS

In a Logging System Role playbook, you define the inputs in the logging_inputs parameter, outputs in the logging_outputs parameter, and the relationships between the inputs and outputs in the logging_flows parameter. The Logging System Role processes these variables with additional options to configure the logging system. You can also enable encryption.

NOTE

Currently, the only available logging system in the Logging System Role is Rsyslog.

- logging_inputs: List of inputs for the logging solution.

  - name: Unique name of the input. Used in the logging_flows: inputs list and a part of the generated config file name.
- **type**: Type of the input element. The type specifies a task type which corresponds to a directory name in `roles/rsyslog/(tasks,vars)/inputs/`.
  - **basics**: Inputs configuring inputs from systemd journal or unix socket.
    - **kernel_message**: Load imklog if set to `true`. Default to `false`.
    - **use_imuxsock**: Use imuxsock instead of imjournal. Default to `false`.
    - **ratelimit_burst**: Maximum number of messages that can be emitted within `ratelimit_interval`. Default to 20000 if `use_imuxsock` is false. Default to 200 if `use_imuxsock` is true.
    - **ratelimit_interval**: Interval to evaluate `ratelimit_burst`. Default to 600 seconds if `use_imuxsock` is false. Default to 0 if `use_imuxsock` is true. 0 indicates rate limiting is turned off.
    - **persist_state_interval**: Journal state is persisted every `value` messages. Default to 10. Effective only when `use_imuxsock` is false.
  - **files**: Inputs configuring inputs from local files.
  - **remote**: Inputs configuring inputs from the other logging system over network.
    - **state**: State of the configuration file. `present` or `absent`. Default to `present`.
    - **logging_outputs**: List of outputs for the logging solution.
      - **files**: Outputs configuring outputs to local files.
      - **forwards**: Outputs configuring outputs to another logging system.
      - **remote_files**: Outputs configuring outputs from another logging system to local files.
    - **logging_flows**: List of flows that define relationships between `logging_inputs` and `logging_outputs`. The `logging_flows` variable has the following keys:
      - **name**: Unique name of the flow
      - **inputs**: List of `logging_inputs` name values
      - **outputs**: List of `logging_outputs` name values.

Additional resources
- Documentation installed with the `rhel-system-roles` package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`

### 16.3. APPLYING A LOCAL LOGGING SYSTEM ROLE

Follow these steps to prepare and apply an Ansible playbook to configure a logging solution on a set of separate machines. Each machine will record logs locally.

**Prerequisites**
- Access and permissions to one or more managed nodes, which are systems you want to configure with the Logging System Role.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems.
  On the control node:

  - The ansible-core and rhel-system-roles packages are installed.

  **IMPORTANT**

  RHEL 8.0-8.5 provided access to a separate Ansible repository that contains Ansible Engine 2.9 for automation based on Ansible. Ansible Engine contains command-line utilities such as ansible, ansible-playbook, connectors such as docker and podman, and many plugins and modules. For information on how to obtain and install Ansible Engine, see the How to download and install Red Hat Ansible Engine Knowledgebase article.

  RHEL 8.6 and 9.0 have introduced Ansible Core (provided as the ansible-core package), which contains the Ansible command-line utilities, commands, and a small set of built-in Ansible plugins. RHEL provides this package through the AppStream repository, and it has a limited scope of support. For more information, see the Scope of support for the Ansible Core package included in the RHEL 9 and RHEL 8.6 and later AppStream repositories Knowledgebase article.

- An inventory file which lists the managed nodes.

  **NOTE**

  You do not have to have the rsyslog package installed, because the system role installs rsyslog when deployed.

**Procedure**

1. Create a playbook that defines the required role:
   a. Create a new YAML file and open it in a text editor, for example:

      ```
      # vi logging-playbook.yml
      ```
   b. Insert the following content:

      ```
      ---
      - name: Deploying basics input and implicit files output
        hosts: all
        roles:
        - rhel-system-roles.logging
        vars:
        logging_inputs:
        - name: system_input
          type: basics
        logging_outputs:
        - name: files_output
          type: files
        logging_flows:
        - name: flow1
          inputs: [system_input]
          outputs: [files_output]
      ```
2. Run the playbook on a specific inventory:

```
# ansible-playbook -i inventory-file /path/to/file/logging-playbook.yml
```

Where:

- `inventory-file` is the inventory file.
- `logging-playbook.yml` is the playbook you use.

**Verification**

1. Test the syntax of the `/etc/rsyslog.conf` file:

```
# rsyslogd -N 1
rsyslogd: version 8.1911.0-6.el8, config validation run (level 1), master config /etc/rsyslog.conf
```

2. Verify that the system sends messages to the log:
   a. Send a test message:

```
# logger test
```

   b. View the `/var/log/messages` log, for example:

```
# cat /var/log/messages
Aug  5 13:48:31 hostname root[6778]: test
```

   Where `hostname` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

### 16.4. FILTERING LOGS IN A LOCAL LOGGING SYSTEM ROLE

You can deploy a logging solution which filters the logs based on the `rsyslog` property-based filter.

**Prerequisites**

- Access and permissions to one or more managed nodes, which are systems you want to configure with the Logging System Role.

- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems.

  On the control node:

  - Red Hat Ansible Core is installed
  - The `rhel-system-roles` package is installed
  - An inventory file which lists the managed nodes.
NOTE
You do not have to have the `rsyslog` package installed, because the System Role installs `rsyslog` when deployed.

Procedure

1. Create a new `playbook.yml` file with the following content:

```yaml
---
- name: Deploying files input and configured files output
  hosts: all
  roles:
    - linux-system-roles.logging
  vars:
    logging_inputs:
      - name: files_input
        type: basics
    logging_outputs:
      - name: files_output0
        type: files
        property: msg
        property_op: contains
        property_value: error
        path: /var/log/errors.log
      - name: files_output1
        type: files
        property: msg
        property_op: "!contains"
        property_value: error
        path: /var/log/others.log
    logging_flows:
      - name: flow0
        inputs: [files_input]
        outputs: [files_output0, files_output1]
```

Using this configuration, all messages that contain the `error` string are logged in `/var/log/errors.log`, and all other messages are logged in `/var/log/others.log`.

You can replace the `error` property value with the string by which you want to filter.

You can modify the variables according to your preferences.

2. Optional: Verify playbook syntax.

```bash
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```bash
# ansible-playbook -i inventory_file /path/to/file/playbook.yml
```

Verification

1. Test the syntax of the `/etc/rsyslog.conf` file:
rsyslogd: version 8.1911.0-6.el8, config validation run (level 1), master config
/etc/rsyslog.conf

2. Verify that the system sends messages that contain the `error` string to the log:
   a. Send a test message:

   ```
   # logger error
   ```

   b. View the `/var/log/errors.log` log, for example:

   ```
   # cat /var/log/errors.log
   Aug 5 13:48:31 hostname root[6778]: error
   ```

   Where `hostname` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

Additional resources

- Documentation installed with the `rhel-system-roles` package in `/usr/share/ansible/roles/rhel-system-roles.logging/README.html`

16.5. APPLYING A REMOTE LOGGING SOLUTION USING THE LOGGING SYSTEM ROLE

Follow these steps to prepare and apply a Red Hat Ansible Core playbook to configure a remote logging solution. In this playbook, one or more clients take logs from `systemd-journal` and forward them to a remote server. The server receives remote input from `remote_rsyslog` and `remote_files` and outputs the logs to local files in directories named by remote host names.

Prerequisites

- Access and permissions to one or more managed nodes, which are systems you want to configure with the Logging System Role.
- Access and permissions to a control node, which is a system from which Red Hat Ansible Core configures other systems.

On the control node:

- The `ansible-core` and `rhel-system-roles` packages are installed.
- An inventory file which lists the managed nodes.

**NOTE**

You do not have to have the `rsyslog` package installed, because the System Role installs `rsyslog` when deployed.

Procedure

1. Create a playbook that defines the required role:
a. Create a new YAML file and open it in a text editor, for example:

```yaml
# vi logging-playbook.yml
```

b. Insert the following content into the file:

```yaml
---
- name: Deploying remote input and remote_files output
  hosts: server
  roles:
    - rhel-system-roles.logging
  vars:
    logging_inputs:
      - name: remote_udp_input
        type: remote
        udp_ports: [ 601 ]
      - name: remote_tcp_input
        type: remote
        tcp_ports: [ 601 ]
    logging_outputs:
      - name: remote_files_output
        type: remote_files
    logging_flows:
      - name: flow_0
        inputs: [remote_udp_input, remote_tcp_input]
        outputs: [remote_files_output]

- name: Deploying basics input and forwards output
  hosts: clients
  roles:
    - rhel-system-roles.logging
  vars:
    logging_inputs:
      - name: basic_input
        type: basics
    logging_outputs:
      - name: forward_output0
        type: forwards
        severity: info
        target: _host1.example.com_
        udp_port: 601
      - name: forward_output1
        type: forwards
        facility: mail
        target: _host1.example.com_
        tcp_port: 601
    logging_flows:
      - name: flows0
        inputs: [basic_input]
        outputs: [forward_output0, forward_output1]

[basic_input]
[forward_output0, forward_output1]
```

Where `host1.example.com` is the logging server.
NOTE
You can modify the parameters in the playbook to fit your needs.

WARNING
The logging solution works only with the ports defined in the SELinux policy of the server or client system and open in the firewall. The default SELinux policy includes ports 601, 514, 6514, 10514, and 20514. To use a different port, modify the SELinux policy on the client and server systems. Configuring the firewall through System Roles is not yet supported.

2. Create an inventory file that lists your servers and clients:
   a. Create a new file and open it in a text editor, for example:

   # vi inventory.ini

   b. Insert the following content into the inventory file:

   [servers]
   server ansible_host=host1.example.com
   [clients]
   client ansible_host=host2.example.com

   Where:
   - host1.example.com is the logging server.
   - host2.example.com is the logging client.

3. Run the playbook on your inventory.

   # ansible-playbook -i /path/to/file/inventory.ini /path/to/file/_logging-playbook.yml

   Where:
   - inventory.ini is the inventory file.
   - logging-playbook.yml is the playbook you created.

Verification
1. On both the client and the server system, test the syntax of the /etc/rsyslog.conf file:

   # rsyslogd -N 1
   rsyslogd: version 8.1911.0-6.el8, config validation run (level 1), master config /etc/rsyslog.conf
2. Verify that the client system sends messages to the server:
   a. On the client system, send a test message:

   ```
   # logger test
   ```

   b. On the server system, view the `/var/log/messages` log, for example:

   ```
   # cat /var/log/messages
   Aug  5 13:48:31 host2.example.com root[6778]: test
   ```

   Where `host2.example.com` is the host name of the client system. Note that the log contains the user name of the user that entered the logger command, in this case `root`.

16.6. USING THE LOGGING SYSTEM ROLE WITH TLS

Transport Layer Security (TLS) is a cryptographic protocol designed to securely communicate over the computer network.

As an administrator, you can use the Logging RHEL System Role to configure secure transfer of logs using Red Hat Ansible Automation Platform.

16.6.1. Configuring client logging with TLS

You can use the Logging System Role to configure logging in RHEL systems that are logged on a local machine and can transfer logs to the remote logging system with TLS by running an Ansible playbook.

This procedure configures TLS on all hosts in the clients group in the Ansible inventory. The TLS protocol encrypts the message transmission for secure transfer of logs over the network.

Prerequisites

- You have permissions to run playbooks on managed nodes on which you want to configure TLS.
- The managed nodes are listed in the inventory file on the control node.
- The `ansible` and `rhel-system-roles` packages are installed on the control node.

Procedure

1. Create a `playbook.yml` file with the following content:

   ```yaml
   ---
   - name: Deploying files input and forwards output with certs
     hosts: clients
   ```
The playbook uses the following parameters:

**logging_pki_files**

Using this parameter you can configure TLS and has to pass `ca_cert_src`, `cert_src`, and `private_key_src` parameters.

**ca_cert**

Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

**cert**

Represents the path to cert. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

**private_key**

Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

**ca_cert_src**

Represents local CA cert file path which is copied to the target host. If `ca_cert` is specified, it is copied to the location.

**cert_src**

Represents the local cert file path which is copied to the target host. If `cert` is specified, it is copied to the location.

**private_key_src**

Represents the local key file path which is copied to the target host. If `private_key` is specified, it is copied to the location.

**tls**

Using this parameter ensures secure transfer of logs over the network. If you do not want a secure wrapper, you can set `tls: true`. 
2. Verify playbook syntax:

```bash
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```bash
# ansible-playbook -i inventory_file playbook.yml
```

### 16.6.2. Configuring server logging with TLS

You can use the Logging System Role to configure logging in RHEL systems as a server and can receive logs from the remote logging system with TLS by running an Ansible playbook.

This procedure configures TLS on all hosts in the server group in the Ansible inventory.

**Prerequisites**

- You have permissions to run playbooks on managed nodes on which you want to configure TLS.
- The managed nodes are listed in the inventory file on the control node.
- The `ansible` and `rhel-system-roles` packages are installed on the control node.

**Procedure**

1. Create a `playbook.yml` file with the following content:

```yaml
---
- name: Deploying remote input and remote_files output with certs
  hosts: server
  roles:
    - rhel-system-roles.logging
  vars:
    logging_pki_files:
      - ca_cert_src: /local/path/to/ca_cert.pem
        cert_src: /local/path/to/cert.pem
        private_key_src: /local/path/to/key.pem
    logging_inputs:
      - name: input_name
        type: remote
        tcp_ports: 514
        tls: true
        permitted_clients: ['clients.example.com']
    logging_outputs:
      - name: output_name
        type: remote_files
        remote_log_path: /var/log/remote/%FROMHOST%/%PROGRAMNAME:::secpath-replace%.log
        async_writing: true
        client_count: 20
        io_buffer_size: 8192
    logging_flows:
```

Red Hat Enterprise Linux 9 Security hardening
The playbook uses the following parameters:

- `logging_pki_files`
  - Using this parameter you can configure TLS and has to pass `ca_cert_src`, `cert_src`, and `private_key_src` parameters.

- `ca_cert`
  - Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

- `cert`
  - Represents the path to cert. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

- `private_key`
  - Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

- `ca_cert_src`
  - Represents local CA cert file path which is copied to the target host. If `ca_cert` is specified, it is copied to the location.

- `cert_src`
  - Represents the local cert file path which is copied to the target host. If `cert` is specified, it is copied to the location.

- `private_key_src`
  - Represents the local key file path which is copied to the target host. If `private_key` is specified, it is copied to the location.

- `tls`
  - Using this parameter ensures secure transfer of logs over the network. If you do not want a secure wrapper, you can set `tls: true`.

2. Verify playbook syntax:

```
# ansible-playbook --syntax-check playbook.yml
```

3. Run the playbook on your inventory file:

```
# ansible-playbook -i inventory_file playbook.yml
```

16.7. USING THE LOGGING SYSTEM ROLES WITH RELP

Reliable Event Logging Protocol (RELP) is a networking protocol for data and message logging over the TCP network. It ensures reliable delivery of event messages and you can use it in environments that do not tolerate any message loss.

The RELP sender transfers log entries in form of commands and the receiver acknowledges them once they are processed. To ensure consistency, RELP stores the transaction number to each transferred command for any kind of message recovery.
You can consider a remote logging system in between the RELP Client and RELP Server. The RELP Client transfers the logs to the remote logging system and the RELP Server receives all the logs sent by the remote logging system.

Administrators can use the Logging System Role to configure the logging system to reliably send and receive log entries.

### 16.7.1. Configuring client logging with RELP

You can use the Logging System Role to configure logging in RHEL systems that are logged on a local machine and can transfer logs to the remote logging system with RELP by running an Ansible playbook.

This procedure configures RELP on all hosts in the `clients` group in the Ansible inventory. The RELP configuration uses Transport Layer Security (TLS) to encrypt the message transmission for secure transfer of logs over the network.

#### Prerequisites

- You have permissions to run playbooks on managed nodes on which you want to configure RELP.
- The managed nodes are listed in the inventory file on the control node.
- The `ansible` and `rhel-system-roles` packages are installed on the control node.

#### Procedure

1. Create a `playbook.yml` file with the following content:

```yaml
---
- name: Deploying basic input and relp output
  hosts: clients
  roles:
    - rhel-system-roles.logging
  vars:
    logging_inputs:
      - name: basic_input
        type: basics
    logging_outputs:
      - name: relp_client
        type: relp
        target: _logging.server.com_
        port: 20514
        tls: true
        ca_cert: _/etc/pki/tls/certs/ca.pem_
        cert: _/etc/pki/tls/certs/client-cert.pem_
        private_key: _/etc/pki/tls/private/client-key.pem_
        pki_authmode: name
        permitted_servers:
          - '*.server.example.com'
    logging_flows:
      - name: _example_flow_
        inputs: [basic_input]
        outputs: [relp_client]
```
The playbooks uses following settings:

- **target**: This is a required parameter that specifies the host name where the remote logging system is running.

- **port**: Port number the remote logging system is listening.

- **tls**: Ensures secure transfer of logs over the network. If you do not want a secure wrapper you can set the `tls` variable to `false`. By default `tls` parameter is set to true while working with RELP and requires key/certificates and triplets `{ca_cert, cert, private_key}` and/or `{ca_cert_src, cert_src, private_key_src}`.

  - If `{ca_cert_src, cert_src, private_key_src}` triplet is set, the default locations `/etc/pki/tls/certs` and `/etc/pki/tls/private` are used as the destination on the managed node to transfer files from control node. In this case, the file names are identical to the original ones in the triplet.

  - If `{ca_cert, cert, private_key}` triplet is set, files are expected to be on the default path before the logging configuration.

  - If both the triplets are set, files are transferred from local path from control node to specific path of the managed node.

- **ca_cert**: Represents the path to CA certificate. Default path is `/etc/pki/tls/certs/ca.pem` and the file name is set by the user.

- **cert**: Represents the path to cert. Default path is `/etc/pki/tls/certs/server-cert.pem` and the file name is set by the user.

- **private_key**: Represents the path to private key. Default path is `/etc/pki/tls/private/server-key.pem` and the file name is set by the user.

- **ca_cert_src**: Represents local CA cert file path which is copied to the target host. If `ca_cert` is specified, it is copied to the location.

- **cert_src**: Represents the local cert file path which is copied to the target host. If `cert` is specified, it is copied to the location.

- **private_key_src**: Represents the local key file path which is copied to the target host. If `private_key` is specified, it is copied to the location.

- **pki_authmode**: Accepts the authentication mode as `name` or `fingerprint`.

- **permitted_servers**: List of servers that will be allowed by the logging client to connect and send logs over TLS.

- **inputs**: List of logging input dictionary.

- **outputs**: List of logging output dictionary.

2. Optional: Verify playbook syntax.
   
   ```bash
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook:
   
   ```bash
   # ansible-playbook -i inventory_file playbook.yml
   ```
16.7.2. Configuring server logging with RELP

You can use the Logging System Role to configure logging in RHEL systems as a server and can receive logs from the remote logging system with RELP by running an Ansible playbook.

This procedure configures RELP on all hosts in the `server` group in the Ansible inventory. The RELP configuration uses TLS to encrypt the message transmission for secure transfer of logs over the network.

**Prerequisites**

- You have permissions to run playbooks on managed nodes on which you want to configure RELP.
- The managed nodes are listed in the inventory file on the control node.
- The `ansible` and `rhel-system-roles` packages are installed on the control node.

**Procedure**

1. Create a `playbook.yml` file with the following content:

   ```yaml
   ---
   - name: Deploying remote input and remote_files output
     hosts: server
     roles:
       - rhel-system-roles.logging
     vars:
       logging_inputs:
         - name: relp_server
           type: relp
           port: 20514
           tls: true
           ca_cert: /etc/pki/tls/certs/ca.pem
           cert: /etc/pki/tls/certs/server-cert.pem
           private_key: /etc/pki/tls/private/server-key.pem
           pki_authmode: name
           permitted_clients:
             - '*example.client.com'
       logging_outputs:
         - name: _remote_files_output_
           type: _remote_files_
       logging_flows:
         - name: _example_flow_
           inputs: _relp_server_
           outputs: _remote_files_output_
   ```

The playbooks uses following settings:

- **port**: Port number the remote logging system is listening.

- **tls**: Ensures secure transfer of logs over the network. If you do not want a secure wrapper you can set the `tls` variable to `false`. By default `tls` parameter is set to true while working with RELP and requires key/certificates and triplets `{ca_cert, cert, private_key}` and/or `{ca_cert_src, cert_src, private_key_src}`.
If \{ca_cert_src, cert_src, private_key_src\} triplet is set, the default locations \\
/etc/pki/tls/certs and /etc/pki/tls/private are used as the destination on the managed \\
node to transfer files from control node. In this case, the file names are identical to the \\
original ones in the triplet.

- If \{ca_cert, cert, private_key\} triplet is set, files are expected to be on the default path \\
before the logging configuration.

- If both the triplets are set, files are transferred from local path from control node to \\
specific path of the managed node.

- **ca_cert**: Represents the path to CA certificate. Default path is /etc/pki/tls/certs/ca.pem \\
and the file name is set by the user.

- **cert**: Represents the path to cert. Default path is /etc/pki/tls/certs/server-cert.pem and the \\
file name is set by the user.

- **private_key**: Represents the path to private key. Default path is /etc/pki/tls/private/server- \\
key.pem and the file name is set by the user.

- **ca_cert_src**: Represents local CA cert file path which is copied to the target host. If ca_cert \\
is specified, it is copied to the location.

- **cert_src**: Represents the local cert file path which is copied to the target host. If cert is \\
specified, it is copied to the location.

- **private_key_src**: Represents the local key file path which is copied to the target host. If \\
private_key is specified, it is copied to the location.

- **pki_authmode**: Accepts the authentication mode as name or fingerprint.

- **permitted_clients**: List of clients that will be allowed by the logging server to connect and \\
send logs over TLS.

- **inputs**: List of logging input dictionary.

- **outputs**: List of logging output dictionary.

2. Optional: Verify playbook syntax.

   ```
   # ansible-playbook --syntax-check playbook.yml
   ```

3. Run the playbook:

   ```
   # ansible-playbook -i inventory_file playbook.yml
   ```
