<td>A shared persistent queue is used as reply queue. The queue must be created beforehand, although some brokers can create them on the fly such as Apache ActiveMQ. To use this you must specify the replyTo queue name. And you can optionally configure <code>replyToType=Shared</code> to make it stand out that shared queues are in use. A shared queue can be used in a clustered environment with multiple nodes running this Camel application at the same time. All using the same shared reply queue. This is possible because JMS Message selectors are used to correlate expected reply messages; this impacts performance though. JMS Message selectors is slower, and therefore not as fast as <strong>Temporary</strong> or <strong>Exclusive</strong> queues. See further below how to tweak this for better performance.</td>
</tr>
</tbody>
</table>
An exclusive persistent queue is used as reply queue. The queue must be created beforehand, although some brokers can create them on the fly such as Apache ActiveMQ. To use this you must specify the replyTo queue name. And you **must** configure `replyToType=Exclusive` to instruct Camel to use exclusive queues, as Shared is used by default, if a replyTo queue name was configured. When using exclusive reply queues, then JMS Message selectors are not in use, and therefore other applications must not use this queue as well. An exclusive queue **cannot** be used in a clustered environment with multiple nodes running this Camel application at the same time; as we do not have control if the reply queue comes back to the same node that sent the request message; that is why shared queues use JMS Message selectors to make sure of this. **Though** if you configure each Exclusive reply queue with an unique name per node, then you can run this in a clustered environment. As then the reply message will be sent back to that queue for the given node, that awaits the reply message.

**Concurrent Consumers**

Camel 2.10.3: Allows to process reply messages concurrently using concurrent message listeners in use. You can specify a range using the concurrentConsumers and maxConcurrentConsumers options. **Notice:** That using Shared reply queues may not work as well with concurrent listeners, so use this option with care.

**Maximum Concurrent Consumers**

Camel 2.10.3: Allows to process reply messages concurrently using concurrent message listeners in use. You can specify a range using the concurrentConsumers and maxConcurrentConsumers options. **Notice:** That using Shared reply queues may not work as well with concurrent listeners, so use this option with care.

The JmsProducer detects the InOut and provides a JMSReplyTo header with the reply destination to be used. By default Camel uses a temporary queue, but you can use the replyTo option on the endpoint to specify a fixed reply queue (see more below about fixed reply queue).

Camel will automatic setup a consumer which listen on the reply queue, so you should **not** do anything. This consumer is a Spring DefaultMessageListenerContainer which listen for replies. However it’s fixed to 1 concurrent consumer. That means replies will be processed in sequence as there are only 1 thread to process the replies. If you want to process replies faster, then we need to use concurrency. But **not** using the concurrentConsumer option. We should use the threads from the Camel DSL instead, as shown in the route below:

Instead of using threads, then use concurrentConsumers option if using Camel 2.10.3 or better. See further below.

```
from(xxx)
.inOut().to("activemq:queue:foo")
.threads(5)
.to(yyy)
.to(zzz);
```

In this route we instruct Camel to route replies asynchronously using a thread pool with 5 threads.
From Camel 2.10.3 onwards you can now configure the listener to use concurrent threads using the `concurrentConsumers` and `maxConcurrentConsumers` options. This allows you to easier configure this in Camel as shown below:

```java
from(xxx)
  .inOut().to("activemq:queue:foo?concurrentConsumers=5")
  .to(yyy)
  .to(zzz);
```

169.12.1. Request-reply over JMS and using a shared fixed reply queue

If you use a fixed reply queue when doing Request Reply over JMS as shown in the example below, then pay attention.

```java
from(xxx)
  .inOut().to("activemq:queue:foo?replyTo=bar")
  .to(yyy)
```

In this example the fixed reply queue named "bar" is used. By default Camel assumes the queue is shared when using fixed reply queues, and therefore it uses a `JMSSelector` to only pickup the expected reply messages (eg based on the `JMSCorrelationID`). See next section for exclusive fixed reply queues. That means its not as fast as temporary queues. You can speedup how often Camel will pull for reply messages using the `receiveTimeout` option. By default its 1000 millis. So to make it faster you can set it to 250 millis to pull 4 times per second as shown:

```java
from(xxx)
  .inOut().to("activemq:queue:foo?replyTo=bar&receiveTimeout=250")
  .to(yyy)
```

Notice this will cause the Camel to send pull requests to the message broker more frequent, and thus require more network traffic.

It is generally recommended to use temporary queues if possible.

169.12.2. Request-reply over JMS and using an exclusive fixed reply queue

Available as of Camel 2.9

In the previous example, Camel would anticipate the fixed reply queue named "bar" was shared, and thus it uses a `JMSSelector` to only consume reply messages which it expects. However there is a drawback doing this as JMS selectos is slower. Also the consumer on the reply queue is slower to update with new JMS selector ids. In fact it only updates when the `receiveTimeout` option times out, which by default is 1 second. So in theory the reply messages could take up till about 1 sec to be detected. On the other hand if the fixed reply queue is exclusive to the Camel reply consumer, then we can avoid using the JMS selectors, and thus be more performant. In fact as fast as using temporary queues. So in Camel 2.9 onwards we introduced the `ReplyToType` option which you can configure to `Exclusive` to tell Camel that the reply queue is exclusive as shown in the example below:

```java
from(xxx)
  .inOut().to("activemq:queue:foo?replyTo=bar&replyToType=Exclusive")
  .to(yyy)
```

Mind that the queue must be exclusive to each and every endpoint. So if you have two routes, then they each need an unique reply queue as shown in the next example:
The same applies if you run in a clustered environment. Then each node in the cluster must use an unique reply queue name. As otherwise each node in the cluster may pickup messages which was intended as a reply on another node. For clustered environments its recommended to use shared reply queues instead.

169.13. SYNCHRONIZING CLOCKS BETWEEN SENDERS AND RECEIVERS

When doing messaging between systems, its desirable that the systems have synchronized clocks. For example when sending a JMS message, then you can set a time to live value on the message. Then the receiver can inspect this value, and determine if the message is already expired, and thus drop the message instead of consume and process it. However this requires that both sender and receiver have synchronized clocks. If you are using ActiveMQ then you can use the timestamp plugin to synchronize clocks.

169.14. ABOUT TIME TO LIVE

Read first above about synchronized clocks.

When you do request/reply (InOut) over JMS with Camel then Camel uses a timeout on the sender side, which is default 20 seconds from the requestTimeout option. You can control this by setting a higher/lower value. However the time to live value is still set on the JMS message being send. So that requires the clocks to be synchronized between the systems. If they are not, then you may want to disable the time to live value being set. This is now possible using the disableTimeToLive option from Camel 2.8 onwards. So if you set this option to disableTimeToLive=true, then Camel does not set any time to live value when sending JMS messages. But the request timeout is still active. So for example if you do request/reply over JMS and have disabled time to live, then Camel will still use a timeout by 20 seconds (the requestTimeout option). That option can of course also be configured. So the two options requestTimeout and disableTimeToLive gives you fine grained control when doing request/reply.

From Camel 2.13/2.12.3 onwards you can provide a header in the message to override and use as the request timeout value instead of the endpoint configured value. For example:

```java
from("direct:someWhere")
.to("jms:queue:foo?replyTo=bar&replyToType=Exclusive")
.to("bean:processReply");
```

In the route above we have a endpoint configured requestTimeout of 30 seconds. So Camel will wait up till 30 seconds for that reply message to come back on the bar queue. If no reply message is received then a org.apache.camel.ExchangeTimedOutException is set on the Exchange and Camel continues routing the message, which would then fail due the exception, and Camel's error handler reacts.

If you want to use a per message timeout value, you can set the header with key org.apache.camel.component.jms.JmsConstants#JMS_REQUEST_TIMEOUT which has constant value "CamelJmsRequestTimeout" with a timeout value as long type.
For example we can use a bean to compute the timeout value per individual message, such as calling the "whatIsTheTimeout" method on the service bean as shown below:

```java
from("direct:someWhere")
  .setHeader("CamelJmsRequestTimeout", method(ServiceBean.class, "whatIsTheTimeout"))
  .to("jms:queue:foo?replyTo=bar&requestTimeout=30s")
  .to("bean:processReply");
```

When you do fire and forget (InOut) over JMS with Camel then Camel by default does not set any time to live value on the message. You can configure a value by using the `timeToLive` option. For example to indicate a 5 sec., you set `timeToLive=5000`. The option `disableTimeToLive` can be used to force disabling the time to live, also for InOnly messaging. The `requestTimeout` option is not being used for InOnly messaging.

### 169.15. Enabling Transacted Consumption

A common requirement is to consume from a queue in a transaction and then process the message using the Camel route. To do this, just ensure that you set the following properties on the component/endpoint:

- `transacted = true`
- `transactionManager = a Transaction Manager` - typically the `JmsTransactionManager`

See the Transactional Client EIP pattern for further details.

Transactions and [Request Reply] over JMS

When using Request Reply over JMS you cannot use a single transaction; JMS will not send any messages until a commit is performed, so the server side won’t receive anything at all until the transaction commits. Therefore to use Request Reply you must commit a transaction after sending the request and then use a separate transaction for receiving the response.

To address this issue the JMS component uses different properties to specify transaction use for oneway messaging and request reply messaging:

The `transacted` property applies only to the InOnly message Exchange Pattern (MEP).

The `transactedInOut` property applies to the InOut(Request Reply) message Exchange Pattern (MEP).

If you want to use transactions for Request Reply (InOut MEP), you must set `transactedInOut=true`.

**Available as of Camel 2.10**

You can leverage the DMLC transacted session API using the following properties on component/endpoint:

- `transacted = true`
- `lazyCreateTransactionManager = false`

The benefit of doing so is that the cacheLevel setting will be honored when using local transactions without a configured TransactionManager. When a TransactionManager is configured, no caching happens at DMLC level and it’s necessary to rely on a pooled connection factory. For more details about this kind of setup see [here](#) and [here](#).
169.16. USING JMSREPLYTO FOR LATE REPLIES

When using Camel as a JMS listener, it sets an Exchange property with the value of the ReplyTo javax.jms.Destination object, having the key ReplyTo. You can obtain this Destination as follows:

```java
Destination replyDestination = exchange.getIn().getHeader(JmsConstants.JMS_REPLY_DESTINATION, Destination.class);
```

And then later use it to send a reply using regular JMS or Camel.

```java
// we need to pass in the JMS component, and in this sample we use ActiveMQ
JmsEndpoint endpoint = JmsEndpoint.newInstance(replyDestination, activeMQComponent);
// now we have the endpoint we can use regular Camel API to send a message to it
template.sendBody(endpoint, "Here is the late reply.");
```

A different solution to sending a reply is to provide the replyDestination object in the same Exchange property when sending. Camel will then pick up this property and use it for the real destination. The endpoint URI must include a dummy destination, however. For example:

```java
// we pretend to send it to some non existing dummy queue
template.send("activemq:queue:dummy, new Processor() {
  public void process(Exchange exchange) throws Exception {
    // and here we override the destination with the ReplyTo destination object so the message is
    // sent to there instead of dummy
    exchange.getIn().setHeader(JmsConstants.JMS_DESTINATION, replyDestination);
    exchange.getIn().setBody("Here is the late reply.");
  }
}
```

169.17. USING A REQUEST TIMEOUT

In the sample below we send a Request Reply style message Exchange (we use the requestBody method = InOut) to the slow queue for further processing in Camel and we wait for a return reply:

169.18. SAMPLES

JMS is used in many examples for other components as well. But we provide a few samples below to get started.

169.18.1. Receiving from JMS

In the following sample we configure a route that receives JMS messages and routes the message to a POJO:

```java
from("jms:queue:foo").
to("bean:myBusinessLogic");
```

You can of course use any of the EIP patterns so the route can be context based. For example, here’s how to filter an order topic for the big spenders:
169.18.2. Sending to JMS

In the sample below we poll a file folder and send the file content to a JMS topic. As we want the content of the file as a **TextMessage** instead of a **BytesMessage**, we need to convert the body to a **String**:

```java
from("file://orders").
    convertBodyTo(String.class).
    to("jms:topic:OrdersTopic");
```

169.18.3. Using Annotations

Camel also has annotations so you can use **POJO Consuming** and **POJO Producing**.

169.18.4. Spring DSL sample

The preceding examples use the Java DSL. Camel also supports Spring XML DSL. Here is the big spender sample using Spring DSL:

```xml
<route>
    <from uri="jms:topic:OrdersTopic"/>
    <filter>
        <method bean="myBean" method="isGoldCustomer"/>
        <to uri="jms:queue:BigSpendersQueue"/>
    </filter>
</route>
```

169.18.5. Other samples

JMS appears in many of the examples for other components and EIP patterns, as well in this Camel documentation. So feel free to browse the documentation. If you have time, check out the this tutorial that uses JMS but focuses on how well Spring Remoting and Camel works together [Tutorial-JmsRemoting](#).

169.18.6. Using JMS as a Dead Letter Queue storing Exchange

Normally, when using JMS as the transport, it only transfers the body and headers as the payload. If you want to use JMS with a **Dead Letter Channel**, using a JMS queue as the Dead Letter Queue, then normally the caused Exception is not stored in the JMS message. You can, however, use the `transferExchange` option on the JMS dead letter queue to instruct Camel to store the entire Exchange in the queue as a **javax.jms.ObjectMessage** that holds a **org.apache.camel.impl.DefaultExchangeHolder**. This allows you to consume from the Dead Letter Queue and retrieve the caused exception from the Exchange property with the key **Exchange.EXCEPTION_CAUGHT**. The demo below illustrates this:

```java
// setup error handler to use JMS as queue and store the entire Exchange
errorHandler(deadLetterChannel("jms:queue:dead?transferExchange=true"));
```
Then you can consume from the JMS queue and analyze the problem:

```java
from("jms:queue:dead").to("bean:myErrorAnalyzer");

// and in our bean
String body = exchange.getIn().getBody();
Exception cause = exchange.getProperty(Exchange.EXCEPTION_CAUGHT, Exception.class);
// the cause message is
String problem = cause.getMessage();
```

### 169.18.7. Using JMS as a Dead Letter Channel storing error only

You can use JMS to store the cause error message or to store a custom body, which you can initialize yourself. The following example uses the Message Translator EIP to do a transformation on the failed exchange before it is moved to the JMS dead letter queue:

```java
// we sent it to a seda dead queue first
errorHandler(deadLetterChannel("seda:dead"));

// and on the seda dead queue we can do the custom transformation before its sent to the JMS queue
from("seda:dead").transform(exceptionMessage()).to("jms:queue:dead");
```

Here we only store the original cause error message in the transform. You can, however, use any Expression to send whatever you like. For example, you can invoke a method on a Bean or use a custom processor.

### 169.19. SENDING AN INONLY MESSAGE AND KEEPING THE JMSREPLYTO HEADER

When sending to a JMS destination using `camel-jms` the producer will use the MEP to detect if its `InOnly` or `InOut` messaging. However there can be times where you want to send an `InOnly` message but keeping the `JMSReplyTo` header. To do so you have to instruct Camel to keep it, otherwise the `JMSReplyTo` header will be dropped.

For example to send an `InOnly` message to the foo queue, but with a `JMSReplyTo` with bar queue you can do as follows:

```java
template.send("activemq:queue:foo?preserveMessageQos=true", new Processor() {
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setBody("World");
        exchange.getIn().setHeader("JMSReplyTo", "bar");
    }
});
```

Notice we use `preserveMessageQos=true` to instruct Camel to keep the `JMSReplyTo` header.

### 169.20. SETTING JMS PROVIDER OPTIONS ON THE DESTINATION

Some JMS providers, like IBM’s WebSphere MQ need options to be set on the JMS destination. For example, you may need to specify the `targetClient` option. Since `targetClient` is a WebSphere MQ option and not a Camel URI option, you need to set that on the JMS destination name like so:

```java
from("jms:queue:dead").to("bean:myErrorAnalyzer");
```

// and in our bean
String body = exchange.getIn().getBody();
Exception cause = exchange.getProperty(Exchange.EXCEPTION_CAUGHT, Exception.class);
// the cause message is
String problem = cause.getMessage();
```
Some versions of WMQ won’t accept this option on the destination name and you will get an exception like:

```java
com.ibm.msg.client.jms.DetailedJMSException: JMSCC0005: The specified value 'MY_QUEUE?targetClient=1' is not allowed for 'XMSC_DESTINATION_NAME'
```

A workaround is to use a custom DestinationResolver:

```java
JmsComponent wmq = new JmsComponent(connectionFactory);

wmq.setDestinationResolver(new DestinationResolver() {
    public Destination resolveDestinationName(Session session, String destinationName, boolean pubSubDomain) throws JMSException {
        MQQueueSession wmqSession = (MQQueueSession) session;
        return wmqSession.createQueue("queue:///"+destinationName+"?targetClient=1");
    }
});
```

CHAPTER 170. JMX COMPONENT

170.1. CAMEL JMX

Apache Camel has extensive support for JMX to allow you to monitor and control the Camel managed objects with a JMX client.

Camel also provides a JMX component that allows you to subscribe to MBean notifications. This page is about how to manage and monitor Camel using JMX.

170.2. OPTIONS

The JMX component has no options.

The JMX endpoint is configured using URI syntax:

```
jmx:serverURL
```

with the following path and query parameters:

170.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>serverURL</td>
<td>server url comes from the remaining endpoint</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

170.2.2. Query Parameters (29 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>format (consumer)</td>
<td>URI Property: Format for the message body. Either xml or raw. If xml, the notification is serialized to xml. If raw, then the raw java object is set as the body.</td>
<td>xml</td>
<td>String</td>
</tr>
<tr>
<td>granularityPeriod (consumer)</td>
<td>URI Property: monitor types only The frequency to poll the bean to check the monitor.</td>
<td>10000</td>
<td>long</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td>monitorType</td>
<td>URI Property: monitor types only The type of monitor to create. One of string, gauge, counter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>objectDomain</td>
<td><strong>Required</strong> URI Property: The domain for the mbean you’re connecting to</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>objectName</td>
<td>URI Property: The name key for the mbean you’re connecting to. This value is mutually exclusive with the object properties that get passed.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>observedAttribute</td>
<td>URI Property: monitor types only The attribute to observe for the monitor bean.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>handback</td>
<td>URI Property: Value to handback to the listener when a notification is received. This value will be put in the message header with the key jmx.handback</td>
<td></td>
<td>Object</td>
</tr>
<tr>
<td>notificationFilter</td>
<td>URI Property: Reference to a bean that implements the NotificationFilter.</td>
<td></td>
<td>NotificationFilter</td>
</tr>
<tr>
<td>objectProperties</td>
<td>URI Property: properties for the object name. These values will be used if the objectName param is not set</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>reconnectDelay</td>
<td>URI Property: The number of seconds to wait before attempting to retry establishment of the initial connection or attempt to reconnect a lost connection</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>reconnectOnConnectionFailure</td>
<td>URI Property: If true the consumer will attempt to reconnect to the JMX server when any connection failure occurs. The consumer will attempt to re-establish the JMX connection every ‘x’ seconds until the connection is made--- where ‘x’ is the configured reconnectDelay</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------</td>
<td>------------</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>testConnectionOnStartup</td>
<td>URI Property: If true the consumer will throw an exception if unable to establish the JMX connection upon startup. If false, the consumer will attempt to establish the JMX connection every <code>x</code> seconds until the connection is made — where <code>x</code> is the configured reconnectionDelay</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>initThreshold</td>
<td>URI Property: counter monitor only Initial threshold for the monitor. The value must exceed this before notifications are fired.</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>modulus</td>
<td>URI Property: counter monitor only The value at which the counter is reset to zero</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>offset</td>
<td>URI Property: counter monitor only The amount to increment the threshold after it’s been exceeded.</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>differenceMode</td>
<td>URI Property: counter gauge monitor only If true, then the value reported in the notification is the difference from the threshold as opposed to the value itself.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>notifyHigh</td>
<td>URI Property: gauge monitor only If true, the gauge will fire a notification when the high threshold is exceeded</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>notifyLow</td>
<td>URI Property: gauge monitor only If true, the gauge will fire a notification when the low threshold is exceeded</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>thresholdHigh</td>
<td>URI Property: gauge monitor only Value for the gauge’s high threshold</td>
<td></td>
<td>Double</td>
</tr>
<tr>
<td>thresholdLow</td>
<td>URI Property: gauge monitor only Value for the gauge’s low threshold</td>
<td></td>
<td>Double</td>
</tr>
<tr>
<td>password</td>
<td>URI Property: credentials for making a remote connection</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>user</td>
<td>URI Property: credentials for making a remote connection</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>notifyDiffer (string)</td>
<td>URI Property: string monitor only If true, the string monitor will fire a notification when the string attribute differs from the string to compare.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>notifyMatch (string)</td>
<td>URI Property: string monitor only If true, the string monitor will fire a notification when the string attribute matches the string to compare.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>stringToCompare (string)</td>
<td>URI Property: string monitor only Value for the string monitor's string to compare.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 170.3. ACTIVATING JMX IN CAMEL

**NOTE**

Spring JAR dependency, required for Camel 2.8 or older

`spring-context.jar`, `spring-aop.jar`, `spring-beans.jar`, and `spring-core.jar` are needed on the classpath by Camel to be able to use JMX instrumentation. If these jars are not on the classpath, Camel will fallback to non JMX mode. This situation is logged at `WARN` level using logger name `org.apache.camel.impl.DefaultCamelContext`.

From Camel 2.9 onwards, the Spring JARs are no longer required to run Camel in JMX mode.

#### 170.3.1. Using JMX to manage Apache Camel

By default, JMX instrumentation agent is enabled in Camel, which means that Camel runtime creates and registers MBean management objects with a `MBeanServer` instance in the VM. This allows Camel users to instantly obtain insights into how Camel routes perform down to the individual processor level.

The supported types of management objects are `endpoint`, `route`, `service`, and `processor`. Some of these management objects also expose lifecycle operations in addition to performance counter attributes.

The `DefaultManagementNamingStrategy` is the default naming strategy which builds object names used for MBean registration. By default, `org.apache.camel` is the domain name for all object names created by `CamelNamingStrategy`. The domain name of the MBean object can be configured by Java VM system property:

```
-Dorg.apache.camel.jmx.mbeanObjectNameDomainName=your.domain.name
```

Or, by adding a `jmxAgent` element inside the `camelContext` element in Spring configuration:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" mbeanObjectNameDomainName="your.domain.name"/>
  ...
</camelContext>
```
Spring configuration always takes precedence over system properties when they both present. It is true for all JMX related configurations.

170.3.2. Disabling JMX instrumentation agent in Camel

You can disable JMX instrumentation agent by setting the Java VM system property as follow:

-Dorg.apache.camel.jmx.disabled=true

The property value is treated as boolean.

Or, by adding a `jmxAgent` element inside the `camelContext` element in Spring configuration:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" disabled="true"/>
  ...
</camelContext>
```

Or in Camel 2.1 it's a bit easier (not having to use JVM system property) if using pure Java as you can disable it as follows:

```java
CamelContext camel = new DefaultCamelContext();
camel.disableJMX();
```

170.3.3. Locating a MBeanServer in the Java VM

Each CamelContext can have an instance of `InstrumentationAgent` wrapped inside the `InstrumentationLifecycleStrategy`. The `InstrumentationAgent` is the object that interfaces with a `MBeanServer` to register / unregister Camel MBeans. Multiple CamelContexts / InstrumentationAgents can / should share a `MBeanServer`. By default, Camel runtime picks the first `MBeanServer` returned by `MBeanServerFactory.findMBeanServer` method that matches the default domain name of `org.apache.camel`.

You may want to change the default domain name to match the `MBeanServer` instance that you are already using in your application. Especially, if your `MBeanServer` is attached to a JMX connector server, you will not need to create a connector server in Camel.

You can configure the matching default domain name via system property.

-Dorg.apache.camel.jmx.mbeanServerDefaultDomain=<your.domain.name>

Or, by adding a `jmxAgent` element inside the `camelContext` element in Spring configuration:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" mbeanServerDefaultDomain="your.domain.name"/>
  ...
</camelContext>
```

If no matching `MBeanServer` can be found, a new one is created and the new `MBeanServer`'s default domain name is set according to the default and configuration as mentioned above.
It is also possible to use the PlatformMBeanServer when it is desirable to manage JVM MBeans by setting the system property. The MBeanServer default domain name configuration is ignored as it is not applicable.

**CAUTION**

Starting in next release (1.5), the default value of usePlatformMBeanServer will be changed to true. You can set the property to false to disable using platform MBeanServer.

```
-Dorg.apache.camel.jmx.usePlatformMBeanServer=True
```

Or, by adding a jmxAgent element inside the camelContext element in Spring configuration:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" usePlatformMBeanServer="true"/>
  ...
</camelContext>
```

### 170.3.4. Creating JMX RMI Connector Server

JMX connector server enables MBeans to be remotely managed by a JMX client such as JConsole; Camel JMX RMI connector server can be optionally turned on by setting system property and the MBeanServer used by Camel is attached to that connector server.

```
-Dorg.apache.camel.jmx.createRmiConnector=True
```

Or, by adding a jmxAgent element inside the camelContext element in Spring configuration:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" createConnector="true"/>
  ...
</camelContext>
```

### 170.3.5. JMX Service URL

The default JMX Service URL has the format:

```
/service:jmx:rmi:///jndi/rmi://localhost:<registryPort>/<serviceUrlPath>
```

*registryPort* is the RMI registry port and the default value is 1099.

You can set the RMI registry port by system property.

```
-Dorg.apache.camel.jmx.rmiConnector.registryPort=<port number>
```

Or, by adding a jmxAgent element inside the camelContext element in Spring configuration:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" createConnector="true" registryPort="<port number"/>
  ...
</camelContext>
```
**serviceUrlPath** is the path name in the URL and the default value is `/jmxrmi/camel`.

You can set the service URL path by system property.

```
-Dorg.apache.camel.jmx.serviceUrlPath=<path>
```

**TIP**

**Setting ManagementAgent settings in Java**

In **Camel 2.4** onwards you can also set the various options on the `ManagementAgent`:

```
context.getManagementStrategy().getManagementAgent().setServiceUrlPath("/foo/bar");
context.getManagementStrategy().getManagementAgent().setRegistryPort(2113);
context.getManagementStrategy().getManagementAgent().setCreateConnector(true);
```

Or, by adding a `jmxAgent` element inside the `camelContext` element in Spring configuration:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" createConnector="true" serviceUrlPath="path"/>
  ...
</camelContext>
```

By default, RMI server object listens on a dynamically generated port, which can be a problem for connections established through a firewall. In such situations, RMI connection port can be explicitly set by the system property.

```
-Dorg.apache.camel.jmx.rmiConnector.connectorPort=<port number>
```

Or, by adding a `jmxAgent` element inside the `camelContext` element in Spring configuration:

```
<camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring">
  <jmxAgent id="agent" createConnector="true" connectorPort="port number"/>
  ...
</camelContext>
```

When the connector port option is set, the JMX service URL will become:

```
```

### 170.3.6. The System Properties for Camel JMX support

<table>
<thead>
<tr>
<th>Property Name</th>
<th>value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.apache.camel.jmx</td>
<td>true or false</td>
<td>if is true, it will enable jmx feature in Camel</td>
</tr>
</tbody>
</table>

See more system properties in this section below: `jmxAgent Properties Reference`. 
170.3.7. How to use authentication with JMX

JMX in the JDK have features for authentication and also for using secure connections over SSL. You have to refer to the SUN documentation how to use this:

- http://java.sun.com/j2se/1.5.0/docs/guide/management/agent.html

170.3.8. JMX inside an Application Server

170.3.8.1. Tomcat 6

See this page for details about enabling JMX in Tomcat.

In short, modify your catalina.sh (or catalina.bat in Windows) file to set the following options...

```
set CATALINA_OPTS=-Dcom.sun.management.jmxremote
-Dcom.sun.management.jmxremote.port=1099
-Dcom.sun.management.jmxremote.ssl=false
-Dcom.sun.management.jmxremote.authenticate=false
```

170.3.8.2. JBoss AS 4

By default JBoss creates its own MBeanServer. To allow Camel to expose to the same server follow these steps:

1. Tell Camel to use the Platform MBeanServer (This defaults to true in Camel 1.5)

```
<camel:camelContext id="camelContext">
  <camel:jmxAgent id="jmxAgent" mbeanObjectName="org.yourname"
      usePlatformMBeanServer="true" />
</camel:camelContext>
```

1. Alter your JBoss instance to use the Platform MBeanServer. Add the following property to your JAVA_OPTS by editing run.sh or run.conf -Djboss.platform.mbeanserver. See http://wiki.jboss.org/wiki/JBossMBeansInJConsole

170.3.8.3. WebSphere

Alter the mbeanServerDefaultDomain to be WebSphere:

```
<camel:jmxAgent id="agent" createConnector="true" mbeanObjectName="org.yourname"
    usePlatformMBeanServer="false" mbeanServerDefaultDomain="WebSphere"/>
```

170.3.8.4. Oracle OC4j

The Oracle OC4J J2EE application server will not allow Camel to access the platform MBeanServer. You can identify this in the log as Camel will log a WARNING.

```
xxx xx, xxxx xx:xx xx org.apache.camel.management.InstrumentationLifecycleStrategy
onContextStart
WARNING: Could not register CamelContext MBean
```
java.lang.SecurityException: Unauthorized access from application: xx to MBean:
java.lang:type=ClassLoading
at
oracle.oc4j.admin.jmx.shared.UserMBeanServer.checkRegisterAccess(UserMBeanServer.java:873)

To resolve this you should disable the JMX agent in Camel, see section Disabling JMX instrumentation agent in Camel.

170.3.9. Advanced JMX Configuration

The Spring configuration file allows you to configure how Camel is exposed to JMX for management. In some cases, you could specify more information here, like the connector’s port or the path name.

170.3.10. Example:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" createConnector="true" registryPort="2000"
    mbeanServerDefaultDomain="org.apache.camel.test"/>
  <route>
    <from uri="seda:start"/>
    <to uri="mock:result"/>
  </route>
</camelContext>
```

If you wish to change the Java 5 JMX settings you can use various JMX system properties.

For example you can enable remote JMX connections to the Sun JMX connector, via setting the following environment variable (using `set` or `export` depending on your platform). These settings only configure the Sun JMX connector within Java 1.5+, not the JMX connector that Camel creates by default.

```
SUNJMX=-Dcom.sun.management.jmxremote=true -Dcom.sun.management.jmxremote.port=1616 \
-Dcom.sun.management.jmxremote.authenticate=false -Dcom.sun.management.jmxremote.ssl=false
```

(The SUNJMX environment variable is simple used by the startup script for Camel, as additional startup parameters for the JVM. If you start Camel directly, you’ll have to pass these parameters yourself.)

170.3.11. jmxAgent Properties Reference

<table>
<thead>
<tr>

<td>Camel 2.16: Whether endpoint runtime statistics is enabled (gathers runtime usage of each incoming and outgoing endpoints).</td>
</tr>
</tbody>
</table>

170.3.12. Configuring whether to register MBeans always, for new routes or just by default

Available as of Camel 2.7

Camel now offers 2 settings to control whether or not to register mbeans

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>registerAlways</td>
<td>false</td>
<td>If enabled then MBeans is always registered.</td>
</tr>
</tbody>
</table>
registerNewRoutes | true | If enabled then adding new routes after CamelContext has been started will also register MBeans from that given route.

By default Camel registers MBeans for all the routes configured when its starting. The registerNewRoutes option control if MBeans should also be registered if you add new routes thereafter. You can disable this, if you for example add and remove temporary routes where management is not needed.

Be a bit caution to use the registerAlways option when using dynamic EIP patterns such as the Recipient List having unique endpoints. If so then each unique endpoint and its associated services/producers would also be registered. This could potential lead to system degration due the rising number of mbeans in the registry. A MBean is not a light-weight object and thus consumes memory.

170.4. MONITORING CAMEL USING JMX

170.4.1. Using JConsole to monitor Camel

The CamelContext should appear in the list of local connections, if you are running JConsole on the same host as Camel.

To connect to a remote Camel instance, or if the local process does not show up, use Remote Process option, and enter an URL. Here is an example localhost URL:service:jmx:rmi:///jndi/rmi://localhost:1099/jmxrmi/camel.

Using the Apache Camel with JConsole:
170.4.2. Which endpoints are registered

In Camel 2.1 onwards only **singleton** endpoints are registered as the overhead for non singleton will be substantial in cases where thousands or millions of endpoints are used. This can happens when using a Recipient List EIP or from a **ProducerTemplate** that sends a lot of messages.

170.4.3. Which processors are registered

See this FAQ.

170.4.4. How to use the JMX NotificationListener to listen the camel events?

The Camel notification events give a coarse grained overview what is happening. You can see lifecycle event from context and endpoints and you can see exchanges being received by and sent to endpoints.

From Camel 2.4 you can use a custom JMX NotificationListener to listen the camel events.

First you need to set up a **JmxNotificationEventNotifier** before you start the CamelContext:

```java
// Set up the JmxNotificationEventNotifier
 notifier = new JmxNotificationEventNotifier();
 notifier.setSource("MyCamel");
 notifier.setIgnoreCamelContextEvents(true);
 notifier.setIgnoreRouteEvents(true);
 notifier.setIgnoreServiceEvents(true);
```
CamelContext context = new DefaultCamelContext(createRegistry());
context.getManagementStrategy().addEventNotifier(notifier);

Second you can register your listener for listening the event:

```java
// register the NotificationListener
ObjectName on = ObjectName.getInstance("org.apache.camel:context=camel-1,type=eventnotifiers,name=JmxEventNotifier");
MyNotificationListener listener = new MyNotificationListener();
context.getManagementStrategy().getManagementAgent().getMBeanServer().addNotificationListener(on,
    listener,
    new NotificationFilter() {
        private static final long serialVersionUID = 1L;

        public boolean isNotificationEnabled(Notification notification) {
            return notification.getSource().equals("MyCamel");
        }
    }, null);
```

**170.4.5. Using the Tracer MBean to get fine grained tracing**

Additionally to the coarse grained notifications above **Camel 2.9.0** support JMX Notification for fine grained trace events.

These can be found in the Tracer MBean. To activate fine grained tracing you first need to activate tracing on the context or on a route.

This can either be done when configuring the context or on the context / route MBeans.

As a second step you have to set the `jmxTraceNotifications` attribute to **true** on the tracer. This can again be done when configuring the context or at runtime on the tracer MBean.

Now you can register for TraceEvent Notifications on the Tracer MBean using JConsole. There will be one Notification for every step on the route with all exchange and message details:
170.5. USING JMX FOR YOUR OWN CAMEL CODE

170.5.1. Registering your own Managed Endpoints

Available as of Camel 2.0

You can decorate your own endpoints with Spring managed annotations `@ManagedResource` to allow to register them in the Camel `MBeanServer` and thus access your custom MBeans using JMX.

NOTE

In Camel 2.1 we have changed this to apply other than just endpoints but then you need to implement the interface `org.apache.camel.spi.ManagementAware` as well. More about this later.

For example we have the following custom endpoint where we define some options to be managed:

```java
@ManagedResource(description = "Our custom managed endpoint")
public class CustomEndpoint extends MockEndpoint implements ManagementAware<CustomEndpoint> {

    public CustomEndpoint(final String endpointUri, final Component component) {
        super(endpointUri, component);
    }

    public Object getManagedObject(CustomEndpoint object) {
        return this;
    }

    public boolean isSingleton() {
        return true;
    }
}
```
Notice from Camel 2.9 onwards it's encouraged to use the `@ManagedResource`, `@ManagedAttribute`, and `@ManagedOperation` from the `org.apache.camel.api.management` package. This allows your custom code to not depend on Spring JARs.

170.5.2. Programming your own Managed Services

Available as of Camel 2.1

Camel now offers to use your own MBeans when registering services for management. What that means is for example you can develop a custom Camel component and have it expose MBeans for endpoints, consumers and producers etc. All you need to do is to implement the interface `org.apache.camel.spi.ManagementAware` and return the managed object Camel should use.

Now before you think oh boys the JMX API is really painful and terrible, then yeah you are right. Lucky for us Spring though too and they created a range of annotations you can use to export management on an existing bean. That means that you often use that and just return this in the `getManagedObject` from the `ManagementAware` interface. For an example see the code example above with the `CustomEndpoint`.

Now in Camel 2.1 you can do this for all the objects that Camel registers for management which are quite a bunch, but not all.

For services which do not implement this `ManagementAware` interface then Camel will fallback to using default wrappers as defined in the table below:

<table>
<thead>
<tr>
<th>Type</th>
<th>MBean wrapper</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelContext</td>
<td>ManagedCamelContext</td>
</tr>
<tr>
<td>Component</td>
<td>ManagedComponent</td>
</tr>
<tr>
<td>Endpoint</td>
<td>ManagedEndpoint</td>
</tr>
<tr>
<td>Consumer</td>
<td>ManagedConsumer</td>
</tr>
<tr>
<td>Producer</td>
<td>ManagedProducer</td>
</tr>
</tbody>
</table>
### Type | MBean wrapper
---|---
Route | ManagedRoute
Processor | ManagedProcessor
Tracer | ManagedTracer
Service | ManagedService

In addition to that there are some extended wrappers for specialized types such as:

<table>
<thead>
<tr>
<th>Type</th>
<th>MBean wrapper</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledPollConsumer</td>
<td>ManagedScheduledPollConsumer</td>
</tr>
<tr>
<td>BrowsableEndpoint</td>
<td>ManagedBrowsableEndpoint</td>
</tr>
<tr>
<td>Throttler</td>
<td>ManagedThrottler</td>
</tr>
<tr>
<td>Delayer</td>
<td>ManagedDelayer</td>
</tr>
<tr>
<td>SendProcessor</td>
<td>ManagedSendProcessor</td>
</tr>
</tbody>
</table>

And in the future we will add additional wrappers for more EIP patterns.

**170.5.3. ManagementNamingStrategy**

Available as of Camel 2.1

Camel provides a pluggable API for naming strategy by `org.apache.camel.spi.ManagementNamingStrategy`. A default implementation is used to compute the MBean names that all MBeans are registered with.

**170.5.4. Management naming pattern**

Available as of Camel 2.10

From Camel 2.10 onwards we made it easier to configure a naming pattern for the MBeans. The pattern is used as part of the `ObjectName` as they key after the domain name.

By default Camel will use MBean names for the `ManagedCamelContextMBean` as follows:

```
org.apache.camel:context=localhost/camel-1,type=context,name=camel-1
```

And from Camel 2.13 onwards the hostname is not included in the MBean names, so the above example would be as follows:

```
org.apache.camel:context=camel-1,type=context,name=camel-1
```
If you configure a name on the CamelContext then that name is part of the ObjectName as well. For example if we have

```xml
<camelContext id="myCamel" ...>
```

Then the MBean names will be as follows:

```java
org.apache.camel:context=localhost/myCamel,type=context,name=myCamel
```

Now if there is a naming clash in the JVM, such as there already exists a MBean with that given name above, then Camel will by default try to auto correct this by finding a new free name in the JMXMBeanServer by using a counter. As shown below the counter is now appended, so we have myCamel-1 as part of the ObjectName:

```java
org.apache.camel:context=localhost/myCamel-1,type=context,name=myCamel
```

This is possible because Camel uses a naming pattern by default that supports the following tokens:

- `camelId` = the CamelContext id (eg the name)
- `name` = same as `camelId`
- `counter` = an incrementing counter
- `bundleId` = the OSGi bundle id (only for OSGi environments)
- `symbolicName` = the OSGi symbolic name (only for OSGi environments)
- `version` = the OSGi bundle version (only for OSGi environments)

The default naming pattern is differentiated between OSGi and non-OSGi as follows:

- non OSGI: `name`
- OSGI: `bundleId-name`
- OSGi Camel 2.13: `symbolicName`

However if there is a naming clash in the JMXMBeanServer then Camel will automatic fallback and use the `counter` in the pattern to remedy this. And thus the following patterns will then be used:

- non OSGI: `name-counter`
- OSGI: `bundleId-name-counter`
- OSGi Camel 2.13: `symbolicName-counter`

If you set an explicit naming pattern, then that pattern is always used, and the default patterns above is not used.

This allows us to have full control, very easily, of the naming for both the CamelContext id in the Registry as well the JMX MBeans in the JMXMBeanRegistry.

From Camel 2.15 onwards you can configure the default management name pattern using a JVM system property, to configure this globally for the JVM. Notice that you can override this pattern by configure it explicit, as shown in the examples further below.
Set a JVM system property to use a default management name pattern that prefixes the name with cool.

```
System.setProperty(JmxSystemPropertyKeys.MANAGEMENT_NAME_PATTERN, "cool-#name#");
```

So if we want to explicit name both the CamelContext and to use fixed MBean names, that do not change (eg has no counters), then we can use the new managementNamePattern attribute:

```
<camelContext id="myCamel" managementNamePattern="#name#">
```

Then the MBean names will always be as follows:

```
org.apache.camel:context=localhost/myCamel,type=context,name=myCamel
```

In Java, you can configure the managementNamePattern as follows:

```
context.getManagementNameStrategy().setNamePattern("#name#");
```

You can also use a different name in the managementNamePattern than the id, so for example we can do:

```
<camelContext id="myCamel" managementNamePattern="coolCamel">
```

You may want to do this in OSGi environments in case you do not want the OSGi bundle id as part of the MBean names. As the OSGi bundle id can change if you restart the server, or uninstall and install the same application. You can then do as follows to not use the OSGi bundle id as part of the name:

```
<camelContext id="myCamel" managementNamePattern="#name#">
```

Note this requires that myCamel is unique in the entire JVM. If you install a 2nd Camel application that has the same CamelContext id and managementNamePattern then Camel will fail upon starting, and report a MBean already exists exception.

170.5.5. ManagementStrategy

Available as of Camel 2.1

Camel now provides a totally pluggable management strategy that allows you to be 100% in control of management. It is a rich interface with many methods for management. Not only for adding and removing managed objects from the MBeanServer, but also event notification is provided as well using the org.apache.camel.spi.EventNotifier API. What it does, for example, is make it easier to provide an adapter for other management products. In addition, it also allows you to provide more details and features that are provided out of the box at Apache.

170.5.6. Configuring level of granularity for performance statistics

Available as of Camel 2.1

You can now set a pre set level whether performance statistics is enabled or not when Camel start ups. The levels are

- **Extended** - As default but with additional statistics gathered during runtime such as fine grained level of usage of endpoints and more. This options requires Camel 2.16
- **All / Default** - Camel will enable statistics for both routes and processors (fine grained). From Camel 2.16 onwards the All option was renamed to Default.

- **RoutesOnly** - Camel will only enable statistics for routes (coarse grained)

- **Off** - Camel will not enable statistics for any.

From Camel 2.9 onwards the performance statistics also include average load statistics per CamelContext and Route MBeans. The statistics is average load based on the number of in-flight exchanges, on a per 1, 5, and 15 minute rate. This is similar to load statistics on Unix systems. Camel 2.11 onwards allows you to explicit disable load performance statistics by setting `loadStatisticsEnabled=false` on the `<jmxAgent>`. Note that it will be off if the statics level is configured to off as well. From Camel 2.13 onwards the load performance statistics is by default disabled. You can enable this by setting `loadStatisticsEnabled=true` on the `<jmxAgent>`.

At runtime you can always use the management console (such as JConsole) to change on a given route or processor whether its statistics are enabled or not.

**NOTE**

*What does statistics enabled mean?*

Statistics enabled means that Camel will do fine grained performance statistics for that particular MBean. The statistics you can see are many, such as: number of exchanges completed/failed, last/total/mina/max/mean processing time, first/last failed time, etc.

Using Java DSL you set this level by:

```java
// only enable routes when Camel starts
context.getManagementStrategy().setStatisticsLevel(ManagementStatisticsLevel.RoutesOnly);
```

And from Spring DSL you do:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" statisticsLevel="RoutesOnly"/>
</camelContext>
```

### 170.6. HIDING SENSITIVE INFORMATION

**Available as of Camel 2.12**

By default, Camel enlists MBeans in JMX such as endpoints configured using URIs. In this configuration, there may be sensitive information such as passwords.

This information can be hidden by enabling the `mask` option as shown below:

Using Java DSL you turn this on by:

```java
// only enable routes when Camel starts
context.getManagementStrategy().getManagementAgent().setMask(true);
```

And from Spring DSL you do:
This will mask URIs having options such as password and passphrase, and use `xxxxxx` as the replacement value.

### 170.6.1. Declaring which JMX attributes and operations to mask

On the `org.apache.camel.api.management.ManagedAttribute` and `org.apache.camel.api.management.ManagedOperation`, the attribute `mask` can be set to `true` to indicate that the result of this JMX attribute/operation should be masked (if enabled on JMX agent, see above).

For example, on the default managed endpoints from camel-core `org.apache.camel.api.management.mbean.ManagedEndpointMBean`, we have declared that the `EndpointUri` JMX attribute is masked:

```xml
@ManagedAttribute(description = "Endpoint URI", mask = true)
String getEndpointUri();
```

### 170.7. SEE ALSO

- Management Example
- Why is my processor not showing up in JConsole
CHAPTER 171. JOLT COMPONENT

Available as of Camel version 2.16

The jolt component allows you to process a JSON messages using a JOLT specification. This can be ideal when doing JSON to JSON transformation.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jolt</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

171.1. URI FORMAT

```
jolt:specName?[?options]
```

Where specName is the classpath-local URI of the specification to invoke; or the complete URL of the remote specification (eg: file://folder/myfile.json).

You can append query options to the URI in the following format, ?option=value&option=value&...

171.2. OPTIONS

The JOLT component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>transform</td>
<td>Explicitly sets the Transform to use. If not set a Transform specified by the transformDsl will be created</td>
<td></td>
<td>Transform</td>
</tr>
<tr>
<td>resolveProperty</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The JOLT endpoint is configured using URI syntax:

```
jolt:resourceUri
```

with the following path and query parameters:

171.2.1. Path Parameters (1 parameters):
### Resource URI

**Name**: resourceUri  
**Description**: Required Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.

**Type**: String

### Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentCache</td>
<td>Sets whether to use resource content cache or not</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>inputType</td>
<td>Specifies if the input is hydrated JSON or a JSON String.</td>
<td>Hydrated</td>
<td>JoltInputOutputType</td>
</tr>
<tr>
<td>outputType</td>
<td>Specifies if the output should be hydrated JSON or a JSON String.</td>
<td>Hydrated</td>
<td>JoltInputOutputType</td>
</tr>
<tr>
<td>transformDsl</td>
<td>Specifies the Transform DSL of the endpoint resource. If none is specified Chainr will be used.</td>
<td>Chainr</td>
<td>JoltTransformType</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### SAMPLES

For example you could use something like

```java
from("activemq:My.Queue").
to("jolt:com/acme/MyResponse.json");
```

And a file based resource:

```java
from("activemq:My.Queue").
to("jolt:file://myfolder/MyResponse.json?contentCache=true").
to("activemq:Another.Queue");
```

You can also specify what specification the component should use dynamically via a header, so for example:
from("direct:in").
setHeader("CamelJoltResourceUri").constant("path/to/my/spec.json").
to("jolt:dummy");

- Component
- Endpoint
- Getting Started
CHAPTER 172. JPA COMPONENT

Available as of Camel version 1.0

The jpa component enables you to store and retrieve Java objects from persistent storage using EJB 3’s Java Persistence Architecture (JPA), which is a standard interface layer that wraps Object/Relational Mapping (ORM) products such as OpenJPA, Hibernate, TopLink, and so on.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jpa</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

172.1. SENDING TO THE ENDPOINT

You can store a Java entity bean in a database by sending it to a JPA producer endpoint. The body of the In message is assumed to be an entity bean (that is, a POJO with an @Entity annotation on it) or a collection or array of entity beans.

If the body is a List of entities, make sure to use entityType=java.util.ArrayList as a configuration passed to the producer endpoint.

If the body does not contain one of the previous listed types, put a Message Translator in front of the endpoint to perform the necessary conversion first.

From Camel 2.19 onwards you can use query, namedQuery or nativeQuery for the producer as well. Also in the value of the parameters, you can use Simple expression which allows you to retrieve parameter values from Message body, header and etc. Those query can be used for retrieving a set of data with using SELECT JPQL/SQL statement as well as executing bulk update/delete with using UPDATE/DELETE JPQL/SQL statement. Please note that you need to specify useExecuteUpdate to true if you execute UPDATE/DELETE with namedQuery as camel don’t look into the named query unlike query and nativeQuery.

172.2. CONSUMING FROM THE ENDPOINT

Consuming messages from a JPA consumer endpoint removes (or updates) entity beans in the database. This allows you to use a database table as a logical queue: consumers take messages from the queue and then delete/update them to logically remove them from the queue.

If you do not wish to delete the entity bean when it has been processed (and when routing is done), you can specify consumeDelete=false on the URI. This will result in the entity being processed each poll.

If you would rather perform some update on the entity to mark it as processed (such as to exclude it from a future query) then you can annotate a method with @Consumed which will be invoked on your entity bean when it has been processed (and when routing is done).

From Camel 2.13 onwards you can use @PreConsumed which will be invoked on your entity bean before it has been processed (before routing).

If you are consuming a lot (100K+) of rows and experience OutOfMemory problems you should set the maximumResults to sensible value.
172.3. URI FORMAT

For sending to the endpoint, the `entityClassName` is optional. If specified, it helps the Type Converter to ensure the body is of the correct type.

For consuming, the `entityClassName` is mandatory.

You can append query options to the URI in the following format, `?option=value&option=value&…`

172.4. OPTIONS

The JPA component supports 5 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>entityManagerFactory</code></td>
<td>To use the EntityManagerFactory. This is strongly recommended to configure.</td>
<td></td>
<td>EntityManagerFactory</td>
</tr>
<tr>
<td><code>transactionManager</code></td>
<td>To use the PlatformTransactionManager for managing transactions.</td>
<td></td>
<td>PlatformTransactionManager</td>
</tr>
<tr>
<td><code>joinTransaction</code></td>
<td>The camel-jpa component will join transaction by default. You can use this option to turn this off, for example if you use LOCAL_RESOURCE and join transaction doesn’t work with your JPA provider. This option can also be set globally on the JpaComponent, instead of having to set it on all endpoints.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>sharedEntityManager</code></td>
<td>Whether to use Spring’s SharedEntityManager for the consumer/producer. Note in most cases joinTransaction should be set to false as this is not an EXTENDED EntityManager.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>resolvePropertyPlaceholders</code></td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The JPA endpoint is configured using URI syntax:

```
jpa:entityType
```

with the following path and query parameters:

172.4.1. Path Parameters (1 parameters):
### 172.4.2. Query Parameters (42 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityType</td>
<td>Required The JPA annotated class to use as entity.</td>
<td></td>
<td>Class&lt;?&gt;</td>
</tr>
<tr>
<td>joinTransaction</td>
<td>The camel-jpa component will join transaction by default. You can use this option to turn this off, for example if you use LOCAL_RESOURCE and join transaction doesn’t work with your JPA provider. This option can also be set globally on the JpaComponent, instead of having to set it on all endpoints.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>maximumResults</td>
<td>Set the maximum number of results to retrieve on the Query.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>namedQuery</td>
<td>To use a named query.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>nativeQuery</td>
<td>To use a custom native query. You may want to use the option resultClass also when using native queries.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>parameters</td>
<td>This key/value mapping is used for building the query parameters. It is expected to be of the generic type java.util.Map where the keys are the named parameters of a given JPA query and the values are their corresponding effective values you want to select for. When it’s used for producer, Simple expression can be used as a parameter value. It allows you to retrieve parameter values from the message body, header and etc.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>persistenceUnit</td>
<td>Required The JPA persistence unit used by default.</td>
<td>camel</td>
<td>String</td>
</tr>
<tr>
<td>query</td>
<td>To use a custom query.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>resultClass</td>
<td>Defines the type of the returned payload (we will call entityManager.createNativeQuery(nativeQuery, resultClass) instead of entityManager.createNativeQuery(nativeQuery)). Without this option, we will return an object array. Only has an affect when using in conjunction with native query when consuming data.</td>
<td></td>
<td>Class&lt;?&gt;</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>sharedEntityManager</td>
<td>Whether to use Spring’s SharedEntityManager for the consumer/producer. Note in most cases joinTransaction should be set to false as this is not an EXTENDED EntityManager.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>consumeDelete</td>
<td>If true, the entity is deleted after it is consumed; if false, the entity is not deleted.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>consumeLockEntity</td>
<td>Specifies whether or not to set an exclusive lock on each entity bean while processing the results from polling.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>deleteHandler</td>
<td>To use a custom DeleteHandler to delete the row after the consumer is done processing the exchange</td>
<td>Object&gt;</td>
<td></td>
</tr>
<tr>
<td>lockModeType</td>
<td>To configure the lock mode on the consumer.</td>
<td>PESSIMISTIC_WRITE</td>
<td>LockModeType</td>
</tr>
<tr>
<td>maxMessagesPerPoll</td>
<td>An integer value to define the maximum number of messages to gather per poll. By default, no maximum is set. Can be used to avoid polling many thousands of messages when starting up the server. Set a value of 0 or negative to disable.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>preDeleteHandler</td>
<td>To use a custom Pre-DeleteHandler to delete the row after the consumer has read the entity.</td>
<td>Object&gt;</td>
<td></td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>skipLockedEntity</td>
<td>To configure whether to use NOWAIT on lock and silently skip the entity.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------</td>
</tr>
<tr>
<td>transacted (consumer)</td>
<td>Whether to run the consumer in transacted mode, by which all messages will either commit or rollback, when the entire batch has been processed. The default behavior (false) is to commit all the previously successfully processed messages, and only rollback the last failed message.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>pollStrategy (consumer)</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td>flushOnSend (producer)</td>
<td>Flashes the EntityManager after the entity bean has been persisted.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>remove (producer)</td>
<td>Indicates to use entityManager.remove(entity).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>useExecuteUpdate (producer)</td>
<td>To configure whether to use executeUpdate() when producer executes a query. When you use INSERT, UPDATE or DELETE statement as a named query, you need to specify this option to ‘true’.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>usePassedInEntityManager (producer)</td>
<td>If set to true, then Camel will use the EntityManager from the header JpaConstants.ENTITYMANAGER instead of the configured entity manager on the component/endpoint. This allows end users to control which entity manager will be in use.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>usePersist (producer)</td>
<td>Indicates to use entityManager.persist(entity) instead of entityManager.merge(entity). Note: entityManager.persist(entity) doesn’t work for detached entities (where the EntityManager has to execute an UPDATE instead of an INSERT query)!</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------</td>
<td>---------------</td>
</tr>
<tr>
<td>entityManagerProperties (advanced)</td>
<td>Additional properties for the entity manager to use.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold (scheduler)</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>backoffIdleThreshold (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>backoffMultiplier (scheduler)</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>delay (scheduler)</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy (scheduler)</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay (scheduler)</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel (scheduler)</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>scheduledExecutorService (scheduler)</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td></td>
<td>ScheduledExecutorService</td>
</tr>
<tr>
<td>scheduler (scheduler)</td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollConsumerScheduler</td>
</tr>
</tbody>
</table>
### 172.5. MESSAGE HEADERS

Camel adds the following message headers to the exchange:

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel JpaTemplate</td>
<td>JpaTemplate</td>
<td>Not supported anymore since Camel 2.12: The JpaTemplate object that is used to access the entity bean. You need this object in some situations, for instance in a type converter or when you are doing some custom processing. See CAMEL-5932 for the reason why the support for this header has been dropped.</td>
</tr>
<tr>
<td>Camel EntityManager</td>
<td>EntityManager</td>
<td>Camel 2.12: JPA consumer / Camel 2.12.2: JPA producer: The JPA EntityManager object being used by JpaConsumer or JpaProducer.</td>
</tr>
</tbody>
</table>

### 172.6. CONFIGURING ENTITYMANAGERFACTORY

It's strongly advised to configure the JPA component to use a specific EntityManagerFactory instance. If failed to do so each JpaEndpoint will auto create their own instance of EntityManagerFactory which most often is not what you want.

For example, you can instantiate a JPA component that references the myEMFactory entity manager factory, as follows:

```xml
<bean id="jpa" class="org.apache.camel.component.jpa.JpaComponent">
  <property name="entityManagerFactory" ref="myEMFactory"/>
</bean>
```

In Camel 2.3 the JpaComponent will auto lookup the EntityManagerFactory from the Registry which means you do not need to configure this on the JpaComponent as shown above. You only need to do so if there is ambiguity, in which case Camel will log a WARN.
172.7. CONFIGURING TRANSACTIONMANAGER

Since Camel 2.3 the JpaComponent will auto lookup the TransactionManager from the Registry. If Camel won't find any TransactionManager instance registered, it will also look up for the TransactionTemplate and try to extract TransactionManager from it.

If none TransactionTemplate is available in the registry, JpaEndpoint will auto create their own instance of TransactionManager which most often is not what you want.

If more than single instance of the TransactionManager is found, Camel will log a WARN. In such cases you might want to instantiate and explicitly configure a JPA component that references the myTransactionManager transaction manager, as follows:

```xml
<bean id="jpa" class="org.apache.camel.component.jpa.JpaComponent">
    <property name="entityManagerFactory" ref="myEMFactory"/>
    <property name="transactionManager" ref="myTransactionManager"/>
</bean>
```

172.8. USING A CONSUMER WITH A NAMED QUERY

For consuming only selected entities, you can use the consumer.namedQuery URI query option. First, you have to define the named query in the JPA Entity class:

```java
@Entity
@NamedQuery(name = "step1", query = "select x from MultiSteps x where x.step = 1")
public class MultiSteps {
    ...
}
```

After that you can define a consumer uri like this one:

```java
from("jpa://org.apache.camel.examples.MultiSteps?consumer.namedQuery=step1")
    .to("bean:myBusinessLogic");
```

172.9. USING A CONSUMER WITH A QUERY

For consuming only selected entities, you can use the consumer.query URI query option. You only have to define the query option:

```java
from("jpa://org.apache.camel.examples.MultiSteps?consumer.query=select o from org.apache.camel.examples.MultiSteps o where o.step = 1")
    .to("bean:myBusinessLogic");
```

172.10. USING A CONSUMER WITH A NATIVE QUERY

For consuming only selected entities, you can use the consumer.nativeQuery URI query option. You only have to define the native query option:

```java
from("jpa://org.apache.camel.examples.MultiSteps?consumer.nativeQuery=select * from MultiSteps where step = 1")
    .to("bean:myBusinessLogic");
```
If you use the native query option, you will receive an object array in the message body.

172.11. USING A PRODUCER WITH A NAMED QUERY

For retrieving selected entities or execute bulk update/delete, you can use the namedQuery URI query option. First, you have to define the named query in the JPA Entity class:

```java
@Entity
@NamedQuery(name = "step1", query = "select x from MultiSteps x where x.step = 1")
public class MultiSteps {
    ...
}
```

After that you can define a producer uri like this one:

```camel
from("direct:namedQuery") .to("jpa://org.apache.camel.examples.MultiSteps?namedQuery=step1");
```

Note that you need to specify `useExecuteUpdate` option to `true` to execute UPDATE/DELETE statement as a named query.

172.12. USING A PRODUCER WITH A QUERY

For retrieving selected entities or execute bulk update/delete, you can use the query URI query option. You only have to define the query option:

```camel
from("direct:query") .to("jpa://org.apache.camel.examples.MultiSteps?query=select o from org.apache.camel.examples.MultiSteps o where o.step = 1");
```

172.13. USING A PRODUCER WITH A NATIVE QUERY

For retrieving selected entities or execute bulk update/delete, you can use the nativeQuery URI query option. You only have to define the native query option:

```camel
from("direct:nativeQuery") .to("jpa://org.apache.camel.examples.MultiSteps?resultClass=org.apache.camel.examples.MultiSteps&nativeQuery=select * from MultiSteps where step = 1");
```

If you use the native query option without specifying `resultClass`, you will receive an object array in the message body.

172.14. EXAMPLE

See Tracer Example for an example using JPA to store traced messages into a database.

172.15. USING THE JPA-BASED IDEMPOTENT REPOSITORY

The Idempotent Consumer from the EIP patterns is used to filter out duplicate messages. A JPA-based idempotent repository is provided.
To use the JPA based idempotent repository.

Procedure

1. Set up a `persistence-unit` in the persistence.xml file:

2. Set up a `org.springframework.orm.jpa.JpaTemplate` which is used by the `org.apache.camel.processor.idempotent.jpa.JpaMessageIdRepository`:

4. Configure the idempotent repository: `org.apache.camel.processor.idempotent.jpa.JpaMessageIdRepository`:

5. Create the JPA idempotent repository in the Spring XML file:

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
<route id="JpaMessageIdRepositoryTest">
  <from uri="direct:start" />
  <idempotentConsumer messageIdRepositoryRef="jpaStore">
    <header>messageId</header>
    <to uri="mock:result" />
  </idempotentConsumer>
</route>
</camelContext>
```

When running this Camel component tests inside your IDE

If you run the tests of this component directly inside your IDE, and not through Maven, then you could see exceptions like these:

```
org.springframework.transaction.CannotCreateTransactionException: Could not open JPA EntityManager for transaction; nested exception is
<openjpa-2.2.1-r422266:1396819 nonfatal user error>
org.apache.openjpa.persistence.ArgumentException: This configuration disallows runtime optimization,
but the following listed types were not enhanced at build time or at class load time with a javaagent: "org.apache.camel.examples.SendEmail".
    at org.springframework.orm.jpa.JpaTransactionManager.doBegin(JpaTransactionManager.java:427)
    at org.springframework.transaction.support.AbstractPlatformTransactionManager.getTransaction(AbstractPlatformTransactionManager.java:371)
    at org.springframework.transaction.support.TransactionTemplate.execute(TransactionTemplate.java:127)
    at org.apache.camel.processor.jpa.JpaRouteTest.cleanupRepository(JpaRouteTest.java:96)
    at org.apache.camel.processor.jpa.JpaRouteTest.createCamelContext(JpaRouteTest.java:67)
    at org.apache.camel.test.junit4.CamelTestSupport.doSetUp(CamelTestSupport.java:238)
```

The problem here is that the source has been compiled or recompiled through your IDE and not through Maven, which would enhance the byte-code at build time. To overcome this you need to enable dynamic byte-code enhancement of OpenJPA. For example, assuming the current OpenJPA version
being used in Camel is 2.2.1, to run the tests inside your IDE you would need to pass the following argument to the JVM:

```
-javaagent:<path_to_your_local_m2_cache>/org/apache/openjpa/openjpa/2.2.1/openjpa-2.2.1.jar
```

CHAPTER 173. JSON FASTJSON DATAFORMAT

Available as of Camel version 2.20

Fastjson is a Data Format which uses the Fastjson Library

```
from("activemq:My.Queue"),
marshal().json(JsonLibrary.Fastjson).
to("mqseries:Another.Queue");
```

173.1. FASTJSON OPTIONS

The JSon Fastjson dataformat supports 19 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectMapper</td>
<td>String</td>
<td></td>
<td>Lookup and use the existing ObjectMapper with the given id when using Jackson.</td>
</tr>
<tr>
<td>useDefaultObjectMapper</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to lookup and use default Jackson ObjectMapper from the registry.</td>
</tr>
<tr>
<td>prettyPrint</td>
<td>false</td>
<td>Boolean</td>
<td>To enable pretty printing output nicely formatted. Is by default false.</td>
</tr>
<tr>
<td>library</td>
<td>XStream</td>
<td>JsonLibrary</td>
<td>Which json library to use.</td>
</tr>
<tr>
<td>unmarshalTypeName</td>
<td>String</td>
<td></td>
<td>Class name of the java type to use when unarmshalling</td>
</tr>
<tr>
<td>jsonView</td>
<td>Class&lt;&gt;</td>
<td></td>
<td>When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations</td>
</tr>
<tr>
<td>include</td>
<td>String</td>
<td></td>
<td>If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NOT_NULL</td>
</tr>
<tr>
<td>allowJmsType</td>
<td>false</td>
<td>Boolean</td>
<td>Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.</td>
</tr>
<tr>
<td>collectionTypeName</td>
<td>String</td>
<td></td>
<td>Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.</td>
</tr>
<tr>
<td>useList</td>
<td>false</td>
<td>Boolean</td>
<td>To unarmshal to a List of Map or a List of Pojo.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enableJaxbAnnotationModule</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.</td>
</tr>
<tr>
<td>moduleClassNames</td>
<td></td>
<td>String</td>
<td>To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.</td>
</tr>
<tr>
<td>moduleRefs</td>
<td></td>
<td>String</td>
<td>To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.</td>
</tr>
<tr>
<td>enableFeatures</td>
<td></td>
<td>String</td>
<td>Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature. Multiple features can be separated by comma.</td>
</tr>
<tr>
<td>disableFeatures</td>
<td></td>
<td>String</td>
<td>Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature. Multiple features can be separated by comma.</td>
</tr>
<tr>
<td>permissions</td>
<td></td>
<td>String</td>
<td>Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo,-com.foo.bar.MySecretBean. The following default permission is always included: - ,java.lang.,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.</td>
</tr>
<tr>
<td>allowUnmarshalType</td>
<td>false</td>
<td>Boolean</td>
<td>If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.</td>
</tr>
<tr>
<td>timezone</td>
<td></td>
<td>String</td>
<td>If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.</td>
</tr>
</tbody>
</table>
Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

### 173.2. DEPENDENCIES

To use Fastjson in your camel routes you need to add the dependency on `camel-fastjson` which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-fastjson</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 174. JSON GSON DATAFORMAT

Available as of Camel version 2.10

Gson is a Data Format which uses the Gson Library

```java
from("activemq:My.Queue").marshal().json(JsonLibrary.Gson).to("mqseries:Another.Queue");
```

174.1. GSON OPTIONS

The JSon GSon dataformat supports 19 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectMapper</td>
<td>String</td>
<td>String</td>
<td>Lookup and use the existing ObjectMapper with the given id when using Jackson.</td>
</tr>
<tr>
<td>useDefaultObjectMapper</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to lookup and use default Jackson ObjectMapper from the registry.</td>
</tr>
<tr>
<td>prettyPrint</td>
<td>false</td>
<td>Boolean</td>
<td>To enable pretty printing output nicely formatted. Is by default false.</td>
</tr>
<tr>
<td>library</td>
<td>XStream</td>
<td>JsonLibrary</td>
<td>Which json library to use.</td>
</tr>
<tr>
<td>unmarshalTypeName</td>
<td>String</td>
<td>String</td>
<td>Class name of the java type to use when unmarshalling</td>
</tr>
<tr>
<td>jsonView</td>
<td>Class&lt;?&gt;</td>
<td>Class</td>
<td>When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations</td>
</tr>
<tr>
<td>include</td>
<td>String</td>
<td>String</td>
<td>If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NOT_NULL</td>
</tr>
<tr>
<td>allowJmsType</td>
<td>false</td>
<td>Boolean</td>
<td>Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.</td>
</tr>
<tr>
<td>collectionTypeName</td>
<td>String</td>
<td>String</td>
<td>Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.</td>
</tr>
<tr>
<td>useList</td>
<td>false</td>
<td>Boolean</td>
<td>To unmarshal to a List of Map or a List of Pojo.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enableJaxbAnnotationModule</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.</td>
</tr>
<tr>
<td>moduleClassNames</td>
<td>String</td>
<td></td>
<td>To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.</td>
</tr>
<tr>
<td>moduleRefs</td>
<td>String</td>
<td></td>
<td>To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.</td>
</tr>
<tr>
<td>enableFeatures</td>
<td>String</td>
<td></td>
<td>Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma</td>
</tr>
<tr>
<td>disableFeatures</td>
<td>String</td>
<td></td>
<td>Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma</td>
</tr>
<tr>
<td>permissions</td>
<td>String</td>
<td></td>
<td>Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo,-com.foo.bar.MySecretBean. The following default permission is always included: -java.lang.,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.</td>
</tr>
<tr>
<td>allowUnmarshalType</td>
<td>false</td>
<td>Boolean</td>
<td>If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.</td>
</tr>
<tr>
<td>timezone</td>
<td>String</td>
<td></td>
<td>If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.</td>
</tr>
</tbody>
</table>
## 174.2. DEPENDENCIES

To use Gson in your camel routes you need to add the dependency on **camel-gson** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-gson</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 175. JSON JACKSON DATAFORMAT

Available as of Camel version 2.0

Jackson is a Data Format which uses the Jackson Library

```java
from("activemq:My.Queue").marshal().json(JsonLibrary.jackson).to("mqseries:Another.Queue");
```

### 175.1. JACKSON OPTIONS

The JSon Jackson dataformat supports 19 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectMapper</td>
<td>String</td>
<td></td>
<td>Lookup and use the existing ObjectMapper with the given id when using Jackson.</td>
</tr>
<tr>
<td>useDefaultObjectMapper</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to lookup and use default Jackson ObjectMapper from the registry.</td>
</tr>
<tr>
<td>prettyPrint</td>
<td>false</td>
<td>Boolean</td>
<td>To enable pretty printing output nicely formatted. Is by default false.</td>
</tr>
<tr>
<td>library</td>
<td>XStream</td>
<td>JsonLibrary</td>
<td>Which json library to use.</td>
</tr>
<tr>
<td>unmarshalTypeName</td>
<td>String</td>
<td></td>
<td>Class name of the java type to use when unmarshalling</td>
</tr>
<tr>
<td>jsonView</td>
<td>Class&lt;?&gt;</td>
<td></td>
<td>When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations</td>
</tr>
<tr>
<td>include</td>
<td>String</td>
<td></td>
<td>If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NOT_NULL</td>
</tr>
<tr>
<td>allowJmsType</td>
<td>false</td>
<td>Boolean</td>
<td>Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.</td>
</tr>
<tr>
<td>collectionTypeName</td>
<td>String</td>
<td></td>
<td>Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.</td>
</tr>
<tr>
<td>useList</td>
<td>false</td>
<td>Boolean</td>
<td>To unmarshal to a List of Map or a List of Pojo.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enableJAXBAnnotationModule</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.</td>
</tr>
<tr>
<td>moduleClassNames</td>
<td>String</td>
<td></td>
<td>To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.</td>
</tr>
<tr>
<td>moduleRefs</td>
<td>String</td>
<td></td>
<td>To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.</td>
</tr>
<tr>
<td>enableFeatures</td>
<td>String</td>
<td></td>
<td>Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma</td>
</tr>
<tr>
<td>disableFeatures</td>
<td>String</td>
<td></td>
<td>Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma</td>
</tr>
<tr>
<td>permissions</td>
<td>String</td>
<td></td>
<td>Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo,-com.foo.bar.MySecretBean. The following default permission is always included: - ,java.lang.,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.</td>
</tr>
<tr>
<td>allowUnmarshalType</td>
<td>false</td>
<td>Boolean</td>
<td>If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.</td>
</tr>
<tr>
<td>timezone</td>
<td>String</td>
<td></td>
<td>If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.</td>
</tr>
</tbody>
</table>
Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

### 175.2. USING CUSTOM OBJECTMAPPER

You can configure `JacksonDataFormat` to use a custom `ObjectMapper` in case you need more control of the mapping configuration.

If you setup a single `ObjectMapper` in the registry, then Camel will automatic lookup and use this `ObjectMapper`. For example if you use Spring Boot, then Spring Boot can provide a default `ObjectMapper` for you if you have Spring MVC enabled. And this would allow Camel to detect that there is one bean of `ObjectMapper` class type in the Spring Boot bean registry and then use it. When this happens you should set a `INFO` logging from Camel.

### 175.3. DEPENDENCIES

To use Jackson in your camel routes you need to add the dependency on `camel-jackson` which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jackson</artifactId>
  <version>x.x.x</version>
</dependency>
</dependency>
```
CHAPTER 176. JSON JOHNZON DATAFORMAT

Available as of Camel version 2.18

Johnzon is a Data Format which uses the Johnzon Library

```java
to("mqseries:Another.Queue");
```

176.1. JOHNZON OPTIONS

The JSon Johnzon dataformat supports 19 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectMapper</td>
<td>String</td>
<td>String</td>
<td>Lookup and use the existing ObjectMapper with the given id when using Jackson.</td>
</tr>
<tr>
<td>useDefaultObjectMapper</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to lookup and use default Jackson ObjectMapper from the registry.</td>
</tr>
<tr>
<td>prettyPrint</td>
<td>false</td>
<td>Boolean</td>
<td>To enable pretty printing output nicely formatted. Is by default false.</td>
</tr>
<tr>
<td>library</td>
<td>XStream</td>
<td>JsonLibrary</td>
<td>Which json library to use.</td>
</tr>
<tr>
<td>unmarshalTypeName</td>
<td>String</td>
<td>String</td>
<td>Class name of the java type to use when unmarshalling</td>
</tr>
<tr>
<td>jsonView</td>
<td>Class&lt;? &gt;</td>
<td>Class ?&gt;</td>
<td>When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations</td>
</tr>
<tr>
<td>include</td>
<td>String</td>
<td>String</td>
<td>If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NOT_NULL</td>
</tr>
<tr>
<td>allowJmsType</td>
<td>false</td>
<td>Boolean</td>
<td>Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.</td>
</tr>
<tr>
<td>collectionTypeName</td>
<td>String</td>
<td>String</td>
<td>Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.</td>
</tr>
<tr>
<td>useList</td>
<td>false</td>
<td>Boolean</td>
<td>To unmarshal to a List of Map or a List of Pojo.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enableJaxbAnnotationModule</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.</td>
</tr>
<tr>
<td>moduleClassNames</td>
<td>String</td>
<td></td>
<td>To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.</td>
</tr>
<tr>
<td>moduleRefs</td>
<td>String</td>
<td></td>
<td>To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.</td>
</tr>
<tr>
<td>enableFeatures</td>
<td>String</td>
<td></td>
<td>Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma</td>
</tr>
<tr>
<td>disableFeatures</td>
<td>String</td>
<td></td>
<td>Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma</td>
</tr>
<tr>
<td>permissions</td>
<td>String</td>
<td></td>
<td>Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo,-com.foo.bar.MySecretBean. The following default permission is always included: -org.apache.camel.xstream.permissions.</td>
</tr>
<tr>
<td>allowUnmarshalType</td>
<td>false</td>
<td>Boolean</td>
<td>If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.</td>
</tr>
<tr>
<td>timezone</td>
<td>String</td>
<td></td>
<td>If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.</td>
</tr>
</tbody>
</table>
### 176.2. DEPENDENCIES

To use Johnzon in your camel routes you need to add the dependency on `camel-johnzon` which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-johnzon</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 177. JSON SCHEMA VALIDATOR COMPONENT

Available as of Camel version 2.20

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-json-validator</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

177.1. URI FORMAT

```
json-validator:resourceUri[?options]
```

Where `resourceUri` is some URL to a local resource on the classpath or a full URL to a remote resource or resource on the file system which contains the JSON Schema to validate against.

177.2. URI OPTIONS

The JSON Schema Validator component has no options.

The JSON Schema Validator endpoint is configured using URI syntax:

```
json-validator:resourceUri
```

with the following path and query parameters:

177.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td><strong>Required</strong> Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

177.2.2. Query Parameters (7 parameters):
### 177.3. EXAMPLE

Assumed we have the following JSON Schema

`myschema.json`

```json
{
    "$schema": "http://json-schema.org/draft-04/schema#",
    "definitions": {},
    "id": "my-schema",
    "properties": {
        "id": {
            "default": 1,
            "description": "An explanation about the purpose of this instance.",
            "id": "/properties/id",
            "title": "The id schema",
            "type": "integer"
        },
        "name": {
            "default": "A green door",
            "description": "An explanation about the purpose of this instance.",
            "id": "/properties/name",
            "title": "The name schema",
```
we can validate incoming JSON with the following Camel route, where `myschema.json` is loaded from the classpath.

```java
from("direct:start")
  .to("json-validator:myschema.json")
  .to("mock:end")
```
CHAPTER 178. JSON XSTREAM DATAFORMAT

Available as of Camel version 2.0

XStream is a Data Format which uses the XStream library to marshal and unmarshal Java objects to and from XML.

To use XStream in your camel routes you need to add the a dependency on camel-xstream which implements this data format.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xstream</artifactId>
  <version>x.x.x</version>
</dependency>
<!-- use the same version as your Camel core version -->
```

178.1. OPTIONS

The JSon XStream dataformat supports 19 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectMapper</td>
<td>String</td>
<td></td>
<td>Lookup and use the existing ObjectMapper with the given id when using Jackson.</td>
</tr>
<tr>
<td>useDefaultObjectMapper</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to lookup and use default Jackson ObjectMapper from the registry.</td>
</tr>
<tr>
<td>prettyPrint</td>
<td>false</td>
<td>Boolean</td>
<td>To enable pretty printing output nicely formatted. Is by default false.</td>
</tr>
<tr>
<td>library</td>
<td>XStream</td>
<td>JsonLibrary</td>
<td>Which json library to use.</td>
</tr>
<tr>
<td>unmarshalTypeName</td>
<td>String</td>
<td></td>
<td>Class name of the java type to use when unarmshalling</td>
</tr>
<tr>
<td>jsonView</td>
<td>Class</td>
<td>&lt;?&gt;</td>
<td>When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations</td>
</tr>
<tr>
<td>include</td>
<td>String</td>
<td></td>
<td>If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NOT_NULL</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>allowJmsType</td>
<td>false</td>
<td>Boolean</td>
<td>Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.</td>
</tr>
<tr>
<td>collectionTypeName</td>
<td>String</td>
<td></td>
<td>Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.</td>
</tr>
<tr>
<td>useList</td>
<td>false</td>
<td>Boolean</td>
<td>To unmarshal to a List of Map or a List of Pojo.</td>
</tr>
<tr>
<td>enableJaxbAnnotationModule</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.</td>
</tr>
<tr>
<td>moduleClassNames</td>
<td>String</td>
<td></td>
<td>To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.</td>
</tr>
<tr>
<td>moduleRefs</td>
<td>String</td>
<td></td>
<td>To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.</td>
</tr>
<tr>
<td>enableFeatures</td>
<td>String</td>
<td></td>
<td>Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma</td>
</tr>
<tr>
<td>disableFeatures</td>
<td>String</td>
<td></td>
<td>Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma</td>
</tr>
</tbody>
</table>
## 178.2. USING THE JAVA DSL

If you would like to configure the XStream instance used by the Camel for the message transformation, you can simply pass a reference to that instance on the DSL level.

```java
XStream xStream = new XStream();
xStream.aliasField("money", PurchaseOrder.class, "cash");
// new Added setModel option since Camel 2.14
xStream.setModel("NO_REFERENCES");
...

from("direct:marshal").marshal(new XStreamDataFormat(xStream)).to("mock:marshaled");
```
178.3. XMLINPUTFACTORY AND XMLOUTPUTFACTORY

The XStream library uses the `javax.xml.stream.XMLInputFactory` and `javax.xml.stream.XMLOutputFactory`, you can control which implementation of this factory should be used.

The Factory is discovered using this algorithm: 1. Use the `javax.xml.stream.XMLInputFactory` , `javax.xml.stream.XMLOutputFactory` system property. 2. Use the `lib/xml.stream.properties` file in the `JRE_HOME` directory. 3. Use the Services API, if available, to determine the classname by looking in the `META-INF/services/javax.xml.stream.XMLInputFactory`, `META-INF/services/javax.xml.stream.XMLOutputFactory` files in jars available to the JRE. 4. Use the platform default XMLInputFactory,XMLOutputFactory instance.

178.4. HOW TO SET THE XML ENCODING IN XSTREAM DATAFORMAT?

From Camel 2.2.0, you can set the encoding of XML in Xstream DataFormat by setting the Exchange’s property with the key `Exchange.CHARSET_NAME`, or setting the encoding property on Xstream from DSL or Spring config.

```java
from("activemq:My.Queue").marshal().xstream("UTF-8").to("mqseries:Another.Queue");
```

178.5. SETTING THE TYPE PERMISSIONS OF XSTREAM DATAFORMAT

In Camel, one can always use its own processing step in the route to filter and block certain XML documents to be routed to the XStream’s unmarshall step. From Camel 2.16.1, 2.15.5, you can set XStream’s type permissions to automatically allow or deny the instantiation of certain types.

The default type permissions setting used by Camel denies all types except for those from java.lang and java.util packages. This setting can be changed by setting System property `org.apache.camel.xstream.permissions`. Its value is a string of comma-separated permission terms, each representing a type being allowed or denied, depending on whether the term is prefixed with ’’ (note ’’ may be omitted) or with ’-’, respectively.

Each term may contain a wildcard character ’’. For example, value ‘-java.lang,java.util.’ indicates denying all types except for java.lang.* and java.util.* classes. Setting this value to an empty string ‘’ reverts to the default XStream’s type permissions handling which denies certain blacklisted classes and allow others.

The type permissions setting can be extended at an individual XStream DataFormat instance by setting its type permissions property.

```xml
<dataFormats>
  <xstream id="xstream-default" permissions="org.apache.camel.samples.xstream.*"/>
...</data Formats>
```
CHAPTER 179. JSONPATH LANGUAGE

Available as of Camel version 2.13

Camel supports JSONPath to allow using Expression or Predicate on json messages.

from("queue:books.new")
.choice()
.when().jsonpath("$.store.book[?(@.price < 10)]")
.to("jms:queue:book.cheap")
.when().jsonpath("$.store.book[?(@.price < 30)]")
.to("jms:queue:book.average")
.otherwise()
.to("jms:queue:book.expensive")

179.1. JSONPATH OPTIONS

The JsonPath language supports 7 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resultType</td>
<td>String</td>
<td></td>
<td>Sets the class name of the result type (type from output)</td>
</tr>
<tr>
<td>suppressExceptions</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to suppress exceptions such as PathNotFoundException.</td>
</tr>
<tr>
<td>allowSimple</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to allow inlined simple exceptions in the JsonPath expression</td>
</tr>
<tr>
<td>allowEasyPredicate</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to allow using the easy predicate parser to pre-parse predicates.</td>
</tr>
<tr>
<td>writeAsString</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to write the output of each row/element as a JSON String value instead of a Map/POJO value.</td>
</tr>
<tr>
<td>headerName</td>
<td>String</td>
<td></td>
<td>Name of header to use as input, instead of the message body</td>
</tr>
<tr>
<td>trim</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to trim the value to remove leading and trailing whitespaces and line breaks</td>
</tr>
</tbody>
</table>

179.2. USING XML CONFIGURATION

If you prefer to configure your routes in your Spring XML file then you can use JSONPath expressions as follows

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <choice>
```
179.3. SYNTAX

See the JSonPath project page for further examples.

179.4. EASY SYNTAX

Available as of Camel 2.19

When you just want to define a basic predicate using jsonpath syntax it can be a bit hard to remember the syntax. So for example to find out all the cheap books you have to do

$.store.book[?(@.price < 20)]

However what if you could just write it as

store.book.price < 20

And you can omit the path if you just want to look at nodes with a price key

price < 20

To support this there is a EasyPredicateParser which kicks-in if you have define the predicate using a basic style. That means the predicate must not start with the $ sign, and only include one operator.

The easy syntax is:

left OP right

You can use Camel simple language in the right operator, eg

store.book.price < ${header.limit}

179.5. SUPPORTED MESSAGE BODY TYPES

Camel JSonPath supports message body using the following types:
<table>
<thead>
<tr>
<th>Type</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>File</td>
<td>Reading from files</td>
</tr>
<tr>
<td>String</td>
<td>Plain strings</td>
</tr>
<tr>
<td>Map</td>
<td>Message bodies as <code>java.util.Map</code> types</td>
</tr>
<tr>
<td>List</td>
<td>Message bodies as <code>java.util.List</code> types</td>
</tr>
<tr>
<td>POJO</td>
<td><strong>Optional</strong> If Jackson is on the classpath, then camel-jsonpath is able to use Jackson to read the message body as POJO and convert to <code>java.util.Map</code> which is supported by JSonPath. For example you can add <code>camel-jackson</code> as dependency to include Jackson.</td>
</tr>
<tr>
<td>InputStream</td>
<td>If none of the above types matches, then Camel will attempt to read the message body as an <code>java.io.InputStream</code>.</td>
</tr>
</tbody>
</table>

If a message body is of unsupported type then an exception is thrown by default, however you can configure JSonPath to suppress exceptions (see below)

## 179.6. SUPPRESS EXCEPTIONS

Available as of Camel 2.16

By default jsonpath will throw an exception if the json payload does not have a valid path accordingly to the configured jsonpath expression. In some use-cases you may want to ignore this in case the json payload contains optional data. Therefore you can set the option suppressExceptions to true to ignore this as shown:

```java
from("direct:start")
    .choice()
        // use true to suppress exceptions
        .when().jsonpath("person.middlename", true)
            .to("mock:middle")
        .otherwise()
            .to("mock:other");
```

And in XML DSL:

```xml
<route>
    <from uri="direct:start"/>
    <choice>
        <when>
            <jsonpath suppressExceptions="true">person.middlename</jsonpath>
            <to uri="mock:middle"/>
        </when>
        <otherwise>
            <to uri="mock:other"/>
        </otherwise>
    </choice>
</route>
```
This option is also available on the @JsonPath annotation.

179.7. INLINE SIMPLE EXCEPTIONS

Available as of Camel 2.18

It's now possible to inline Simple language expressions in the JsonPath expression using the simple syntax ${xxx}. An example is shown below:

```xml
<route>
  <from uri="direct:start"/>
  <choice>
    <when>
      <jsonpath>$_weapon[?(@.price < $[header.cheap])]</jsonpath>
      <to uri="mock:cheap"/>
    </when>
    <when>
      <jsonpath>$_weapon[?(@.price < $[header.average])]</jsonpath>
      <to uri="mock:average"/>
    </when>
    <otherwise>
      <to uri="mock:expensive"/>
    </otherwise>
  </choice>
</route>

And in XML DSL:

```xml
<route>
  <from uri="direct:start"/>
  <choice>
    <when>
      <jsonpath>$store.book[?(@.price < $header.cheap)]</jsonpath>
      <to uri="mock:cheap"/>
    </when>
    <when>
      <jsonpath>$store.book[?(@.price < $header.average)]</jsonpath>
      <to uri="mock:average"/>
    </when>
    <otherwise>
      <to uri="mock:expensive"/>
    </otherwise>
  </choice>
</route>
```

You can turn off support for inlined simple expression by setting the option allowSimple to false as shown:

```java
.when().jsonpath("$store.book[?(@.price < 10)]", false, false)
```

And in XML DSL:

```xml
<jsonpath allowSimple="false">$store.book[?(@.price < 10)]</jsonpath>
```

179.8. JSONPATH INJECTION
You can use Bean Integration to invoke a method on a bean and use various languages such as JSONPath to extract a value from the message and bind it to a method parameter.

For example

```java
public class Foo {
    @Consume(uri = "activemq:queue:books.new")
    public void doSomething(@JsonPath("$.store.book[*].author") String author, @Body String json) {
        // process the inbound message here
    }
}
```

### 179.9. ENCODING DETECTION

Since Camel version 2.16, the encoding of the JSON document is detected automatically, if the document is encoded in unicode (UTF-8, UTF-16LE, UTF-16BE, UTF-32LE, UTF-32BE) as specified in RFC-4627. If the encoding is a non-unicode encoding, you can either make sure that you enter the document in String format to the JSONPath component or you can specify the encoding in the header "CamelJsonPathJsonEncoding" (JsonpathConstants.HEADER_JSON_ENCODING).

### 179.10. SPLIT JSON DATA INTO SUB ROWS AS JSON

You can use jsonpath to split a JSON document, such as:

```camel
from("direct:start")
    .split().jsonpath("$.store.book[*]")
    .to("log:book");
```

Then each book is logged, however the message body is a Map instance. Sometimes you may want to output this as plain String JSON value instead, which can be done from Camel 2.20 onwards with the writeAsString option as shown:

```camel
from("direct:start")
    .split().jsonpathWriteAsString("$.store.book[*]")
    .to("log:book");
```

Then each book is logged as a String JSON value. For earlier versions of Camel you would need to use camel-jackson dataformat and marshal the message body to make it convert the message body from Map to a String type.

### 179.11. USING HEADER AS INPUT

Available as of Camel 2.20

By default jsonpath uses the message body as the input source. However you can also use a header as input by specifying the headerName option.

For example to count the number of books from a json document that was stored in a header named books you can do:

```camel
from("direct:start")
    .setHeader("numberOfBooks")
```
In the `jsonpath` expression above we specify the name of the header as `books` and we also told that we wanted the result to be converted as an integer by `int.class`.

The same example in XML DSL would be:

```xml
<route>
  <from uri="direct:start"/>
  <setHeader headerName="numberOfBooks">
    <jsonpath headerName="books" resultType="int">$..store.book.length()</jsonpath>
  </setHeader>
  <to uri="mock:result"/>
</route>
```

### 179.12. DEPENDENCIES

To use JSonPath in your camel routes you need to add the a dependency on `camel-jsonpath` which implements the JSonPath language.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jsonpath</artifactId>
  <version>x.x.x</version>
</dependency>
```
CHAPTER 180. JT400 COMPONENT

Available as of Camel version 1.5

The **jt400** component allows you to exchange messages with an AS/400 system using data queues.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId.camel-jt400</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

180.1. URI FORMAT

- `jt400://user:password@system/QSYS.LIB/LIBRARY.LIB/QUEUE.DTAQ[?options]`

To call remote program (Camel 2.7)

- `jt400://user:password@system/QSYS.LIB/LIBRARY.LIB/program.PGM[?options]`

You can append query options to the URI in the following format, `?option=value&option=value&...`

180.2. JT400 OPTIONS

The JT400 component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectionPool</td>
<td>Returns the default connection pool used by this component.</td>
<td>AS400Connection Pool</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The JT400 endpoint is configured using URI syntax:

- `jt400:userID:password/systemName/objectPath.type`

with the following path and query parameters:

180.2.1. Path Parameters (5 parameters):
### 180.2.2. Query Parameters (30 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ccsid (common)</td>
<td>Sets the CCSID to use for the connection with the AS/400 system.</td>
<td>int</td>
<td>Format</td>
</tr>
<tr>
<td>format (common)</td>
<td>Sets the data format for sending messages.</td>
<td>text</td>
<td>Format</td>
</tr>
<tr>
<td>guiAvailable (common)</td>
<td>Sets whether AS/400 prompting is enabled in the environment running Camel.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>keyed (common)</td>
<td>Whether to use keyed or non-keyed data queues.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>outputFieldsIdxArray (common)</td>
<td>Specifies which fields (program parameters) are output parameters.</td>
<td>Integer[]</td>
<td></td>
</tr>
<tr>
<td>outputFieldsLengthArray (common)</td>
<td>Specifies the fields (program parameters) length as in the AS/400 program definition.</td>
<td>Integer[]</td>
<td></td>
</tr>
<tr>
<td>searchKey (common)</td>
<td>Search key for keyed data queues.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>searchType (common)</td>
<td>Search type such as EQ for equal etc.</td>
<td>EQ</td>
<td>SearchType</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>readTimeout (consumer)</td>
<td>Timeout in millis the consumer will wait while trying to read a new message of the data queue.</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>pollStrategy (consumer)</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold (scheduler)</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffIdleThreshold (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>backoffMultiplier (scheduler)</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>delay (scheduler)</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy (scheduler)</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay (scheduler)</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel (scheduler)</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>scheduledExecutorService (scheduler)</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td></td>
<td>ScheduledExecutorService</td>
</tr>
<tr>
<td>scheduler (scheduler)</td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollConsumerScheduler</td>
</tr>
<tr>
<td>schedulerProperties (scheduler)</td>
<td>To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>startScheduler (scheduler)</td>
<td>Whether the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>timeUnit (scheduler)</td>
<td>Time unit for initialDelay and delay options.</td>
<td>MILLISECONDS</td>
<td>TimeUnit</td>
</tr>
<tr>
<td>useFixedDelay (scheduler)</td>
<td>Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>procedureName (procedureName)</td>
<td>Procedure name from a service program to call</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
secured (security) | Whether connections to AS/400 are secured with SSL. | false | boolean

### 180.3. USAGE

When configured as a consumer endpoint, the endpoint will poll a data queue on a remote system. For every entry on the data queue, a new Exchange is sent with the entry’s data in the *In* message’s body, formatted either as a String or a byte[], depending on the format. For a provider endpoint, the *In* message body contents will be put on the data queue as either raw bytes or text.

### 180.4. CONNECTION POOL

Available as of Camel 2.10

Connection pooling is in use from Camel 2.10 onwards. You can explicit configure a connection pool on the Jt400Component, or as an uri option on the endpoint.

#### 180.4.1. Remote program call (Camel 2.7)

This endpoint expects the input to be either a String array or byte[] array (depending on format) and handles all the CCSID handling through the native jt400 library mechanisms. A parameter can be omitted by passing null as the value in its position (the remote program has to support it). After the program execution the endpoint returns either a String array or byte[] array with the values as they were returned by the program (the input only parameters will contain the same data as the beginning of the invocation). This endpoint does not implement a provider endpoint!

### 180.5. EXAMPLE

In the snippet below, the data for an exchange sent to the direct:george endpoint will be put in the data queue PENNYLANE in library BEATLES on a system named LIVERPOOL.

Another user connects to the same data queue to receive the information from the data queue and forward it to the mock:ringo endpoint.

```java
public class Jt400RouteBuilder extends RouteBuilder {
    @Override
    public void configure() throws Exception {
        from("direct:george").to("jt400://GEORGE:EGROEG@LIVERPOOL/QSYS.LIB/BEATLES.LIB/PENNYLANE.DTAQ");

        from("jt400://RINGO:OGNIR@LIVERPOOL/QSYS.LIB/BEATLES.LIB/PENNYLANE.DTAQ").to("mock:ringo");
    }
}
```

#### 180.5.1. Remote program call example (Camel 2.7)

In the snippet below, the data Exchange sent to the direct:work endpoint will contain three string that
will be used as the arguments for the program “compute” in the library “assets”. This program will write the output values in the 2nd and 3rd parameters. All the parameters will be sent to the direct:play endpoint.

```java
public class Jt400RouteBuilder extends RouteBuilder {
    @Override
    public void configure() throws Exception {
        from("direct:work").to("jt400://GRUPO:ATWORK@server/QSYS.LIB/assets.LIB/compute.PGM?
            fieldsLength=10,10,512&ouputFieldsIdx=2,3").to("direct:play");
    }
}
```

180.5.2. Writing to keyed data queues

```java
from("jms:queue:input")
    .to("jt400://username:password@system/lib.lib/MSGINDQ.DTAQ?keyed=true");
```

180.5.3. Reading from keyed data queues

```java
from("jt400://username:password@system/lib.lib/MSGOUTDQ.DTAQ?
    keyed=true&searchKey=MYKEY&searchType=GE")
    .to("jms:queue:output");
```

180.6. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 181. KAFKA COMPONENT

Available as of Camel version 2.13

The kafka: component is used for communicating with Apache Kafka message broker.

Maven users will need to add the following dependency to their pom.xml for this component.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-kafka</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

181.1. URI FORMAT

kafka:topic[?options]

181.2. OPTIONS

The Kafka component supports 8 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>Allows to pre-configure the Kafka component with common options that the endpoints will reuse.</td>
<td></td>
<td>KafkaConfiguration</td>
</tr>
<tr>
<td>brokers</td>
<td>URL of the Kafka brokers to use. The format is host1:port1,host2:port2, and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as bootstrap.servers in the Kafka documentation.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>workerPool</td>
<td>To use a shared custom worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing. If using this option then you must handle the lifecycle of the thread pool to shut the pool down when no longer needed.</td>
<td></td>
<td>ExecutorService</td>
</tr>
<tr>
<td>useGlobalSslContext</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
**breakOnFirstError** (consumer)  
This option controls what happens when a consumer is processing an exchange and it fails. If the option is false then the consumer continues to the next message and processes it. If the option is true then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, e.g. a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.

**allowManualCommit** (consumer)  
Whether to allow doing manual commits via KafkaManualCommit. If this option is enabled then an instance of KafkaManualCommit is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.

**kafkaManualCommit Factory** (consumer)  
Factory to use for creating KafkaManualCommit instances. This allows to plugin a custom factory to create custom KafkaManualCommit instances in case special logic is needed when doing manual commits that deviates from the default implementation that comes out of the box.

**resolveProperty Placeholders** (advanced)  
Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

The Kafka endpoint is configured using URI syntax:

```markdown
kafka:topic
```

with the following path and query parameters:

### 181.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>topic</td>
<td><strong>Required</strong> Name of the topic to use. On the consumer you can use comma to separate multiple topics. A producer can only send a message to a single topic.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 181.2.2. Query Parameters (93 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>brokers (common)</td>
<td>URL of the Kafka brokers to use. The format is host1:port1,host2:port2, and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as bootstrap.servers in the Kafka documentation.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientId (common)</td>
<td>The client id is a user-specified string sent in each request to help trace calls. It should logically identify the application making the request.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>headerFilterStrategy (common)</td>
<td>To use a custom HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>reconnectBackoffMaxMs (common)</td>
<td>The maximum amount of time in milliseconds to wait when reconnecting to a broker that has repeatedly failed to connect. If provided, the backoff per host will increase exponentially for each consecutive connection failure, up to this maximum. After calculating the backoff increase, 20% random jitter is added to avoid connection storms.</td>
<td>1000</td>
<td>Integer</td>
</tr>
<tr>
<td>allowManualCommit (consumer)</td>
<td>Whether to allow doing manual commits via KafkaManualCommit. If this option is enabled then an instance of KafkaManualCommit is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>autoCommitEnable (consumer)</td>
<td>If true, periodically commit to ZooKeeper the offset of messages already fetched by the consumer. This committed offset will be used when the process fails as the position from which the new consumer will begin.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td>autoCommitIntervalMs (consumer)</td>
<td>The frequency in ms that the consumer offsets are committed to zookeeper.</td>
<td>5000</td>
<td>Integer</td>
</tr>
<tr>
<td>autoCommitOnStop (consumer)</td>
<td>Whether to perform an explicit auto commit when the consumer stops to ensure the broker has a commit from the last consumed message. This requires the option autoCommitEnable is turned on. The possible values are: sync, async, or none. And sync is the default value.</td>
<td>sync</td>
<td>String</td>
</tr>
<tr>
<td>autoOffsetReset (consumer)</td>
<td>What to do when there is no initial offset in ZooKeeper or if an offset is out of range: smallest : automatically reset the offset to the smallest offset largest : automatically reset the offset to the largest offset fail: throw exception to the consumer</td>
<td>latest</td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td><code>breakOnError</code> (consumer)</td>
<td>This option controls what happens when a consumer is processing an exchange and it fails. If the option is false then the consumer continues to the next message and processes it. If the option is true then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, eg a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>bridgeErrorHandler</code> (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>checkCrcs</code> (consumer)</td>
<td>Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td><code>consumerRequestTimeoutMs</code> (consumer)</td>
<td>The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.</td>
<td>40000</td>
<td>Integer</td>
</tr>
<tr>
<td><code>consumersCount</code> (consumer)</td>
<td>The number of consumers that connect to kafka server</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td><code>consumerStreams</code> (consumer)</td>
<td>Number of concurrent consumers on the consumer</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>fetchMaxBytes (consumer)</td>
<td>The maximum amount of data the server should return for a fetch request. This is not an absolute maximum, if the first message in the first non-empty partition of the fetch is larger than this value, the message will still be returned to ensure that the consumer can make progress. The maximum message size accepted by the broker is defined via message.max.bytes (broker config) or max.message.bytes (topic config). Note that the consumer performs multiple fetches in parallel.</td>
<td>52428</td>
<td>Integer</td>
</tr>
<tr>
<td>fetchMinBytes (consumer)</td>
<td>The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request.</td>
<td>1</td>
<td>Integer</td>
</tr>
<tr>
<td>fetchWaitMaxMs (consumer)</td>
<td>The maximum amount of time the server will block before answering the fetch request if there isn’t sufficient data to immediately satisfy fetch.min.bytes</td>
<td>500</td>
<td>Integer</td>
</tr>
<tr>
<td>groupId (consumer)</td>
<td>A string that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group id multiple processes indicate that they are all part of the same consumer group. This option is required for consumers.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>heartbeatInterval Ms (consumer)</td>
<td>The expected time between heartbeats to the consumer coordinator when using Kafka’s group management facilities. Heartbeats are used to ensure that the consumer’s session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than session.timeout.ms, but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.</td>
<td>3000</td>
<td>Integer</td>
</tr>
<tr>
<td>kafkaHeaderDeserializer (consumer)</td>
<td>Sets custom KafkaHeaderDeserializer for deserialization kafka headers values to camel headers values.</td>
<td></td>
<td>KafkaHeaderDeserializer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>

<tr>
<td>keyDeserializer</td>
<td>Deserializer class for key that implements the Deserializer interface.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>maxPartitionFetchBytes</td>
<td>The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be partitions max.partition.fetch.bytes. This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition.</td>
<td>1048576</td>
<td>Integer</td>
</tr>
<tr>
<td>maxPollIntervalMs</td>
<td>The maximum delay between invocations of poll() when using consumer group management. This places an upper bound on the amount of time that the consumer can be idle before fetching more records. If poll() is not called before expiration of this timeout, then the consumer is considered failed and the group will rebalance in order to reassign the partitions to another member.</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>maxPollRecords</td>
<td>The maximum number of records returned in a single call to poll()</td>
<td>500</td>
<td>Integer</td>
</tr>
<tr>
<td>offsetRepository</td>
<td>The offset repository to use in order to locally store the offset of each partition of the topic. Defining one will disable the autocommit.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>partitionAssignor</td>
<td>The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used</td>
<td></td>
<td>String</td>

</table>
**lingerMs**  
*producer*  
The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle’s algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get `batch.size` worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will ’linger’ for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting `linger.ms=5`, for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absence of load.

<td>Whether the producer should store the RecordMetadata results from sending to Kafka. The results are stored in a List containing the RecordMetadata metadata's. The list is stored on a header with the key link KafkaConstantsKAFKA_RECORDMETA</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>requestRequiredAcks (producer)</td>
<td>The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common: acks=0 If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won’t generally know of any failures). The offset given back for each record will always be set to -1. acks=1 This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost. acks=all This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee.</td>
<td>1</td>
<td>String</td>

181.3. MESSAGE HEADERS

181.3.1. Consumer headers

The following headers are available when consuming messages from Kafka.

<table>
<thead>
<tr>
<th>Header constant</th>
<th>Header value</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KafkaConstants.TOPIC</td>
<td>&quot;kafka.TOPIC&quot;</td>
<td>String</td>
<td>The topic from where the message originated</td>
</tr>
<tr>
<td>KafkaConstants.PARTITION</td>
<td>&quot;kafka.PARTITION&quot;</td>
<td>Integer</td>
<td>The partition where the message was stored</td>
</tr>
</tbody>
</table>
181.3.2. Producer headers

Before sending a message to Kafka you can configure the following headers.

<table>
<thead>
<tr>
<th>Header constant</th>
<th>Header value</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KafkaConstants.OFFSET</td>
<td>&quot;kafka.OFFSET&quot;</td>
<td>Long</td>
<td>The offset of the message</td>
</tr>
<tr>
<td>KafkaConstants.KEY</td>
<td>&quot;kafka.KEY&quot;</td>
<td>Object</td>
<td>The key of the message if configured</td>
</tr>
<tr>
<td>KafkaConstants.HEADERS</td>
<td>&quot;kafka.HEADER_S&quot;</td>
<td>Object</td>
<td>The record headers</td>
</tr>
<tr>
<td>KafkaConstants.LAST_RECORD_BEFORE_COMMIT</td>
<td>&quot;kafka.LAST_RECORD_BEFORE_COMMIT&quot;</td>
<td>Boolean</td>
<td>Whether or not it’s the last record before commit (only available if autoCommitEnable endpoint parameter is false)</td>
</tr>
<tr>
<td>KafkaConstants.TOPIC</td>
<td>&quot;kafka.TOPIC&quot;</td>
<td>String</td>
<td>The topic to which send the message (only read if the bridgeEndpoint endpoint parameter is true)</td>
</tr>
<tr>
<td>KafkaConstants.PARTITION_KEY</td>
<td>&quot;kafka.PARTITION_KEY&quot;</td>
<td>Integer</td>
<td>Explicitly specify the partition (only used if the KafkaConstants.KEY header is defined)</td>
</tr>
</tbody>
</table>

After the message is sent to Kafka, the following headers are available.
181.4. SAMPLES

181.4.1. Consuming messages from Kafka

Here is the minimal route you need in order to read messages from Kafka.

```java
from("kafka:test?brokers=localhost:9092")
  .log("Message received from Kafka : ${body}")
  .log(" on the topic ${headers[org.apache.kafka.clients.producer.RecordMetadata]}")
  .log(" on the partition ${headers[org.apache.kafka.clients.producer.RecordMetadata]}")
  .log(" with the offset ${headers[org.apache.kafka.clients.producer.RecordMetadata]}")
  .log(" with the key ${headers[org.apache.kafka.clients.producer.RecordMetadata]}")
```

When consuming messages from Kafka you can use your own offset management and not delegate this management to Kafka. In order to keep the offsets the component needs a `StateRepository` implementation such as `FileStateRepository`. This bean should be available in the registry. Here how to use it:

```java
// Create the repository in which the Kafka offsets will be persisted
FileStateRepository repository = FileStateRepository.fileStateRepository(new File("/path/to/repo.dat"));

// Bind this repository into the Camel registry
JndiRegistry registry = new JndiRegistry();
registry.bind("offsetRepo", repository);

// Configure the camel context
DefaultCamelContext camelContext = new DefaultCamelContext(registry);
camelContext.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("kafka:\${topic}?brokers=localhost:{{kafkaPort}}&groupId=A" +
            "&autoOffsetReset=earliest" +
            "&offsetRepository=#offsetRepo")
            // Keep the offsets in the previously configured repository
            .to("mock:result");
    }
});
```

181.4.2. Producing messages to Kafka
Here is the minimal route you need in order to write messages to Kafka.

```java
from("direct:start")
  .setBody(constant("Message from Camel")) // Message to send
  .setHeader(KafkaConstants.KEY, constant("Camel")) // Key of the message
  .to("kafka:test?brokers=localhost:9092");
```

### 181.5. SSL CONFIGURATION

You have 2 different ways to configure the SSL communication on the Kafka component.

The first way is through the many SSL endpoint parameters

```java
from("kafka:" + TOPIC + "?brokers=localhost:{kafkaPort}" +
  "&groupId=A" +
  "&sslKeystoreLocation=/path/to/keystore.jks" +
  "&sslKeystorePassword=changeit" +
  "&sslKeyPassword=changeit")
  .to("mock:result");
```

The second way is to use the `sslContextParameters` endpoint parameter.

```java
// Configure the SSLContextParameters object
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/path/to/keystore.jks");
ksp.setPassword("changeit");
KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("changeit");
SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

// Bind this SSLContextParameters into the Camel registry
JndiRegistry registry = new JndiRegistry();
registry.bind("ssl", scp);

// Configure the camel context
DefaultCamelContext camelContext = new DefaultCamelContext(registry);
camelContext.addRoutes(new RouteBuilder() {
  @Override
  public void configure() throws Exception {
    from("kafka:" + TOPIC + "?brokers=localhost:{kafkaPort}" +
      "&groupId=A" +
      "&sslContextParameters=#ssl") // Reference the SSL configuration
      .to("mock:result");
  }
});
```

### 181.6. USING THE KAFKA IDEMPOTENT REPOSITORY

Available from Camel 2.19
The camel-kafka library provides a Kafka topic-based idempotent repository. This repository stores all changes to idempotent state (add/remove) in a Kafka topic, and populates a local in-memory cache for each repository’s process instance through event sourcing.

The topic used must be unique per idempotent repository instance. The mechanism does not have any requirements about the number of topic partitions; as the repository consumes from all partitions at the same time. It also does not have any requirements about the replication factor of the topic.

Each repository instance that uses the topic (e.g. typically on different machines running in parallel) controls its own consumer group, so in a cluster of 10 Camel processes using the same topic each will control its own offset.

On startup, the instance subscribes to the topic and renews the offset to the beginning, rebuilding the cache to the latest state. The cache will not be considered warmed up until one poll of pollDurationMs in length returns 0 records. Startup will not be completed until either the cache has warmed up, or 30 seconds go by; if the latter happens the idempotent repository may be in an inconsistent state until its consumer catches up to the end of the topic.

A KafkaIdempotentRepository has the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>topic</td>
<td>The name of the Kafka topic to use to broadcast changes. (required)</td>
</tr>
<tr>
<td>bootstrapServers</td>
<td>The bootstrap.servers property on the internal Kafka producer and consumer. Use this as shorthand if not setting consumerConfig and producerConfig. If used, this component will apply sensible default configurations for the producer and consumer.</td>
</tr>
<tr>
<td>producerConfig</td>
<td>Sets the properties that will be used by the Kafka producer that broadcasts changes. Overrides bootstrapServers, so must define the Kafka bootstrap.servers property itself</td>
</tr>
<tr>
<td>consumerConfig</td>
<td>Sets the properties that will be used by the Kafka consumer that populates the cache from the topic. Overrides bootstrapServers, so must define the Kafka bootstrap.servers property itself</td>
</tr>
<tr>
<td>maxCacheSize</td>
<td>How many of the most recently used keys should be stored in memory (default 1000).</td>
</tr>
<tr>
<td>pollDurationMs</td>
<td>The poll duration of the Kafka consumer. The local caches are updated immediately. This value will affect how far behind other peers that update their caches from the topic are relative to the idempotent consumer instance that sent the cache action message. The default value of this is 100 ms. If setting this value explicitly, be aware that there is a tradeoff between the remote cache liveness and the volume of network traffic between this repository’s consumer and the Kafka brokers. The cache warmup process also depends on there being one poll that fetches nothing - this indicates that the stream has been consumed up to the current point. If the poll duration is excessively long for the rate at which messages are sent on the topic, there exists a possibility that the cache cannot be warmed up and will operate in an inconsistent state relative to its peers until it catches up.</td>
</tr>
</tbody>
</table>
The repository can be instantiated by defining the `topic` and `bootstrapServers`, or the `producerConfig` and `consumerConfig` property sets can be explicitly defined to enable features such as SSL/SASL.

To use, this repository must be placed in the Camel registry, either manually or by registration as a bean in Spring/Blueprint, as it is `CamelContext` aware.

Sample usage is as follows:

```java
KafkaIdempotentRepository kafkaIdempotentRepository = new KafkaIdempotentRepository("idempotent-db-inserts", "localhost:9091");

SimpleRegistry registry = new SimpleRegistry();
registry.put("insertDbIdemRepo", kafkaIdempotentRepository); // must be registered in the registry, to enable access to the CamelContext
CamelContext context = new CamelContext(registry);

// later in RouteBuilder...
from("direct:performInsert")
    .idempotentConsumer(header("id")).messageIdRepositoryRef("insertDbIdemRepo")
    .// once-only insert into database
    .end()
```

In XML:

```xml
<!-- simple -->
<bean id="insertDbIdemRepo"
    class="org.apache.camel.processor.idempotent.kafka.KafkaIdempotentRepository">
    <property name="topic" value="idempotent-db-inserts"/>
    <property name="bootstrapServers" value="localhost:9091"/>
</bean>

<!-- complex -->
<bean id="insertDbIdemRepo"
    class="org.apache.camel.processor.idempotent.kafka.KafkaIdempotentRepository">
    <property name="topic" value="idempotent-db-inserts"/>
    <property name="maxCacheSize" value="10000"/>
    <property name="consumerConfig">
        <props>
            <prop key="bootstrap.servers">localhost:9091</prop>
        </props>
    </property>
    <property name="producerConfig">
        <props>
            <prop key="bootstrap.servers">localhost:9091</prop>
        </props>
    </property>
</bean>
```

## 181.7. USING MANUAL COMMIT WITH KAFKA CONSUMER

Available as of Camel 2.21

By default the Kafka consumer will use auto commit, where the offset will be committed automatically in the background using a given interval.
In case you want to force manual commits, you can use `KafkaManualCommit` API from the Camel Exchange, stored on the message header. This requires to turn on manual commits by either setting the option `allowManualCommit` to `true` on the `KafkaComponent` or on the endpoint, for example:

```java
KafkaComponent kafka = new KafkaComponent();
kafka.setAllowManualCommit(true);
...
camelContext.addComponent("kafka", kafka);
```

You can then use the `KafkaManualCommit` from Java code such as a Camel `Processor`:

```java
public void process(Exchange exchange) {
    KafkaManualCommit manual = exchange.getIn().getHeader(KafkaConstants.MANUAL_COMMIT, KafkaManualCommit.class);
    manual.commitSync();
}
```

This will force a synchronous commit which will block until the commit is acknowledge on Kafka, or if it fails an exception is thrown.

If you want to use a custom implementation of `KafkaManualCommit` then you can configure a custom `KafkaManualCommitFactory` on the `KafkaComponent` that creates instances of your custom implementation.

### 181.8. KAFKA HEADERS PROPAGATION

**Available as of Camel 2.22**

When consuming messages from Kafka, headers will be propagated to camel exchange headers automatically. Producing flow backed by same behaviour - camel headers of particular exchange will be propagated to kafka message headers.

Since kafka headers allows only `byte[]` values, in order camel exchnage header to be propagated its value should be serialized to `bytes[]`, otherwise header will be skipped. Following header value types are supported: `String`, `Integer`, `Long`, `Double`, `Boolean`, `byte[]`. Note: all headers propagated from kafka to camel exchange will contain `byte[]` value by default. In order to override default functionality uri parameters can be set: `kafkaHeaderDeserializer` for `from` route and `kafkaHeaderSerializer` for `to` route. Example:

```java
from("kafka:my_topic?kafkaHeaderDeserializer=#myDeserializer")
...
.to("kafka:my_topic?kafkaHeaderSerializer=#mySerializer")
```

By default all headers are being filtered by `KafkaHeaderFilterStrategy`. Strategy filters out headers which start with `Camel` or `org.apache.camel` prefixes. Default strategy can be overridden by using `headerFilterStrategy` uri parameter in both `to` and `from` routes:

```java
from("kafka:my_topic?headerFilterStrategy=#myStrategy")
...
.to("kafka:my_topic?headerFilterStrategy=#myStrategy")
```

`myStrategy` object should be subclass of `HeaderFilterStrategy` and must be placed in the Camel registry, either manually or by registration as a bean in Spring/Blueprint, as it is `CamelContext` aware.
The Kestrel component allows messages to be sent to a Kestrel queue, or messages to be consumed from a Kestrel queue. This component uses the spymemcached client for memcached protocol communication with Kestrel servers.

**WARNING**
The kestrel project is inactive and the Camel team regard this components as deprecated.

### 182.1. URI FORMAT

```kestrel://[addresslist]/queuename[?options]```

Where `queuename` is the name of the queue on Kestrel. The `addresslist` part of the URI may include one or more `host:port` pairs. For example, to connect to the queue `foo` on `kserver01:22133`, use:

```
kestrel://kserver01:22133/foo
```

If the addresslist is omitted, `localhost:22133` is assumed, i.e.:

```
kestrel://foo
```

Likewise, if a port is omitted from a `host:port` pair in addresslist, the default port 22133 is assumed, i.e.:

```
kestrel://kserver01/foo
```

Here is an example of a Kestrel endpoint URI used for producing to a clustered queue:

```
kestrel://kserver01:22133,kserver02:22133,kserver03:22133/massive
```

Here is an example of a Kestrel endpoint URI used for consuming concurrently from a queue:

```
kestrel://kserver03:22133/massive?concurrentConsumers=25&waitTimeMs=500
```

### 182.2. OPTIONS

The Kestrel component supports 2 options which are listed below.
The Kestrel endpoint is configured using URI syntax:

kestrel:addresses/queue

with the following path and query parameters:

### 182.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>addresses</td>
<td>The address(es) on which kestrel is running</td>
<td>localhost:2213</td>
<td>String[]</td>
</tr>
<tr>
<td>queue</td>
<td><strong>Required</strong> The queue we are polling</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 182.2.2. Query Parameters (6 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>concurrentConsumers</td>
<td>How many concurrent listeners to schedule for the thread pool</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>waitTimeMs</td>
<td>How long a given wait should block (server side), in milliseconds</td>
<td>100</td>
<td>int</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
---|---|---|---
exceptionHandler (consumer) | To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored. | | ExceptionHandler
exchangePattern (consumer) | Sets the exchange pattern when the consumer creates an exchange. | | ExchangePattern
synchronous (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

## 182.3. Configuring the Kestrel Component Using Spring XML

The simplest form of explicit configuration is as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.springframework.org/schema/beans
                        http://www.springframework.org/schema/beans/spring-beans.xsd
  <bean id="kestrel" class="org.apache.camel.component.kestrel.KestrelComponent"/>
  <camelContext xmlns="http://camel.apache.org/schema/spring"/>
</beans>
```

That will enable the Kestrel component with all default settings, i.e. it will use `localhost:22133`, 100ms wait time, and a single non-concurrent consumer by default.

To use specific options in the base configuration (which supplies configuration to endpoints whose `properties` are not specified), you can set up a KestrelConfiguration POJO as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.springframework.org/schema/beans
                        http://www.springframework.org/schema/beans/spring-beans.xsd
  <bean id="kestrelConfiguration" class="org.apache.camel.component.kestrel.KestrelConfiguration">
    <property name="addresses" value="kestrel01:22133"/>
    <property name="waitTimeMs" value="100"/>
  </bean>
</beans>
```
182.4. USAGE EXAMPLES

182.4.1. Example 1: Consuming

```java
from("kestrel://kserver02:22133/massive?concurrentConsumers=10&waitTimeMs=500")
  .bean("myConsumer", "onMessage");
```

```java
public class MyConsumer {
    public void onMessage(String message) {
        ...
    }
}
```

182.4.2. Example 2: Producing

```java
public class MyProducer {
    @EndpointInject(uri = "kestrel://kserver01:22133,kserver02:22133/myqueue")
    ProducerTemplate producerTemplate;

    public void produceSomething() {
        producerTemplate.sendBody("Hello, world.");
    }
}
```

182.4.3. Example 3: Spring XML Configuration

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from url="kestrel://ks01:22133/sequential?concurrentConsumers=1&waitTimeMs=500"/>
    <bean ref="myBean" method="onMessage"/>
  </route>
  <route>
    <from url="direct:start"/>
    <to url="kestrel://ks02:22133/stuff"/>
  </route>
</camelContext>
```

```java
public class MyBean {
    public void onMessage(String message) {
        ...
    }
}
```
182.5. DEPENDENCIES

The Kestrel component has the following dependencies:

- **spymemcached** 2.5 (or greater)

182.5.1. spymemcached

You must have the `spymemcached` jar on your classpath. Here is a snippet you can use in your `pom.xml`:

```xml
<dependency>
  <groupId>spy</groupId>
  <artifactId>memcached</artifactId>
  <version>2.5</version>
</dependency>
```

Alternatively, you can download the jar directly.

Warning: Limitations

**NOTE**

The spymemcached client library does not work properly with kestrel when JVM assertions are enabled. There is a known issue with spymemcached when assertions are enabled and a requested key contains the `/t=...` extension (i.e. if you’re using the `waitTimeMs` option on an endpoint URI, which is highly encouraged). Fortunately, JVM assertions are disabled by default, unless you explicitly enable them, so this should not present a problem under normal circumstances. Something to note is that Maven’s Surefire test plugin enables assertions. If you’re using this component in a Maven test environment, you may need to set `enableAssertions` to `false`. Please refer to the surefire:test reference for details.

182.6. SEE ALSO

- Component
- Endpoint
- Getting Started
CHAPTER 183. KIE-CAMEL

183.1. OVERVIEW

Kie-Camel is an Apache Camel component (endpoint) that integrates with KIE (Drools). It allows you to specify a KIE module (using maven GAV) which you can pull into the route and execute. Also, It enables you to specify portions of the message body as facts.

For more details about the kie-camel component, see Apache Camel Integration.
CHAPTER 184. KRATI COMPONENT (DEPRECATED)

Available as of Camel version 2.9

This component allows the use krati datastores and datasets inside Camel. Krati is a simple persistent
data store with very low latency and high throughput. It is designed for easy integration with read-write-
intensive applications with little effort in tuning configuration, performance and JVM garbage collection.

Camel provides a producer and consumer for krati datastore _(key/value engine)_ . It also provides an
idempotent repository for filtering out duplicate messages.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-krati</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

184.1. URI FORMAT

```
krati:[the path of the datastore][?options]
```

The path of the datastore is the relative path of the folder that krati will use for its datastore.

You can append query options to the URI in the following format, ?option=value&option=value&…

184.2. KRATI OPTIONS

The Krati component has no options.

The Krati endpoint is configured using URI syntax:

```
krati:path
```

with the following path and query parameters:

184.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Required Path of the datastore is the relative path of the folder that krati will use for its datastore.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

184.2.2. Query Parameters (29 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>hashFunction (common)</td>
<td>The hash function to use.</td>
<td></td>
<td>HashFunction&lt;byte[]&gt;</td>
</tr>
<tr>
<td>initialCapacity (common)</td>
<td>The initial capacity of the store.</td>
<td>100</td>
<td>int</td>
</tr>
<tr>
<td>keySerializer (common)</td>
<td>The serializer that will be used to serialize the key.</td>
<td></td>
<td>Object&gt;</td>
</tr>
<tr>
<td>segmentFactory (common)</td>
<td>Sets the segment factory of the target store.</td>
<td></td>
<td>SegmentFactory</td>
</tr>
<tr>
<td>segmentFileSize (common)</td>
<td>Data store segments size in MB.</td>
<td>64</td>
<td>int</td>
</tr>
<tr>
<td>valueSerializer (common)</td>
<td>The serializer that will be used to serialize the value.</td>
<td></td>
<td>Object&gt;</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>maxMessagesPerPoll (consumer)</td>
<td>The maximum number of messages which can be received in one poll. This can be used to avoid reading in too much data and taking up too much memory.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------</td>
</tr>
<tr>
<td>pollStrategy (consumer)</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td>key (producer)</td>
<td>The key.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>operation (producer)</td>
<td>Specifies the type of operation that will be performed to the datastore.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>value (producer)</td>
<td>The Value.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold (scheduler)</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>backoffIdleThreshold (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>backoffMultiplier (scheduler)</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>delay (scheduler)</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy (scheduler)</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay (scheduler)</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
</tbody>
</table>
### runLoggingLevel

The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>runLoggingLevel (scheduler)</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
</tbody>
</table>

### scheduledExecutorService

Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheduledExecutorService (scheduler)</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td>ScheduledExecutorService</td>
</tr>
</tbody>
</table>

### scheduler

To use a cron scheduler from either camel-spring or camel-quartz2 component

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheduler (scheduler)</td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollConsumerScheduler</td>
</tr>
</tbody>
</table>

### schedulerProperties

To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedulerProperties (scheduler)</td>
<td>To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.</td>
<td>Map</td>
</tr>
</tbody>
</table>

### startScheduler

Whether the scheduler should be auto started.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>startScheduler (scheduler)</td>
<td>Whether the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### timeZone

Time unit for initialDelay and delay options.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeZone (scheduler)</td>
<td>Time unit for initialDelay and delay options.</td>
<td>MILLIES</td>
<td>TimeUnit</td>
</tr>
</tbody>
</table>

### useFixedDelay

Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>useFixedDelay (scheduler)</td>
<td>Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### krati:/tmp/krati?operation=CamelKratiGet&initialCapacity=10000&keySerializer=#myCustomSerializer

For producer endpoint you can override all of the above URI options by passing the appropriate headers to the message.

#### 184.2.3. Message Headers for datastore

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelKratiOperation</td>
<td>The operation to be performed on the datastore. The valid options are CamelKratiAdd, CamelKratiGet, CamelKratiDelete, CamelKratiDeleteAll</td>
</tr>
<tr>
<td>CamelKratiKey</td>
<td>The key.</td>
</tr>
</tbody>
</table>
184.3. USAGE SAMPLES

184.3.1. Example 1: Putting to the datastore.

This example will show you how you can store any message inside a datastore.

```java
from("direct:put").to("krati:target/test/producertest");
```

In the above example you can override any of the URI parameters with headers on the message. Here is how the above example would look like using xml to define our route.

```xml
<route>
  <from uri="direct:put"/>
  <to uri="krati:target/test/producerspringtest"/>
</route>
```

184.3.2. Example 2: Getting/Reading from a datastore

This example will show you how you can read the content of a datastore.

```java
from("direct:get")
  .setHeader(KratiConstants.KRATI_OPERATION, constant(KratiConstants.KRATI_OPERATION_GET))
  .to("krati:target/test/producertest");
```

In the above example you can override any of the URI parameters with headers on the message. Here is how the above example would look like using xml to define our route.

```xml
<route>
  <from uri="direct:get"/>
  <to uri="krati:target/test/producerspringtest?operation=CamelKratiGet"/>
</route>
```

184.3.3. Example 3: Consuming from a datastore

This example will consume all items that are under the specified datastore.

```java
from("krati:target/test/consumertest")
  .to("direct:next");
```

You can achieve the same goal by using xml, as you can see below.
184.4. IDEMPOTENT REPOSITORY

As already mentioned this component also offers an idempotent repository which can be used for filtering out duplicate messages.

```java
from("direct://in").idempotentConsumer(header("messageId"), new KratiIdempotentRepository("/tmp/idempotent")).to("log://out");
```

184.4.1. See also

Krati Website
CHAPTER 185. KUBERNETES COMPONENTS

Available as of Camel version 2.17

The Kubernetes components integrate your application with Kubernetes standalone or on top of OpenShift.

The camel-kubernetes consists of 13 components:

- Kubernetes ConfigMap
- Kubernetes Namespace
- Kubernetes Node
- Kubernetes Persistent Volume
- Kubernetes Persistent Volume Claim
- Kubernetes Pod
- Kubernetes Replication Controller
- Kubernetes Resource Quota
- Kubernetes Secrets
- Kubernetes Service Account
- Kubernetes Service

In OpenShift, also:

- Kubernetes Build Config
- Kubernetes Build

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-kubernetes</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 185.2. USAGE

#### 185.2.1. Producer examples

Here we show some examples of producer using camel-kubernetes.

#### 185.2.2. Create a pod

```java
from("direct:createPod")
    .toF("kubernetes-pods://%s?oauthToken=%s&operation=createPod", host, authToken);
```

By using the KubernetesConstants.KUBERNETES_POD_SPEC header you can specify your PodSpec and pass it to this operation.

#### 185.2.3. Delete a pod

```java
from("direct:createPod")
    .toF("kubernetes-pods://%s?oauthToken=%s&operation=deletePod", host, authToken);
```

By using the KubernetesConstants.KUBERNETES_POD_NAME header you can specify your Pod name and pass it to this operation.
CHAPTER 186. KUBERNETES COMPONENT (DEPRECATED)

Available as of Camel version 2.17

IMPORTANT

The composite kubernetes component has been deprecated. Use individual component splitted as following.

- Kubernetes Components
  - Kubernetes Build Config
  - Kubernetes Build
  - Kubernetes ConfigMap
  - Kubernetes Namespace
  - Kubernetes Node
  - Kubernetes Persistent Volume
  - Kubernetes Persistent Volume Claim
  - Kubernetes Pod
  - Kubernetes Replication Controller
  - Kubernetes Resource Quota
  - Kubernetes Secrets
  - Kubernetes Service Account
  - Kubernetes Service

The Kubernetes component is a component for integrating your application with Kubernetes standalone or on top of Openshift.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-kubernetes</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

186.1. URI FORMAT

The URI format is

```
kubernetes:masterUrl[?options]
```

You can append query options to the URI in the following format, ?option=value&option=value&…
186.2. OPTIONS

The Kubernetes component has no options.

The Kubernetes endpoint is configured using URI syntax:

```text
kubernetes:masterUrl
```

with the following path and query parameters:

186.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterUrl</td>
<td>Required Kubernetes Master url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

186.2.2. Query Parameters (28 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The Kubernetes API Version to use</td>
<td></td>

186.4. CATEGORIES

Actually the camel-kubernetes component supports the following Kubernetes resources

- Namespaces
- Pods
- Replication Controllers
- Services
- Persistent Volumes
- Persistent Volume Claims
- Secrets
- Resource Quota
- Service Accounts
- Nodes
- Configmaps

In Openshift also

- Builds
- BuildConfigs

186.5. USAGE

186.5.1. Producer examples

Here we show some examples of producer using camel-kubernetes.

186.5.2. Create a pod
By using the KubernetesConstants.KUBERNETES_POD_SPEC header you can specify your PodSpec and pass it to this operation.

186.5.3. Delete a pod

By using the KubernetesConstants.KUBERNETES_POD_NAME header you can specify your Pod name and pass it to this operation.
CHAPTER 187. KUBERNETES CONFIGMAP COMPONENT

Available as of Camel version 2.17

The **Kubernetes ConfigMap** component is one of **Kubernetes Components** which provides a producer to execute kubernetes ConfigMap operations.

### 187.1. COMPONENT OPTIONS

The Kubernetes ConfigMap component has no options.

### 187.2. ENDPOINT OPTIONS

The Kubernetes ConfigMap endpoint is configured using URI syntax:

```
kubernetes-config-maps:masterUrl
```

with the following path and query parameters:

#### 187.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterUrl</td>
<td>Required Kubernetes Master url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

#### 187.2.2. Query Parameters (19 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The Kubernetes API Version to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>dnsDomain</td>
<td>The dns domain, used for ServiceCall EIP</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>kubernetesClient</td>
<td>Default KubernetesClient to use if provided</td>
<td></td>
<td>KubernetesClient</td>
</tr>
<tr>
<td>operation</td>
<td>Producer operation to do on Kubernetes</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>portName</td>
<td>The port name, used for ServiceCall EIP</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>connectionTimeout</td>
<td>Connection timeout in milliseconds to use when making requests to the Kubernetes API server.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>caCertData (security)</td>
<td>The CA Cert Data</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>caCertFile (security)</td>
<td>The CA Cert File</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientCertData (security)</td>
<td>The Client Cert Data</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientCertFile (security)</td>
<td>The Client Cert File</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientKeyAlgo (security)</td>
<td>The Key Algorithm used by the client</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientKeyData (security)</td>
<td>The Client Key data</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientKeyFile (security)</td>
<td>The Client Key file</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientKeyPassphrase (security)</td>
<td>The Client Key Passphrase</td>
<td></td>
<td>String</td>
</tr>
<tr>

<tr>
<td>username (security)</td>
<td>Username to connect to Kubernetes</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
CHAPTER 188. KUBERNETES DEPLOYMENTS COMPONENT

Available as of Camel version 2.20

The Kubernetes Deployments component is one of Kubernetes Components which provides a producer to execute kubernetes secret operations.

188.1. COMPONENT OPTIONS

The Kubernetes Deployments component has no options.

188.2. ENDPOINT OPTIONS

The Kubernetes Deployments endpoint is configured using URI syntax:

```
kubernetes-deployments:masterUrl
```

with the following path and query parameters:

188.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterUrl</td>
<td>Required Kubernetes Master url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

188.2.2. Query Parameters (27 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</tbody>
</table>
CHAPTER 189. KUBERNETES NAMESPACES COMPONENT

Available as of Camel version 2.17

The Kubernetes Namespaces component is one of Kubernetes Components which provides a producer to execute kubernetes namespace operations and a consumer to consume kubernetes namespace events.

189.1. COMPONENT OPTIONS

The Kubernetes Namespaces component has no options.

189.2. ENDPOINT OPTIONS

The Kubernetes Namespaces endpoint is configured using URI syntax:

```
kubernetes-namespaces:masterUrl
```

with the following path and query parameters:

189.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterUrl</td>
<td>Required Kubernetes Master url</td>

</tbody>
</table>
CHAPTER 190. KUBERNETES NODES COMPONENT

Available as of Camel version 2.17

The Kubernetes Nodes component is one of Kubernetes Components which provides a producer to execute kubernetes node operations and a consumer to consume kubernetes node events.

190.1. COMPONENT OPTIONS

The Kubernetes Nodes component has no options.

190.2. ENDPOINT OPTIONS

The Kubernetes Nodes endpoint is configured using URI syntax:

```
kubernetes-nodes:masterUrl
```

with the following path and query parameters:

190.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterUrl</td>
<td>Required Kubernetes Master url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

190.2.2. Query Parameters (27 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The Kubernetes API Version to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(common)</td>
<td></td>
<td></td>

CHAPTER 198. KUBERNETES SERVICES COMPONENT

Available as of Camel version 2.17

The Kubernetes Services component is one of Kubernetes Components which provides a producer to execute kubernetes service operations and a consumer to consume kubernetes service events.

198.1. COMPONENT OPTIONS

The Kubernetes Services component has no options.

198.2. ENDPOINT OPTIONS

The Kubernetes Services endpoint is configured using URI syntax:

```
kubernetes-services:masterUrl
```

with the following path and query parameters:

198.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterUrl</td>
<td>Required Kubernetes Master url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

198.2.2. Query Parameters (27 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The Kubernetes API Version to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td></td>
<td>(common)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dnsDomain</td>
<td>The dns domain, used for ServiceCall EIP</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td></td>

<td>Define if the certs we used are trusted anyway or not</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>username (security)</td>
<td>Username to connect to Kubernetes</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 198.3. ECLIPSE KURA COMPONENT

Available as of Camel 2.15

This documentation page covers the integration options of Camel with the Eclipse Kura M2M gateway. The common reason to deploy Camel routes into the Eclipse Kura is to provide enterprise integration patterns and Camel components to the messaging M2M gateway. For example you might want to install Kura on Raspberry PI, then read temperature from the sensor attached to that Raspberry PI using Kura services and finally forward the current temperature value to your data center service using Camel EIP and components.

### 198.3.1. KuraRouter activator
Bundles deployed to the Eclipse Kura are usually developed as bundle activators. So the easiest way to deploy Apache Camel routes into the Kura is to create an OSGi bundle containing the class extending org.apache.camel.kura.KuraRouter class:

```java
public class MyKuraRouter extends KuraRouter {
    @Override
    public void configure() throws Exception {
        from("timer:trigger").
            to("netty-http:http://app.mydatacenter.com/api");
    }
}
```

Keep in mind that KuraRouter implements the org.osgi.framework.BundleActivator interface, so you need to register its start and stop lifecycle methods while creating Kura bundle component class.

Kura router starts its own OSGi-aware CamelContext. It means that for every class extending KuraRouter, there will be a dedicated CamelContext instance. Ideally we recommend to deploy one KuraRouter per OSGi bundle.

### 198.3.2. Deploying KuraRouter

Bundle containing your Kura router class should import the following packages in the OSGi manifest:

```text
Import-Package: org.osgi.framework;version="1.3.0",
               org.slf4j;version="1.6.4",

               org.apache.camel,org.apache.camel.impl,org.apache.camel.core.osgi,org.apache.camel.builder,org.apache.camel.model,
               org.apache.camel.component.kura
```

Keep in mind that you don’t have to import every Camel component bundle you plan to use in your routes, as Camel components are resolved as the services on the runtime level.

Before you deploy your router bundle, be sure that you have deployed (and started) the following Camel core bundles (using Kura GoGo shell)...

```bash
install file:///home/user/.m2/repository/org/apache/camel/camel-core/2.15.0/camel-core-2.15.0.jar
start <camel-core-bundle-id>
install file:///home/user/.m2/repository/org/apache/camel/camel-core-osgi/2.15.0/camel-core-osgi-2.15.0.jar
start <camel-core-osgi-bundle-id>
install file:///home/user/.m2/repository/org/apache/camel/camel-kura/2.15.0/camel-kura-2.15.0.jar
start <camel-kura-bundle-id>
```

...and all the components you plan to use in your routes:

```bash
install file:///home/user/.m2/repository/org/apache/camel/camel-stream/2.15.0/camel-stream-2.15.0.jar
start <camel-stream-bundle-id>
```

Then finally deploy your router bundle:
198.3.3. KuraRouter utilities

Kura router base class provides many useful utilities. This section explores each of them.

198.3.3.1. SLF4J logger

Kura uses SLF4J facade for logging purposes. Protected member `log` returns SLF4J logger instance associated with the given Kura router.

```java
public class MyKuraRouter extends KuraRouter {

    @Override
    public void configure() throws Exception {
        log.info("Configuring Camel routes!");
        ...
    }
}
```

198.3.3.2. BundleContext

Protected member `bundleContext` returns bundle context associated with the given Kura router.

```java
public class MyKuraRouter extends KuraRouter {

    @Override
    public void configure() throws Exception {
        ServiceReference<MyService> serviceRef = bundleContext.getServiceReference(LogService.class.getName());
        MyService myService = bundleContext.getService(serviceRef);
        ...
    }
}
```

198.3.3.3. CamelContext

Protected member `camelContext` is the `CamelContext` associated with the given Kura router.

```java
public class MyKuraRouter extends KuraRouter {

    @Override
    public void configure() throws Exception {
        camelContext.getStatus();
        ...
    }
}
```
198.3.3.4. ProducerTemplate

Protected member `producerTemplate` is the `ProducerTemplate` instance associated with the given Camel context.

```java
public class MyKuraRouter extends KuraRouter {
    @Override
    public void configure() throws Exception {
        producerTemplate.sendBody("jms:temperature", 22.0);
        ...
    }
}
```

198.3.3.5. ConsumerTemplate

Protected member `consumerTemplate` is the `ConsumerTemplate` instance associated with the given Camel context.

```java
public class MyKuraRouter extends KuraRouter {
    @Override
    public void configure() throws Exception {
        double currentTemperature = producerTemplate.receiveBody("jms:temperature", Double.class);
        ...
    }
}
```

198.3.3.6. OSGi service resolver

OSGi service resolver (`service(Class<T> serviceType)`) can be used to easily retrieve service by type from the OSGi bundle context.

```java
public class MyKuraRouter extends KuraRouter {
    @Override
    public void configure() throws Exception {
        MyService myService = service(MyService.class);
        ...
    }
}
```

If service is not found, a `null` value is returned. If you want your application to fail if the service is not available, use `requiredService(Class)` method instead. The `requiredService` throws `IllegalStateException` if a service cannot be found.

```java
public class MyKuraRouter extends KuraRouter {
    @Override
    public void configure() throws Exception {
        MyService myService = requiredService(MyService.class);
    }
}
```
198.3.4. KuraRouter activator callbacks

Kura router comes with the lifecycle callbacks that can be used to customize the way the Camel router works. For example to configure the CamelContext instance associated with the router just before the former is started, override beforeStart method of the KuraRouter class:

```java
public class MyKuraRouter extends KuraRouter {

  ...

  protected void beforeStart(CamelContext camelContext) {
    OsgiDefaultCamelContext osgiContext = (OsgiCamelContext) camelContext;
    osgiContext.setName("NameOfTheRouter");
  }

}
```

198.3.5. Loading XML routes from ConfigurationAdmin

Sometimes it is desired to read the XML definition of the routes from the server configuration. This a common scenario for IoT gateways where over-the-air redeployment cost may be significant. To address this requirement each KuraRouter looks for the kura.camel.BUNDLE-SYMBOLIC-NAME.route property from the kura.camel PID using the OSGi ConfigurationAdmin. This approach allows you to define Camel XML routes file per deployed KuraRouter. In order to update a route, just edit an appropriate configuration property and restart a bundle associated with it. The content of the kura.camel.BUNDLE-SYMBOLIC-NAME.route property is expected to be Camel XML route file, for example:

```xml
<routes xmlns="http://camel.apache.org/schema/spring">
  <route id="loaded">
    <from uri="direct:bar"/>
    <to uri="mock:bar"/>
  </route>
</routes>
```

198.3.6. Deploying Kura router as a declarative OSGi service

If you would like to deploy your Kura router as a declarative OSGi service, you can use activate and deactivate methods provided by KuraRouter.

```xml
<scr:component name="org.eclipse.kura.example.camel.MyKuraRouter" activate="activate" deactivate="deactivate" enabled="true" immediate="true">
  <implementation class="org.eclipse.kura.example.camel.MyKuraRouter"/>
</scr:component>
```
198.3.7. See Also

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 199. LANGUAGE COMPONENT

Available as of Camel version 2.5

The language component allows you to send Exchange to an endpoint which executes a script by any of
the supported Languages in Camel.
By having a component to execute language scripts, it allows more dynamic routing capabilities. For
example by using the Routing Slip or Dynamic Router EIPs you can send messages to language
endpoints where the script is dynamic defined as well.

This component is provided out of the box in camel-core and hence no additional JARs is needed. You
only have to include additional Camel components if the language of choice mandates it, such as using
Groovy or JavaScript languages.

199.1. URI FORMAT

language://languageName[:script][?options]

And from Camel 2.11 onwards you can refer to an external resource for the script using same notation as
supported by the other Languages in Camel

language://languageName:resource:scheme:location[?options]

199.2. URI OPTIONS

The Language component has no options.

The Language endpoint is configured using URI syntax:

language:languageName:resourceUri

with the following path and query parameters:

199.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>languageName</td>
<td>Required Sets the name of the language to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>resourceUri</td>
<td>Path to the resource, or a reference to lookup a bean in the Registry to use as the resource</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

199.2.2. Query Parameters (6 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
</table>
### 199.3. MESSAGE HEADERS

The following message headers can be used to affect the behavior of the component:

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelLanguageScript</td>
<td>The script to execute provided in the header. Takes precedence over script configured on the endpoint.</td>
</tr>
</tbody>
</table>

### 199.4. EXAMPLES

For example you can use the Simple language to Message Translator a message:

In case you want to convert the message body type you can do this as well:

You can also use the Groovy language, such as this example where the input message will by multiplied with 2:

You can also provide the script as a header as shown below. Here we use XPath language to extract the text from the `<foo>` tag.
199.5. LOADING SCRIPTS FROM RESOURCES

Available as of Camel 2.9

You can specify a resource uri for a script to load in either the endpoint uri, or in the Exchange.LANGUAGE_SCRIPT header.
The uri must start with one of the following schemes: file:, classpath:, or http:

For example to load a script from the classpath:

By default the script is loaded once and cached. However you can disable the contentCache option and have the script loaded on each evaluation.
For example if the file myscript.txt is changed on disk, then the updated script is used:

From Camel 2.11 onwards you can refer to the resource similar to the other Languages in Camel by prefixing with "resource:" as shown below:
CHAPTER 200. LDAP COMPONENT

Available as of Camel version 1.5

The `ldap` component allows you to perform searches in LDAP servers using filters as the message payload. This component uses standard JNDI (`javax.naming` package) to access the server.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ldap</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

200.1. URI FORMAT

`ldap:ldapServerBean[?options]`

The `ldapServerBean` portion of the URI refers to a `DirContext` bean in the registry. The LDAP component only supports producer endpoints, which means that an `ldap` URI cannot appear in the `from` at the start of a route.

You can append query options to the URI in the following format, `?option=value&option=value&…`

200.2. OPTIONS

The LDAP component has no options.

The LDAP endpoint is configured using URI syntax:

`ldap:dirContextName`

with the following path and query parameters:

200.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>dirContextName</td>
<td><strong>Required</strong> Name of either a javax.naming.directory.DirContext, or java.util.Hashtable, or Map bean to lookup in the registry. If the bean is either a Hashtable or Map then a new javax.naming.directory.DirContext instance is created for each use. If the bean is a javax.naming.directory.DirContext then the bean is used as given. The latter may not be possible in all situations where the javax.naming.directory.DirContext must not be shared, and in those situations it can be better to use java.util.Hashtable or Map instead.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 200.2.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>base (producer)</td>
<td>The base DN for searches.</td>
<td>ou=sys tem</td>
<td>String</td>
</tr>
<tr>
<td>pageSize (producer)</td>
<td>When specified the Ldap module uses paging to retrieve all results (most LDAP Servers throw an exception when trying to retrieve more than 1000 entries in one query). To be able to use this a LdapContext (subclass of DirContext) has to be passed in as ldapServerBean (otherwise an exception is thrown)</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>returnedAttributes (producer)</td>
<td>Comma-separated list of attributes that should be set in each entry of the result</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>scope (producer)</td>
<td>Specifies how deeply to search the tree of entries, starting at the base DN.</td>
<td>subtree</td>
<td>String</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 200.3. RESULT

The result is returned in the Out body as a `ArrayList<javax.naming.directory.SearchResult>` object.

### 200.4. DIRCONTEXT
The URI, `ldap:ldapserver`, references a Spring bean with the ID, `ldapserver`. The `ldapserver` bean may be defined as follows:

```xml
<bean id="ldapserver" class="javax.naming.directory.InitialDirContext" scope="prototype">
  <constructor-arg>
    <props>
      <prop key="java.naming.factory.initial">com.sun.jndi.ldap.LdapCtxFactory</prop>
      <prop key="java.naming.provider.url">ldap://localhost:10389</prop>
      <prop key="java.naming.security.authentication">none</prop>
    </props>
  </constructor-arg>
</bean>
```

The preceding example declares a regular Sun based LDAP `DirContext` that connects anonymously to a locally hosted LDAP server.

**NOTE**

`DirContext` objects are *not* required to support concurrency by contract. It is therefore important that the directory context is declared with the setting, `scope="prototype"`, in the `bean` definition or that the context supports concurrency. In the Spring framework, `prototype` scoped objects are instantiated each time they are looked up.

### 200.5. SAMPLES

Following on from the Spring configuration above, the code sample below sends an LDAP request to filter search a group for a member. The Common Name is then extracted from the response.

```java
ProducerTemplate<Exchange> template = exchange.getContext().createProducerTemplate();

Collection<?> results = (Collection<?>) (template.sendBody("ldap:ldapserver?base=ou=mygroup,ou=groups,ou=system", "(member=uid=huntc,ou=users,ou=system)");

if (results.size() > 0) {
  // Extract what we need from the device's profile

  Iterator<?> resultIter = results.iterator();
  SearchResult searchResult = (SearchResult) resultIter.next();
  Attributes attributes = searchResult.getAttributes();
  Attribute deviceCNAttr = attributes.get("cn");
  String deviceCN = (String) deviceCNAttr.get();

  ...
```

If no specific filter is required - for example, you just need to look up a single entry - specify a wildcard filter expression. For example, if the LDAP entry has a Common Name, use a filter expression like:

```java
(cn=*)
```
200.5.1. Binding using credentials

A Camel end user donated this sample code he used to bind to the ldap server using credentials.

```java
Properties props = new Properties();
props.setProperty(Context.INITIAL_CONTEXT_FACTORY, "com.sun.jndi.ldap.LdapCtxFactory");
props.setProperty(Context.PROVIDER_URL, "ldap://localhost:389");
props.setProperty(Context.URL_PKG_PREFIXES, "com.sun.jndi.url");
props.setProperty(Context.REFERRAL, "ignore");
props.setProperty(Context.SECURITY_AUTHENTICATION, "simple");
props.setProperty(Context.SECURITY_PRINCIPAL, "cn=Manager");
props.setProperty(Context.SECURITY_CREDENTIALS, "secret");

SimpleRegistry reg = new SimpleRegistry();
reg.put("myldap", new InitialLdapContext(props, null));

CamelContext context = new DefaultCamelContext(reg);
context.addRoutes(
    new RouteBuilder() {
        public void configure() throws Exception {
            from("direct:start").to("ldap:myldap?base=ou=test");
        }
    }
);
context.start();

ProducerTemplate template = context.createProducerTemplate();

Endpoint endpoint = context.getEndpoint("direct:start");
Exchange exchange = endpoint.createExchange();
exchange.getIn().setBody("(uid=test)");
Exchange out = template.send(endpoint, exchange);

Collection<SearchResult> data = out.getOut().getBody(Collection.class);
assert data != null;
assert !data.isEmpty();
System.out.println(out.getOut().getBody());
context.stop();
```

200.6. CONFIGURING SSL

All required is to create a custom socket factory and reference it in the InitialDirContext bean - see below sample.

SSL Configuration

```xml
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.osgi.org/xmlns/blueprint/v1.0.0
    http://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd
    http://camel.apache.org/schema/blueprint http://camel.apache.org/schema/blueprint/camel-
    blueprint.xsd">
```
Custom Socket Factory

```java
import org.apache.camel.util.jsse.SSLContextParameters;
import javax.net.SocketFactory;
import javax.net.ssl.SSLContext;
import javax.net.ssl.SSLSocketFactory;
import javax.net.ssl.TrustManagerFactory;
import java.io.IOException;
import java.net.InetAddress;
import java.net.Socket;
import java.security.KeyStore;

/**
 * The CustomSocketFactory. Loads the KeyStore and creates an instance of SSLSocketFactory
 */
public class CustomSocketFactory extends SSLSocketFactory {

    private static SSLSocketFactory socketFactory;

    /**
     * Called by the getDefault() method.
     */
    public CustomSocketFactory() {
```
/**
 * Called by Blueprint DI to initialise an instance of SocketFactory
 *
 * @param sslContextParameters
 */
public CustomSocketFactory(SSLContextParameters sslContextParameters) {
    try {
        KeyStore keyStore =
            sslContextParameters.getKeyManagers().getKeyStore().createKeyStore();
        TrustManagerFactory tmf = TrustManagerFactory.getInstance("SunX509");
        tmf.init(keyStore);
        SSLContext ctx = SSLContext.getInstance("TLS");
        ctx.init(null, tmf.getTrustManagers(), null);
        socketFactory = ctx.getSocketFactory();
    } catch (Exception ex) {
        ex.printStackTrace(System.err); /* handle exception */
    }
}

/**
 * Getter for the SocketFactory
 *
 * @return
 */
public static SocketFactory getDefault() {
    return new CustomSocketFactory();
}

@Override
public String[] getDefaultCipherSuites() {
    return socketFactory.getDefaultCipherSuites();
}

@Override
public String[] getSupportedCipherSuites() {
    return socketFactory.getSupportedCipherSuites();
}

@Override
public Socket createSocket(Socket socket, String string, int i, boolean bln) throws IOException {
    return socketFactory.createSocket(socket, string, i, bln);
}

@Override
public Socket createSocket(String string, int i) throws IOException {
    return socketFactory.createSocket(string, i);
}

@Override
public Socket createSocket(String string, int i, InetAddress ia, int i1) throws IOException {
    return socketFactory.createSocket(string, i, ia, i1);
}

@Override

public Socket createSocket(InetAddress ia, int i) throws IOException {
    return socketFactory.createSocket(ia, i);
}

@Override
public Socket createSocket(InetAddress ia, int i, InetAddress ia1, int i1) throws IOException {
    return socketFactory.createSocket(ia, i, ia1, i1);
}

### 200.7. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 201. LDIF COMPONENT

Available as of Camel version 2.20

The ldif component allows you to do updates on an LDAP server from a LDIF body content.

This component uses a basic URL syntax to access the server. It uses the Apache DS LDAP library to process the LDIF. After processing the LDIF, the response body will be a list of statuses for success/failure of each entry.

NOTE

The Apache LDAP API is very sensitive to LDIF syntax errors. If in doubt, refer to the unit tests to see an example of each change type.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ldif</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

201.1. URI FORMAT

```
ldap:ldapServerBean[?options]
```

The ldapServerBean portion of the URI refers to a LdapConnection. This should be constructed from a factory at the point of use to avoid connection timeouts. The LDIF component only supports producer endpoints, which means that an ldif URI cannot appear in the from at the start of a route.

For SSL configuration, refer to the camel-ldap component where there is an example of setting up a custom SocketFactory instance.

You can append query options to the URI in the following format, ?option=value&option=value&…

201.2. OPTIONS

The LDIF component has no options.

The LDIF endpoint is configured using URI syntax:

```
ldif:ldapConnectionName
```

with the following path and query parameters:

201.2.1. Path Parameters (1 parameters):
## 201.2.2. Query Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 201.3. BODY TYPES:

The body can be a URL to an LDIF file or an inline LDIF file. To signify the difference in body types, an inline LDIF must start with:

```text
version: 1
```

If not, the component will try to parse the body as a URL.

### 201.4. RESULT

The result is returned in the Out body as a `ArrayList<java.lang.String>` object. This contains either "success" or an Exception message for each LDIF entry.

### 201.5. LDAPCONNECTION

The URI, `ldif:ldapConnectionName`, references a bean with the ID, `ldapConnectionName`. The LdapConnection can be configured using a `LdapConnectionConfig` bean. Note that the scope must have a scope of `prototype` to avoid the connection being shared or picking up a stale connection.

The `LdapConnection` bean may be defined as follows in Spring XML:

```xml
<bean id="ldapConnectionOptions"
      class="org.apache.directory.ldap.client.api.LdapConnectionConfig">
  <property name="ldapHost" value="${ldap.host}"/>
  <property name="ldapPort" value="${ldap.port}"/>
  <property name="name" value="${ldap.username}"/>
  <property name="credentials" value="${ldap.password}"/>
  <property name="useSsl" value="false"/>
  <property name="useTls" value="false"/>
</bean>
```
or in a OSGi blueprint.xml:

```xml
<bean id="ldapConnectionFactory"
class="org.apache.directory.ldap.client.api.DefaultLdapConnectionFactory">
  <constructor-arg index="0" ref="ldapConnectionOptions"/>
</bean>

<bean id="ldapConnection" factory-ref="ldapConnectionFactory" factory-
method="newLdapConnection" scope="prototype"/>
```

201.6. SAMPLES

Following on from the Spring configuration above, the code sample below sends an LDAP request to filter search a group for a member. The Common Name is then extracted from the response.

```java
ProducerTemplate<Exchange> template = exchange.getContext().createProducerTemplate();
List<?> results = (Collection<?>) template.sendBody("ldap:ldapConnection, LDiff goes here");
if (results.size() > 0) {
    // Check for no errors
    for (String result : results) {
        if ("success".equalTo(result)) {
            // LDIF entry success
        } else {
            // LDIF entry failure
        }
    }
}
```

201.7. LEVELDB

Available as of Camel 2.10
Leveldb is a very lightweight and embedable key value database. It allows together with Camel to provide persistent support for various Camel features such as Aggregator.

Current features it provides:

- LevelDBAggregationRepository

201.7.1. Using LevelDBAggregationRepository

LevelDBAggregationRepository is an AggregationRepository which on the fly persists the aggregated messages. This ensures that you will not loose messages, as the default aggregator will use an in memory only AggregationRepository.

It has the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>repositoryName</td>
<td>String</td>
<td>A mandatory repository name. Allows you to use a shared LevelDBFile for multiple repositories.</td>
</tr>
<tr>
<td>persistentFileName</td>
<td>String</td>
<td>Filename for the persistent storage. If no file exists on startup a new file is created.</td>
</tr>
<tr>
<td>levelDBFile</td>
<td>LevelDBFile</td>
<td>Use an existing configured org.apache.camel.component.leveldb.LevelDBFile instance.</td>
</tr>
<tr>
<td>sync</td>
<td>boolean</td>
<td>Camel 2.12: Whether or not the LevelDBFile should sync on write or not. Default is false. By sync on write ensures that its always waiting for all writes to be spooled to disk and thus will not loose updates. See LevelDB docs for more details about async vs sync writes.</td>
</tr>
<tr>
<td>returnOldExchange</td>
<td>boolean</td>
<td>Whether the get operation should return the old existing Exchange if any existed. By default this option is false to optimize as we do not need the old exchange when aggregating.</td>
</tr>
<tr>
<td>useRecovery</td>
<td>boolean</td>
<td>Whether or not recovery is enabled. This option is by default true. When enabled the Camel Aggregator automatic recover failed aggregated exchange and have them resubmitted.</td>
</tr>
<tr>
<td>recoveryInterval</td>
<td>long</td>
<td>If recovery is enabled then a background task is run every x’th time to scan for failed exchanges to recover and resubmit. By default this interval is 5000 millis.</td>
</tr>
<tr>
<td>maximumRedeliveries</td>
<td>int</td>
<td>Allows you to limit the maximum number of redelivery attempts for a recovered exchange. If enabled then the Exchange will be moved to the dead letter channel if all redelivery attempts failed. By default this option is disabled. If this option is used then the deadLetterUri option must also be provided.</td>
</tr>
</tbody>
</table>
An endpoint uri for a Dead Letter Channel where exhausted recovered Exchanges will be moved. If this option is used then the maximumRedeliveries option must also be provided.

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deadLetterUri</td>
<td>String</td>
<td>An endpoint uri for a Dead Letter Channel where exhausted recovered Exchanges will be moved. If this option is used then the maximumRedeliveries option must also be provided.</td>
</tr>
</tbody>
</table>

The repositoryName option must be provided. Then either the persistentFileName or the levelDBFile must be provided.

### 201.7.2. What is preserved when persisting

LevelDBAggregationRepository will only preserve any Serializable compatible message body data types. Message headers must be primitive / string / numbers / etc. If a data type is not such a type its dropped and a WARN is logged. And it only persists the Message body and the Message headers. The Exchange properties are not persisted.

### 201.7.3. Recovery

The LevelDBAggregationRepository will by default recover any failed Exchange. It does this by having a background tasks that scans for failed Exchanges in the persistent store. You can use the checkInterval option to set how often this task runs. The recovery works as transactional which ensures that Camel will try to recover and redeliver the failed Exchange. Any Exchange which was found to be recovered will be restored from the persistent store and resubmitted and send out again.

The following headers is set when an Exchange is being recovered/redelivered:

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exchange.REDELIVERED</td>
<td>Boolean</td>
<td>Is set to true to indicate the Exchange is being redelivered.</td>
</tr>
<tr>
<td>Exchange.REDELIVERY_COUNTER</td>
<td>Integer</td>
<td>The redelivery attempt, starting from 1.</td>
</tr>
</tbody>
</table>

Only when an Exchange has been successfully processed it will be marked as complete which happens when the confirm method is invoked on the AggregationRepository. This means if the same Exchange fails again it will be kept retried until it success.

You can use option maximumRedeliveries to limit the maximum number of redelivery attempts for a given recovered Exchange. You must also set the deadLetterUri option so Camel knows where to send the Exchange when the maximumRedeliveries was hit.

You can see some examples in the unit tests of camel-leveldb, for example this test.
201.7.3.1. Using LevelDBAggregationRepository in Java DSL

In this example we want to persist aggregated messages in the `target/data/leveldb.dat` file.

201.7.3.2. Using LevelDBAggregationRepository in Spring XML

The same example but using Spring XML instead:

201.7.4. Dependencies

To use LevelDB in your camel routes you need to add the a dependency on `camel-leveldb`.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-leveldb</artifactId>
    <version>2.10.0</version>
</dependency>
```

CHAPTER 202. LINKEDIN COMPONENT

Available as of Camel version 2.14

The LinkedIn component provides access to all of LinkedIn REST APIs documented at https://developer.linkedin.com/rest.

LinkedIn uses OAuth2.0 for all client application authentication. In order to use camel-linkedin with your account, you’ll need to create a new application for LinkedIn at https://www.linkedin.com/secure/developer. The LinkedIn application’s client id and secret will allow access to LinkedIn REST APIs which require a current user. A user access token is generated and managed by component for an end user. Alternatively the Camel application can register an implementation of org.apache.camel.component.linkedin.api.OAuthSecureStorage to provide an org.apache.camel.component.linkedin.api.OAuthToken OAuth token.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-linkedin</artifactId>
  <version>${camel-version}</version>
</dependency>
```

202.1. URI FORMAT

```linkedin://endpoint-prefix/endpoint?[options]```

Endpoint prefix can be one of:

- comments
- companies
- groups
- jobs
- people
- posts
- search

202.2. LINKEDINCOMPONENT

The Linkedin component supports 2 options, which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration (common)</td>
<td>To use the shared configuration</td>
<td></td>
<td>LinkedInConfiguration</td>
</tr>
</tbody>
</table>
Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

The Linkedin endpoint is configured using URI syntax:

```
linkedin:apiName/methodName
```

with the following path and query parameters:

### 202.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiName</td>
<td>Required What kind of operation to perform</td>
<td></td>
<td>LinkedInApiName</td>
</tr>
<tr>
<td>methodName</td>
<td>Required What sub operation to use for the selected operation</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 202.2.2. Query Parameters (16 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
</table>
LinkedIn access token to avoid username and password login procedure. LinkedIn responds to login forms by using a CAPTCHA. This makes it impossible for a standalone, headless process to log in to LinkedIn by specifying a username and password. To work around this, obtain a LinkedIn access token and provide the token as the setting of the accessToken parameter. Obtaining a LinkedIn access token is a multi-step procedure. You must configure your LinkedIn application, obtain a LinkedIn authorization code, and exchange that code for the LinkedIn access token. For details, see: https://developer.linkedin.com/docs/oauth2

The default behavior is that the access token expires after 60 days. To change this, specify a value for the expiryTime parameter. If the access token expires, the LinkedIn component tries to log in to LinkedIn by providing a username and password, which results in a CAPTCHA so the login fails. The LinkedIn component cannot refresh the access token. You must manually obtain a new access token each time an access token expires. When you update the access token you must restart the application so that it uses the new token.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessToken (common)</td>
<td>LinkedIn access token to avoid username and password login procedure. LinkedIn responds to login forms by using a CAPTCHA. This makes it impossible for a standalone, headless process to log in to LinkedIn by specifying a username and password. To work around this, obtain a LinkedIn access token and provide the token as the setting of the accessToken parameter. Obtaining a LinkedIn access token is a multi-step procedure. You must configure your LinkedIn application, obtain a LinkedIn authorization code, and exchange that code for the LinkedIn access token. For details, see: <a href="https://developer.linkedin.com/docs/oauth2">https://developer.linkedin.com/docs/oauth2</a> The default behavior is that the access token expires after 60 days. To change this, specify a value for the expiryTime parameter. If the access token expires, the LinkedIn component tries to log in to LinkedIn by providing a username and password, which results in a CAPTCHA so the login fails. When you update the access token you must restart the application so that it uses the new token.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientId (common)</td>
<td>LinkedIn application client ID</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientSecret (common)</td>
<td>LinkedIn application client secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>expiryTime (common)</td>
<td>A number of milliseconds since the UNIX Epoch. The default is 60 days. A LinkedIn access token expires when this amount of time elapses after the token is in use.</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>httpParams (common)</td>
<td>Custom HTTP parameters, for example, proxy host and port. Use constants from AllClientPNames.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>inBody (common)</td>
<td>Sets the name of a parameter to be passed in the exchange In Body</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>lazyAuth (common)</td>
<td>Flag to enable/disable lazy OAuth, default is true. When enabled, OAuth token retrieval or generation is not done until the first REST call.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### redirectUri (common)
Application redirect URI, although the component never redirects to this page to avoid having to have a functioning redirect server. For testing, one could use https://localhost.

- **Default**: None
- **Type**: String

### scopes (common)
List of LinkedIn scopes as specified at https://developer.linkedin.com/documents/authentication#granting.

- **Default**: None
- **Type**: OAuthScope[]

### secureStorage (common)
Callback interface for providing an OAuth token or to store the token generated by the component. The callback should return null on the first call and then save the created token in the saveToken() callback. If the callback returns null the first time, a userPassword MUST be provided.

- **Default**: None
- **Type**: OAuthSecureStorage

### userName (common)
LinkedIn user account name, MUST be provided

- **Default**: None
- **Type**: String

### userPassword (common)
LinkedIn account password

- **Default**: None
- **Type**: String

### bridgeErrorHandler (consumer)
Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.

- **Default**: false
- **Type**: boolean

### exceptionHandler (consumer)
To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.

- **Default**: None
- **Type**: ExceptionHandler

### exchangePattern (consumer)
Sets the exchange pattern when the consumer creates an exchange.

- **Default**: None
- **Type**: ExchangePattern

### synchronous (advanced)
Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).

- **Default**: false
- **Type**: boolean

### 202.3. SPRING BOOT AUTO-CONFIGURATION
The component supports 15 options, which are listed below.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>camel.component.linkedin.configuration.access-token</td>
<td>LinkedIn access token to avoid username and password login procedure. LinkedIn responds to login forms by using a CAPTCHA. <td>camel.component.linkedin.enabled</td>
<td>Enable linkedin component</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td>camel.component.linkedin.resolve-property-placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

202.4. PRODUCER ENDPOINTS:
Producer endpoints can use endpoint prefixes followed by endpoint names and associated options described next. A shorthand alias can be used for some endpoints. The endpoint URI MUST contain a prefix.

Endpoint options that are not mandatory are denoted by [ ]. When there are no mandatory options for an endpoint, one of the set of [ ] options MUST be provided. Producer endpoints can also use a special option inBody that in turn should contain the name of the endpoint option whose value will be contained in the Camel Exchange In message.

Any of the endpoint options can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format CamelLinkedIn.<option>. Note that the inBody option overrides message header, i.e. the endpoint option inBody=option would override a CamelLinkedIn.option header.

For more information on the endpoints and options see LinkedIn REST API documentation at https://developer.linkedin.com/rest.

202.4.1. Endpoint prefix comments

The following endpoints can be invoked with the prefix comments as follows:

 línedin://comments/endpoint?[options]

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Shorthand Alias</th>
<th>Options</th>
<th>Result Body Type</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

**URI Options for companies**

If a value is not provided for one of the option(s) [companySizes, count, email_domain, end_timestamp, event_type, geos, industries, is_company_admin, jobFunc, secure_urls, seniorities, start, start_timestamp, time_granularity] either in the endpoint URI or in a message header, it will be assumed to be null. Note that the null value(s) will only be used if other options do not satisfy matching endpoints.

<table>

</table>

### 202.4.3. Endpoint prefix groups

The following endpoints can be invoked with the prefix `groups` as follows:

```markdown
linkedin://groups/endpoint?[options]
```

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Shorthand Alias</th>
<th>Options</th>
<th>Result Body Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>addPost</td>
<td>post</td>
<td>group_id, post</td>
<td>org.apache.camel.component.linkedin.api.model.Group</td>
</tr>
<tr>
<td>getGroup</td>
<td>group</td>
<td>group_id</td>
<td></td>
</tr>
</tbody>
</table>

URI Options for `groups`
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_id</td>
<td>Long</td>
</tr>
<tr>
<td>post</td>
<td>org.apache.camel.component.linkedin.api.model.Post</td>
</tr>
</tbody>
</table>

### 202.4.4. Endpoint prefix jobs

The following endpoints can be invoked with the prefix `jobs` as follows:

```markdown
linkedin://jobs/endpoint?[options]
```

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Shorthand Alias</th>
<th>Options</th>
<th>Result Body Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>addJob</td>
<td>job</td>
<td>job</td>
<td></td>
</tr>
<tr>
<td>editJob</td>
<td>job, partner_job_id</td>
<td></td>
<td></td>
</tr>
<tr>
<td>getJob</td>
<td>job</td>
<td>fields, job_id</td>
<td>org.apache.camel.component.linkedin.api.model.Job</td>
</tr>
</tbody>
</table>

**URI Options for jobs**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
</tr>

</tbody>
</table>
202.4.6. Endpoint prefix posts

The following endpoints can be invoked with the prefix posts as follows:

```
linkedin://posts/endpoint?[options]
```

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Shorthand Alias</th>
<th>Options</th>
<th>Result Body Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>addComment</td>
<td>comment</td>
<td>comment, post_id</td>
<td></td>
</tr>
<tr>
<td>flagCategory</td>
<td></td>
<td>post_id, postcategorycode</td>
<td></td>
</tr>
<tr>
<td>followPost</td>
<td></td>
<td>isfollowing, post_id</td>
<td></td>
</tr>
<tr>
<td>getPost</td>
<td>post</td>
<td>count, fields, post_id, start</td>
<td></td>
</tr>
<tr>
<td>getPostComments</td>
<td>postComments</td>
<td>count, fields, post_id, start</td>
<td></td>
</tr>
<tr>
<td>likePost</td>
<td></td>
<td>isliked, post_id</td>
<td></td>
</tr>
<tr>
<td>removePost</td>
<td>post</td>
<td>post_id</td>
<td></td>
</tr>
</tbody>
</table>

URI Options for posts

If a value is not provided for one of the option(s) [count, start] either in the endpoint URI or in a message header, it will be assumed to be null. Note that the null value(s) will only be used if other options do not satisfy matching endpoints.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>comment</td>
<td>org.apache.camel.component.linkedin.api.model.Com ment</td>
</tr>
<tr>
<td>count</td>
<td>Long</td>
</tr>
<tr>
<td>fields</td>
<td>String</td>
</tr>
<tr>
<td>isfollowing</td>
<td>org.apache.camel.component.linkedin.api.model.IsFollowing</td>
</tr>
<tr>

<td>org.apache.camel.component.linkedin.api.model.IsLiked</td>
</tr>
</tbody>
</table>
### 202.4.7. Endpoint prefix search

The following endpoints can be invoked with the prefix `search` as follows:

```
linkedin://search/endpoint?[options]
```

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Shorthand Alias</th>
<th>Options</th>
<th>Result Body Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>searchCompanies</td>
<td>companies</td>
<td>count, facet, facets, fields, hq_only, keywords, sort, start</td>
<td>org.apache.camel.component.linkedin.api.model. CompanySearch</td>
</tr>
<tr>
<td>searchJobs</td>
<td>jobs</td>
<td>company_name, count, country_code, distance, facet, facets, fields, job_title, keywords, postal_code, sort, start</td>
<td>org.apache.camel.component.linkedin.api.model. JobSearch</td>
</tr>
<tr>
<td>searchPeople</td>
<td>people</td>
<td>company_name, count, country_code, current_company, current_school, current_title, distance, facet, facets, fields, first_name, keywords, last_name, postal_code, school_name, sort, start, title</td>
<td>org.apache.camel.component.linkedin.api.model. PeopleSearch</td>
</tr>
</tbody>
</table>

**URI Options for search**

If a value is not provided for one of the option(s) `[company_name, count, country_code, current_company, current_school, current_title, distance, facet, facets, first_name, hq_only, job_title, keywords, last_name, postal_code, school_name, sort, start, title]` either in the endpoint URI or in a message header, it will be assumed to be `null`. Note that the `null` value(s) will only be used if other options do not satisfy matching endpoints.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>Long</td>
</tr>
<tr>
<td>country_code</td>
<td>String</td>
</tr>
<tr>
<td>current_company</td>
<td>String</td>
</tr>
<tr>
<td>current_school</td>

<tr>
<td>postal_code</td>
<td>String</td>
</tr>
<tr>
<td>school_name</td>
<td>String</td>
</tr>
<tr>
<td>sort</td>
<td>String</td>
</tr>
<tr>
<td>start</td>
<td>Long</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
</tr>
</tbody>
</table>

### 202.5. CONSUMER ENDPOINTS

Any of the producer endpoints can be used as a consumer endpoint. Consumer endpoints can use [Scheduled Poll Consumer Options](#) with a `consumer` prefix to schedule endpoint invocation. By default Consumer endpoints that return an array or collection will generate one exchange per element,
and their routes will be executed once for each exchange. To change this behavior use the property `consumer.splitResults=true` to return a single exchange for the entire list or array.

### 202.6. MESSAGE HEADERS

Any URI option can be provided in a message header for producer endpoints with a `CamelLinkedIn` prefix.

### 202.7. MESSAGE BODY

All result message bodies utilize objects provided by the Camel LinkedIn API SDK, which is built using Apache CXF JAX-RS. Producer endpoints can specify the option name for incoming message body in the `inBody` endpoint parameter.

### 202.8. USE CASES

The following route gets user’s profile:

```java
from("direct:foo")
  .to("linkedin://people/person");
```

The following route polls user’s connections every 30 seconds:

```java
from("linkedin://people/connections?consumer.timeUnit=SECONDS&consumer.delay=30")
  .to("bean:foo");
```

The following route uses a producer with dynamic header options. The `personId` header has the LinkedIn person ID, so it’s assigned to the `CamelLinkedIn.person_id` header as follows:

```java
from("direct:foo")
  .setHeader("CamelLinkedIn.person_id", header("personId"))
  .to("linkedin://people/connectionsById")
  .to("bean://bar");
```
CHAPTER 203. LOG COMPONENT

Available as of Camel version 1.1

The log: component logs message exchanges to the underlying logging mechanism.

Camel uses sfl4j which allows you to configure logging via, among others:

- Log4j
- Logback
- Java Util Logging

203.1. URI FORMAT

log:loggingCategory[?options]

Where loggingCategory is the name of the logging category to use. You can append query options to the URI in the following format, ?option=value&option=value&...

INFO:*Using Logger instance from the the Registry* As of Camel 2.12.4/2.13.1, if there’s single instance of org.slf4j.Logger found in the Registry, the loggingCategory is no longer used to create logger instance. The registered instance is used instead. Also it is possible to reference particular Logger instance using ?logger=#myLogger URI parameter. Eventually, if there’s no registered and URI logger parameter, the logger instance is created using loggingCategory.

For example, a log endpoint typically specifies the logging level using the level option, as follows:

log:org.apache.camel.example?level=DEBUG

The default logger logs every exchange (regular logging). But Camel also ships with the Throughput logger, which is used whenever the groupSize option is specified.

TIP:*Also a log in the DSL* There is also a log directly in the DSL, but it has a different purpose. Its meant for lightweight and human logs. See more details at LogEIP.

203.2. OPTIONS

The Log component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>exchangeFormatter (advanced)</td>
<td>Sets a custom ExchangeFormatter to convert the Exchange to a String suitable for logging. If not specified, we default to DefaultExchangeFormatter.</td>
<td></td>
<td>ExchangeFormatter</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
The Log endpoint is configured using URI syntax:

`log:loggerName`

with the following path and query parameters:

### 203.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>loggerName</td>
<td>Required The logger name to use</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 203.2.2. Query Parameters (26 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupActiveOnly</td>
<td>If true, will hide stats when no new messages have been received for a time interval, if false, show stats regardless of message traffic.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td>groupDelay</td>
<td>Set the initial delay for stats (in millis)</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>groupInterval</td>
<td>If specified will group message stats by this time interval (in millis)</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>groupSize</td>
<td>An integer that specifies a group size for throughput logging.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>level</td>
<td>Logging level to use. The default value is INFO.</td>
<td>INFO</td>
<td>String</td>
</tr>
<tr>
<td>logMask</td>
<td>If true, mask sensitive information like password or passphrase in the log.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>marker</td>
<td>An optional Marker name to use.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>maxChars</td>
<td>Limits the number of characters logged per line.</td>
<td>10000</td>
<td>int</td>
</tr>
<tr>
<td>multiline</td>
<td>If enabled then each information is outputted on a newline.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>showAll (formatting)</td>
<td>Quick option for turning all options on. (multiline, maxChars has to be manually set if to be used)</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showBody (formatting)</td>
<td>Show the message body.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>showBodyType (formatting)</td>
<td>Show the body Java type.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>showCaughtException (formatting)</td>
<td>If the exchange has a caught exception, show the exception message (no stack trace). A caught exception is stored as a property on the exchange (using the key link org.apache.camel.ExchangeEXCEPTION_CAUGHT and for instance a doCatch can catch exceptions.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showException (formatting)</td>
<td>If the exchange has an exception, show the exception message (no stacktrace)</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showExchangeId (formatting)</td>
<td>Show the unique exchange ID.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showExchangePattern (formatting)</td>
<td>Shows the Message Exchange Pattern (or MEP for short).</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>showFiles (formatting)</td>
<td>If enabled Camel will output files</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showFuture (formatting)</td>
<td>If enabled Camel will on Future objects wait for it to complete to obtain the payload to be logged.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showHeaders (formatting)</td>
<td>Show the message headers.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showOut (formatting)</td>
<td>If the exchange has an out message, show the out message.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showProperties (formatting)</td>
<td>Show the exchange properties.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>showStackTrace (formatting)</td>
<td>Show the stack trace, if an exchange has an exception. Only effective if one of showAll, showException or showCaughtException are enabled.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### 203.3. REGULAR LOGGER SAMPLE

In the route below we log the incoming orders at **DEBUG** level before the order is processed:

```xml
<route>
    <from uri="activemq:orders"/>
    <to uri="log:com.mycompany.order?level=DEBUG"/>
    <to uri="bean:processOrder"/>
</route>
```

Or using Spring XML to define the route:

```xml
from("activemq:orders").to("log:com.mycompany.order?level=DEBUG").to("bean:processOrder");
```

### 203.4. REGULAR LOGGER WITH FORMATTER SAMPLE

In the route below we log the incoming orders at **INFO** level before the order is processed.

```xml
from("activemq:orders").
    to("log:com.mycompany.order?showAll=true&multiline=true").to("bean:processOrder");
```

### 203.5. THROUGHPUT LOGGER WITH GROUPSIZE SAMPLE

In the route below we log the throughput of the incoming orders at **DEBUG** level grouped by 10 messages.

```xml
from("activemq:orders").
    to("log:com.mycompany.order?level=DEBUG&groupSize=10").to("bean:processOrder");
```

### 203.6. THROUGHPUT LOGGER WITH GROUPINTERVAL SAMPLE
This route will result in message stats logged every 10s, with an initial 60s delay and stats should be displayed even if there isn’t any message traffic.

```java
from("activemq:orders").
to("log:com.mycompany.order?level=DEBUG&groupInterval=10000&groupDelay=60000&groupActiveOnly=false").to("bean:process Order");
```

The following will be logged:

```
"Received: 1000 new messages, with total 2000 so far. Last group took: 10000 millis which is: 100 messages per second. average: 100"
```

### 203.7. MASKING SENSITIVE INFORMATION LIKE PASSWORD

**Available as of Camel 2.19**

You can enable security masking for logging by setting `logMask` flag to `true`. Note that this option also affects Log EIP.

To enable mask in Java DSL at CamelContext level:

```java
camelContext.setLogMask(true);
```

And in XML:

```xml
<camelContext logMask="true"/>
```

You can also turn it on|off at endpoint level. To enable mask in Java DSL at endpoint level, add `logMask=true` option in the URI for the log endpoint:

```java
from("direct:start").to("log:foo?logMask=true");
```

And in XML:

```xml
<from url="direct:foo"/>
<to url="log:foo?logMask=true"/>
```

`org.apache.camel.processor.DefaultMaskingFormatter` is used for the masking by default. If you want to use a custom masking formatter, put it into registry with the name `CamelCustomLogMask`. Note that the masking formatter must implement `org.apache.camel.spi.MaskingFormatter`.

### 203.8. FULL CUSTOMIZATION OF THE LOGGING OUTPUT

**Available as of Camel 2.11**

With the options outlined in the `#Formatting` section, you can control much of the output of the logger. However, log lines will always follow this structure:

```
Exchange[Id:ID-machine-local-50656-1234567901234-1-2, ExchangePattern:InOut,
```

---

**CHAPTER 203. LOG COMPONENT**

1323
This format is unsuitable in some cases, perhaps because you need to...

- ... filter the headers and properties that are printed, to strike a balance between insight and verbosity.
- ... adjust the log message to whatever you deem most readable.
- ... tailor log messages for digestion by log mining systems, e.g. Splunk.
- ... print specific body types differently.
- ... etc.

Whenever you require absolute customization, you can create a class that implements the ExchangeFormatter interface. Within the format(Exchange) method you have access to the full Exchange, so you can select and extract the precise information you need, format it in a custom manner and return it. The return value will become the final log message.

You can have the Log component pick up your custom ExchangeFormatter in either of two ways:

Explicitly instantiating the LogComponent in your Registry:

```xml
<bean name="log" class="org.apache.camel.component.log.LogComponent">
    <property name="exchangeFormatter" ref="myCustomFormatter"/>
</bean>
```

203.8.1. Convention over configuration:*

Simply by registering a bean with the name logFormatter; the Log Component is intelligent enough to pick it up automatically.

```xml
<bean name="logFormatter" class="com.xyz.MyCustomExchangeFormatter"/>
```

**(NOTE)**

the ExchangeFormatter gets applied to all Log endpoints within that Camel Context. If you need different ExchangeFormatters for different endpoints, just instantiate the LogComponent as many times as needed, and use the relevant bean name as the endpoint prefix.

From Camel 2.11.2/2.12 onwards when using a custom log formatter, you can specify parameters in the log uri, which gets configured on the custom log formatter. Though when you do that you should define the "logFormatter" as prototype scoped so its not shared if you have different parameters, eg:

```xml
<bean name="logFormatter" class="com.xyz.MyCustomExchangeFormatter" scope="prototype"/>
```

And then we can have Camel routes using the log uri with different options:
203.9. USING LOG COMPONENT IN OSGI

Improvement as of Camel 2.12.4/2.13.1

When using Log component inside OSGi (e.g., in Karaf), the underlying logging mechanisms are provided by PAX logging. It searches for a bundle which invokes `org.slf4j.LoggerFactory.getLogger()` method and associates the bundle with the logger instance. Without specifying custom `org.slf4j.Logger` instance, the logger created by Log component is associated with `camel-core` bundle.

In some scenarios it is required that the bundle associated with logger should be the bundle which contains route definition. To do this, either register single instance of `org.slf4j.Logger` in the Registry or reference it using `logger` URI parameter.

203.10. SEE ALSO

- LogEIP for using log directly in the DSL for human logs.
CHAPTER 204. LUCENE COMPONENT

Available as of Camel version 2.2

The lucene component is based on the Apache Lucene project. Apache Lucene is a powerful high-performance, full-featured text search engine library written entirely in Java. For more details about Lucene, please see the following links

- http://lucene.apache.org/java/docs/
- http://lucene.apache.org/java/docs/features.html

The lucene component in camel facilitates integration and utilization of Lucene endpoints in enterprise integration patterns and scenarios. The lucene component does the following

- builds a searchable index of documents when payloads are sent to the Lucene Endpoint
- facilitates performing of indexed searches in Camel

This component only supports producer endpoints.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-lucene</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

204.1. URI FORMAT

```
lucene:searcherName:insert[?options]
lucene:searcherName:query[?options]
```

You can append query options to the URI in the following format, `?option=value&option=value&…`

204.2. INSERT OPTIONS

The Lucene component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>config (advanced)</td>
<td>To use a shared lucene configuration</td>
<td></td>
<td>LuceneConfiguration</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
The Lucene endpoint is configured using URI syntax:

```
lucene:host:operation
```

with the following path and query parameters:

### 204.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required The URL to the lucene server</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>operation</td>
<td>Operation to do such as insert or query.</td>
<td></td>
<td>LuceneOperation</td>
</tr>
</tbody>
</table>

### 204.2.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>analyzer (producer)</td>
<td>An Analyzer builds TokenStreams, which analyze text. It thus represents a policy for extracting index terms from text. The value for analyzer can be any class that extends the abstract class org.apache.lucene.analysis.Analyzer. Lucene also offers a rich set of analyzers out of the box</td>
<td></td>
<td>Analyzer</td>
</tr>
<tr>
<td>indexDir (producer)</td>
<td>A file system directory in which index files are created upon analysis of the document by the specified analyzer</td>
<td></td>
<td>File</td>
</tr>
<tr>
<td>maxHits (producer)</td>
<td>An integer value that limits the result set of the search operation</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>srcDir (producer)</td>
<td>An optional directory containing files to be used to be analyzed and added to the index at producer startup.</td>
<td></td>
<td>File</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 204.3. SENDING/RECEIVING MESSAGES TO/FROM THE CACHE

#### 204.3.1. Message Headers
<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY</td>
<td>The Lucene Query to performed on the index. The query may include wildcards and phrases</td>
</tr>
<tr>
<td>RETURN_LUCENE_DOCS</td>
<td>Camel 2.15: Set this header to true to include the actual Lucene documentation when returning hit information.</td>
</tr>
</tbody>
</table>

204.3.2. Lucene Producers

This component supports 2 producer endpoints.

- **insert** - The insert producer builds a searchable index by analyzing the body in incoming exchanges and associating it with a token (“content”).
- **query** - The query producer performs searches on a pre-created index. The query uses the searchable index to perform score & relevance based searches. Queries are sent via the incoming exchange contains a header property name called ‘QUERY’. The value of the header property ‘QUERY’ is a Lucene Query. For more details on how to create Lucene Queries check out [http://lucene.apache.org/java/3_0_0/queryparsersyntax.html](http://lucene.apache.org/java/3_0_0/queryparsersyntax.html)

204.3.3. Lucene Processor

There is a processor called LuceneQueryProcessor available to perform queries against lucene without the need to create a producer.

204.4. LUCENE USAGE SAMPLES

204.4.1. Example 1: Creating a Lucene index

```java
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("direct:start").
            to("lucene:whitespaceQuotesIndex:insert?analyzer=#whitespaceAnalyzer&indexDir=#whitespace&srcDir=#load_dir").
            to("mock:result");
    }
};
```

204.4.2. Example 2: Loading properties into the JNDI registry in the Camel Context

```java
@Override
protected JndiRegistry createRegistry() throws Exception {
    JndiRegistry registry =
        new JndiRegistry(createJndiContext());
    registry.bind("whitespace", new File("./whitespaceIndexDir"));
    registry.bind("load_dir",
        new File("src/test/resources/sources"));
    registry.bind("whitespaceAnalyzer",
```
new WhitespaceAnalyzer();
return registry;
}
...  
CamelContext context = new DefaultCamelContext(createRegistry());

204.4.3. Example 2: Performing searches using a Query Producer

RouteBuilder builder = new RouteBuilder() {
public void configure() {
    from("direct:start").
        setHeader("QUERY", constant("Seinfeld")).
            to("lucene:searchIndex:query?
                analyzer=#whitespaceAnalyzer&indexDir=#whitespace&maxHits=20").
                    to("direct:next");

    from("direct:next").process(new Processor() {
        public void process(Exchange exchange) throws Exception {
            Hits hits = exchange.getIn().getBody(Hits.class);
            printResults(hits);
        }
    }); 
}

private void printResults(Hits hits) {
    LOG.debug("Number of hits: " + hits.getNumberOfHits());
    for (int i = 0; i < hits.getNumberOfHits(); i++) {
        LOG.debug("Hit " + i + " Index Location:" + hits.getHit().get(i).getHitLocation());
        LOG.debug("Hit " + i + " Score:" + hits.getHit().get(i).getScore());
        LOG.debug("Hit " + i + " Data:" + hits.getHit().get(i).getData());
    }
});

204.4.4. Example 3: Performing searches using a Query Processor

RouteBuilder builder = new RouteBuilder() {
public void configure() {
    try {
        from("direct:start").
            setHeader("QUERY", constant("Rodney Dangerfield")).
                process(new LuceneQueryProcessor("target/stdindexDir", analyzer, null, 20)).
                    to("direct:next");
    } catch (Exception e) {
        e.printStackTrace();
    }

    from("direct:next").process(new Processor() {
        public void process(Exchange exchange) throws Exception {
            Hits hits = exchange.getIn().getBody(Hits.class);
            printResults(hits);
        }
    });

private void printResults(Hits hits) {

LOG.debug("Number of hits: " + hits.getNumberOfHits());
for (int i = 0; i < hits.getNumberOfHits(); i++) {
    LOG.debug("Hit " + i + " Index Location:" + hits.getHit().get(i).getHitLocation());
    LOG.debug("Hit " + i + " Score:" + hits.getHit().get(i).getScore());
    LOG.debug("Hit " + i + " Data:" + hits.getHit().get(i).getData());
}
}.to("mock:searchResult");
CHAPTER 205. LUMBERJACK COMPONENT

Available as of Camel version 2.18

The Lumberjack component retrieves logs sent over the network using the Lumberjack protocol, from Filebeat for instance. The network communication can be secured with SSL.

This component only supports consumer endpoints.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-lumberjack</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

205.1. URI FORMAT

```
lumberjack:host
lumberjack:host:port
```

You can append query options to the URI in the following format, `?option=value&option=value&…`

205.2. OPTIONS

The Lumberjack component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>sslContextParameters (security)</td>
<td>Sets the default SSL configuration to use for all the endpoints. You can also configure it directly at the endpoint level.</td>
<td></td>
<td>SSLContextParameters</td>
</tr>
<tr>
<td>useGlobalSslContextParameters (security)</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Lumberjack endpoint is configured using URI syntax:

```
lumberjack:host:port
```

with the following path and query parameters:
205.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required Network interface on which to listen for Lumberjack</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>Network port on which to listen for Lumberjack</td>
<td>5044</td>
<td>int</td>
</tr>
</tbody>
</table>

205.2.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sslContextParameters (consumer)</td>
<td>SSL configuration</td>
<td></td>
<td>SSLContextParameters</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

205.3. RESULT

The result body is a `Map<String, Object>` object.

205.4. LUMBERJACK USAGE SAMPLES

205.4.1. Example 1: Streaming the log messages

-
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("lumberjack:0.0.0.0"). // Listen on all network interfaces using the default port
            setBody(simple("${body[message]}")). // Select only the log message
            to("stream:out"); // Write it into the output stream
    }
};
CHAPTER 206. LZF DEFLATE COMPRESSION DATAFORMAT

Available as of Camel version 2.17

The LZF Data Format is a message compression and de-compression format. It uses the LZF deflate algorithm. Messages marshalled using LZF compression can be unmarshalled using LZF decompression just prior to being consumed at the endpoint. The compression capability is quite useful when you deal with large XML and Text based payloads or when you read messages previously compressed using LZF algorithm.

206.1. OPTIONS

The LZF Deflate Compression dataformat supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usingParallelCompression</td>
<td>false</td>
<td>Boolean</td>
<td>Enable encoding (compress) using multiple processing cores.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

206.2. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload employing LZF compression format and send it an ActiveMQ queue called MY_QUEUE.

```
from("direct:start").marshal().lzf().to("activemq:queue:MY_QUEUE");
```

206.3. UNMARSHAL

In this example we unmarshal a LZF payload from an ActiveMQ queue called MY_QUEUE to its original format, and forward it for processing to the UnGZippedMessageProcessor.

```
from("activemq:queue:MY_QUEUE").unmarshal().lzf().process(new UnCompressedMessageProcessor());
```

206.4. DEPENDENCIES

To use LZF compression in your camel routes you need to add a dependency on camel-lzf which implements this data format.

If you use Maven you can just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
```
<groupId>org.apache.camel</groupId>
<artifactId>camel-lzf</artifactId>
<version>x.x.x</version>

<!-- use the same version as your Camel core version -->
</dependency>
CHAPTER 207. MAIL COMPONENT

Available as of Camel version 1.0

The mail component provides access to Email via Spring’s Mail support and the underlying JavaMail system.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mail</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

WARNING

Geronimo mail .jar

We have discovered that the geronimo mail .jar (v1.6) has a bug when polling mails with attachments. It cannot correctly identify the Content-Type. So, if you attach a .jpeg file to a mail and you poll it, the Content-Type is resolved as text/plain and not as image/jpeg. For that reason, we have added an org.apache.camel.component.ContentTypeResolver SPI interface which enables you to provide your own implementation and fix this bug by returning the correct Mime type based on the file name. So if the file name ends with jpeg/jpg, you can return image/jpeg.

You can set your custom resolver on the MailComponent instance or on the MailEndpoint instance.

TIP

POP3 or IMAP POP3 has some limitations and end users are encouraged to use IMAP if possible.

INFO: Using mock-mail for testing You can use a mock framework for unit testing, which allows you to test without the need for a real mail server. However you should remember to not include the mock-mail when you go into production or other environments where you need to send mails to a real mail server. Just the presence of the mock-javamail.jar on the classpath means that it will kick in and avoid sending the mails.

207.1. URI FORMAT

Mail endpoints can have one of the following URI formats (for the protocols, SMTP, POP3, or IMAP, respectively):

- smtp://[username@]host[:port]?options
- pop3://[username@]host[:port]?options
- imap://[username@]host[:port]?options
The mail component also supports secure variants of these protocols (layered over SSL). You can enable the secure protocols by adding `s` to the scheme:

```
smtps://[username@[host[:port]]?options]
pop3s://[username@[host[:port]]?options]
imaps://[username@[host[:port]]?options]
```

You can append query options to the URI in the following format, `?option=value&option=value&...`

### 207.2.

The Mail component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>Sets the Mail configuration</td>
<td></td>
<td>MailConfiguration</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>contentTypeResolver</td>
<td>Resolver to determine Content-Type for file attachments.</td>
<td></td>
<td>ContentTypeResolver</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>useGlobalSslContextParameters</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>(security)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 207.3.

The Mail endpoint is configured using URI syntax:

```
imap:host:port
```

with the following path and query parameters:

#### 207.3.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td><strong>Required</strong> The mail server host name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>The port number of the mail server</td>
<td></td>
<td>int</td>
</tr>
</tbody>
</table>
### 207.3.2. Query Parameters (62 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>closeFolder</td>
<td>Whether the consumer should close the folder after polling. Setting this option to false and having disconnect=false as well, then the consumer keep the folder open between polls.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>copyTo</td>
<td>After processing a mail message, it can be copied to a mail folder with the given name. You can override this configuration value, with a header with the key copyTo, allowing you to copy messages to folder names configured at runtime.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>delete</td>
<td>Deletes the messages after they have been processed. This is done by setting the DELETED flag on the mail message. If false, the SEEN flag is set instead. As of Camel 2.10 you can override this configuration option by setting a header with the key delete to determine if the mail should be deleted or not.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>disconnect</td>
<td>Whether the consumer should disconnect after polling. If enabled this forces Camel to connect on each poll.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>handleFailedMessage</td>
<td>If the mail consumer cannot retrieve a given mail message, then this option allows to handle the caused exception by the consumer’s error handler. By enable the bridge error handler on the consumer, then the Camel routing error handler can handle the exception instead. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>maxMessagesPerPoll</td>
<td>Specifies the maximum number of messages to gather per poll. By default, no maximum is set. Can be used to set a limit of e.g. 1000 to avoid downloading thousands of files when the server starts up. Set a value of 0 or negative to disable this option.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------</td>
</tr>
<tr>
<td>mimeDecodeHeaders (consumer)</td>
<td>This option enables transparent MIME decoding and unfolding for mail headers.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>peek (consumer)</td>
<td>Will mark the javax.mail.Message as peeked before processing the mail message. This applies to IMAPMessage messages types only. By using peek the mail will not be eager marked as SEEN on the mail server, which allows us to rollback the mail message if there is an error processing in Camel.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>skipFailedMessage (consumer)</td>
<td>If the mail consumer cannot retrieve a given mail message, then this option allows to skip the message and move on to retrieve the next mail message. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>unseen (consumer)</td>
<td>Whether to limit by unseen mails only.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>fetchSize (consumer)</td>
<td>Sets the maximum number of messages to consume during a poll. This can be used to avoid overloading a mail server, if a mailbox folder contains a lot of messages. Default value of -1 means no fetch size and all messages will be consumed. Setting the value to 0 is a special corner case, where Camel will not consume any messages at all.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>folderName (consumer)</td>
<td>The folder to poll.</td>
<td>INBOX</td>
<td>String</td>
</tr>
<tr>
<td>mailUidGenerator (consumer)</td>
<td>A pluggable MailUidGenerator that allows to use custom logic to generate UUID of the mail message.</td>
<td></td>
<td>MailUidGenerator</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>mapMailMessage (consumer)</td>
<td>Specifies whether Camel should map the received mail message to Camel body/headers. If set to true, the body of the mail message is mapped to the body of the Camel IN message and the mail headers are mapped to IN headers. If this option is set to false then the IN message contains a raw javax.mail.Message. You can retrieve this raw message by calling exchange.getIn().getBody(javax.mail.Message.class).</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>pollStrategy (consumer)</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td>postProcessAction (consumer)</td>
<td>Refers to an MailBoxPostProcessAction for doing post processing tasks on the mailbox once the normal processing ended.</td>
<td></td>
<td>MailBoxPostProcessAction</td>
</tr>
<tr>
<td>bcc (producer)</td>
<td>Sets the BCC email address. Separate multiple email addresses with comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>cc (producer)</td>
<td>Sets the CC email address. Separate multiple email addresses with comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>from (producer)</td>
<td>The from email address</td>
<td></td>
<td>camel@localhost</td>
</tr>
<tr>
<td>replyTo (producer)</td>
<td>The Reply-To recipients (the receivers of the response mail). Separate multiple email addresses with a comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>subject (producer)</td>
<td>The Subject of the message being sent. Note: Setting the subject in the header takes precedence over this option.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>to (producer)</td>
<td>Sets the To email address. Separate multiple email addresses with comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>javaMailSender (producer)</td>
<td>To use a custom org.apache.camel.component.mail.JavaMailSender for sending emails.</td>
<td></td>
<td>JavaMailSender</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td>additionalJavaMailProperties</td>
<td>Sets additional java mail properties, that will append/override any default properties that is set based on all the other options. This is useful if you need to add some special options but want to keep the others as is.</td>
<td></td>
<td>Properties</td>
</tr>
<tr>
<td>alternativeBodyHeader</td>
<td>Specifies the key to an IN message header that contains an alternative email body. For example, if you send emails in text/html format and want to provide an alternative mail body for non-HTML email clients, set the alternative mail body with this key as a header.</td>
<td></td>
<td>CamelMailAlternativeBody String</td>
</tr>
<tr>
<td>attachmentsContentTransferEncodingResolver</td>
<td>To use a custom AttachmentsContentTransferEncodingResolver to resolve what content-type-encoding to use for attachments.</td>
<td></td>
<td>AttachmentsContentTransferEncodingResolver</td>
</tr>
<tr>
<td>binding</td>
<td>Sets the binding used to convert from a Camel message to and from a Mail message</td>
<td></td>
<td>MailBinding</td>
</tr>
<tr>
<td>connectionTimeout</td>
<td>The connection timeout in milliseconds.</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td>contentType</td>
<td>The mail message content type. Use text/html for HTML mails.</td>
<td>text/plain</td>
<td>String</td>
</tr>
<tr>
<td>contentTypeResolver</td>
<td>Resolver to determine Content-Type for file attachments.</td>
<td></td>
<td>ContentTyp Resolver</td>
</tr>
<tr>
<td>debugMode</td>
<td>Enable debug mode on the underlying mail framework. The SUN Mail framework logs the debug messages to System.out by default.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>headerFilterStrategy</td>
<td>To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>ignoreUnsupportedCharset</td>
<td>Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>

</tr>
</tbody>
</table>

### 207.3.3. Sample endpoints

Typically, you specify a URI with login credentials as follows (taking SMTP as an example):

```
smtp://[username[@]host[:port]]?password=somepwd
```

Alternatively, it is possible to specify both the user name and the password as query options:

```
smtp://host[:port]?password=somepwd&username=someuser
```

For example:

```
smtp://mycompany.mailserver:30?password=tiger&username=scott
```

### 207.4. COMPONENTS

- IMAP
- IMAPs
- POP3s
- POP3s
- SMTP
- SMTPs

#### 207.4.1. Default ports
Default port numbers are supported. If the port number is omitted, Camel determines the port number to use based on the protocol.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Default Port Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMTP</td>
<td>25</td>
</tr>
<tr>
<td>SMTPS</td>
<td>465</td>
</tr>
<tr>
<td>POP3</td>
<td>110</td>
</tr>
<tr>
<td>POP3S</td>
<td>995</td>
</tr>
<tr>
<td>IMAP</td>
<td>143</td>
</tr>
<tr>
<td>IMAPS</td>
<td>993</td>
</tr>
</tbody>
</table>

### 207.5. SSL SUPPORT

The underlying mail framework is responsible for providing SSL support. You may either configure SSL/TLS support by completely specifying the necessary Java Mail API configuration options, or you may provide a configured SSLContextParameters through the component or endpoint configuration.

#### 207.5.1. Using the JSSE Configuration Utility

As of Camel 2.10, the mail component supports SSL/TLS configuration through the Camel JSSE Configuration Utility. This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the mail component.

**Programmatic configuration of the endpoint**

```java
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/truststore.jks");
ksp.setPassword("keystorePassword");
TrustManagersParameters tmp = new TrustManagersParameters();
tmp.setKeyStore(ksp);
SSLContextParameters scp = new SSLContextParameters();
scp.setTrustManagers(tmp);
Registry registry = ...
registry.bind("sslContextParameters", scp);
...
from(...)

&amp;nbsp; &amp;nbsp; .to("smtps://smtp.google.com?
username=user@gmail.com&amp;password=password&amp;sslContextParameters=#sslContextParameters");
```

**Spring DSL based configuration of endpoint**

```java
from(...)

&emsp; .to("smtps://smtp.google.com?
username=user@gmail.com&amp;password=password&amp;sslContextParameters=#sslContextParameters");
```
207.5.2. Configuring JavaMail Directly

Camel uses SUN JavaMail, which only trusts certificates issued by well known Certificate Authorities (the default JVM trust configuration). If you issue your own certificates, you have to import the CA certificates into the JVM’s Java trust/key store files, override the default JVM trust/key store files (see SSLNOTES.txt in JavaMail for details).

207.6. MAIL MESSAGE CONTENT

Camel uses the message exchange’s IN body as the MimeMessage text content. The body is converted to String.class.

Camel copies all of the exchange’s IN headers to the MimeMessage headers.

The subject of the MimeMessage can be configured using a header property on the IN message. The code below demonstrates this:

The same applies for other MimeMessage headers such as recipients, so you can use a header property as To:

Since Camel 2.11 When using the MailProducer the send the mail to server, you should be able to get the message id of the MimeMessage with the key CamelMailMessageId from the Camel message header.

207.7. HEADERS TAKE PRECEDENCE OVER PRE-CONFIGURED RECIPIENTS

The recipients specified in the message headers always take precedence over recipients pre-configured in the endpoint URI. The idea is that if you provide any recipients in the message headers, that is what you get. The recipients pre-configured in the endpoint URI are treated as a fallback.

In the sample code below, the email message is sent to davsclaus@apache.org, because it takes precedence over the pre-configured recipient, info@mycompany.com. Any CC and BCC settings in the endpoint URI are also ignored and those recipients will not receive any mail. The choice between headers and pre-configured settings is all or nothing: the mail component either takes the recipients exclusively from the headers or exclusively from the pre-configured settings. It is not possible to mix and match headers and pre-configured settings.

```java
Map<String, Object> headers = new HashMap<String, Object>();
headers.put("to", "davsclaus@apache.org");

template.sendBodyAndHeaders("smtp://admin@localhost?to=info@mycompany.com", "Hello World", headers);
```
207.8. MULTIPLE RECIPIENTS FOR EASIER CONFIGURATION

It is possible to set multiple recipients using a comma-separated or a semicolon-separated list. This applies both to header settings and to settings in an endpoint URI. For example:

```java
Map<String, Object> headers = new HashMap<String, Object>();
hdrers.put("to", "davsclaus@apache.org ; jstrachan@apache.org ; ningjiang@apache.org");
```

The preceding example uses a semicolon, ;, as the separator character.

207.9. SETTING SENDER NAME AND EMAIL

You can specify recipients in the format, name <email>, to include both the name and the email address of the recipient.

For example, you define the following headers on the a Message:

```java
Map headers = new HashMap();
headers.put("To", "Claus Ibsen <davsclaus@apache.org>");
headers.put("From", "James Strachan <jstrachan@apache.org>");
headers.put("Subject", "Camel is cool");
```

207.10. JAVAMAIL API (EX SUN JAVAMAIL)

JavaMail API is used under the hood for consuming and producing mails. We encourage end-users to consult these references when using either POP3 or IMAP protocol. Note particularly that POP3 has a much more limited set of features than IMAP.

- JavaMail POP3 API
- JavaMail IMAP API
- And generally about the MAIL Flags

207.11. SAMPLES

We start with a simple route that sends the messages received from a JMS queue as emails. The email account is the admin account on mymailserver.com.

```java
from("jms://queue:subscription").to("smtp://admin@mymailserver.com?password=secret");
```

In the next sample, we poll a mailbox for new emails once every minute. Notice that we use the special consumer option for setting the poll interval, consumer.delay, as 60000 milliseconds = 60 seconds.

```java
from("imap://admin@mymailserver.com
        password=secret&unseen=true&consumer.delay=60000")
    .to("seda://mails");
```

In this sample we want to send a mail to multiple recipients:

207.12. SENDING MAIL WITH ATTACHMENT SAMPLE
ATTACHMENTS ARE NOT SUPPORTED BY ALL CAMEL COMPONENTS

The Attachments API is based on the Java Activation Framework and is generally only used by the Mail API. Since many of the other Camel components do not support attachments, the attachments could potentially be lost as they propagate along the route. The rule of thumb, therefore, is to add attachments just before sending a message to the mail endpoint.

The mail component supports attachments. In the sample below, we send a mail message containing a plain text message with a logo file attachment.

207.13. SSL SAMPLE

In this sample, we want to poll our Google mail inbox for mails. To download mail onto a local mail client, Google mail requires you to enable and configure SSL. This is done by logging into your Google mail account and changing your settings to allow IMAP access. Google have extensive documentation on how to do this.

```
from("imaps://imap.gmail.com?
    username=YOUR_USERNAME@gmail.com&password=YOUR_PASSWORD"
    + "&delete=false&unseen=true&consumer.delay=60000").to("log:newmail");
```

The preceding route polls the Google mail inbox for new mails once every minute and logs the received messages to the newmail logger category.

Running the sample with DEBUG logging enabled, we can monitor the progress in the logs:

```
2008-05-08 06:32:09,640 DEBUG MailConsumer - Connecting to MailStore
    imaps://imap.gmail.com:993 (SSL enabled), folder=INBOX
    (SSL enabled), folder=INBOX
2008-05-08 06:32:11,640 DEBUG MailConsumer - Fetching 1 messages. Total 1 messages.
2008-05-08 06:32:12,171 DEBUG MailConsumer - Processing message: messageNumber=[332],
    from=[James Bond <007@mi5.co.uk>], to=YOUR_USERNAME@gmail.com, subject=[...
2008-05-08 06:32:12,187 INFO  newmail - Exchange[MailMessage: messageNumber=[332], from=[James Bond <007@mi5.co.uk>], to=YOUR_USERNAME@gmail.com, subject=[...
```

207.14. CONSUMING MAILS WITH ATTACHMENT SAMPLE

In this sample we poll a mailbox and store all attachments from the mails as files. First, we define a route to poll the mailbox. As this sample is based on google mail, it uses the same route as shown in the SSL sample:

```
from("imaps://imap.gmail.com?
    username=YOUR_USERNAME@gmail.com&password=YOUR_PASSWORD"
    + "&delete=false&unseen=true&consumer.delay=60000").process(new MyMailProcessor());
```

Instead of logging the mail we use a processor where we can process the mail from java code:
public void process(Exchange exchange) throws Exception {
    // the API is a bit clunky so we need to loop
    Map<String, DataHandler> attachments = exchange.getIn().getAttachments();
    if (attachments.size() > 0) {
        for (String name : attachments.keySet()) {
            DataHandler dh = attachments.get(name);
            // get the file name
            String filename = dh.getName();

            // get the content and convert it to byte[]
            byte[] data = exchange.getContext().getTypeConverter() // convertTo(byte[].class, dh.getInputStream());

            // write the data to a file
            FileOutputStream out = new FileOutputStream(filename);
            out.write(data);
            out.flush();
            out.close();
        }
    }
}

As you can see the API to handle attachments is a bit clunky but it’s there so you can get the javax.activation.DataHandler so you can handle the attachments using standard API.

207.15. HOW TO SPLIT A MAIL MESSAGE WITH ATTACHMENTS

In this example we consume mail messages which may have a number of attachments. What we want to do is to use the Splitter EIP per individual attachment, to process the attachments separately. For example if the mail message has 5 attachments, we want the Splitter to process five messages, each having a single attachment. To do this we need to provide a custom Expression to the Splitter where we provide a List<Message> that contains the five messages with the single attachment.

The code is provided out of the box in Camel 2.10 onwards in the camel-mail component. The code is in the class: org.apache.camel.component.mail.SplitAttachmentsExpression, which you can find the source code here

In the Camel route you then need to use this Expression in the route as shown below:

If you use XML DSL then you need to declare a method call expression in the Splitter as shown below

```
<split>
  <method beanType="org.apache.camel.component.mail.SplitAttachmentsExpression"/>
  <to uri="mock:split"/>
</split>
```

From Camel 2.16 onwards you can also split the attachments as byte[] to be stored as the message body. This is done by creating the expression with boolean true

```
SplitAttachmentsExpression split = SplitAttachmentsExpression(true);
```

And then use the expression with the splitter eip.
207.16. USING CUSTOM SEARCHTERM

Available as of Camel 2.11

You can configure a `searchTerm` on the `MailEndpoint` which allows you to filter out unwanted mails.

For example to filter mails to contain Camel in either Subject or Text you can do as follows:

```
<route>
  <from uri="imaps://mymailseerver?username=foo&password=secret&searchTerm.subjectOrBody=Camel"/>
  <to uri="bean:myBean"/>
</route>
```

Notice we use the `"searchTerm.subjectOrBody"` as parameter key to indicate that we want to search on mail subject or body, to contain the word "Camel".

The class `org.apache.camel.component.mail.SimpleSearchTerm` has a number of options you can configure:

Or to get the new unseen emails going 24 hours back in time you can do. Notice the "now-24h" syntax. See the table below for more details.

```
<route>
  <from uri="imaps://mymailseerver?username=foo&password=secret&searchTerm.fromSentDate=now-24h"/>
  <to uri="bean:myBean"/>
</route>
```

You can have multiple `searchTerm` in the endpoint uri configuration. They would then be combined together using AND operator, eg so both conditions must match. For example to get the last unseen emails going back 24 hours which has Camel in the mail subject you can do:

```
<route>
  <from uri="imaps://mymailseerver?username=foo&password=secret&searchTerm.subject=Camel&searchTerm.fromSentDate=now-24h"/>
  <to uri="bean:myBean"/>
</route>
```

The `SimpleSearchTerm` is designed to be easily configurable from a POJO, so you can also configure it using a `<bean>` style in XML:

```
<bean id="mySearchTerm" class="org.apache.camel.component.mail.SimpleSearchTerm">
  <property name="subject" value="Order"/>
  <property name="to" value="acme-order@acme.com"/>
  <property name="fromSentDate" value="now"/>
</bean>
```

You can then refer to this bean, using `#beanId` in your Camel route as shown:

```
<route>
  <from uri="imaps://mymailseerver?username=foo&password=secret&searchTerm=#mySearchTerm"/>
</route>
```
In Java there is a builder class to build compound SearchTerms using the
org.apache.camel.component.mail.SearchTermBuilder class. This allows you to build complex terms
such as:

```java
// we just want the unseen mails which is not spam
SearchTermBuilder builder = new SearchTermBuilder();

builder.unseen().body(Op.not, "Spam").subject(Op.not, "Spam")
    .from("foo@somewhere.com").from(Op.or, "bar@somewhere.com");

// .. and we could continue building the terms

SearchTerm term = builder.build();
```

### 207.17. SEE ALSO

- Configuring Camel

- Endpoint
- Getting Started
CHAPTER 208. MASTER COMPONENT

Available as of Camel version 2.20

The **camel-master** endpoint provides a way to ensure only a single consumer in a cluster consumes from a given endpoint; with automatic failover if that JVM dies.

This can be very useful if you need to consume from some legacy back end which either doesn’t support concurrent consumption or due to commercial or stability reasons you can only have a single connection at any point in time.

### 208.1. USING THE MASTER ENDPOINT

Just prefix any camel endpoint with **master:someName**: where *someName* is a logical name and is used to acquire the master lock. e.g.

```java
from("master:cheese:jms:foo").to("activemq:wine");
```

The above simulates the [Exclusive Consumers](http://activemq.apache.org/exclusive-consumer.html) type feature in ActiveMQ; but on any third party JMS provider which maybe doesn’t support exclusive consumers.

### 208.2. URI FORMAT

```
master:namespace:endpoint[?options]
```

Where endpoint is any Camel endpoint you want to run in master/slave mode.

### 208.3. OPTIONS

The Master component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>service (advanced)</td>
<td>Inject the service to use.</td>
<td></td>
<td>CamelClusterService</td>
</tr>
<tr>
<td>serviceSelector (advanced)</td>
<td>Inject the service selector used to lookup the CamelClusterService to use.</td>
<td></td>
<td>Selector</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Master endpoint is configured using URI syntax:

```
master:namespace:delegateUri
```
with the following path and query parameters:

### 208.3.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>namespace</td>
<td><strong>Required</strong> The name of the cluster namespace to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>delegateUri</td>
<td><strong>Required</strong> The endpoint uri to use in master/slave mode</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 208.3.2. Query Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 208.4. EXAMPLE

You can protect a clustered Camel application to only consume files from one active node.

```java
// the file endpoint we want to consume from
String url = "file:target/inbox?delete=true";

// use the camel master component in the clustered group named myGroup
// to run a master/slave mode in the following Camel url
from("master:myGroup:" + url)
```
The master component leverages CamelClusterService you can configure using

- **Java**

```java
ZooKeeperClusterService service = new ZooKeeperClusterService();
service.setId("camel-node-1");
service.setNodes("myzk:2181");
service.setBasePath("/camel/cluster");

camelContext.addService(service);
```

- **Xml (Spring/Blueprint)**

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.springframework.org/schema/beans
                           http://www.springframework.org/schema/beans/spring-beans.xsd
                           http://camel.apache.org/schema/spring
                           http://camel.apache.org/schema/spring/camel-spring.xsd">

  <bean id="cluster"
       class="org.apache.camel.component.zookeeper.cluster.ZooKeeperClusterService">
    <property name="id" value="camel-node-1"/>
    <property name="basePath" value="/camel/cluster"/>
    <property name="nodes" value="myzk:2181"/>
  </bean>

  <camelContext xmlns="http://camel.apache.org/schema/spring" autoStartup="false">
    ...
  </camelContext>

</beans>
```

- **Spring boot**

```java
camel.component.zookeeper.cluster.service.enabled = true
camel.component.zookeeper.cluster.service.id = camel-node-1
camel.component.zookeeper.cluster.service.base-path = /camel/cluster
camel.component.zookeeper.cluster.service.nodes = myzk:2181
```

## 208.5. IMPLEMENTATIONS

Camel provide the following ClusterService implementations:

- camel-atomix
- camel-consul
• camel-file
• camel-kubernetes
• camel-zookeeper

208.6. SEE ALSO

• Configuring Camel
• Component
• Endpoint
• Getting Started
CHAPTER 209. METRICS COMPONENT

209.1. METRICS COMPONENT

The metrics: component allows to collect various metrics directly from Camel routes. Supported metric types are counter, histogram, meter, timer and gauge. Metrics provides simple way to measure behaviour of application. Configurable reporting backend is enabling different integration options for collecting and visualizing statistics. The component also provides a MetricsRoutePolicyFactory which allows to expose route statistics using Dropwizard Metrics, see bottom of page for details.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-metrics</artifactId>
    <version>x.x.x</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

209.2. URI FORMAT

metrics:[ meter | counter | histogram | timer | gauge ]:metricname[?options]

209.3. OPTIONS

The Metrics component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>metricRegistry</td>
<td>To use a custom configured MetricRegistry.</td>
<td></td>
<td>MetricRegistry</td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Metrics endpoint is configured using URI syntax:

metrics:metricsType:metricsName

with the following path and query parameters:

209.3.1. Path Parameters (2 parameters):
### Name | Description | Default | Type
--- | --- | --- | ---
metricsType | Required Type of metrics |  | MetricsType
metricsName | Required Name of metrics |  | String

#### 209.3.2. Query Parameters (7 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>action</strong> (producer)</td>
<td>Action when using timer type</td>
<td></td>
<td>MetricsTimerAction</td>
</tr>
<tr>
<td><strong>decrement</strong> (producer)</td>
<td>Decrement value when using counter type</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td><strong>increment</strong> (producer)</td>
<td>Increment value when using counter type</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td><strong>mark</strong> (producer)</td>
<td>Mark when using meter type</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td><strong>subject</strong> (producer)</td>
<td>Subject value when using gauge type</td>
<td></td>
<td>Object</td>
</tr>
<tr>
<td><strong>value</strong> (producer)</td>
<td>Value value when using histogram type</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td><strong>synchronous</strong> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 209.4. METRIC REGISTRY

Camel Metrics component uses by default a `MetricRegistry` instance with a `Slf4jReporter` that has a 60 second reporting interval. This default registry can be replaced with a custom one by providing a `MetricRegistry` bean. If multiple `MetricRegistry` beans exist in the application, the one with name `metricRegistry` is used.

For example using Spring Java Configuration:

```java
@Configuration
public static class MyConfig extends SingleRouteCamelConfiguration {

    @Bean
    @Override
    public RouteBuilder route() {
        return new RouteBuilder() {
            @Override
            public void configure() throws Exception {
```
Or using CDI:

```java
@Bean(name = MetricsComponent.METRIC_REGISTRY_NAME)
public MetricRegistry getMetricRegistry() {
    MetricRegistry registry = ...;
    return registry;
}
```

CAUTION

`MetricRegistry` uses internal thread(s) for reporting. There is no public API in version DropWizard 3.0.1 for users to clean up on exit. Thus using Camel Metrics Component leads to Java classloader leak and my cause `OutOfMemoryErrors` in some cases.

209.5. USAGE

Each metric has type and name. Supported types are `counter`, `histogram`, `meter`, `timer` and `gauge`. Metric name is simple string. If metric type is not provided then type `meter` is used by default.

209.5.1. Headers

Metric name defined in URI can be overridden by using header with name `CamelMetricsName`.

For example

```java
from("direct:in")
    .setHeader(MetricsConstants.HEADER_METRIC_NAME, constant("new.name"))
    .to("metrics:counter:name.not.used")
    .to("direct:out");
```
will update counter with name **new.name** instead of **name.not.used**.

All Metrics specific headers are removed from the message once Metrics endpoint finishes processing of exchange. While processing exchange Metrics endpoint will catch all exceptions and write log entry using level **warn**.

### 209.6. METRICS TYPE COUNTER

```
metrics:counter:metricname?[?options]
```

#### 209.6.1. Options

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>increment</td>
<td>-</td>
<td>Long value to add to the counter</td>
</tr>
<tr>
<td>decrement</td>
<td>-</td>
<td>Long value to subtract from the counter</td>
</tr>
</tbody>
</table>

If neither **increment** or **decrement** is defined then counter value will be incremented by one. If **increment** and **decrement** are both defined only increment operation is called.

```c
// update counter simple.counter by 7
from("direct:in")
  .to("metric:counter:simple.counter?increment=7")
  .to("direct:out");
```

```c
// increment counter simple.counter by 1
from("direct:in")
  .to("metric:counter:simple.counter")
  .to("direct:out");
```

```c
// decrement counter simple.counter by 3
from("direct:in")
  .to("metric:counter:simple.counter?decrement=3")
  .to("direct:out");
```

#### 209.6.2. Headers

Message headers can be used to override **increment** and **decrement** values specified in Metrics component URI.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel Metrics Count Increment</td>
<td>Override increment value in URI</td>
<td>Long</td>
</tr>
<tr>
<td>Camel Metrics Count Decrease</td>
<td>Override decrement value in URI</td>
<td>Long</td>
</tr>
</tbody>
</table>

```// update counter simple.counter by 417
from("direct:in")
   .setHeader(MetricsConstants.HEADER_COUNTER_INCREMENT, constant(417L))
   .to("metric:counter:simple.counter?increment=7")
   .to("direct:out");
```

```// updates counter using simple language to evaluate body.length
from("direct:in")
   .setHeader(MetricsConstants.HEADER_COUNTER_INCREMENT, simple("${body.length}"))
   .to("metrics:counter:body.length")
   .to("mock:out");
```

### 209.7. METRIC TYPE HISTOGRAM

`metrics:histogram:metricname[?options]`

#### 209.7.1. Options

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>-</td>
<td>Value to use in histogram</td>
</tr>
</tbody>
</table>

If no `value` is not set nothing is added to histogram and warning is logged.

```// adds value 9923 to simple.histogram
from("direct:in")
   .to("metric:histogram:simple.histogram?value=9923")
   .to("direct:out");
```

```// nothing is added to simple.histogram; warning is logged
from("direct:in")
```
209.7.2. Headers

Message header can be used to override value specified in Metrics component URI.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMetricsHistogramValue</td>
<td>Override histogram value in URI</td>
<td>Long</td>
</tr>
</tbody>
</table>

```java
// adds value 992 to simple.histogram
from("direct:in")
    .setHeader(MetricsConstants.HEADER_HISTOGRAM_VALUE, constant(992L))
    .to("metric:histogram:simple.histogram?value=700")
    .to("direct:out")
```

209.8. METRIC TYPE METER

metrics:meter:metricname[?options]

209.8.1. Options

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mark</td>
<td>-</td>
<td>Long value to use as mark</td>
</tr>
</tbody>
</table>

If `mark` is not set then `meter.mark()` is called without argument.

```java
// marks simple.meter without value
from("direct:in")
    .to("metric:Simple.meter")
    .to("direct:out");
```

```java
// marks simple.meter with value 81
from("direct:in")
    .to("metric:Simple.meter?mark=81")
    .to("direct:out");
```

209.8.2. Headers

Message header can be used to override `mark` value specified in Metrics component URI.
Camel Metrics Meter Mark

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel</td>
<td>Override mark value in URI</td>
<td>Long</td>
</tr>
</tbody>
</table>

```java
// updates meter simple.meter with value 345
from("direct:in")
    .setHeader(MetricsConstants.HEADER_METER_MARK, constant(345L))
    .to("metric:meter:simple.meter?mark=123")
    .to("direct:out");
```

## 209.9. METRICS TYPE TIMER

metrics:timer:metricname[?options]

### 209.9.1. Options

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>-</td>
<td>start or stop</td>
</tr>
</tbody>
</table>

If no `action` or invalid value is provided then warning is logged without any timer update. If action `start` is called on already running timer or `stop` is called on not running timer then nothing is updated and warning is logged.

```java
// measure time taken by route "calculate"
from("direct:in")
    .to("metrics:timer:simple.timer?action=start")
    .to("direct:calculate")
    .to("metrics:timer:simple.timer?action=stop");
```

**TimerContext** objects are stored as Exchange properties between different Metrics component calls.

### 209.9.2. Headers

Message header can be used to override action value specified in Metrics component URI.
### camel-Metrics TimerAction

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel Metrics TimerAction</td>
<td>Override timer action in URI</td>
<td>org.apache.camel.component.metrics.timer.TimerEndpoint.TimerAction</td>
</tr>
</tbody>
</table>

```java
// sets timer action using header
from("direct:in")
  .setHeader(MetricsConstants.HEADER_TIMER_ACTION, TimerAction.start)
  .to("metric:timer:simple.timer")
  .to("direct:out");
```

### Metric Type Gauge

**metrics:gauge:metricname[?options]**

#### 209.10. Options

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subject</td>
<td>-</td>
<td>Any object to be observed by the gauge</td>
</tr>
</tbody>
</table>

If **subject** is not defined it’s simply ignored, i.e. the gauge is not registered.

```java
// update gauge “simple.gauge” by a bean “mySubjectBean”
from("direct:in")
  .to("metric:gauge:simple.gauge?subject=#mySubjectBean")
  .to("direct:out");
```

#### 209.10.2. Headers

Message headers can be used to override **subject** values specified in Metrics component URI. Note: if **CamelMetricsName** header is specified, then new gauge is registered in addition to default one specified in a URI.
209.11. METRICSROUTEPOLICYFACTORY

This factory allows to add a RoutePolicy for each route which exposes route utilization statistics using Dropwizard metrics. This factory can be used in Java and XML as the examples below demonstrates.

NOTE

Instead of using the MetricsRoutePolicyFactory you can define a MetricsRoutePolicy per route you want to instrument, in case you only want to instrument a few selected routes.

From Java you just add the factory to the CamelContext as shown below:

```java
context.addRoutePolicyFactory(new MetricsRoutePolicyFactory());
```

And from XML DSL you define a `<bean>` as follows:

```xml
<!-- use camel-metrics route policy to gather metrics for all routes -->
<bean id="metricsRoutePolicyFactory" class="org.apache.camel.component.metrics.routepolicy.MetricsRoutePolicyFactory"/>
```

The MetricsRoutePolicyFactory and MetricsRoutePolicy supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>useJmx</td>
<td>false</td>
<td>Whether to report fine grained statistics to JMX by using the com.codahale.metrics.JmxReporter. Notice that if JMX is enabled on CamelContext then a MetricsRegistryService mbean is enlisted under the services type in the JMX tree. That mbean has a single operation to output the statistics using json. Setting useJmx to true is only needed if you want fine grained mbeans per statistics type.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>jmxDomain</td>
<td>org.apache.camel.metrics</td>
<td>The JMX domain name</td>
</tr>
<tr>
<td>prettyPrint</td>
<td>false</td>
<td>Whether to use pretty print when outputting statistics in json format</td>
</tr>
<tr>
<td>metricsRegistry</td>
<td></td>
<td>Allow to use a shared <code>com.codahale.metrics.MetricRegistry</code>. If none is provided then Camel will create a shared instance used by the this CamelContext.</td>
</tr>
<tr>
<td>rateUnit</td>
<td>TimeUnit.SEconds</td>
<td>The unit to use for rate in the metrics reporter or when dumping the statistics as json.</td>
</tr>
<tr>
<td>durationUnit</td>
<td>TimeUnit.Milliseconds</td>
<td>The unit to use for duration in the metrics reporter or when dumping the statistics as json.</td>
</tr>
<tr>
<td>namePattern</td>
<td>name. routeId.type</td>
<td>Camel 2.17: The name pattern to use. Uses dot as separators, but you can change that. The values <code>name</code>, <code>routeId</code>, and <code>type</code> will be replaced with actual value. Where <code>name</code> is the name of the CamelContext. <code>routeId</code> is the name of the route. And <code>type</code> is the value of responses.</td>
</tr>
</tbody>
</table>

From Java code you can get hold of the `com.codahale.metrics.MetricRegistry` from the `org.apache.camel.component.metrics.routePolicy.MetricsRegistryService` as shown below:

```java
MetricRegistryService registryService = context.hasService(MetricsRegistryService.class);
if (registryService != null) {
    MetricsRegistry registry = registryService.getMetricsRegistry();
    ...
}
```

### 209.12. METRICSMESSAGEHISTORYFACTORY

**Available as of Camel 2.17**

This factory allows to use metrics to capture Message History performance statistics while routing messages. It works by using a metrics Timer for each node in all the routes. This factory can be used in Java and XML as the examples below demonstrates.

From Java you just set the factory to the `CamelContext` as shown below:

```java
context.setMessageHistoryFactory(new MetricsMessageHistoryFactory());
```
And from XML DSL you define a `<bean>` as follows:

```xml
<!-- use camel-metrics message history to gather metrics for all messages being routed -->
<bean id="metricsMessageHistoryFactory" class="org.apache.camel.component.metrics.messagehistory.MetricsMessageHistoryFactory"/>
```

The following options is supported on the factory:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>
| useJmx         | false   | Whether to report fine grained statistics to JMX by using the `com.codahale.metrics.JmxReporter`.
|                |         | Notice that if JMX is enabled on CamelContext then a `MetricsRegistryService` mbean is enlisted under the services type in the JMX tree. That mbean has a single operation to output the statistics using json. Setting `useJmx` to true is only needed if you want fine grained mbeans per statistics type. |
| jmxDomain      | org.apache.camel.metrics | The JMX domain name |
| prettyPrint    | false   | Whether to use pretty print when outputting statistics in json format |
| metricsRegistry |         | Allow to use a shared `com.codahale.metrics.MetricRegistry`. If none is provided then Camel will create a shared instance used by the this CamelContext. |
| rateUnit       | TimeUnit.SECONDS | The unit to use for rate in the metrics reporter or when dumping the statistics as json. |
| durationUnit   | TimeUnit.MILISECONDS | The unit to use for duration in the metrics reporter or when dumping the statistics as json. |
| namePattern    | name,routeId,type | The name pattern to use. Uses dot as separators, but you can change that. The values `name`, `routeId`, `type`, and `id` will be replaced with actual value. Where `name` is the name of the CamelContext. `routeId` is the name of the route. The `id` pattern represents the node id. And `type` is the value of history. |

At runtime the metrics can be accessed from Java API or JMX which allows to gather the data as json output.

From Java code you can do get the service from the CamelContext as shown:

```java
MetricsMessageHistoryService service = context.hasService(MetricsMessageHistoryService.class);
String json = service.dumpStatisticsAsJson();
```
And the JMX API the MBean is registered in the type=services tree with name=MetricsMessageHistoryService.

209.13. INSTRUMENTEDTHREADPOOLFACTORY

Available as of Camel 2.18

This factory allows you to gather performance information about Camel Thread Pools by injecting a InstrumentedThreadPoolFactory which collects information from inside of Camel. See more details at Advanced configuration of CamelContext using Spring

209.14. SEE ALSO

- The camel-example-cdi-metrics example that illustrates the integration between Camel, Metrics and CDI.
CHAPTER 210. OPC UA CLIENT COMPONENT

Available as of Camel version 2.19

The Milo Client component provides access to OPC UA servers using the Eclipse Milo™ implementation.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-milo</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The OPC UA Client component supports 6 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultConfiguration (common)</td>
<td>All default options for client</td>
<td>MiloClientConfigu</td>
<td>riation</td>
</tr>
<tr>
<td>applicationName (common)</td>
<td>Default application name</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>applicationUri (common)</td>
<td>Default application URI</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>productUri (common)</td>
<td>Default product URI</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>reconnectTimeout (common)</td>
<td>Default reconnect timeout</td>
<td>Long</td>
<td></td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true boolean</td>
<td></td>
</tr>
</tbody>
</table>

210.1. URI FORMAT

The URI syntax of the endpoint is:

```
milo-client:tcp://[user:password@]host:port/path/to/service?node=RAW(nsu=urn:foo:bar;s=item-1)
```

If the server does not use a path, then it is possible to simply omit it:

```
milo-client:tcp://[user:password@]host:port?node=RAW(nsu=urn:foo:bar;s=item-1)
```
If no user credentials are provided the client will switch to anonymous mode.

210.2. URI OPTIONS

All configuration options in the group client are applicable to the shared client instance. Endpoints will share client instances for each endpoint URI. So the first time a request for that endpoint URI is made, the options of the client group are applied. All further instances will be ignored.

If you need alternate options for the same endpoint URI it is possible though to set the clientId option which will be added internally to the endpoint URI in order to select a different shared connection instance. In other words, shared connections located by the combination of endpoint URI and client id.

The OPC UA Client endpoint is configured using URI syntax:

milo-client:endpointUri

with the following path and query parameters:

210.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>endpointUri</td>
<td>Required The OPC UA server endpoint</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

210.2.2. Query Parameters (24 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>clientId (common)</td>
<td>A virtual client id to force the creation of a new connection instance</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>defaultAwaitWrites (common)</td>
<td>Default await setting for writes</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>node (common)</td>
<td>The node definition (see Node ID)</td>
<td></td>
<td>ExpandedNodeId</td>
</tr>
<tr>
<td>samplingInterval (common)</td>
<td>The sampling interval in milliseconds</td>
<td></td>
<td>Double</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------------</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>allowedSecurityPolicies</td>
<td>A set of allowed security policy URIs. Default is to accept all and use the highest.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>applicationName</td>
<td>The application name</td>
<td>Apache Camel adapter for Eclipse Milo</td>
<td>String</td>
</tr>
<tr>
<td>applicationUri</td>
<td>The application URI</td>
<td><a href="http://camel.apache.org/EclipseMilo/Client">http://camel.apache.org/EclipseMilo/Client</a></td>
<td>String</td>
</tr>
<tr>
<td>channelLifetime</td>
<td>Channel lifetime in milliseconds</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>keyAlias</td>
<td>The name of the key in the keystore file</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>keyPassword</td>
<td>The key password</td>

<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyStoreUrl (client)</td>
<td>The URL where the key should be loaded from</td>
<td></td>
<td>URL</td>
</tr>
<tr>
<td>maxPendingPublishRequests (client)</td>
<td>The maximum number of pending publish requests</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>maxResponseMessageSize (client)</td>
<td>The maximum number of bytes a response message may have</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>overrideHost (client)</td>
<td>Override the server reported endpoint host with the host from the endpoint URI.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>productUri (client)</td>
<td>The product URI</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>requestTimeout (client)</td>
<td>Request timeout in milliseconds</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>sessionName (client)</td>
<td>Session name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>sessionTimeout (client)</td>
<td>Session timeout in milliseconds</td>
<td></td>
<td>Long</td>
</tr>
</tbody>
</table>

#### 210.2.3. Node ID

In order to define a target node a namespace and node id is required. In previous versions this was possible by specifying **nodeId** and either **namespaceUri** or **namespaceIndex**. However this only allowed for using string based node IDs. And while this configuration is still possible, the newer one is preferred.

The new approach is to specify a full namespace+node ID in the format `ns=1;i=1` which also allows to use the other node ID formats (like numeric, GUID/UUID or opaque). If the **node** parameter is used the older ones must not be used. The syntax of this node format is a set of `key=value` pairs delimited by a semi-colon (`;`).

Exactly one namespace and one node id key must be used. See the following table for possible keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ns</td>
<td>namespace</td>
<td>Numeric namespace index</td>
</tr>
</tbody>
</table>
As the values generated by the syntax cannot be transparently encoded into a URI parameter value, it is necessary to escape them. However Camel allows to wrap the actual value inside RAW(...), which makes escaping unnecessary. For example:

milo-client://user:password@localhost:12345?node=RAW(nsu=http://foo.bar;s=foo/bar)

210.2.4. Security policies

When setting the allowing security policies is it possible to use the well known OPC UA URIs (e.g. http://opcfoundation.org/UA/SecurityPolicy#Basic128Rsa15) or to use the Milo enum literals (e.g. None). Specifying an unknown security policy URI or enum is an error.

The known security policy URIs and enum literals are can be seen here: SecurityPolicy.java

Note: In any case security policies are considered case sensitive.

210.3. SEE ALSO

- Configuring Camel

- Endpoint
- Getting Started
CHAPTER 211. OPC UA SERVER COMPONENT

Available as of Camel version 2.19

The Milo Server component provides an OPC UA server using the Eclipse Milo™ implementation.

Java 8: This component requires Java 8 at runtime.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-milo</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Messages sent to the endpoint from Camel will be available from the OPC UA server to OPC UA Clients. Value write requests from OPC UA Client will trigger messages which are sent into Apache Camel.

The OPC UA Server component supports 19 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>namespaceUri</td>
<td>The URI of the namespace, defaults to urn:org:apache:camel</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>applicationName</td>
<td>The application name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>applicationUri</td>
<td>The application URI</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>productUri</td>
<td>The product URI</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bindPort</td>
<td>The TCP port the server binds to</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>strictEndpointUrlsEnabled</td>
<td>Set whether strict endpoint URLs are enforced</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>serverName</td>
<td>Server name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>hostname</td>
<td>Server hostname</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>---------</td>
<td>------</td>
</tr>
<tr>
<td>securityPolicies</td>
<td>Security policies</td>
<td></td>
<td>Set</td>
</tr>
<tr>
<td>securityPoliciesByUri</td>
<td>Security policies by URI or name</td>
<td></td>
<td>String&gt;</td>
</tr>
<tr>
<td>userAuthenticationCredentials</td>
<td>Set user password combinations in the form of user1:pwd1,user2:pwd2 Usernames and passwords will be URL decoded</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>enableAnonymousAuthentication</td>
<td>Enable anonymous authentication, disabled by default</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>bindAddresses</td>
<td>Set the addresses of the local addresses the server should bind to</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>buildInfo</td>
<td>Server build info</td>
<td></td>
<td>BuildInfo</td>
</tr>
<tr>
<td>serverCertificate</td>
<td>Server certificate</td>
<td></td>
<td>Result</td>
</tr>
<tr>
<td>certificateManager</td>
<td>Server certificate manager</td>
<td></td>
<td>CertificateManager</td>
</tr>
<tr>
<td>certificateValidator</td>
<td>Validator for client certificates</td>
<td></td>
<td>CertificateValidator&gt;</td>
</tr>
<tr>
<td>defaultCertificateValidator</td>
<td>Validator for client certificates using default file based approach</td>
<td></td>
<td>File</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 211.1. URI FORMAT

milo-server:itemId[?options]

### 211.2. URI OPTIONS

The OPC UA Server endpoint is configured using URI syntax:
milo-server:itemld

with the following path and query parameters:

### 211.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>itemld</td>
<td>Required ID of the item</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 211.2.2. Query Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>

CHAPTER 212. MIME MULTIPART DATAFORMAT

Available as of Camel version 2.17

This data format that can convert a Camel message with attachments into a Camel message having a MIME-Multipart message as message body (and no attachments).

The use case for this is to enable the user to send attachments over endpoints that do not directly support attachments, either as special protocol implementation (e.g. send a MIME-multipart over an HTTP endpoint) or as a kind of tunneling solution (e.g. because camel-jms does not support attachments but by marshalling the message with attachments into a MIME-Multipart, sending that to a JMS queue, receiving the message from the JMS queue and unmarshalling it again (into a message body with attachments).

The marshal option of the mime-multipart data format will convert a message with attachments into a MIME-Multipart message. If the parameter “multipartWithoutAttachment” is set to true it will also marshal messages without attachments into a multipart message with a single part, if the parameter is set to false it will leave the message alone.

MIME headers of the multipart as "MIME-Version" and "Content-Type" are set as camel headers to the message. If the parameter "headersInline" is set to true it will also create a MIME multipart message in any case. Furthermore the MIME headers of the multipart are written as part of the message body, not as camel headers.

The unmarshal option of the mime-multipart data format will convert a MIME-Multipart message into a camel message with attachments and leaves other messages alone. MIME-Headers of the MIME-Multipart message have to be set as Camel headers. The unmarshalling will only take place if the "Content-Type" header is set to a "multipart" type. If the option "headersInline" is set to true, the body is always parsed as a MIME message. As a consequence if the message body is a stream and stream caching is not enabled, a message body that is actually not a MIME message with MIME headers in the message body will be replaced by an empty message. Up to Camel version 2.17.1 this will happen all message bodies that do not contain a MIME multipart message regardless of body type and stream cache setting.

212.1. OPTIONS

The MIME Multipart dataformat supports 6 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>multipartSubType</td>
<td>mixed</td>
<td>String</td>
<td>Specify the subtype of the MIME Multipart. Default is mixed.</td>
</tr>
<tr>
<td>multipartWithout Attachment</td>
<td>false</td>
<td>Boolean</td>
<td>Defines whether a message without attachment is also marshaled into a MIME Multipart (with only one body part). Default is false.</td>
</tr>
<tr>
<td>headersInline</td>
<td>false</td>
<td>Boolean</td>
<td>Defines whether the MIME-Multipart headers are part of the message body (true) or are set as Camel headers (false). Default is false.</td>
</tr>
</tbody>
</table>
### 212.2. MESSAGE HEADERS (MARSHAL)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message-Id</td>
<td>String</td>
<td>The marshal operation will set this parameter to the generated MIME message id if the &quot;headersInline&quot; parameter is set to false.</td>
</tr>
<tr>
<td>MIME-Version</td>
<td>String</td>
<td>The marshal operation will set this parameter to the applied MIME version (1.0) if the &quot;headersInline&quot; parameter is set to false.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>String</td>
<td>The content of this header will be used as a content type for the message body part. If no content type is set, &quot;application/octet-stream&quot; is assumed. After the marshal operation the content type is set to &quot;multipart/related&quot; or empty if the &quot;headersInline&quot; parameter is set to true.</td>
</tr>
<tr>
<td>Content-Encoding</td>
<td>String</td>
<td>If the incoming content type is &quot;text/*&quot; the content encoding will be set to the encoding parameter of the Content-Type MIME header of the body part. Furthermore the given charset is applied for text to binary conversions.</td>
</tr>
</tbody>
</table>

### 212.3. MESSAGE HEADERS (UNMARSHAL)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
If this header is not set to "multipart/*" the unmarshal operation will not do anything. In other cases the multipart will be parsed into a camel message with attachments and the header is set to the Content-Type header of the body part, except if this is application/octet-stream. In the latter case the header is removed.

If the content-type of the body part contains an encoding parameter this header will be set to the value of this encoding parameter (converted from MIME encoding descriptor to Java encoding descriptor).

The unmarshal operation will read this header and use it for parsing the MIME multipart. The header is removed afterwards.

**212.4. EXAMPLES**

```java
from(...).marshal().mimeMultipart()
```

With a message where no Content-Type header is set, will create a Message with the following message Camel headers:

**Camel Message Headers**

```
Content-Type=multipart/mixed; \n boundary="-----=_Part_0_14180567.1447658227051"
Message-Id=<...>
MIME-Version=1.0
```

The message body will be:

**Camel Message Body**

```
-----=_Part_0_14180567.1447658227051
Content-Type: application/octet-stream
Content-Transfer-Encoding: base64
Qm9keSB0ZXh0
-----=_Part_0_14180567.1447658227051
Content-Type: application/binary
Content-Transfer-Encoding: base64
Content-Disposition: attachment; filename="Attachment File Name"
AAECAwQFBgc=
-----=_Part_0_14180567.1447658227051--
```

A message with the header Content-Type set to "text/plain" sent to the route

```java
from("...").marshal().mimeMultipart("related", true, true, ".-(.*|\.)", true);
```
will create a message without any specific MIME headers set as Camel headers (the Content-Type header is removed from the Camel message) and the following message body that includes also all headers of the original message starting with “x-“ and the header with name “included”:

Camel Message Body

<table>
<thead>
<tr>
<th>Message-ID: &lt;...&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIME-Version: 1.0</td>
</tr>
<tr>
<td>Content-Type: multipart/related;</td>
</tr>
</tbody>
</table>
| boundary="-----=_Part_0_1134128170.1447659361365"
| x-bar: also there |
| included: must be included |
| x-foo: any value |

-----=_Part_0_1134128170.1447659361365
| Content-Type: text/plain |
| Content-Transfer-Encoding: 8bit |

Body text

-----=_Part_0_1134128170.1447659361365
| Content-Type: application/binary |
| Content-Transfer-Encoding: binary |
| Content-Disposition: attachment; filename="Attachment File Name" |

[binary content]

-----=_Part_0_1134128170.1447659361365

212.5. DEPENDENCIES

To use MIME-Multipart in your Camel routes you need to add a dependency on camel-mail which implements this data format.

If you use Maven you can just add the following to your pom.xml:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mail</artifactId>
  <version>x.x.x</version> <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 213. MINA2 COMPONENT

Available as of Camel version 2.10

The mina2: component is a transport for working with Apache MINA 2.x

TIP

Favor using Netty as Netty is a much more active maintained and popular project than Apache Mina currently is

INFO: Be careful with sync=false on consumer endpoints. Since camel-mina2 all consumer exchanges are InOut. This is different to camel-mina.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mina2</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

213.1. URI FORMAT

mina2:tcp://hostname[:port]?options
mina2:udp://hostname[:port]?options
mina2:vm://hostname[:port]?options

You can specify a codec in the Registry using the codec option. If you are using TCP and no codec is specified then the textline flag is used to determine if text line based codec or object serialization should be used instead. By default the object serialization is used.

For UDP if no codec is specified the default uses a basic ByteBuffer based codec.

The VM protocol is used as a direct forwarding mechanism in the same JVM.

A Mina producer has a default timeout value of 30 seconds, while it waits for a response from the remote server.

In normal use, camel-mina only supports marshalling the body content—message headers and exchange properties are not sent.
However, the option, transferExchange, does allow you to transfer the exchange itself over the wire.
See options below.

You can append query options to the URI in the following format, ?option=value&option=value&...

213.2. OPTIONS

The Mina2 component supports 3 options which are listed below.
The Mina2 endpoint is configured using URI syntax:

```
mina2:protocol:host:port
```

with the following path and query parameters:

### 213.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol</td>
<td>Required Protocol to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td>Required Hostname to use. Use localhost or 0.0.0.0 for local server as consumer. For producer use the hostname or ip address of the remote server.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>Required Port number</td>
<td></td>
<td>int</td>
</tr>
</tbody>
</table>

### 213.2.2. Query Parameters (27 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>disconnect (common)</td>
<td>Whether or not to disconnect(close) from Mina session right after use. Can be used for both consumer and producer.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>minaLogger (common)</td>
<td>You can enable the Apache MINA logging filter. Apache MINA uses slf4j logging at INFO level to log all input and output.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>sync (common)</td>
<td>Setting to set endpoint as one-way or request-response.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>timeout (common)</td>
<td>You can configure the timeout that specifies how long to wait for a response from a remote server. The timeout unit is in milliseconds, so 60000 is 60 seconds.</td>
<td>30000</td>
<td>long</td>
</tr>
<tr>
<td>writeTimeout (common)</td>
<td>Maximum amount of time it should take to send data to the MINA session. Default is 10000 milliseconds.</td>
<td>10000</td>
<td>long</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pick up incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default, the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>clientMode (consumer)</td>
<td>If the clientMode is true, the mina consumer will connect the address as a TCP client.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>disconnectOnNoReply (consumer)</td>
<td>If sync is enabled then this option dictates MinaConsumer if it should disconnect where there is no reply to send back.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>noReplyLogLevel (consumer)</td>
<td>If sync is enabled this option dictates MinaConsumer which logging level to use when logging a there is no reply to send back.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>cachedAddress (producer)</td>
<td>Whether to create the InetAddress once and reuse. Setting this to false allows to pickup DNS changes in the network.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### CHAPTER 213. MINA2 COMPONENT

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>lazySessionCreation (producer)</td>
<td>Sessions can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>maximumPoolSize (advanced)</td>
<td>Number of worker threads in the worker pool for TCP and UDP</td>
<td>16</td>
<td>int</td>
</tr>
<tr>
<td>orderedThreadPoolExecutor (advanced)</td>
<td>Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>transferExchange (advanced)</td>
<td>Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>allowDefaultCodec (codec)</td>
<td>The mina component installs a default codec if both, codec is null and textline is false. Setting allowDefaultCodec to false prevents the mina component from installing a default codec as the first element in the filter chain. This is useful in scenarios where another filter must be the first in the filter chain, like the SSL filter.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>codec (codec)</td>
<td>To use a custom minda codec implementation.</td>
<td></td>
<td>ProtocolCodecFactory</td>
</tr>
<tr>
<td>decoderMaxLengthLength (codec)</td>
<td>To set the textline protocol decoder max line length. By default the default value of Mina itself is used which are 1024.</td>
<td>1024</td>
<td>int</td>
</tr>
<tr>
<td>encoderMaxLengthLength (codec)</td>
<td>To set the textline protocol encoder max line length. By default the default value of Mina itself is used which are Integer.MAX_VALUE.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>encoding (codec)</td>
<td>You can configure the encoding (a charset name) to use for the TCP textline codec and the UDP protocol. If not provided, Camel will use the JVM default Charset</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
213.3. USING A CUSTOM CODEC

See the Mina how to write your own codec. To use your custom codec with camel-mina, you should register your codec in the Registry; for example, by creating a bean in the Spring XML file. Then use the codec option to specify the bean ID of your codec. See HL7 that has a custom codec.

213.4. SAMPLE WITH SYNC=FALSE

In this sample, Camel exposes a service that listens for TCP connections on port 6200. We use the textline codec. In our route, we create a Mina consumer endpoint that listens on port 6200:

```java
from("mina2:tcp://localhost:" + port1 + "\?textline=true&sync=false").to("mock:result");
```

As the sample is part of a unit test, we test it by sending some data to it on port 6200.

```java
MockEndpoint mock = getMockEndpoint("mock:result");
mock.expectedBodiesReceived("Hello World");

template.sendBody("mina2:tcp://localhost:" + port1 + "\?textline=true&sync=false", "Hello World");

assertMockEndpointsSatisfied();
```

213.5. SAMPLE WITH SYNC=TRUE

In the next sample, we have a more common use case where we expose a TCP service on port 6201 also use the textline codec. However, this time we want to return a response, so we set the sync option to true on the consumer.

```java
from("mina2:tcp://localhost:" + port2 + "\?textline=true&sync=true").process(new Processor() { 
```
Then we test the sample by sending some data and retrieving the response using the `template.requestBody()` method. As we know the response is a `String`, we cast it to `String` and can assert that the response is, in fact, something we have dynamically set in our processor code logic.

```java
String response = (String)template.requestBody("mina2:tcp://localhost:" + port2 + ",?textline=true&sync=true", "World");
assertEquals("Bye World", response);
```

### 213.6. Sample with Spring DSL

Spring DSL can, of course, also be used for MINA. In the sample below we expose a TCP server on port 5555:

```xml
<route>
  <from uri="mina2:tcp://localhost:5555?textline=true"/>
  <to uri="bean:myTCPOrderHandler"/>
</route>
```

In the route above, we expose a TCP server on port 5555 using the textline codec. We let the Spring bean with ID, `myTCPOrderHandler`, handle the request and return a reply. For instance, the handler bean could be implemented as follows:

```java
public String handleOrder(String payload) {
  ...
  return "Order: OK"
}
```

### 213.7. Closing Session When Complete

When acting as a server you sometimes want to close the session when, for example, a client conversion is finished. To instruct Camel to close the session, you should add a header with the key `CamelMinaCloseSessionWhenComplete` set to a boolean `true` value.

For instance, the example below will close the session after it has written the `bye` message back to the client:

```java
from("mina2:tcp://localhost:8080?sync=true&textline=true").process(new Processor() {
  public void process(Exchange exchange) throws Exception {
    String body = exchange.getIn().getBody(String.class);
    exchange.getOut().setBody("Bye " + body);
    exchange.getOut().setHeader(Mina2Constants.MINA_CLOSE_SESSION_WHEN_COMPLETE, true);
  }
});
```
213.8. GET THE IOSESSION FOR MESSAGE

You can get the IoSession from the message header with this key `Mina2Constants.MINA_IOSESSION`, and also get the local host address with the key `Mina2Constants.MINA_LOCAL_ADDRESS` and remote host address with the key `Mina2Constants.MINA_REMOTE_ADDRESS`.

213.9. CONFIGURING MINA FILTERS

Filters permit you to use some Mina Filters, such as `SslFilter`. You can also implement some customized filters. Please note that `codec` and `logger` are also implemented as Mina filters of type, `IoFilter`. Any filters you may define are appended to the end of the filter chain; that is, after `codec` and `logger`.

213.10. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
- Netty
CHAPTER 214. MLLP COMPONENT

Available as of Camel version 2.17

The MLLP component is specifically designed to handle the nuances of the MLLP protocol and provide the functionality required by Healthcare providers to communicate with other systems using the MLLP protocol. The MLLP component provides a simple configuration URI, automated HL7 acknowledgment generation and automatic acknowledgement interrogation.

The MLLP protocol does not typically use a large number of concurrent TCP connections - a single active TCP connection is the normal case. Therefore, the MLLP component uses a simple thread-per-connection model based an standard Java Sockets. This keeps the implementation simple and eliminates the dependencies other than Camel itself.

The component supports the following:

- A Camel consumer using a TCP Server
- A Camel producer using a TCP Client

The MLLP component uses byte[] payloads, and relies on Camel Type Conversion to convert byte[] to other types.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mllp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

214.1. MLLP OPTIONS

The MLLP component supports 5 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>logPhi (advanced)</td>
<td>Set the component to log PHI data.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td>logPhiMaxBytes (advanced)</td>
<td>Set the maximum number of bytes of PHI that will be logged in a log entry.</td>
<td>5120</td>
<td>Integer</td>
</tr>
<tr>
<td>defaultCharset (advanced)</td>
<td>Set the default character set to use for byte to/from String conversions.</td>
<td>ISO-8859-1</td>
<td>String</td>
</tr>
<tr>
<td>configuration (common)</td>
<td>Sets the default configuration to use when creating MLLP endpoints.</td>
<td></td>
<td>MllpConfiguration</td>
</tr>
</tbody>
</table>
resolveProperty Placeholders (advanced)

Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

true  boolean

The MLLP endpoint is configured using URI syntax:

mllp:hostname:port

with the following path and query parameters:

214.1.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname</td>
<td>Required Hostname or IP for connection for the TCP connection. The default value is null, which means any local IP address</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>Required Port number for the TCP connection</td>
<td></td>
<td>int</td>
</tr>
</tbody>
</table>

214.1.2. Query Parameters (27 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>autoAck (common)</td>
<td>Enable/Disable the automatic generation of a MLLP Acknowledgement MLLP Consumers only</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>bufferWrites (common)</td>
<td>Deprecated Enable/Disable the buffering of HL7 payloads before writing to the socket.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>hl7Headers (common)</td>
<td>Enable/Disable the automatic generation of message headers from the HL7 Message MLLP Consumers only</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>requireEndOfData (common)</td>
<td>Enable/Disable strict compliance to the MLLP standard. The MLLP standard specifies START_OF_BLOCKhl7 payloadEND_OF_BLOCKEND_OF_DATA, however, some systems do not send the final END_OF_DATA byte. This setting controls whether or not the final END_OF_DATA byte is required or optional.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>stringPayload (common)</td>
<td>Enable/Disable converting the payload to a String. If enabled, HL7 Payloads received from external systems will be validated converted to a String. If the charsetName property is set, that character set will be used for the conversion. If the charsetName property is not set, the value of MSH-18 will be used to determine the appropriate character set. If MSH-18 is not set, then the default ISO-8859-1 character set will be use.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>validatePayload (common)</td>
<td>Enable/Disable the validation of HL7 Payloads. If enabled, HL7 Payloads received from external systems will be validated (see Hl7Util.generateInvalidPayloadExceptionMessage for details on the validation). If an invalid payload is detected, a MllpInvalidMessageException (for consumers) or a MllpInvalidAcknowledgementException will be thrown.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to receive incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. If disabled, the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions by logging them at WARN or ERROR level and ignored.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>InOut</td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used (this component only supports synchronous operations).</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>backlog (tcp)</td>
<td>The maximum queue length for incoming connection indications (a request to connect) is set to the backlog parameter. If a connection indication arrives when the queue is full, the connection is refused.</td>
<td>5</td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>lenientBind</strong> (tcp)</td>
<td>TCP Server Only - Allow the endpoint to start before the TCP ServerSocket is bound.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>maxConcurrentConsumers</strong> (tcp)</td>
<td>The maximum number of concurrent MLLP Consumer connections that will be allowed. If a new connection is received and the maximum is number are already established, the new connection will be reset immediately.</td>
<td>5</td>
<td>int</td>
</tr>
<tr>
<td><strong>reuseAddress</strong> (tcp)</td>
<td>Enable/disable the SO_REUSEADDR socket option.</td>
<td>false</td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>acceptTimeout</strong> (timeout)</td>
<td>Timeout (in milliseconds) while waiting for a TCP connection TCP Server Only</td>
<td>60000</td>
<td>int</td>
</tr>
<tr>
<td><strong>bindRetryInterval</strong> (timeout)</td>
<td>TCP Server Only - The number of milliseconds to wait between bind attempts</td>
<td>5000</td>
<td>int</td>
</tr>
<tr>
<td><strong>bindTimeout</strong> (timeout)</td>
<td>TCP Server Only - The number of milliseconds to retry binding to a server port</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td><strong>connectTimeout</strong> (timeout)</td>
<td>Timeout (in milliseconds) for establishing for a TCP connection TCP Client only</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td><strong>idleTimeout</strong> (timeout)</td>
<td>The approximate idle time allowed before the Client TCP Connection will be reset. A null value or a value less than or equal to zero will disable the idle timeout.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>maxReceiveTimeouts</strong> (timeout)</td>
<td>Deprecated The maximum number of timeouts (specified by receiveTimeout) allowed before the TCP Connection will be reset.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>keepAlive</strong> (tcp)</td>
<td>Enable/disable the SO_KEEPALIVE socket option.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>receiveBufferSize</strong> (tcp)</td>
<td>Sets the SO_RCVBUF option to the specified value (in bytes)</td>
<td>8192</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>sendBufferSize</strong> (tcp)</td>
<td>Sets the SO_SNDBUF option to the specified value (in bytes)</td>
<td>8192</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>tcpNoDelay</strong> (tcp)</td>
<td>Enable/disable the TCP_NODELAY socket option.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>readTimeout</strong> (timeout)</td>
<td>The SO_TIMEOUT value (in milliseconds) used after the start of an MLLP frame has been received</td>
<td>5000</td>
<td>int</td>
</tr>
</tbody>
</table>
214.2. MLLP CONSUMER

The MLLP Consumer supports receiving MLLP-framed messages and sending HL7 Acknowledgements. The MLLP Consumer can automatically generate the HL7 Acknowledgement (HL7 Application Acknowledgements only - AA, AE and AR), or the acknowledgement can be specified using the CamelMllpAcknowledgement exchange property. Additionally, the type of acknowledgement that will be generated can be controlled by setting the CamelMllpAcknowledgementType exchange property.

214.3. MESSAGE HEADERS

The MLLP Consumer adds these headers on the Camel message:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMllpLocalAddress</td>
<td>The local TCP Address of the Socket</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpRemoteAddress</td>
<td>The local TCP Address of the Socket</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpSendingApplication</td>
<td>MSH-3 value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpSendingFacility</td>
<td>MSH-4 value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpReceivingApplication</td>
<td>MSH-5 value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpReceivingFacility</td>
<td>MSH-6 value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpTimestamp</td>
<td>MSH-7 value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpSecurity</td>
<td>MSH-8 value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpMessageType</td>
<td>MSH-9 value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpEventType</td>
<td>MSH-9-1 value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CamelMllpTriggerEvent</td>
<td>MSH-9-2 value</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### All headers are String types. If a header value is missing, its value is null.

#### 214.4. EXCHANGE PROPERTIES

The type of acknowledgment the MLLP Consumer generates and state of the TCP Socket can be controlled by these properties on the Camel exchange:

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMllpAcknowledgement</td>
<td>byte[]</td>
<td>If present, this property will be sent to client as the MLLP Acknowledgement</td>
</tr>
<tr>
<td>CamelMllpAcknowledgementString</td>
<td>String</td>
<td>If present and CamelMllpAcknowledgement is not present, this property will be sent to client as the MLLP Acknowledgement</td>
</tr>
<tr>
<td>CamelMllpAcknowledgementMsaText</td>
<td>String</td>
<td>If neither CamelMllpAcknowledgement or CamelMllpAcknowledgementString are present and autoAck is true, this property can be used to specify the contents of MSA-3 in the generated HL7 acknowledgement</td>
</tr>
<tr>
<td>CamelMllpAcknowledgementType</td>
<td>String</td>
<td>If neither CamelMllpAcknowledgement or CamelMllpAcknowledgementString are present and autoAck is true, this property can be used to specify the HL7 acknowledgement type (i.e. AA, AE, AR)</td>
</tr>
<tr>
<td>CamelMllpAutoAcknowledge</td>
<td>Boolean</td>
<td>Overrides the autoAck query parameter</td>
</tr>
<tr>
<td>CamelMllpCloseConnectionBeforeSend</td>
<td>Boolean</td>
<td>If true, the Socket will be closed before sending data</td>
</tr>
</tbody>
</table>
CamelMllpResetConnectionBeforeSend | Boolean | If true, the Socket will be reset before sending data
CamelMllpCloseConnectionAfterSend | Boolean | If true, the Socket will be closed immediately after sending data
CamelMllpResetConnectionAfterSend | Boolean | If true, the Socket will be reset immediately after sending any data

214.5. MLLP PRODUCER

The MLLP Producer supports sending MLLP-framed messages and receiving HL7 Acknowledgements. The MLLP Producer interrogates the HL7 Acknowledgments and raises exceptions if a negative acknowledgement is received. The received acknowledgement is interrogated and an exception is raised in the event of a negative acknowledgement.

214.6. MESSAGE HEADERS

The MLLP Producer adds these headers on the Camel message:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMllpLocalAddress</td>
<td>The local TCP Address of the Socket</td>
</tr>
<tr>
<td>CamelMllpRemoteAddress</td>
<td>The remote TCP Address of the Socket</td>
</tr>
<tr>
<td>CamelMllpAcknowledgement</td>
<td>The HL7 Acknowledgment byte[] received</td>
</tr>
<tr>
<td>CamelMllpAcknowledgementString</td>
<td>The HL7 Acknowledgement received, converted to a String</td>
</tr>
</tbody>
</table>

214.7. EXCHANGE PROPERTIES

The state of the TCP Socket can be controlled by these properties on the Camel exchange:

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMllpCloseConnectionBeforeSend</td>
<td>Boolean</td>
<td>If true, the Socket will be closed before sending data</td>
</tr>
<tr>
<td>CamelMllpResetConnectionBeforeSend</td>
<td>Boolean</td>
<td>If true, the Socket will be reset before sending data</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------</td>
<td>------------------------------------------------------</td>
</tr>
<tr>
<td>CamelMllpCloseConnectionAfterSend</td>
<td>Boolean</td>
<td>If true, the Socket will be closed immediately after sending data</td>
</tr>
<tr>
<td>CamelMllpResetConnectionAfterSend</td>
<td>Boolean</td>
<td>If true, the Socket will be reset immediately after sending any data</td>
</tr>
</tbody>
</table>
CHAPTER 215. MOCK COMPONENT

Documentation for Mock component is currently unavailable.
CHAPTER 216. MONGODB COMPONENT

Available as of Camel version 2.10

According to Wikipedia: “NoSQL is a movement promoting a loosely defined class of non-relational data stores that break with a long history of relational databases and ACID guarantees.” NoSQL solutions have grown in popularity in the last few years, and major extremely-used sites and services such as Facebook, LinkedIn, Twitter, etc. are known to use them extensively to achieve scalability and agility.

Basically, NoSQL solutions differ from traditional RDBMS (Relational Database Management Systems) in that they don’t use SQL as their query language and generally don’t offer ACID-like transactional behaviour nor relational data. Instead, they are designed around the concept of flexible data structures and schemas (meaning that the traditional concept of a database table with a fixed schema is dropped), extreme scalability on commodity hardware and blazing-fast processing.

MongoDB is a very popular NoSQL solution and the camel-mongodb component integrates Camel with MongoDB allowing you to interact with MongoDB collections both as a producer (performing operations on the collection) and as a consumer (consuming documents from a MongoDB collection).

MongoDB revolves around the concepts of documents (not as is office documents, but rather hierarchical data defined in JSON/BSON) and collections. This component page will assume you are familiar with them. Otherwise, visit [http://www.mongodb.org/](http://www.mongodb.org/).

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mongodb</artifactId>
  <version>x.y.z</version>
</dependency>

<!-- use the same version as your Camel core version -->
```

216.1. URI FORMAT

```
mongodb:connectionBean?database=databaseName&collection=collectionName&operation=operationName[&moreOptions...]
```

216.2. MONGODB OPTIONS

The MongoDB component has no options.

The MongoDB endpoint is configured using URI syntax:

```
mongodb:connectionBean
```

with the following path and query parameters:

216.2.1. Path Parameters (1 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectionBean</td>
<td>Required Name of com.mongodb.Mongo to use.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 216.2.2. Query Parameters (23 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>collection</td>
<td>Sets the name of the MongoDB collection to bind to this endpoint</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>collectionIndex</td>
<td>Sets the collection index (JSON FORMAT : field1 : order1, field2 : order2)</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>createCollection</td>
<td>Create collection during initialisation if it doesn’t exist. Default is true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>database</td>
<td>Sets the name of the MongoDB database to target</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
| operation    | Sets the operation this endpoint will execute against MongoDB. For possible values, see
<p>|              | MongoDBOperation.                                                          |         | MongoDbOperation |
| outputType   | Convert the output of the producer to the selected type : DBOBJECTLIST DBOBJECT or DBCursor. DBOBJECTLIST or DBCursor applies to findAll and aggregate. DBOBJECT applies to all other operations. |         | MongoDbOutputType |
| writeConcern | Set the WriteConcern for write operations on MongoDB using the standard ones. Resolved from the fields of the WriteConcern class by calling the link WriteConcernvalueOf(String) method. | ACKNOWLDGED | WriteConcern |
| bridgeErrorHandler | Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored. | false   | boolean  |</p>
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>exceptionHandler</code> (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td><code>exchangePattern</code> (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td><code>cursorRegenerationDelay</code> (advanced)</td>
<td>MongoDB tailable cursors will block until new data arrives. If no new data is inserted, after some time the cursor will be automatically freed and closed by the MongoDB server. The client is expected to regenerate the cursor if needed. This value specifies the time to wait before attempting to fetch a new cursor, and if the attempt fails, how long before the next attempt is made. Default value is 1000ms.</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td><code>dynamicity</code> (advanced)</td>
<td>Sets whether this endpoint will attempt to dynamically resolve the target database and collection from the incoming Exchange properties. Can be used to override at runtime the database and collection specified on the otherwise static endpoint URI. It is disabled by default to boost performance. Enabling it will take a minimal performance hit.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>readPreference</code> (advanced)</td>
<td>Sets a MongoDB ReadPreference on the Mongo connection. Read preferences set directly on the connection will be overridden by this setting. The link <code>ReadPreference.valueOf(String)</code> utility method is used to resolve the passed readPreference value. Some examples for the possible values are nearest, primary or secondary etc.</td>
<td></td>
<td>ReadPreference</td>
</tr>
<tr>
<td><code>synchronous</code> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>writeResultAsHeader</code> (advanced)</td>
<td>In write operations, it determines whether instead of returning WriteResult as the body of the OUT message, we transfer the IN message to the OUT and attach the WriteResult as a header.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>persistentId</code> (tail)</td>
<td>One tail tracking collection can host many trackers for several tailable consumers. To keep them separate, each tracker should have its own unique persistentId.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
**Name** | **Description** | **Default** | **Type**
--- | --- | --- | ---
persistentTailTracking (tail) | Enable persistent tail tracking, which is a mechanism to keep track of the last consumed message across system restarts. The next time the system is up, the endpoint will recover the cursor from the point where it last stopped slurping records. | false | boolean
persistRecords (tail) | Sets the number of tailed records after which the tail tracking data is persisted to MongoDB. | -1 | int
tailTrackCollection (tail) | Collection where tail tracking information will be persisted. If not specified, link MongoDBTailTrackingConfigDEFAULT_COLLECTION will be used by default. | String
tailTrackDb (tail) | Indicates what database the tail tracking mechanism will persist to. If not specified, the current database will be picked by default. Dynamicity will not be taken into account even if enabled, i.e. the tail tracking database will not vary past endpoint initialisation. | String
tailTrackField (tail) | Field where the last tracked value will be placed. If not specified, link MongoDBTailTrackingConfigDEFAULT_FIELD will be used by default. | String
tailTrackIncreasingField (tail) | Correlation field in the incoming record which is of increasing nature and will be used to position the tailing cursor every time it is generated. The cursor will be (re)created with a query of type: tailTrackIncreasingField lastValue (possibly recovered from persistent tail tracking). Can be of type Integer, Date, String, etc. NOTE: No support for dot notation at the current time, so the field should be at the top level of the document. | String
tailTrackingStrategy (tail) | Sets the strategy used to extract the increasing field value and to create the query to position the tail cursor. | LITERAL | MongoDBTailTracking Enum

### 216.3. CONFIGURATION OF DATABASE IN SPRING XML

The following Spring XML creates a bean defining the connection to a MongoDB instance.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd">

```
216.4. SAMPLE ROUTE

The following route defined in Spring XML executes the operation `dbStats` on a collection.

Get DB stats for specified collection

```xml
<route>
  <from uri="direct:start" />
  <!-- using bean 'mongoBean' defined above -->
  <to uri="mongodb:mongoBean?
database=${mongodb.database}&collection=${mongodb.collection}&operation=getDbStats" />
  <to uri="direct:result" />
</route>
```

216.5. MONGODB OPERATIONS - PRODUCER ENDPOINTS

216.5.1. Query operations

216.5.1.1. findById

This operation retrieves only one element from the collection whose _id field matches the content of the IN message body. The incoming object can be anything that has an equivalent to a BSON type. See [http://bsonspec.org/specification](http://bsonspec.org/specification) and [http://www.mongodb.org/display/DOCS/Java+Types](http://www.mongodb.org/display/DOCS/Java+Types).

TIP

```camel
from("direct:findById")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=findById")
  .to("mock:resultFindById");
```

216.5.1.2. findOneByQuery

Use this operation to retrieve just one element from the collection that matches a MongoDB query. **The query object is extracted from the IN message body**, i.e. it should be of type `DBObject` or convertible to `DBObject`. It can be a JSON String or a Hashmap. See [#Type conversions](http://www.redhat.com/docs/en-US/Red_Hat_Fuse/7.2/apidocs/javadoc/index.html?api/com/mongodb/DBObject.html) for more info.

Example with no query (returns any object of the collection):

```camel
from("direct:findOneByQuery")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=findOneByQuery")
  .to("mock:resultFindOneByQuery");
```
Example with a query (returns one matching result):

```java
from("direct:findOneByQuery")
    .setBody().constant("{ "name": "Raul Kripalani" }")
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findOneByQuery")
    .to("mock:resultFindOneByQuery");
```

**TIP**

**Supports optional parameters.** This operation supports specifying a fields filter and/or a sort clause. See [Specifying optional parameters](#).  

### 216.5.1.3. findAll

The `findAll` operation returns all documents matching a query, or none at all, in which case all documents contained in the collection are returned. **The query object is extracted from the IN message body**, i.e. it should be of type `DBObject` or convertible to `DBObject`. It can be a JSON String or a Hashmap. See [#Type conversions](#) for more info.

Example with no query (returns all object in the collection):

```java
from("direct:findAll")
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findAll")
    .to("mock:resultFindAll");
```

Example with a query (returns all matching results):

```java
from("direct:findAll")
    .setBody().constant("{ "name": "Raul Kripalani" }")
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findAll")
    .to("mock:resultFindAll");
```

Paging and efficient retrieval is supported via the following headers:

<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from Mongo DB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

1401
<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMongoOdbNameToSkip</td>
<td>NUM_TO_SKIP</td>
<td>Discards a given number of elements at the beginning of the cursor.</td>
<td>int/Integer</td>
</tr>
<tr>
<td>CamelMongoOdbNameLimit</td>
<td>LIMIT</td>
<td>Limits the number of elements returned.</td>
<td>int/Integer</td>
</tr>
<tr>
<td>CamelMongoOdbNameBatchSize</td>
<td>BATCH_SIZE</td>
<td>Limits the number of elements returned in one batch. A cursor typically fetches a batch of result objects and stores them</td>
<td>int/Integer</td>
</tr>
<tr>
<td>Header key</td>
<td>Quick constant</td>
<td>Description (extracted from MongoDB API doc)</td>
<td>Expected type</td>
</tr>
<tr>
<td>------------</td>
<td>----------------</td>
<td>---------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If batchSize is positive, it represents the size of each batch of objects retrieved. It can be adjusted to optimize performance and limit data transfer. If batchSize is negative, it will limit the number of objects returned, that fit within the max batch size limit (usually 4MB), and cursor will be closed. For example if batchSize is -10, then</td>
<td></td>
</tr>
</tbody>
</table>
The server will return a maximum of 10 documents and as many as can fit in 4MB, then close the cursor. Note that this feature is different from limit() in that documents must fit within a maximum size, and it removes the need to send a request to close the cursor server-side. The batch size can be changed even after a cursor is iterated, in

<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from Mongo DB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>and as many as can fit in 4MB, then close the cursor. Note that this feature is different from limit() in that documents must fit within a maximum size, and it removes the need to send a request to close the cursor server-side. The batch size can be changed even after a cursor is iterated, in</td>
<td></td>
</tr>
</tbody>
</table>
You can also "stream" the documents returned from the server into your route by including `outputType=DBCursor (Camel 2.16+)` as an endpoint option which may prove simpler than setting the above headers. This hands your Exchange the DBCursor from the Mongo driver, just as if you were executing the `findAll()` within the Mongo shell, allowing your route to iterate over the results. By default and without this option, this component will load the documents from the driver’s cursor into a List and return this to your route - which may result in a large number of in-memory objects. Remember, with a DBCursor do not ask for the number of documents matched - see the MongoDB documentation site for details.

Example with option `outputType=DBCursor` and batch size:

```java
from("direct:findAll")
  .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
  .setBody().constant("{ \"name\": \"Raul Kripalani\" }")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=findAll&outputType=DBCursor")
  .to("mock:resultFindAll");
```

The `findAll` operation will also return the following OUT headers to enable you to iterate through result pages if you are using paging:

<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>retrieval</td>
<td></td>
</tr>
<tr>
<td>Header key</td>
<td>Quick constant</td>
<td>Description (extracted from MongoDB API doc)</td>
<td>Data type</td>
</tr>
<tr>
<td>----------------------------</td>
<td>----------------</td>
<td>-----------------------------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>CamelMongoDBResultTotalSize</td>
<td></td>
<td>Numbeor of objects matching the query. This does not take limit/skip into consideration.</td>
<td>int/Integer</td>
</tr>
<tr>
<td>CamelmongoDBResultPageSize</td>
<td></td>
<td>Numbeor of objects matching the query. This does not take limit/skip into consideration.</td>
<td>int/Integer</td>
</tr>
</tbody>
</table>

**TIP**

**Supports optional parameters** This operation supports specifying a fields filter and/or a sort clause. See [Specifying optional parameters](#).

### 216.5.1.4. count

Returns the total number of objects in a collection, returning a Long as the OUT message body. The following example will count the number of records in the "dynamicCollectionName" collection. Notice how dynamicity is enabled, and as a result, the operation will not run against the "notableScientists" collection, but against the "dynamicCollectionName" collection.
From Camel 2.14 onwards you can provide a `com.mongodbDBObject` object in the message body as a query, and operation will return the amount of documents matching this criteria.

```java
DBObject query = ...;
Long count = template.requestBodyAndHeader("direct:count", query, MongoDbConstants.COLLECTION, "dynamicCollectionName");
```

### 216.5.1.5. Specifying a fields filter (projection)

Query operations will, by default, return the matching objects in their entirety (with all their fields). If your documents are large and you only require retrieving a subset of their fields, you can specify a field filter in all query operations, simply by setting the relevant `DBObject` (or type convertible to `DBObject`, such as a JSON String, Map, etc.) on the `CamelMongoDbFieldsFilter` header, constant shortcut: `MongoDbConstants.FIELDS_FILTER`.

Here is an example that uses MongoDB’s `BasicDBObjectBuilder` to simplify the creation of `DBObject`s. It retrieves all fields except `_id` and `boringField`:

```java
// route: from("direct:findAll").to("mongodb:myDb?database=tickets&collection=tickets&operation=findAll")
DBObject fieldFilter = BasicDBObjectBuilder.start().add("_id", 0).add("boringField", 0).get();
Object result = template.requestBodyAndHeader("direct:findAll", (Object) null, MongoDbConstants.FIELDS_FILTER, fieldFilter);
```

### 216.5.1.6. Specifying a sort clause

There is often a requirement to fetch the min/max record from a collection based on sorting by a particular field. In MongoDB the operation is performed using syntax similar to:

```java
db.collection.find().sort({ _id: -1 }).limit(1)
// or
db.collection.findOne({$query: {},$orderby: {_id:-1}})
```

In a Camel route the `SORT_BY` header can be used with the `findOneByQuery` operation to achieve the same result. If the `FIELDS_FILTER` header is also specified the operation will return a single field/value pair that can be passed directly to another component (for example, a parameterized MyBatis SELECT query). This example demonstrates fetching the temporally newest document from a collection and reducing the result to a single field, based on the `documentTimestamp` field:

```java
.from("direct:someTriggeringEvent")
.setHeader(MongoDbConstants.SORT_BY).constant("{"documentTimestamp": -1}")
.setHeader(MongoDbConstants.FIELDS_FILTER).constant("{"documentTimestamp": 1}")
.setBody().constant("{}")
```
216.5.2. Create/update operations

216.5.2.1. insert

Inserts a new object into the MongoDB collection, taken from the IN message body. Type conversion is attempted to turn it into DBObject or a List. Two modes are supported: single insert and multiple insert. For multiple insert, the endpoint will expect a List, Array or Collections of objects of any type, as long as they are - or can be converted to - DBObject. All objects are inserted at once. The endpoint will intelligently decide which backend operation to invoke (single or multiple insert) depending on the input.

Example:

```
insert
```

The operation will return a WriteResult, and depending on the WriteConcern or the value of the invokeGetLastError option, getLastError() would have been called already or not. If you want to access the ultimate result of the write operation, you need to retrieve the CommandResult by calling getLastError() or getCachedLastError() on the WriteResult. Then you can verify the result by calling CommandResult.ok(), CommandResult.getErrorMessage() and/or CommandResult.getException().

Note that the new object’s _id must be unique in the collection. If you don’t specify the value, MongoDB will automatically generate one for you. But if you do specify it and it is not unique, the insert operation will fail (and for Camel to notice, you will need to enable invokeGetLastError or set a WriteConcern that waits for the write result).

This is not a limitation of the component, but it is how things work in MongoDB for higher throughput. If you are using a custom _id, you are expected to ensure at the application level that is unique (and this is a good practice too).

Since Camel 2.15: OID(s) of the inserted record(s) is stored in the message header under CamelMongoOid key (MongoDBConstants.OID constant). The value stored is org.bson.types.ObjectId for single insert or java.util.List<org.bson.types.ObjectId> if multiple records have been inserted.

216.5.2.2. save

The save operation is equivalent to an upsert (UPdate, inSERT) operation, where the record will be updated, and if it doesn’t exist, it will be inserted, all in one atomic operation. MongoDB will perform the matching based on the _id field.

Beware that in case of an update, the object is replaced entirely and the usage of MongoDB’s $modifiers is not permitted. Therefore, if you want to manipulate the object if it already exists, you have two options:

1. perform a query to retrieve the entire object first along with all its fields (may not be efficient), alter it inside Camel and then save it.
2. use the update operation with $modifiers, which will execute the update at the server-side instead. You can enable the upsert flag, in which case if an insert is required, MongoDB will apply the $modifiers to the filter query object and insert the result.

For example:

```java
from("direct:insert")
.to("mongodb:myDb?database=flights&collection=tickets&operation=save");
```

### 216.5.2.3. update

Update one or multiple records on the collection. Requires a `List<DBObject>` as the IN message body containing exactly 2 elements:

- Element 1 (index 0) ⇒ filter query ⇒ determines what objects will be affected, same as a typical query object
- Element 2 (index 1) ⇒ update rules ⇒ how matched objects will be updated. All modifier operations from MongoDB are supported.

#### NOTE

**Multiupdates.** By default, MongoDB will only update 1 object even if multiple objects match the filter query. To instruct MongoDB to update all matching records, set the `CamelMongoDbMultiUpdate` IN message header to `true`.

A header with key `CamelMongoDbRecordsAffected` will be returned (MongoDBConstants.RECORDS_AFFECTED constant) with the number of records updated (copied from WriteResult.getN()).

Supports the following IN message headers:

<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
</table>
### Header key | Quick constant | Description (extracted from MongoDB API doc) | Expected type
--- | --- | --- | ---
CamelMongoDbMultiUpdate | MongoDbConstants.MULTIUPTDATE | If the update should be applied to all objects matching. See http://www.mongodb.org/display/DOCS/Atomic+Operations | boolean/Boolean
CamelMongoDbUpsert | MongoDbConstants.UPSERT | If the database should create the element if it does not exist | boolean/Boolean

For example, the following will update all records whose filterField field equals true by setting the value of the "scientist" field to "Darwin":

```java
// route: from("direct:update").to("mongodb:myDb?
database=science&collection=notableScientists&operation=update");
DBObject filterField = new BasicDBObject("filterField", true);
DBObject updateObj = new BasicDBObject("$set", new BasicDBObject("scientist", "Darwin"));
Object result = template.requestBodyAndHeader("direct:update", new Object[] {filterField, updateObj},
MongoDbConstants.MULTIUPTDATE, true);
```

### 216.5.3. Delete operations
216.5.3.1. remove

Remove matching records from the collection. The IN message body will act as the removal filter query, and is expected to be of type `DBObject` or a type convertible to it.

The following example will remove all objects whose field 'conditionField' equals true, in the science database, notableScientists collection:

```java
// route: from("direct:remove").to("mongodb:myDb?
    database=science&collection=notableScientists&operation=remove");
DBObject conditionField = new BasicDBObject("conditionField", true);
Object result = template.requestBody("direct:remove", conditionField);
```

A header with key `CamelMongoDbRecordsAffected` is returned (MongoDbConstants.RECORDS_AFFECTED constant) with type `int`, containing the number of records deleted (copied from WriteResult.getN()).

216.5.4. Bulk Write Operations

216.5.4.1. bulkWrite

Available as of Camel 2.21

Performs write operations in bulk with controls for order of execution. Requires a `List<WriteModel<DBObject>>` as the IN message body containing commands for insert, update, and delete operations.

The following example will insert a new scientist "Pierre Curie", update record with id "5" by setting the value of the "scientist" field to "Marie Curie" and delete record with id "3":

```java
// route: from("direct:bulkWrite").to("mongodb:myDb?
    database=science&collection=notableScientists&operation=bulkWrite");
List<WriteModel<DBObject>> bulkOperations = Arrays.asList(
    new InsertOneModel<>(new BasicDBObject("scientist", "Pierre Curie")),
    new UpdateOneModel<>(new BasicDBObject("_id", "5"),
        new BasicDBObject("$set", new BasicDBObject("scientist", "Marie Curie")) ),
    new DeleteOneModel<>(new BasicDBObject("_id", "3")));
BulkWriteResult result = template.requestBody("direct:bulkWrite", bulkOperations,
    BulkWriteResult.class);
```

By default, operations are executed in order and interrupted on the first write error without processing any remaining write operations in the list. To instruct MongoDB to continue to process remaining write operations in the list, set the `CamelMongoDbBulkOrdered` IN message header to `false`. Unordered operations are executed in parallel and this behavior is not guaranteed.
### Other operations

#### aggregate

**Available as of Camel 2.14**

Perform a aggregation with the given pipeline contained in the body. *Aggregations could be long and heavy operations. Use with care.*

```java
// route: from("direct:aggregate").to("mongodb:myDb?database=science&collection=notableScientists&operation=aggregate");
from("direct:aggregate")
  .setBody().constant("[{ $match : {$or : [{"scientist" : "Darwin"},{"scientist" : "Einstein"}]}},{ $group: { _id: "$scientist", count: { $sum: 1 } } } ]")
  .to("mongodb:myDb?database=science&collection=notableScientists&operation=aggregate")
  .to("mock:resultAggregate");
```

Supports the following IN message headers:
<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel MongoDbBatchSize</td>
<td>MongoDbConstants.BATCH_SIZE</td>
<td>Sets the number of documents to return per batch.</td>
<td>int/Integer</td>
</tr>
<tr>
<td>Camel MongoDbAllowDiskUse</td>
<td>MongoDbConstants.ALLOW_DISK_USE</td>
<td>Enable aggregation pipeline stages to write data to temporary files.</td>
<td>boolean/Boolean</td>
</tr>
</tbody>
</table>

Efficient retrieval is supported via `outputType=DBCursor`.

You can also "stream" the documents returned from the server into your route by including `outputType=DBCursor` (Camel 2.21+) as an endpoint option which may prove simpler than setting the above headers. This hands your Exchange the DBCursor from the Mongo driver, just as if you were executing the `aggregate()` within the Mongo shell, allowing your route to iterate over the results. By default and without this option, this component will load the documents from the driver’s cursor into a List and return this to your route - which may result in a large number of in-memory objects. Remember, with a DBCursor do not ask for the number of documents matched - see the MongoDB documentation site for details.

Example with option `outputType=DBCursor` and batch size:

```java
// route: from("direct:aggregate").to("mongodb:myDb?
database=science&collection=notableScientists&operation=aggregate");
from("direct:aggregate")
  .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
  .setBody().constant([{$match: {$or: [{$"scientist": "Darwin"},{$"scientist": "Einstein"}]}}], { $group: { _id: "$scientist", count: { $sum: 1 } } }])
```
216.5.5.2. getDbStats

Equivalent of running the \texttt{db.stats()} command in the MongoDB shell, which displays useful statistic figures about the database.

For example:

\begin{verbatim}
> db.stats();
{
  "db": "test",
  "collections": 7,
  "objects": 719,
  "avgObjSize": 59.73296244784423,
  "dataSize": 42948,
  "storageSize": 1000058880,
  "numExtents": 9,
  "indexes": 4,
  "indexSize": 32704,
  "fileSize": 1275068416,
  "nsSizeMB": 16,
  "ok": 1
}
\end{verbatim}

Usage example:

\begin{verbatim}
// from("direct:getDbStats").to("mongodb:myDb?
database=science&collection=notableScientists&operation=aggregate&outputType=DBCursor")
.to("mock:resultAggregate");
\end{verbatim}

The operation will return a data structure similar to the one displayed in the shell, in the form of a \texttt{DBObject} in the OUT message body.

216.5.5.3. getColStats

Equivalent of running the \texttt{db.collection.stats()} command in the MongoDB shell, which displays useful statistic figures about the collection.

For example:

\begin{verbatim}
> db.camelTest.stats();
{
  "ns": "test.camelTest",
  "count": 100,
  "size": 5792,
  "avgObjSize": 57.92,
  "storageSize": 20480,
  "numExtents": 2,
  "nindexes": 1,
  "lastExtentSize": 16384,
  "paddingFactor": 1,
  "flags": 1,
\end{verbatim}
"totalIndexSize" : 8176,
"indexSizes" : {
    "_id_" : 8176
},
"ok" : 1

Usage example:

```java
// from("direct:getColStats").to("mongodb:myDb?database=flights&collection=tickets&operation=getColStats");
Object result = template.requestBody("direct:getColStats", "irrelevantBody");
assertTrue("Result is not of type DBObject", result instanceof DBObject);
```

The operation will return a data structure similar to the one displayed in the shell, in the form of a `DBObject` in the OUT message body.

216.5.5.4. command

Available as of Camel 2.15

Run the body as a command on database. Usefull for admin operation as getting host informations, replication or sharding status.

Collection parameter is not use for this operation.

```java
// route: from("command").to("mongodb:myDb?database=science&operation=command");
DBObject commandBody = new BasicDBObject("hostInfo", "1");
Object result = template.requestBody("direct:command", commandBody);
```

216.5.6. Dynamic operations

An Exchange can override the endpoint's fixed operation by setting the `CamelMongoDbOperation` header, defined by the `MongoDbConstants.OPERATION_HEADER` constant.

The values supported are determined by the MongoDbOperation enumeration and match the accepted values for the `operation` parameter on the endpoint URI.

For example:

```java
// from("direct:insert").to("mongodb:myDb?database=flights&collection=tickets&operation=insert");
Object result = template.requestBodyAndHeader("direct:insert", "irrelevantBody",
MongoDbConstants.OPERATION_HEADER, "count");
assertTrue("Result is not of type Long", result instanceof Long);
```

216.6. TAILABLE CURSOR CONSUMER

MongoDB offers a mechanism to instantaneously consume ongoing data from a collection, by keeping
the cursor open just like the `tail -f` command of *nix systems. This mechanism is significantly more
efficient than a scheduled poll, due to the fact that the server pushes new data to the client as it
becomes available, rather than making the client ping back at scheduled intervals to fetch new data. It
also reduces otherwise redundant network traffic.

There is only one requisite to use tailable cursors: the collection must be a "capped collection", meaning
that it will only hold N objects, and when the limit is reached, MongoDB flushes old objects in the same order they were originally inserted. For more information, please refer to: http://www.mongodb.org/display/DOCS/Tailable+Cursors.

The Camel MongoDB component implements a tailable cursor consumer, making this feature available for you to use in your Camel routes. As new objects are inserted, MongoDB will push them as DBObjects in natural order to your tailable cursor consumer, who will transform them to an Exchange and will trigger your route logic.

### 216.7. HOW THE TAILABLE CURSOR CONSUMER WORKS

To turn a cursor into a tailable cursor, a few special flags are to be signalled to MongoDB when first generating the cursor. Once created, the cursor will then stay open and will block upon calling the DBCursor.next() method until new data arrives. However, the MongoDB server reserves itself the right to kill your cursor if new data doesn’t appear after an indeterminate period. If you are interested to continue consuming new data, you have to regenerate the cursor. And to do so, you will have to remember the position where you left off or else you will start consuming from the top again.

The Camel MongoDB tailable cursor consumer takes care of all these tasks for you. You will just need to provide the key to some field in your data of increasing nature, which will act as a marker to position your cursor every time it is regenerated, e.g. a timestamp, a sequential ID, etc. It can be of any datatype supported by MongoDB. Date, Strings and Integers are found to work well. We call this mechanism “tail tracking” in the context of this component.

The consumer will remember the last value of this field and whenever the cursor is to be regenerated, it will run the query with a filter like: increasingField > lastValue, so that only unread data is consumed.

**Setting the increasing field:** Set the key of the increasing field on the endpoint URI tailTrackingIncreasingField option. In Camel 2.10, it must be a top-level field in your data, as nested navigation for this field is not yet supported. That is, the "timestamp" field is okay, but "nested.timestamp" will not work. Please open a ticket in the Camel JIRA if you do require support for nested increasing fields.

**Cursor regeneration delay:** One thing to note is that if new data is not already available upon initialisation, MongoDB will kill the cursor instantly. Since we don’t want to overwhelm the server in this case, a cursorRegenerationDelay option has been introduced (with a default value of 1000ms.), which you can modify to suit your needs.

An example:

```camel
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime")
.id("tailableCursorConsumer1")
.autoStartup(false)
.to("mock:test");
```

The above route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms.

### 216.8. PERSISTENT TAIL TRACKING

Standard tail tracking is volatile and the last value is only kept in memory. However, in practice you will need to restart your Camel container every now and then, but your last value would then be lost and your tailable cursor consumer would start consuming from the top again, very likely sending duplicate records into your route.
To overcome this situation, you can enable the persistent tail tracking feature to keep track of the last consumed increasing value in a special collection inside your MongoDB database too. When the consumer initialises again, it will restore the last tracked value and continue as if nothing happened.

The last read value is persisted on two occasions: every time the cursor is regenerated and when the consumer shuts down. We may consider persisting at regular intervals too in the future (flush every 5 seconds) for added robustness if the demand is there. To request this feature, please open a ticket in the Camel JIRA.

### 216.9. ENABLING PERSISTENT TAIL TRACKING

To enable this function, set at least the following options on the endpoint URI:

- **persistentTailTracking** option to **true**
- **persistentId** option to a unique identifier for this consumer, so that the same collection can be reused across many consumers

Additionally, you can set the **tailTrackDb**, **tailTrackCollection** and **tailTrackField** options to customise where the runtime information will be stored. Refer to the endpoint options table at the top of this page for descriptions of each option.

For example, the following route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms, with persistent tail tracking turned on, and persisting under the "cancellationsTracker" id on the "flights.camelTailTracking", storing the last processed value under the "lastTrackingValue" field (camelTailTracking and lastTrackingValue are defaults).

```java
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTracking=true")
.id("tailableCursorConsumer2")
.autoStartup(false)
.to("mock:test");
```

Below is another example identical to the one above, but where the persistent tail tracking runtime information will be stored under the "trackers.camelTrackers" collection, in the "lastProcessedDepartureTime" field:

```java
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTracking=true")
"&persistentId=cancellationsTracker")
.id("tailableCursorConsumer3")
.autoStartup(false)
.to("mock:test");
```

### 216.10. OPLOG TAIL TRACKING

The oplog collection tracking feature allows to implement trigger like functionality in MongoDB. In order to activate this collection you will have first to activate a replica set. For more information on this topic please check [https://docs.mongodb.com/manual/tutorial/deploy-replica-set/](https://docs.mongodb.com/manual/tutorial/deploy-replica-set/).
Below you can find an example of a Java DSL based route demonstrating how you can use the component to track the `oplog` collection. In this specific case we are filtering the events which affect a collection `customers` in database `oplog_test`. Note that the `tailTrackIncreasingField` is a timestamp field (`ts`) which implies that you have to use the `tailTrackingStrategy` parameter with the `TIMESTAMP` value.

```java
import com.mongodb.BasicDBObject;
import com.mongodb.MongoClient;
import org.apache.camel.Exchange;
import org.apache.camel.Message;
import org.apache.camel.Processor;
import org.apache.camel.builder.RouteBuilder;
import org.apache.camel.component.mongodb.MongoDBTailTrackingEnum;
import org.apache.camel.main.Main;
import java.io.InputStream;

/**
 * For this to work you need to turn on the replica set
 * <p>
 * Commands to create a replica set:
 * <p>
 * rs.initiate( {
 * _id : "rs0",
 * members: [ { _id : 0, host : "localhost:27017" } ]
 * } )
 * */

public class MongoDbTracker {

    private final String database;
    private final String collection;
    private final String increasingField;
    private MongoDBTailTrackingEnum trackingStrategy;
    private int persistRecords = -1;
    private boolean persistenTailTracking;

    public MongoDbTracker(String database, String collection, String increasingField) {
        this.database = database;
        this.collection = collection;
        this.increasingField = increasingField;
    }

    public static void main(String[] args) throws Exception {
        final MongoDbTracker mongoDbTracker = new MongoDbTracker("local", "oplog.rs", "ts");
        mongoDbTracker.setTrackingStrategy(MongoDBTailTrackingEnum.TIMESTAMP);
        mongoDbTracker.setPersistRecords(5);
        mongoDbTracker.setPersistenTailTracking(true);
        mongoDbTracker.startRouter();
        // run until you terminate the JVM
        System.out.println("Starting Camel. Use ctrl + c to terminate the JVM.\n");
    }
}
```
public void setTrackingStrategy(MongoDBTailTrackingEnum trackingStrategy) {
    this.trackingStrategy = trackingStrategy;
}

public void setPersistRecords(int persistRecords) {
    this.persistRecords = persistRecords;
}

public void setPersistenTailTracking(boolean persistenTailTracking) {
    this.persistenTailTracking = persistenTailTracking;
}

void startRouter() throws Exception {
    // create a Main instance
    Main main = new Main();
    main.bind(MongoConstants.CONN_NAME, new MongoClient("localhost", 27017));
    main.addRouteBuilder(new RouteBuilder() {
        @Override
        public void configure() throws Exception {
           (getContext().getTypeConverterRegistry().addTypeConverter(InputStream.class, BasicDBObject.class, new MongoToInputStreamConverter());
            from("mongodb://" + MongoConstants.CONN_NAME + "?database=" + database
                + "&collection=" + collection
                + "&persistentTailTracking=" + persistenTailTracking
                + "&persistentId=trackerName" + "&tailTrackDb=local"
                + "&tailTrackCollection=talendTailTracking"
                + "&tailTrackField=lastTrackingValue"
                + "&tailTrackIncreasingField=" + increasingField
                + "&tailTrackingStrategy=" + trackingStrategy.toString()
                + "&persistRecords=" + persistRecords
                + "&cursorRegenerationDelay=1000"
            .filter().jsonpath("@[?(@.ns=='optlog_test.customers')]
                .id("logger")
            .to("log:logger?level=WARN")
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    Message message = exchange.getIn();
                    System.out.println(message.getBody().toString());
                    exchange.getOut().setBody(message.getBody().toString());
                }
            }));
        }
    });
    main.run();
}

216.11. TYPE CONVERSIONS

The `MongoDbBasicConverters` type converter included with the camel-mongodb component provides the following conversions:
<table>
<thead>
<tr>
<th>Name</th>
<th>From type</th>
<th>To type</th>
<th>How?</th>
</tr>
</thead>
<tbody>
<tr>
<td>fromMapToDBObject</td>
<td>Map</td>
<td>DBObject</td>
<td>constructs a new BasicDBObject via the <code>new BasicDBObject(Map m)</code> constructor</td>
</tr>
<tr>
<td>fromBasicDBObjectToMap</td>
<td>BasicDBObject</td>
<td>Map</td>
<td>BasicDBObject already implements Map</td>
</tr>
<tr>
<td>fromStringToDBObject</td>
<td>String</td>
<td>DBObject</td>
<td>uses <code>com.mongodb.util.JSON.parse(String s)</code></td>
</tr>
<tr>
<td>fromAnyObjectToDBObject</td>
<td>Object</td>
<td>DBObject</td>
<td>uses the Jackson library to convert the object to a Map, which is in turn used to initialise a new BasicDBObject</td>
</tr>
</tbody>
</table>

This type converter is auto-discovered, so you don’t need to configure anything manually.

CHAPTER 217. MONGODB GRIDFS COMPONENT

Available as of Camel version 2.18

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mongodb-gridfs</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

217.1. URI FORMAT

```
mongodb-gridfs:connectionBean?database=databaseName&bucket=bucketName[&moreOptions...]
```

217.2. MONGODB GRIDFS OPTIONS

The MongoDB GridFS component has no options.

The MongoDB GridFS endpoint is configured using URI syntax:

```
mongodb-gridfs:connectionBean
```

with the following path and query parameters:

217.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectionBean</td>
<td>Required Name of com.mongodb.Mongo to use.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

217.2.2. Query Parameters (17 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bucket</td>
<td>Sets the name of the GridFS bucket within the database. Default is fs.</td>
<td>fs</td>
<td>String</td>
</tr>
<tr>
<td>database</td>
<td>Required Sets the name of the MongoDB database to target</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------------</td>
</tr>
<tr>
<td>readPreference</td>
<td>Sets a MongoDB ReadPreference on the MongoDB connection. Read preferences set directly on the connection will be overridden by this setting. The link com.mongodb.ReadPreference.valueOf(String) utility method is used to resolve the passed readPreference value. Some examples for the possible values are nearest, primary or secondary etc.</td>
<td></td>
<td>ReadPreference</td>
</tr>
<tr>
<td>writeConcern</td>
<td>Set the WriteConcern for write operations on MongoDB using the standard ones. Resolved from the fields of the WriteConcern class by calling the link WriteConcern.valueOf(String) method.</td>
<td></td>
<td>WriteConcern</td>
</tr>
<tr>
<td>writeConcernRef</td>
<td>Set the WriteConcern for write operations on MongoDB, passing in the bean ref to a custom WriteConcern which exists in the Registry. You can also use standard WriteConcerns by passing in their key. See the link setWriteConcern(String) setWriteConcern method.</td>
<td></td>
<td>WriteConcern</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>delay</td>
<td>Sets the delay between polls within the Consumer. Default is 500ms</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>fileAttributeName</td>
<td>If the QueryType uses a FileAttribute, this sets the name of the attribute that is used. Default is camel-processed.</td>
<td>camel-processed</td>
<td>String</td>
</tr>
<tr>
<td>initialDelay</td>
<td>Sets the initialDelay before the consumer will start polling. Default is 1000ms</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>persistentTSCollection</td>
<td>If the QueryType uses a persistent timestamp, this sets the name of the collection within the DB to store the timestamp.</td>
<td>camel-timestamp</td>
<td>String</td>
</tr>
<tr>
<td>persistentTSOBJECT</td>
<td>If the QueryType uses a persistent timestamp, this is the ID of the object in the collection to store the timestamp.</td>
<td>camel-timestamp</td>
<td>String</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
--- | --- | --- | ---
**query** (consumer) | Additional query parameters (in JSON) that are used to configure the query used for finding files in the GridFsConsumer | | String
**queryStrategy** (consumer) | Sets the QueryStrategy that is used for polling for new files. Default is Timestamp | Timestamp | QueryStrategy
**exceptionHandler** (consumer) | To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored. | | ExceptionHandler
**exchangePattern** (consumer) | Sets the exchange pattern when the consumer creates an exchange. | | ExchangePattern
**operation** (producer) | Sets the operation this endpoint will execute against GridRS. | | String
**synchronous** (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

### 217.3. CONFIGURATION OF DATABASE IN SPRING XML

The following Spring XML creates a bean defining the connection to a MongoDB instance.

```xml
  <bean id="mongoBean" class="com.mongodb.Mongo">
    <constructor-arg name="host" value="${mongodb.host}" />
    <constructor-arg name="port" value="${mongodb.port}" />
  </bean>
</beans>
```

### 217.4. SAMPLE ROUTE

The following route defined in Spring XML executes the operation **findOne** on a collection.

Get a file from GridFS

```xml
<route>
  <from url="direct:start" />
</route>
```
217.5. GRIDFS OPERATIONS - PRODUCER ENDPOINT

217.5.1. count

Returns the total number of file in the collection, returning an Integer as the OUT message body.

```
// from("direct:count").to("mongodb-gridfs?database=tickets&operation=count");
Integer result = template.requestBodyAndHeader("direct:count", "irrelevantBody");
assertTrue("Result is not of type Long", result instanceof Integer);
```

You can provide a filename header to provide a count of files matching that filename.

```
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(Exchange.FILE_NAME, "filename.txt");
Integer count = template.requestBodyAndHeaders("direct:count", query, headers);
```

217.5.2. listAll

Returns an Reader that lists all the filenames and their IDs in a tab separated stream.

```
// from("direct:listAll").to("mongodb-gridfs?database=tickets&operation=listAll");
Reader result = template.requestBodyAndHeader("direct:listAll", "irrelevantBody");

filename1.txt   1252314321
filename2.txt   2897651254
```

217.5.3. findOne

Finds a file in the GridFS system and sets the body to an InputStream of the content. Also provides the metadata has headers. It uses Exchange.FILE_NAME from the incoming headers to determine the file to find.

```
// from("direct:findOne").to("mongodb-gridfs?database=tickets&operation=findOne");
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(Exchange.FILE_NAME, "filename.txt");
InputStream result = template.requestBodyAndHeaders("direct:findOne", "irrelevantBody", headers);
```

217.5.4. create

Creates a new file in the GridFs database. It uses the Exchange.FILE_NAME from the incoming headers for the name and the body contents (as an InputStream) as the content.
217.5.5. remove

Removes a file from the GridFS database.

```
// from("direct:create").to("mongodb-gridfs?database=tickets&operation=create");
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(Exchange.FILE_NAME, "filename.txt");
InputStream stream = ... the data for the file ...
template.requestBodyAndHeaders("direct:create", stream, headers);
```

217.6. GRIDFS CONSUMER

CHAPTER 218. MONGODB COMPONENT

Available as of Camel version 2.19

Note: Camel MongoDB3 component Use the Mongo Driver for Java 3.4. If you are looking for previews versions look the Camel MongoDB component

According to Wikipedia: "NoSQL is a movement promoting a loosely defined class of non-relational data stores that break with a long history of relational databases and ACID guarantees." NoSQL solutions have grown in popularity in the last few years, and major extremely-used sites and services such as Facebook, LinkedIn, Twitter, etc. are known to use them extensively to achieve scalability and agility.

Basically, NoSQL solutions differ from traditional RDBMS (Relational Database Management Systems) in that they don’t use SQL as their query language and generally don’t offer ACID-like transactional behaviour nor relational data. Instead, they are designed around the concept of flexible data structures and schemas (meaning that the traditional concept of a database table with a fixed schema is dropped), extreme scalability on commodity hardware and blazing-fast processing.

MongoDB is a very popular NoSQL solution and the camel-mongodb component integrates Camel with MongoDB allowing you to interact with MongoDB collections both as a producer (performing operations on the collection) and as a consumer (-consuming documents from a MongoDB collection).

MongoDB revolves around the concepts of documents (not as is office documents, but rather hierarchical data defined in JSON/BSON) and collections. This component page will assume you are familiar with them. Otherwise, visit http://www.mongodb.org/.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mongodb3</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

218.1. URI FORMAT

```
mongodb3:connectionBean?
database=databaseName&collection=collectionName&operation=operationName[&moreOptions...]
```

218.2. MONGODB OPTIONS

The MongoDB component has no options.

The MongoDB endpoint is configured using URI syntax:

```
mongodb3:connectionBean
```

with the following path and query parameters:

218.2.1. Path Parameters (1 parameters):
### connectionBean

**Required** Name of com.mongodb.Mongo to use.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectionBean</td>
<td>Required Name of com.mongodb.Mongo to use.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 218.2.2. Query Parameters (19 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>collection</td>
<td>Sets the name of the MongoDB collection to bind to this endpoint</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>collectionIndex</td>
<td>Sets the collection index (JSON FORMAT : field1 : order1, field2 : order2)</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>createCollection</td>
<td>Create collection during initialisation if it doesn’t exist. Default is true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>database</td>
<td>Sets the name of the MongoDB database to target</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>operation</td>
<td>Sets the operation this endpoint will execute against MongoDB. For possible values, see MongoDbOperation.</td>
<td></td>
<td>MongoDbOperation</td>
</tr>
<tr>
<td>outputType</td>
<td>Convert the output of the producer to the selected type : DocumentList Document or Mongolterable. DocumentList or Mongolterable applies to findAll and aggregate. Document applies to all other operations.</td>
<td></td>
<td>MongoDbOutputType</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>cursorRegenerationDelay</td>
<td>MongoDB tailable cursors will block until new data arrives. If no new data is inserted, after some time the cursor will be automatically freed and closed by the MongoDB server. The client is expected to regenerate the cursor if needed. This value specifies the time to wait before attempting to fetch a new cursor, and if the attempt fails, how long before the next attempt is made. Default value is 1000ms.</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>dynamicity</td>
<td>Sets whether this endpoint will attempt to dynamically resolve the target database and collection from the incoming Exchange properties. Can be used to override at runtime the database and collection specified on the otherwise static endpoint URI. It is disabled by default to boost performance. Enabling it will take a minimal performance hit.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>writeResultAsHeader</td>
<td>In write operations, it determines whether instead of returning WriteResult as the body of the OUT message, we transfer the IN message to the OUT and attach the WriteResult as a header.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>persistentId</td>
<td>One tail tracking collection can host many trackers for several tailable consumers. To keep them separate, each tracker should have its own unique persistentId.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>persistentTailTracking</td>
<td>Enable persistent tail tracking, which is a mechanism to keep track of the last consumed message across system restarts. The next time the system is up, the endpoint will recover the cursor from the point where it last stopped slurping records.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>tailTrackCollection</td>
<td>Collection where tail tracking information will be persisted. If not specified, link MongoDBTailTrackingConfigDEFAULT_COLLECTION will be used by default.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### Name

- **tailTrackDb (tail)**

  Indicates what database the tail tracking mechanism will persist to. If not specified, the current database will be picked by default. Dynamicity will not be taken into account even if enabled, i.e. the tail tracking database will not vary past endpoint initialisation.

  **Type**: String

- **tailTrackField (tail)**

  Field where the last tracked value will be placed. If not specified, link 
  `MongoDBTailTrackingConfigDEFAULT_FIELD` will be used by default.

  **Type**: String

- **tailTrackIncreasingField (tail)**

  Correlation field in the incoming record which is of increasing nature and will be used to position the tailing cursor every time it is generated. The cursor will be (re)created with a query of type: `tailTrackIncreasingField lastValue` (possibly recovered from persistent tail tracking). Can be of type Integer, Date, String, etc. NOTE: No support for dot notation at the current time, so the field should be at the top level of the document.

  **Type**: String

---

**Note on options of MongoDB component**

**writeConcern Remove in camel 2.19.** See Mongo client options  **Section 218.3, “Configuration of database in Spring XML”.** Set the WriteConcern for write operations on MongoDB using the standard ones. Resolved from the fields of the WriteConcern class by calling the link `WriteConcern.valueOf(String)` method.

**readPreference Remove in camel 2.19.** See Mongo client options  **Section 218.3, “Configuration of database in Spring XML”.** Sets a MongoDB ReadPreference on the Mongo connection. Read preferences set directly on the connection will be overridden by this setting. The link `com.mongodb.ReadPreference.valueOf(String)` utility method is used to resolve the passed readPreference value. Some examples for the possible values are nearest primary or secondary etc.

---

### 218.3. CONFIGURATION OF DATABASE IN SPRING XML

The following Spring XML creates a bean defining the connection to a MongoDB instance.

Since mongo java driver 3, the WriteConcern and readPreference options are not dynamically modifiable. They are defined in the mongoClient object

```xml
<beans
xmlns="http://www.springframework.org/schema/beans"
xmns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmns:context="http://www.springframework.org/schema/context"
xmns:mongo="http://www.springframework.org/schema/data/mongo"
xsi:schemaLocation="http://www.springframework.org/schema/context
http://www.springframework.org/schema/context/spring-context.xsd
http://www.springframework.org/schema/data/mongo
http://www.springframework.org/schema/data/mongo/spring-mongo.xsd
http://www.springframework.org/schema/beans"```
218.4. SAMPLE ROUTE

The following route defined in Spring XML executes the operation `dbStats` on a collection.

Get DB stats for specified collection

```xml
<route>
  <from uri="direct:start"/>
  <!-- using bean 'mongoBean' defined above -->
  <to uri="mongodb3:myDb?database=${mongodb.database}&collection=${mongodb.collection}&operation=getDbStats"/>
  <to uri="direct:result"/>
</route>
```

218.5. MONGODB OPERATIONS - PRODUCER ENDPOINTS

218.5.1. Query operations

218.5.1.1. findById

This operation retrieves only one element from the collection whose _id field matches the content of the IN message body. The incoming object can be anything that has an equivalent to a `Bson` type. See [http://bsonspec.org//specification][1] and [http://www.mongodb.org/display/DOCS/Java+Types][2].

```java
from("direct:findById")
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findById")
  .to("mock:resultFindById");
```

TIP

Supports optional parameters. This operation supports specifying a fields filter. See [Specifying optional parameters][3].

218.5.1.2. findOneByQuery

Use this operation to retrieve just one element (the first) from the collection that matches a MongoDB query. The query object is extracted `CamelMongoDbCriteria` header. If the `CamelMongoDbCriteria` header is null the query object is extracted message body, i.e. it should be of type `Bson` or convertible to `Bson`. It can be a JSON String or a Hashmap. See [Type conversions][4] for more info. you can use the Filters class from MongoDB Driver.

Example with no query (returns any object of the collection):
Example with a query (returns one matching result):

from("direct:findOneByQuery")
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findOneByQuery")
  .to("mock:resultFindOneByQuery");

Example with no query (returns all object in the collection):

from("direct:findAll")
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findAll")
  .to("mock:resultFindAll");

Example with a query (returns all matching results):

from("direct:findAll")
  .setHeader(MongoDbConstants.CRITERIA, Filters.eq("name", "Raul Kripalani"))
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findAll")
  .to("mock:resultFindAll");

Paging and efficient retrieval is supported via the following headers:

<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMongoDbNumToSkip</td>
<td>MongodbcstromConstants.NUM_TO_SKIP</td>
<td>Discards a given number of elements at the beginning of the cursor.</td>
<td>int/Integer</td>
</tr>
</tbody>
</table>

TIP

Supports optional parameters. This operation supports specifying a fields projection and/or a sort clause. See Specifying optional parameters.

218.5.1.3. findAll

The findAll operation returns all documents matching a query, or none at all, in which case all documents contained in the collection are returned. The query object is extracted CamelMongoDbCriteria header. if the CamelMongoDbCriteria header is null the query object is extracted message body, i.e. it should be of type Bson or convertible to Bson. It can be a JSON String or a Hashmap. See #Type conversions for more info.

Example with a query (returns one matching result):

from("direct:findOneByQuery")
  .setHeader(MongoDbConstants.CRITERIA, Filters.eq("name", "Raul Kripalani"))
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findOneByQuery")
  .to("mock:resultFindOneByQuery");
<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMongoDbLimit</td>
<td>MongodbcOnstants.LIMIT</td>
<td>Limits the number of elements returned.</td>
<td>int/Integer</td>
</tr>
<tr>
<td>CamelMongoDbBatchSize</td>
<td>MongodbcOnstants.BATCH_SIZE</td>
<td>Limits the number of elements returned in one batch. A cursor typically fetches a batch of result objects and store them locally. If batchSize is positive, it represents the size of each batch of objects retrieved. It can be adjusted to optimize performance and limit data transfer. If batchSize is negative, it will limit of number objects returned, that fit within the max batch size limit (usually 4MB), and cursor will be closed. For example if batchSize is -10, then the server will return a maximum of 10 documents and as many as can fit in 4MB, then close the cursor. Note that this feature is different from limit() in that documents must fit within a maximum size, and it removes the need to send a request to close the cursor server-side. The batch size can be changed even after a cursor is iterated, in which case the setting will apply on the next batch retrieval.</td>
<td>int/Integer</td>
</tr>
</tbody>
</table>

Example with option outputType=MongoIterable and batch size:

```java
from("direct:findAll")
  .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
  .setHeader(MongoDbConstants.CRITERIA, Filters.eq("name", "Raul Kripalani"))
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findAll&outputType=MongoIterable")
  .to("mock:resultFindAll");
```

The `findAll` operation will also return the following OUT headers to enable you to iterate through result pages if you are using paging:

<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMongoDbResultTotalSize</td>
<td>MongodbcOnstants.RESULT_TOTAL_SIZE</td>
<td>Number of objects matching the query. This does not take limit/skip into consideration.</td>
<td>int/Integer</td>
</tr>
</tbody>
</table>
Number of objects matching the query. This does not take limit/skip into consideration.  

TIP

**Supports optional parameters.** This operation supports specifying a fields projection and/or a sort clause. See Specifying optional parameters.

### 218.5.1.4. count

Returns the total number of objects in a collection, returning a Long as the OUT message body. The following example will count the number of records in the "dynamicCollectionName" collection. Notice how dynamicity is enabled, and as a result, the operation will not run against the "notableScientists" collection, but against the "dynamicCollectionName" collection.

```java
// from("direct:count").to("mongodb3:myDb?
database=tickets&collection=flights&operation=count&dynamicity=true");
Long result = template.requestBodyAndHeader("direct:count", "irrelevantBody",
MongoDbConstants.COLLECTION, "dynamicCollectionName");
assertTrue("Result is not of type Long", result instanceof Long);
```

You can provide a query The query object is extracted CamelMongoDbCriteria header. if the CamelMongoDbCriteria header is null the query object is extracted message body, i.e. it should be of type Bson or convertible to Bson, and operation will return the amount of documents matching this criteria.

```java
Document query = ...
Long count = template.requestBodyAndHeader("direct:count", query,
MongoDbConstants.COLLECTION, "dynamicCollectionName");
```

### 218.5.1.5. Specifying a fields filter (projection)

Query operations will, by default, return the matching objects in their entirety (with all their fields). If your documents are large and you only require retrieving a subset of their fields, you can specify a field filter in all query operations, simply by setting the relevant Bson (or type convertible to Bson, such as a JSON String, Map, etc.) on the CamelMongoDbFieldsProjection header, constant shortcut: 

MongoDbConstants.FIELDS_PROJECTION.

Here is an example that uses MongoDB's Projections to simplify the creation of Bson. It retrieves all fields except _id and boringField:
Here is an example that uses MongoDB’s Projections to simplify the creation of Bson. It retrieves all fields except \_id and boringField:

```java
// route: from("direct:findAll").to("mongodb3:myDb?database=flights&collection=tickets&operation=findAll")
Bson fieldProjection = Projection.exclude("_id", "boringField");
Object result = template.requestBodyAndHeader("direct:findAll", ObjectUtils.NULL,
MongoDbConstants.FIELDS_PROJECTION, fieldProjection);
```

218.5.1.6. Specifying a sort clause

There is often a requirement to fetch the min/max record from a collection based on sorting by a particular field that uses MongoDB’s Sorts to simplify the creation of Bson. It retrieves all fields except \_id and boringField:

```java
// route: from("direct:findAll").to("mongodb3:myDb?database=flights&collection=tickets&operation=findAll")
Bson sorts = Sorts.descending("_id");
Object result = template.requestBodyAndHeader("direct:findAll", ObjectUtils.NULL,
MongoDbConstants.SORT_BY, sorts);
```

In a Camel route the SORT_BY header can be used with the findOneByQuery operation to achieve the same result. If the FIELDS_PROJECTION header is also specified the operation will return a single field/value pair that can be passed directly to another component (for example, a parameterized MyBatis SELECT query). This example demonstrates fetching the temporally newest document from a collection and reducing the result to a single field, based on the documentTimestamp field:

```java
// route: from("direct:someTriggeringEvent")
.setHeader(MongoDbConstants.SORT_BY).constant(Sorts.descending("documentTimestamp"))
.setHeader(MongoDbConstants.FIELDS_PROJECTION).constant(Projection.include("documentTimestamp"))
.setBody().constant(
"{}"
).to("mongodb3:myDb?database=local&collection=myDemoCollection&operation=findOneByQuery")
.to("direct:aMyBatisParameterizedSelect")
```

218.5.2. Create/update operations

218.5.2.1. insert

Inserts an new object into the MongoDB collection, taken from the IN message body. Type conversion is attempted to turn it into Document or a List.

Two modes are supported: single insert and multiple insert. For multiple insert, the endpoint will expect a List, Array or Collections of objects of any type, as long as they are - or can be converted to - Document. Example:
from("direct:insert")
    .to("mongodb3:myDb?database=flights&collection=tickets&operation=insert");

The operation will return a WriteResult, and depending on the WriteConcern or the value of the invokeGetLastError option, getLastError() would have been called already or not. If you want to access the ultimate result of the write operation, you need to retrieve the CommandResult by calling getLastError() or getCachedLastError() on the WriteResult. Then you can verify the result by calling CommandResult.ok(), CommandResult.getMessage() and/or CommandResult.getException().

Note that the new object's _id must be unique in the collection. If you don’t specify the value, MongoDB will automatically generate one for you. But if you do specify it and it is not unique, the insert operation will fail (and for Camel to notice, you will need to enable invokeGetLastError or set a WriteConcern that waits for the write result).

This is not a limitation of the component, but it is how things work in MongoDB for higher throughput. If you are using a custom _id, you are expected to ensure at the application level that is unique (and this is a good practice too).

OID(s) of the inserted record(s) is stored in the message header under CamelMongoOid key (MongoDbConstants.OID constant). The value stored is org.bson.types.ObjectId for single insert or java.util.List<org.bson.types.ObjectId> if multiple records have been inserted.

In MongoDB Java Driver 3.x the insertOne and insertMany operation return void. The Camel insert operation return the Document or List of Documents inserted. Note that each Documents are Updated by a new OID if need.

218.5.2.2. save

The save operation is equivalent to an upsert (UPdate, inSERT) operation, where the record will be updated, and if it doesn’t exist, it will be inserted, all in one atomic operation. MongoDB will perform the matching based on the _id field.

Beware that in case of an update, the object is replaced entirely and the usage of MongoDB’s $modifiers is not permitted. Therefore, if you want to manipulate the object if it already exists, you have two options:

1. perform a query to retrieve the entire object first along with all its fields (may not be efficient), alter it inside Camel and then save it.

2. use the update operation with $modifiers, which will execute the update at the server-side instead. You can enable the upsert flag, in which case if an insert is required, MongoDB will apply the $modifiers to the filter query object and insert the result.

If the document to be saved does not contain the _id attribute, the operation will be an insert, and the new _id created will be placed in the CamelMongoOid header.

For example:

from("direct:insert")
    .to("mongodb3:myDb?database=flights&collection=tickets&operation=save");

218.5.2.3. update

Update one or multiple records on the collection. Requires a filter query and a update rules.
You can define the filter using MongoDBConstants.CRITERIA header as Bson and define the update rules as Bson in Body.

The second way Require a List<Bson> as the IN message body containing exactly 2 elements:

- Element 1 (index 0) => filter query => determines what objects will be affected, same as a typical query object
- Element 2 (index 1) => update rules => how matched objects will be updated. All modifier operations from MongoDB are supported.

**NOTE**

Multiupdates. By default, MongoDB will only update 1 object even if multiple objects match the filter query. To instruct MongoDB to update all matching records, set the CamelMongoDbMultiUpdate IN message header to true.

A header with key CamelMongoDbRecordsAffected will be returned (MongoDBConstants.RECORDS_AFFECTED constant) with the number of records updated (copied from WriteResult.getN()).

Supports the following IN message headers:

<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMongoDbMultiUpdate</td>
<td>MongoDbConstants.MULTIUPDATE</td>
<td>If the update should be applied to all objects matching. See <a href="http://www.mongod.org/display/DOCS/Atomic+Operations">http://www.mongod.org/display/DOCS/Atomic+Operations</a></td>
<td>boolean/Boolean</td>
</tr>
</tbody>
</table>
For example, the following will update all records whose filterField field equals true by setting the value of the "scientist" field to "Darwin":"n
```
// route: from("direct:update").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=update");
Bson filterField = Filters.eq("filterField", true);
String updateObj = Updates.set("scientist", "Darwin");
Object result = template.requestBodyAndHeader("direct:update",
new Bson[] {filterField, Document.parse(updateObj)},
MongoDbConstants.MULTIUPDATE, true);
```

```java
// route: from("direct:update").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=update");
Maps<String, Object> headers = new HashMap<>(2);
headers.add(MongoDbConstants.MULTIUPDATE, true);
headers.add(MongoDbConstants.FIELDS_FILTER, Filters.eq("filterField", true));
String updateObj = Updates.set("scientist", "Darwin");
Object result = template.requestBodyAndHeaders("direct:update", updateObj, headers);
```

```java
// route: from("direct:update").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=update");
String updateObj = "[{"filterField": true}, {"$set": {"scientist": "Darwin"}}]";
Object result = template.requestBodyAndHeader("direct:update", updateObj,
MongoDbConstants.MULTIUPDATE, true);
```

### 218.5.3. Delete operations

#### 218.5.3.1. remove

Remove matching records from the collection. The IN message body will act as the removal filter query, and is expected to be of type **DBObject** or a type convertible to it.
The following example will remove all objects whose field 'conditionField' equals true, in the science database, notableScientists collection:

```java
// route: from("direct:remove").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=remove");
Bson conditionField = Filters.eq("conditionField", true);
Object result = template.requestBody("direct:remove", conditionField);
```

A header with key CamelMongoDbRecordsAffected is returned (MongoDbConstants.RECORDS_AFFECTED constant) with type int, containing the number of records deleted (copied from WriteResult.getN()).

### 218.5.4. Bulk Write Operations

#### 218.5.4.1. bulkWrite

Available as of Camel 2.21

Performs write operations in bulk with controls for order of execution. Requires a `List<WriteModel<Document>>` as the IN message body containing commands for insert, update, and delete operations.

The following example will insert a new scientist "Pierre Curie", update record with id "5" by setting the value of the "scientist" field to "Marie Curie" and delete record with id "3":

```java
// route: from("direct:bulkWrite").to("mongodb:myDb?
database=science&collection=notableScientists&operation=bulkWrite");
List<WriteModel<Document>> bulkOperations = Arrays.asList(
    new InsertOneModel<>(new Document("scientist", "Pierre Curie")),
    new UpdateOneModel<>(new Document("_id", "5"),
        new Document("$set", new Document("scientist", "Marie Curie"))),
    new DeleteOneModel<>(new Document("_id", "3"));

BulkWriteResult result = template.requestBody("direct:bulkWrite", bulkOperations,
    BulkWriteResult.class);
```

By default, operations are executed in order and interrupted on the first write error without processing any remaining write operations in the list. To instruct MongoDB to continue to process remaining write operations in the list, set the CamelMongoDbBulkOrdered IN message header to false. Unordered operations are executed in parallel and this behavior is not guaranteed.
### Camel

<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMongoDbBulkOrdered</td>
<td>MongoDbConstants.BULK_ORDERED</td>
<td>Perform an ordered or unordered operation execution. Default is to true.</td>
<td>boolean/Boolean</td>
</tr>
</tbody>
</table>

#### 218.5.5. Other operations

**218.5.5.1. aggregate**

Perform a aggregation with the given pipeline contained in the body. **Aggregations could be long and heavy operations. Use with care.**

```java
// route: from("direct:aggregate").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=aggregate");
List<Bson> aggregate = Arrays.asList(match(or(eq("scientist", "Darwin"), eq("scientist", 
group("$scientist", sum("count", 1)));
from("direct:aggregate")
  .setBody().constant(aggregate)
  .to("mongodb3:myDb?database=science&collection=notableScientists&operation=aggregate")
  .to("mock:resultAggregate");
```

Supports the following IN message headers:
<table>
<thead>
<tr>
<th>Header key</th>
<th>Quick constant</th>
<th>Description (extracted from MongoDB API doc)</th>
<th>Expected type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMongoDbBatchSize</td>
<td>MangoDbConstants.BATCH_SIZE</td>
<td>Sets the number of documents to return per batch.</td>
<td>int/Integer</td>
</tr>
<tr>
<td>CamelMongoDbAllowDiskUse</td>
<td>MangoDbConstantsALLOW_DISK_USE</td>
<td>Enable aggregation pipeline stages to write data to temporary files.</td>
<td>boolean/Boolean</td>
</tr>
</tbody>
</table>

Efficient retrieval is supported via outputType=MongoIterable.

You can also "stream" the documents returned from the server into your route by including outputType=DCursor (Camel 2.21+) as an endpoint option which may prove simpler than setting the above headers. This hands your Exchange the DBCursor from the Mongo driver, just as if you were executing the aggregate() within the Mongo shell, allowing your route to iterate over the results. By default and without this option, this component will load the documents from the driver’s cursor into a List and return this to your route - which may result in a large number of in-memory objects. Remember, with a DBCursor do not ask for the number of documents matched - see the MongoDB documentation site for details.

Example with option outputType=MongoIterable and batch size:

```java
// route: from("direct:aggregate").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=aggregate&outputType=MongoIterable");
List<Bson> aggregate = Arrays.asList(match(or(eq("scientist", "Darwin"), eq("scientist",
group("$scientist", sum("count", 1)));
from("direct:aggregate")
 .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
 .setBody().constant(aggregate)
```
218.5.5.2. getDbStats

Equivalent of running the `db.stats()` command in the MongoDB shell, which displays useful statistic figures about the database.

For example:

```
> db.stats();
{
  "db" : "test",
  "collections" : 7,
  "objects" : 719,
  "avgObjSize" : 59.73296244784423,
  "dataSize" : 42948,
  "storageSize" : 1000058880,
  "numExtents" : 9,
  "indexes" : 4,
  "indexSize" : 32704,
  "fileSize" : 1275068416,
  "nsSizeMB" : 16,
  "ok" : 1
}
```

Usage example:

```
// from("direct:getDbStats").to("mongodb3:myDb?
database=flights&collection=tickets&operation=getDbStats");
Object result = template.requestBody("direct:getDbStats", "irrelevantBody");
assertTrue("Result is not of type Document", result instanceof Document);
```

The operation will return a data structure similar to the one displayed in the shell, in the form of a Document in the OUT message body.

218.5.5.3. getColStats

Equivalent of running the `db.collection.stats()` command in the MongoDB shell, which displays useful statistic figures about the collection.

For example:

```
> db.camelTest.stats();
{
  "ns" : "test.camelTest",
  "count" : 100,
  "size" : 5792,
  "avgObjSize" : 57.92,
  "storageSize" : 20480,
  "numExtents" : 2,
  "nindexes" : 1,
  "lastExtentSize" : 16384,
  "paddingFactor" : 1,
  "flags" : 1,
}
```
Usage example:

```java
// from("direct:getColStats").to("mongodb3:myDb?database=flights&collection=tickets&operation=getColStats");
Object result = template.requestBody("direct:getColStats", "irrelevantBody");
assertTrue("Result is not of type Document", result instanceof Document);
```

The operation will return a data structure similar to the one displayed in the shell, in the form of a Document in the OUT message body.

### 218.5.5.4. command

Run the body as a command on database. Usefull for admin operation as getting host informations, replication or sharding status.

Collection parameter is not use for this operation.

```java
// route: from("command").to("mongodb3:myDb?database=science&operation=command");
DBObject commandBody = new BasicDBObject("hostInfo", "1");
Object result = template.requestBody("direct:command", commandBody);
```

### 218.5.6. Dynamic operations

An Exchange can override the endpoint’s fixed operation by setting the CamelMongoDbOperation header, defined by the `MongoDbConstants.OPERATION_HEADER` constant. The values supported are determined by the MongoDbOperation enumeration and match the accepted values for the operation parameter on the endpoint URI.

For example:

```java
// from("direct:insert").to("mongodb3:myDb?database=flights&collection=tickets&operation=insert");
Object result = template.requestBodyAndHeader("direct:insert", "irrelevantBody",
MongoDbConstants.OPERATION_HEADER, "count");
assertTrue("Result is not of type Long", result instanceof Long);
```

### 218.6. TAILABLE CURSOR CONSUMER

MongoDB offers a mechanism to instantaneously consume ongoing data from a collection, by keeping the cursor open just like the `tail -f` command of *nix systems. This mechanism is significantly more efficient than a scheduled poll, due to the fact that the server pushes new data to the client as it becomes available, rather than making the client ping back at scheduled intervals to fetch new data. It also reduces otherwise redundant network traffic.

There is only one requisite to use tailable cursors: the collection must be a “capped collection”, meaning that it will only hold N objects, and when the limit is reached, MongoDB flushes old objects in the same order they were originally inserted. For more information, please refer to:
The Camel MongoDB component implements a tailable cursor consumer, making this feature available for you to use in your Camel routes. As new objects are inserted, MongoDB will push them as Document in natural order to your tailable cursor consumer, who will transform them to an Exchange and will trigger your route logic.

218.7. HOW THE TAILABLE CURSOR CONSUMER WORKS

To turn a cursor into a tailable cursor, a few special flags are to be signalled to MongoDB when first generating the cursor. Once created, the cursor will then stay open and will block upon calling the MongoCursor.next() method until new data arrives. However, the MongoDB server reserves itself the right to kill your cursor if new data doesn’t appear after an indeterminate period. If you are interested to continue consuming new data, you have to regenerate the cursor. And to do so, you will have to remember the position where you left off or else you will start consuming from the top again.

The Camel MongoDB tailable cursor consumer takes care of all these tasks for you. You will just need to provide the key to some field in your data of increasing nature, which will act as a marker to position your cursor every time it is regenerated, e.g. a timestamp, a sequential ID, etc. It can be of any datatype supported by MongoDB. Date, Strings and Integers are found to work well. We call this mechanism "tail tracking" in the context of this component.

The consumer will remember the last value of this field and whenever the cursor is to be regenerated, it will run the query with a filter like: increasingField > lastValue, so that only unread data is consumed.

**Setting the increasing field:** Set the key of the increasing field on the endpoint URI tailTrackingIncreasingField option. In Camel 2.10, it must be a top-level field in your data, as nested navigation for this field is not yet supported. That is, the "timestamp" field is okay, but "nested.timestamp" will not work. Please open a ticket in the Camel JIRA if you do require support for nested increasing fields.

**Cursor regeneration delay:** One thing to note is that if new data is not already available upon initialisation, MongoDB will kill the cursor instantly. Since we don’t want to overwhelm the server in this case, a cursorRegenerationDelay option has been introduced (with a default value of 1000ms.), which you can modify to suit your needs.

An example:

```xml
from("mongodb3:myDb?database=flights&collection=cancellations&tailTrackIncreasingField=departureTime")
.id("tailableCursorConsumer1")
.autoStartup(false)
.to("mock:test");
```

The above route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms.

218.8. PERSISTENT TAIL TRACKING

Standard tail tracking is volatile and the last value is only kept in memory. However, in practice you will need to restart your Camel container every now and then, but your last value would then be lost and your tailable cursor consumer would start consuming from the top again, very likely sending duplicate records into your route.
To overcome this situation, you can enable the **persistent tail tracking** feature to keep track of the last consumed increasing value in a special collection inside your MongoDB database too. When the consumer initialises again, it will restore the last tracked value and continue as if nothing happened.

The last read value is persisted on two occasions: every time the cursor is regenerated and when the consumer shuts down. We may consider persisting at regular intervals too in the future (flush every 5 seconds) for added robustness if the demand is there. To request this feature, please open a ticket in the Camel JIRA.

### 218.9. ENABLING PERSISTENT TAIL TRACKING

To enable this function, set at least the following options on the endpoint URI:

- **persistentTailTracking** option to `true`
- **persistentId** option to a unique identifier for this consumer, so that the same collection can be reused across many consumers

Additionally, you can set the **tailTrackDb**, **tailTrackCollection** and **tailTrackField** options to customise where the runtime information will be stored. Refer to the endpoint options table at the top of this page for descriptions of each option.

For example, the following route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms, with persistent tail tracking turned on, and persisting under the "cancellationsTracker" id on the "flights.camelTailTracking", storing the last processed value under the "lastTrackingValue" field (**camelTailTracking** and **lastTrackingValue** are defaults).

```java
from("mongodb3:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTracking=true")
  .id("tailableCursorConsumer2")
  .autoStartup(false)
  .to("mock:test");
```

Below is another example identical to the one above, but where the persistent tail tracking runtime information will be stored under the "trackers.camelTrackers" collection, in the "lastProcessedDepartureTime" field:

```java
from("mongodb3:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTracking=true")
  .id("tailableCursorConsumer3")
  .autoStartup(false)
  .to("mock:test");
```

### 218.10. TYPE CONVERSIONS

The **MongoDbBasicConverters** type converter included with the camel-mongodb component provides the following conversions:
<table>
<thead>
<tr>
<th>Name</th>
<th>From type</th>
<th>To type</th>
<th>How?</th>
</tr>
</thead>
<tbody>
<tr>
<td>fromMapToDocument</td>
<td>Map</td>
<td>Document</td>
<td>constructs a new Document via the new Document(Map m) constructor.</td>
</tr>
<tr>
<td>fromDocumentToMap</td>
<td>Document</td>
<td>Map</td>
<td>Document already implements Map.</td>
</tr>
<tr>
<td>fromAnyObjectToDocument</td>
<td>Object</td>
<td>Document</td>
<td>uses the Jackson library to convert the object to a Map, which is in turn used to initialise a new Document.</td>
</tr>
<tr>
<td>fromStringToList</td>
<td>String</td>
<td>List&lt;Bson&gt;</td>
<td>uses org.bson.codecs.configuration.CodecRegistries to convert to BsonArray then to List&lt;Bson&gt;.</td>
</tr>
</tbody>
</table>

This type converter is auto-discovered, so you don’t need to configure anything manually.

CHAPTER 219. MQTT COMPONENT

Available as of Camel version 2.10

The `mqtt:` component is used for communicating with MQTT compliant message brokers, like Apache ActiveMQ or Mosquitto.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mqtt</artifactId>
  <version>x.x.x</version>
</dependency>
```

219.1. URI FORMAT

```
mqtt://name[?options]
```

Where `name` is the name you want to assign the component.

219.2. OPTIONS

The MQTT component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>host</code> (common)</td>
<td>The URI of the MQTT broker to connect too - this component also supports SSL - e.g. <code>ssl://127.0.0.1:8883</code></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>userName</code> (security)</td>
<td>Username to be used for authentication against the MQTT broker</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>password</code> (security)</td>
<td>Password to be used for authentication against the MQTT broker</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>resolveProperty Placeholders</code></td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The MQTT endpoint is configured using URI syntax:

```
mqtt:name
```

with the following path and query parameters:
### 219.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td><strong>Required</strong> A logical name to use which is not the topic name.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 219.2.2. Query Parameters (39 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>blockingExecutor</td>
<td>SSL connections perform blocking operations against internal thread pool unless you call the setBlockingExecutor method to configure that executor they will use instead.</td>
<td></td>
<td>Executor</td>
</tr>
<tr>
<td>byDefaultRetain</td>
<td>The default retain policy to be used on messages sent to the MQTT broker</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>cleanSession</td>
<td>Set to false if you want the MQTT server to persist topic subscriptions and ack positions across client sessions. Defaults to true.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>clientId</td>
<td>Use to set the client Id of the session. This is what an MQTT server uses to identify a session where setCleanSession(false); is being used. The id must be 23 characters or less. Defaults to auto generated id (based on your socket address, port and timestamp).</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>connectAttemptsMax</td>
<td>The maximum number of reconnect attempts before an error is reported back to the client on the first attempt by the client to connect to a server. Set to -1 to use unlimited attempts. Defaults to -1.</td>
<td>-1</td>
<td>long</td>
</tr>
<tr>
<td>connectWaitInSeconds</td>
<td>Delay in seconds the Component will wait for a connection to be established to the MQTT broker</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>disconnectWaitInSeconds</td>
<td>The number of seconds the Component will wait for a valid disconnect on stop() from the MQTT broker</td>
<td>5</td>
<td>int</td>
</tr>
<tr>
<td>dispatchQueue</td>
<td>A HawtDispatch dispatch queue is used to synchronize access to the connection. If an explicit queue is not configured via the setDispatchQueue method, then a new queue will be created for the connection. Setting an explicit queue might be handy if you want multiple connection to share the same queue for synchronization.</td>
<td></td>
<td>DispatchQueue</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>host (common)</td>
<td>The URI of the MQTT broker to connect too - this component also supports SSL - e.g. ssl://127.0.0.1:8883</td>
<td>tcp://127.0.0.1:8883</td>
<td>URI</td>
</tr>
<tr>
<td>keepAlive (common)</td>
<td>Configures the Keep Alive timer in seconds. Defines the maximum time interval between messages received from a client. It enables the server to detect that the network connection to a client has dropped, without having to wait for the long TCP/IP timeout.</td>
<td></td>
<td>short</td>
</tr>
<tr>
<td>localAddress (common)</td>
<td>The local InetAddress and port to use</td>
<td></td>
<td>URI</td>
</tr>
<tr>
<td>maxReadRate (common)</td>
<td>Sets the maximum bytes per second that this transport will receive data at. This setting throttles reads so that the rate is not exceeded. Defaults to 0 which disables throttling.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>maxWriteRate (common)</td>
<td>Sets the maximum bytes per second that this transport will send data at. This setting throttles writes so that the rate is not exceeded. Defaults to 0 which disables throttling.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>mqttQosPropertyName (common)</td>
<td>The property name to look for on an Exchange for an individual published message. If this is set (one of AtMostOnce, AtLeastOnce or ExactlyOnce) - then that QoS will be set on the message sent to the MQTT message broker.</td>
<td>MQTT Qos</td>
<td>String</td>
</tr>
<tr>
<td>mqttRetainPropertyName (common)</td>
<td>The property name to look for on an Exchange for an individual published message. If this is set (expects a Boolean value) - then the retain property will be set on the message sent to the MQTT message broker.</td>
<td>MQTT Retain</td>
<td>String</td>
</tr>
<tr>
<td>mqttTopicPropertyName (common)</td>
<td>These a properties that are looked for in an Exchange - to publish to</td>
<td>MQTT TopicPropertyName</td>
<td>String</td>
</tr>
<tr>
<td>publishTopicName (common)</td>
<td>The default Topic to publish messages on</td>
<td>camel/mqtt/test</td>
<td>String</td>
</tr>
<tr>
<td>qualityOfService (common)</td>
<td>Quality of service level to use for topics.</td>
<td>AtLeastOnce</td>
<td>String</td>
</tr>
<tr>
<td>receiveBufferSize (common)</td>
<td>Sets the size of the internal socket receive buffer. Defaults to 65536 (64k)</td>
<td>65536</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>reconnectAttemptsMax (common)</td>
<td>The maximum number of reconnect attempts before an error is reported back to the client after a server connection had previously been established. Set to -1 to use unlimited attempts. Defaults to -1.</td>
<td>-1</td>
<td>long</td>
</tr>
<tr>
<td>reconnectBackoffMultiplier (common)</td>
<td>The Exponential backoff be used between reconnect attempts. Set to 1 to disable exponential backoff. Defaults to 2.</td>
<td>2.0</td>
<td>double</td>
</tr>
<tr>
<td>reconnectDelay (common)</td>
<td>How long to wait in ms before the first reconnect attempt. Defaults to 10.</td>
<td>10</td>
<td>long</td>
</tr>
<tr>
<td>reconnectDelayMax (common)</td>
<td>The maximum amount of time in ms to wait between reconnect attempts. Defaults to 30,000.</td>
<td>30000</td>
<td>long</td>
</tr>
<tr>
<td>sendBufferSize (common)</td>
<td>Sets the size of the internal socket send buffer. Defaults to 65536 (64k)</td>
<td>65536</td>
<td>int</td>
</tr>
<tr>
<td>sendWaitInSeconds (common)</td>
<td>The maximum time the Component will wait for a receipt from the MQTT broker to acknowledge a published message before throwing an exception</td>
<td>5</td>
<td>int</td>
</tr>
<tr>
<td>sslContext (common)</td>
<td>To configure security using SSLContext configuration</td>
<td>SSLContext</td>
<td></td>
</tr>
<tr>
<td>subscribeTopicName (common)</td>
<td>Deprecated These are set on the Endpoint - together with properties inherited from MQTT</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>subscribeTopicNames (common)</td>
<td>A comma-delimited list of Topics to subscribe to for messages. Note that each item of this list can contain MQTT wildcards ( and/or ), in order to subscribe to topics matching a certain pattern within a hierarchy. For example, is a wildcard for all topics at a level within the hierarchy, so if a broker has topics/topics/one and topics/two, then topics/ can be used to subscribe to both. A caveat to consider here is that if the broker adds topics/three, the route would also begin to receive messages from that topic.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>trafficClass (common)</td>
<td>Sets traffic class or type-of-service octet in the IP header for packets sent from the transport. Defaults to 8 which means the traffic should be optimized for throughput.</td>
<td>8</td>
<td>int</td>
</tr>
<tr>
<td>version (common)</td>
<td>Set to 3.1.1 to use MQTT version 3.1.1. Otherwise defaults to the 3.1 protocol version.</td>
<td>3.1</td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------</td>
</tr>
<tr>
<td>willMessage</td>
<td>The Will message to send. Defaults to a zero length message.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>willQos</td>
<td>Sets the quality of service to use for the Will message. Defaults to AT_MOST_ONCE.</td>
<td></td>
<td>QoS</td>
</tr>
<tr>
<td>willRetain</td>
<td>Set to true if you want the Will to be published with the retain option.</td>
<td></td>
<td>QoS</td>
</tr>
<tr>
<td>willTopic</td>
<td>If set the server will publish the client’s Will message to the specified topics if the client has an unexpected disconnection.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>lazySessionCreation</td>
<td>Sessions can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 219.3. SAMPLES

**Sending messages:**
```
from("direct:foo").to("mqtt:cheese?publishTopicName=test.mqtt.topic");
```

**Consuming messages:**

-
Camel supports the Message Endpoint pattern using the Endpoint interface. Endpoints are usually created by a Component and Endpoints are usually referred to in the DSL via their URIs.

From an Endpoint you can use the following methods

- `createProducer()` will create a Producer for sending message exchanges to the endpoint
- `createConsumer()` implements the Event Driven Consumer pattern for consuming message exchanges from the endpoint via a Processor when creating a Consumer
- `createPollingConsumer()` implements the Polling Consumer pattern for consuming message exchanges from the endpoint via a PollingConsumer

### 219.5. SEE ALSO

- Configuring Camel
- Message Endpoint pattern
- URIs
- Writing Components
CHAPTER 220. MSV COMPONENT

Available as of Camel version 1.1

The MSV component performs XML validation of the message body using the MSV Library and any of the supported XML schema languages, such as XML Schema or RelaxNG XML Syntax.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-msv</artifactId>
    <version>x.x.x</version>
</dependency>
```

Note that the Jing component also supports RelaxNG Compact Syntax

220.1. URI FORMAT

```text
msv:someLocalOrRemoteResource[?options]
```

Where `someLocalOrRemoteResource` is some URL to a local resource on the classpath or a full URL to a remote resource or resource on the file system. For example

```text
msv:org/foo/bar.rng
msv:file:../foo/bar.rng
msv:http://acme.com/cheese.rng
```

You can append query options to the URI in the following format, `?option=value&option=value&…`

220.2. OPTIONS

The MSV component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaFactory</td>
<td>To use the javax.xml.validation.SchemaFactory.</td>
<td></td>
<td>SchemaFactory</td>
</tr>
<tr>
<td>resourceResolverFactor</td>
<td>To use a custom LSResourceResolver which depends on a dynamic endpoint resource URI</td>
<td></td>
<td>ValidatorResourceResolverFactory</td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The MSV endpoint is configured using URI syntax:
msv:resourceUri

with the following path and query parameters:

### 220.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td>Required URL to a local resource on the classpath, or a reference to lookup a bean in the Registry, or a full URL to a remote resource or resource on the file system which contains the XSD to validate against.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 220.2.2. Query Parameters (11 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>failOnNullBody (producer)</td>
<td>Whether to fail if no body exists.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>failOnNullHeader (producer)</td>
<td>Whether to fail if no header exists when validating against a header.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>headerName (producer)</td>
<td>To validate against a header instead of the message body.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>errorHandler (advanced)</td>
<td>To use a custom org.apache.camel.processor.validation.ValidatorErrorHandler. The default error handler captures the errors and throws an exception.</td>
<td></td>
<td>ValidatorErrorHandler</td>
</tr>
<tr>
<td>resourceResolver (advanced)</td>
<td>To use a custom LSResourceResolver. Do not use together with resourceResolverFactory</td>
<td></td>
<td>LSResourceResolver</td>
</tr>
<tr>
<td>resourceResolverFactory (advanced)</td>
<td>To use a custom LSResourceResolver which depends on a dynamic endpoint resource URL. The default resource resolver factory returns a resource resolver which can read files from the class path and file system. Do not use together with resourceResolver.</td>
<td></td>
<td>ValidatorResourceResolverFactory</td>
</tr>
<tr>
<td>schemaFactory (advanced)</td>
<td>To use a custom javax.xml.validation.SchemaFactory</td>
<td></td>
<td>SchemaFactory</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td><code>schemaLanguage</code> (advanced)</td>
<td>Configures the W3C XML Schema Namespace URI.</td>
<td><a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a></td>
<td>String</td>
</tr>
<tr>
<td><code>synchronous</code> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>useDom</code> (advanced)</td>
<td>Whether DOMSource/DOMResult or SaxSource/SaxResult should be used by the validator.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>useSharedSchema</code> (advanced)</td>
<td>Whether the Schema instance should be shared or not. This option is introduced to work around a JDK 1.6.x bug. Xerces should not have this issue.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 220.3. EXAMPLE

The following example shows how to configure a route from endpoint `direct:start` which then goes to one of two endpoints, either `mock:valid` or `mock:invalid` based on whether or not the XML matches the given RelaxNG XML Schema (which is supplied on the classpath).

### 220.4. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 221. MUSTACHE COMPONENT

Available as of Camel version 2.12

The mustache: component allows for processing a message using a Mustache template. This can be ideal when using Templating to generate responses for requests.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mustache</artifactId>
  <version>x.x.x</version> <!-- use the same version as your Camel core version -->
</dependency>
```

221.1. URI FORMAT

mustache:templateName[?options]

Where templateName is the classpath-local URI of the template to invoke; or the complete URL of the remote template (eg: file://folder/myfile.mustache).

You can append query options to the URI in the following format, ?option=value&option=value&…

221.2. OPTIONS

The Mustache component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>mustacheFactory</td>
<td>To use a custom MustacheFactory</td>
<td></td>
<td>MustacheFactory</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Mustache endpoint is configured using URI syntax:

mustache:resourceUri

with the following path and query parameters:

221.2.1. Path Parameters (1 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td><strong>Required</strong> Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 221.2.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentCache</td>
<td>Sets whether to use resource content cache or not</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>encoding</td>
<td>Character encoding of the resource content.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>endDelimiter</td>
<td>Characters used to mark template code end.</td>
<td>}</td>
<td>String</td>
</tr>
<tr>
<td>startDelimiter</td>
<td>Characters used to mark template code beginning.</td>
<td>{}</td>
<td>String</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 221.3. MUSTACHE CONTEXT

Camel will provide exchange information in the Mustache context (just a Map). The Exchange is transferred as:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>exchange</td>
<td>The Exchange itself.</td>
</tr>
<tr>
<td>exchange.properties</td>
<td>The Exchange properties.</td>
</tr>
<tr>
<td>key</td>
<td>value</td>
</tr>
<tr>
<td>-------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>headers</td>
<td>The headers of the In message.</td>
</tr>
<tr>
<td>camel Context</td>
<td>The Camel Context.</td>
</tr>
<tr>
<td>request</td>
<td>The In message.</td>
</tr>
<tr>
<td>body</td>
<td>The In message body.</td>
</tr>
<tr>
<td>response</td>
<td>The Out message (only for InOut message exchange pattern).</td>
</tr>
</tbody>
</table>

### 221.4. DYNAMIC TEMPLATES

Camel provides two headers by which you can define a different resource location for a template or the template content itself. If any of these headers is set then Camel uses this over the endpoint configured resource. This allows you to provide a dynamic template at runtime.

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MustacheConstants.MUSTACHE_HE_SOURCE_URI</td>
<td>String</td>
<td>A URI for the template resource to use instead of the endpoint configured.</td>
</tr>
</tbody>
</table>
### 221.5. SAMPLES

For example you could use something like:

```java
from("activemq:My.Queue").
to("mustache:com/acme/MyResponse.mustache");
```

To use a Mustache template to formulate a response for a message for InOut message exchanges (where there is a `JMSReplyTo` header).

If you want to use InOnly and consume the message and send it to another destination you could use:

```java
from("activemq:My.Queue").
to("mustache:com/acme/MyResponse.mustache").
to("activemq:Another.Queue");
```

It’s possible to specify what template the component should use dynamically via a header, so for example:

```java
from("direct:in").
setHeader(MustacheConstants.MUSTACHE_RESOURCE_URI).constant("path/to/my/template.mustache").
to("mustache:dummy");
```

### 221.6. THE EMAIL SAMPLE

In this sample we want to use Mustache templating for an order confirmation email. The email template is laid out in Mustache as:

```mustache
Dear {{headers.lastName}}, {{headers.firstName}}

Thanks for the order of {{headers.item}}.

Regards Camel Riders Bookstore
{{body}}
```
221.7. SEE ALSO

- Endpoint
- Getting Started
CHAPTER 222. MVEL COMPONENT

Available as of Camel version 2.12

The **mvel:** component allows you to process a message using an MVEL template. This can be ideal when using Templating to generate responses for requests.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mvel</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

222.1. URI FORMAT

```
mvel:templateName[?options]
```

Where **templateName** is the classpath-local URI of the template to invoke; or the complete URL of the remote template (eg: file://folder/myfile.mvel).

You can append query options to the URI in the following format, `?option=value&option=value&…`

222.2. OPTIONS

The MVEL component has no options.

The MVEL endpoint is configured using URI syntax:

```
mvel:resourceUri
```

with the following path and query parameters:

222.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td><strong>Required</strong> Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

222.2.2. Query Parameters (3 parameters):
### 222.3. MESSAGE HEADERS

The mvel component sets a couple headers on the message.

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMvelResourceUri</td>
<td>The <code>templateName</code> as a <code>String</code> object.</td>
</tr>
</tbody>
</table>

### 222.4. MVEL CONTEXT

Camel will provide exchange information in the MVEL context (just a `Map`). The `Exchange` is transferred as:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>exchange</td>
<td>The <code>Exchange</code> itself.</td>
</tr>
<tr>
<td>exchange.properties</td>
<td>The <code>Exchange</code> properties.</td>
</tr>
<tr>
<td>headers</td>
<td>The headers of the In message.</td>
</tr>
<tr>
<td>camelContext</td>
<td>The Camel Context intance.</td>
</tr>
<tr>
<td>request</td>
<td>The In message.</td>
</tr>
</tbody>
</table>
222.5. HOT RELOADING

The mvel template resource is, by default, hot reloadable for both file and classpath resources (expanded jar). If you set `contentCache=true`, Camel will only load the resource once, and thus hot reloading is not possible. This scenario can be used in production, when the resource never changes.

222.6. DYNAMIC TEMPLATES

Camel provides two headers by which you can define a different resource location for a template or the template content itself. If any of these headers is set then Camel uses this over the endpoint configured resource. This allows you to provide a dynamic template at runtime.

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMvelResourceUri</td>
<td>String</td>
<td>A URI for the template resource to use instead of the endpoint configured.</td>
</tr>
<tr>
<td>CamelMvelTemplate</td>
<td>String</td>
<td>The template to use instead of the endpoint configured.</td>
</tr>
</tbody>
</table>

222.7. SAMPLES

For example you could use something like

```java
from("activemq:My.Queue").
to("mvel:com/acme/MyResponse.mvel");
```

To use a MVEL template to formulate a response to a message for InOut message exchanges (where there is a `JMSReplyTo` header).

To specify what template the component should use dynamically via a header, so for example:

```java
from("direct:in").
setHeader("CamelMvelResourceUri").constant("path/to/my/template.mvel").
to("mvel:dummy");
```
To specify a template directly as a header the component should use dynamically via a header, so for example:

```java
from("direct:in").
    setHeader("CamelMvelTemplate").constant("@{"The result is \" + request.body * 3\" }").
    to("velocity:dummy");
```

### 222.8. SEE ALSO

- Component
- Endpoint
- Getting Started
CHAPTER 223. MVEL LANGUAGE

Available as of Camel version 2.0

Camel allows Mvel to be used as an Expression or Predicate the DSL or Xml Configuration.

You could use Mvel to create an Predicate in a Message Filter or as an Expression for a Recipient List.

You can use Mvel dot notation to invoke operations. If you for instance have a body that contains a POJO that has a `getFamilyName` method then you can construct the syntax as follows:

```java
"request.body.familyName"
// or
"getRequest().getBody().getFamilyName()"
```

223.1. MVEL OPTIONS

The MVEL language supports 1 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trim</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to trim the value to remove leading and trailing whitespaces and line breaks</td>
</tr>
</tbody>
</table>

223.2. VARIABLES

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>this</td>
<td>Exchange</td>
<td>the Exchange is the root object</td>
</tr>
<tr>
<td>exchange</td>
<td>Exchange</td>
<td>the Exchange object</td>
</tr>
<tr>
<td>exception</td>
<td>Throwable</td>
<td>the Exchange exception (if any)</td>
</tr>
<tr>
<td>exchangeld</td>
<td>String</td>
<td>the exchange id</td>
</tr>
<tr>
<td>fault</td>
<td>Message</td>
<td>the Fault message (if any)</td>
</tr>
<tr>
<td>request</td>
<td>Message</td>
<td>the exchange.in message</td>
</tr>
<tr>
<td>Variable</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>response</td>
<td>Message</td>
<td>the exchange.out message (if any)</td>
</tr>
<tr>
<td>properties</td>
<td>Map</td>
<td>the exchange properties</td>
</tr>
<tr>
<td>property(name)</td>
<td>Object</td>
<td>the property by the given name</td>
</tr>
<tr>
<td>property(name, type)</td>
<td>Type</td>
<td>the property by the given name as the given type</td>
</tr>
</tbody>
</table>

### 223.3. SAMPLES

For example you could use Mvel inside a Message Filter in XML:

```xml
<route>
    <from uri="seda:foo"/>
    <filter>
        <mvel>request.headers.foo == 'bar'</mvel>
    </filter>
    <to uri="seda:bar"/>
</route>
```

And the sample using Java DSL:

```java
from("seda:foo").filter().mvel("request.headers.foo == 'bar'").to("seda:bar");
```

### 223.4. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as "classpath:"; "file:"; or "http:". 
This is done using the following syntax: "resource:scheme:location", eg to refer to a file on the classpath you can do:

```java
.setHeader("myHeader").mvel("resource:classpath:script.mvel")
```

### 223.5. DEPENDENCIES

To use Mvel in your camel routes you need to add the a dependency on camel-mvel which implements the Mvel language.
If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mvel</artifactId>
  <version>x.x.x</version>
</dependency>
```
CHAPTER 224. MYBATIS COMPONENT

Available as of Camel version 2.7

The **mybatis** component allows you to query, poll, insert, update and delete data in a relational database using MyBatis.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mybatis</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

224.1. URI FORMAT

```
mybatis:statementName[?options]
```

Where `statementName` is the statement name in the MyBatis XML mapping file which maps to the query, insert, update or delete operation you wish to evaluate.

You can append query options to the URI in the following format, `?option=value&option=value&…`

This component will by default load the MyBatis SqlMapConfig file from the root of the classpath with the expected name of `SqlMapConfig.xml`.
If the file is located in another location, you will need to configure the `configurationUri` option on the `MyBatisComponent` component.

224.2. OPTIONS

The MyBatis component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sqlSessionFactory</code> (advanced)</td>
<td>To use the SqlSessionFactory</td>
<td><code>SqlSessionFactory</code></td>
<td><code>SqlSessionFactory</code></td>
</tr>
<tr>
<td><code>configurationUri</code> (common)</td>
<td>Location of MyBatis xml configuration file. The default value is: SqlMapConfig.xml loaded from the classpath</td>
<td><code>SqlMapConfig.xml</code></td>
<td><code>String</code></td>
</tr>
<tr>
<td><code>resolveProperty Placeholders</code> (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td><code>true</code></td>
<td><code>boolean</code></td>
</tr>
</tbody>
</table>

The MyBatis endpoint is configured using URI syntax:
mybatis:statement

with the following path and query parameters:

### 224.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>statement</td>
<td><strong>Required</strong> The statement name in the MyBatis XML mapping file which maps to the query, insert, update or delete operation you wish to evaluate.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 224.2.2. Query Parameters (29 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>outputHeader (common)</td>
<td>Store the query result in a header instead of the message body. By default, outputHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. Setting outputHeader will also omit populating the default CamelMyBatisResult header since it would be the same as outputHeader all the time.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>inputHeader (consumer)</td>
<td>User the header value for input parameters instead of the message body. By default, inputHeader == null and the input parameters are taken from the message body. If outputHeader is set, the value is used and query parameters will be taken from the header instead of the body.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>maxMessagesPerPoll (consumer)</td>
<td>This option is intended to split results returned by the database pool into</td>
<td>0</td>
<td>int</td>
</tr>
<tr>
<td></td>
<td>the batches and deliver them in multiple exchanges. This integer defines the</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>maximum messages to deliver in single exchange. By default, no maximum is</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>set. Can be used to set a limit of e.g. 1000 to avoid when starting up the</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>server that there are thousands of files. Set a value of 0 or negative to</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>disable it.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>onConsume (consumer)</td>
<td>Statement to run after data has been processed in the route</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>routeEmptyResultSet (consumer)</td>
<td>Whether allow empty resultset to be routed to the next hop</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td>to send an empty message (no body) instead.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>transacted (consumer)</td>
<td>Enables or disables transaction. If enabled then if processing an exchange</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td>failed then the consumer break out processing any further exchanges to cause</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>a rollback eager</td>
<td></td>
<td></td>
</tr>
<tr>
<td>useIterator (consumer)</td>
<td>Process resultset individually or as a list</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td></td>
<td>bridgeErrorHandler is enabled then this options is not in use. By default</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>the consumer will deal with exceptions, that will be logged at WARN or ERROR</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>level and ignored.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td></td>
<td>provide your custom implementation to control error handling usually</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>occurred during the poll operation before an Exchange have been created and</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>being routed in Camel.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>processingStrategy (consumer)</td>
<td>To use a custom MyBatisProcessingStrategy</td>
<td></td>
<td>MyBatisProcessingStrategy</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>executorType (producer)</td>
<td>The executor type to be used while executing statements. simple - executor does nothing special. reuse - executor reuses prepared statements. batch - executor reuses statements and batches updates.</td>
<td>SIMPL E</td>
<td>ExecutorType</td>
</tr>
<tr>
<td>statementType (producer)</td>
<td>Mandatory to specify for the producer to control which kind of operation to invoke.</td>
<td></td>
<td>StatementType</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold (scheduler)</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffIdleThreshold (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffMultiplier (scheduler)</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>delay (scheduler)</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy (scheduler)</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay (scheduler)</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel (scheduler)</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>scheduledExecutorService (scheduler)</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td></td>
<td>ScheduledExecutorService</td>
</tr>
</tbody>
</table>
To use a cron scheduler from either camel-spring or camel-quartz2 component

### scheduler (scheduler)

To use a cron scheduler from either camel-spring or camel-quartz2 component

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheduler</td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollConsumerScheduler</td>
</tr>
<tr>
<td>schedulerProperties</td>
<td>To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>startScheduler</td>
<td>Whether the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>timeUnit</td>
<td>Time unit for initialDelay and delay options.</td>
<td>MILLIES</td>
<td>TimeUnit</td>
</tr>
<tr>
<td>useFixedDelay</td>
<td>Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 224.3. MESSAGE HEADERS

Camel will populate the result message, either IN or OUT with a header with the statement used:

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelMyBatisIsStatementName</td>
<td>String</td>
<td>The statementName used (for example: insertAccount).</td>
</tr>
<tr>
<td>CamelMyBatisIsResult</td>
<td>Object</td>
<td>The response returned from MtBatis in any of the operations. For instance an INSERT could return the auto-generated key, or number of rows etc.</td>
</tr>
</tbody>
</table>

### 224.4. MESSAGE BODY

The response from MyBatis will only be set as the body if it’s a SELECT statement. That means, for example, for INSERT statements Camel will not replace the body. This allows you to continue routing and keep the original body. The response from MyBatis is always stored in the header with the key CamelMyBatisResult.

### 224.5. SAMPLES

For example if you wish to consume beans from a JMS queue and insert them into a database you could do the following:
Notice we have to specify the `statementType`, as we need to instruct Camel which kind of operation to invoke.

Where `insertAccount` is the MyBatis ID in the SQL mapping file:

```xml
<!-- Insert example, using the Account parameter class -->
<insert id="insertAccount" parameterType="Account">
  insert into ACCOUNT (  
    ACC_ID,  
    ACC_FIRST_NAME,  
    ACC_LAST_NAME,  
    ACC_EMAIL  
  )
  values (  
    #{id},  
    #{firstName},  
    #{lastName},  
    #{emailAddress}  
  )
</insert>
```

### 224.6. USING STATEMENTTYPE FOR BETTER CONTROL OF MYBATIS

When routing to an MyBatis endpoint you will want more fine grained control so you can control whether the SQL statement to be executed is a **SELECT**, **UPDATE**, **DELETE** or **INSERT** etc. So for instance if we want to route to an MyBatis endpoint in which the IN body contains parameters to a **SELECT** statement we can do:

In the code above we can invoke the MyBatis statement `selectAccountById` and the IN body should contain the account id we want to retrieve, such as an `Integer` type.

We can do the same for some of the other operations, such as **SelectList**:

And the same for **UPDATE**, where we can send an `Account` object as the IN body to MyBatis:

#### 224.6.1. Using InsertList StatementType

**Available as of Camel 2.10**

MyBatis allows you to insert multiple rows using its for-each batch driver. To use this, you need to use the `<foreach>` in the mapper XML file. For example as shown below:

Then you can insert multiple rows, by sending a Camel message to the `mybatis` endpoint which uses the `InsertList` statement type, as shown below:

#### 224.6.2. Using UpdateList StatementType

**Available as of Camel 2.11**

MyBatis allows you to update multiple rows using its for-each batch driver. To use this, you need to use the `<foreach>` in the mapper XML file. For example as shown below:
Then you can update multiple rows, by sending a Camel message to the mybatis endpoint which uses the UpdateList statement type, as shown below:

```camel
from("direct:start")
    .to("mybatis:batchUpdateAccount?statementType=UpdateList")
    .to("mock:result");
```

224.6.3. Using DeleteList StatementType

Available as of Camel 2.11

MyBatis allows you to delete multiple rows using its for-each batch driver. To use this, you need to use the `<foreach>` in the mapper XML file. For example as shown below:

```xml
<delete id="batchDeleteAccountByAccountId" parameterType="java.util.List">
    delete from ACCOUNT
    where
    ACC_ID in
    <foreach item="AccountID" collection="list" open="" close="" separator="",">
        #{AccountID}
    </foreach>
</delete>
```

Then you can delete multiple rows, by sending a Camel message to the mybatis endpoint which uses the DeleteList statement type, as shown below:

```camel
from("direct:start")
    .to("mybatis:batchDeleteAccount?statementType=DeleteList")
    .to("mock:result");
```

224.6.4. Notice on InsertList, UpdateList and DeleteList StatementTypes

Parameter of any type (List, Map, etc.) can be passed to mybatis and an end user is responsible for handling it as required with the help of mybatis dynamic queries capabilities.

224.6.5. Scheduled polling example

This component supports scheduled polling and can therefore be used as a Polling Consumer. For example to poll the database every minute:

```camel
from("mybatis:selectAllAccounts?delay=60000").to("activemq:queue:allAccounts");
```

See "ScheduledPollConsumer Options" on Polling Consumer for more options.
Alternatively you can use another mechanism for triggering the scheduled polls, such as the Timer or Quartz components. In the sample below we poll the database, every 30 seconds using the Timer component and send the data to the JMS queue:

```java
from("timer://pollTheDatabase?delay=30000").to("mybatis:selectAllAccounts").to("activemq:queue:allAccounts");
```

And the MyBatis SQL mapping file used:

```xml
<!-- Select with no parameters using the result map for Account class. -->
<select id="selectAllAccounts" resultMap="AccountResult">
    select * from ACCOUNT
</select>
```

### 224.6.6. Using onConsume

This component supports executing statements after data have been consumed and processed by Camel. This allows you to do post updates in the database. Notice all statements must be UPDATE statements. Camel supports executing multiple statements whose names should be separated by commas.

The route below illustrates we execute the consumeAccount statement data is processed. This allows us to change the status of the row in the database to processed, so we avoid consuming it twice or more.

And the statements in the sqlmap file:

### 224.6.7. Participating in transactions

Setting up a transaction manager under camel-mybatis can be a little bit fiddly, as it involves externalising the database configuration outside the standard MyBatis SqlMapConfig.xml file.

The first part requires the setup of a DataSource. This is typically a pool (either DBCP, or c3p0), which needs to be wrapped in a Spring proxy. This proxy enables non-Spring use of the DataSource to participate in Spring transactions (the MyBatis SqlSessionFactory does just this).

```xml
<bean id="dataSource"
    class="org.springframework.jdbc.datasource.TransactionAwareDataSourceProxy">
    <constructor-arg>
        <bean class="com.mchange.v2.c3p0.ComboPooledDataSource">
            <property name="driverClass" value="org.postgresql.Driver"/>
            <property name="jdbcUrl" value="jdbc:postgresql://localhost:5432/myDatabase"/>
            <property name="user" value="myUser"/>
            <property name="password" value="myPassword"/>
        </bean>
    </constructor-arg>
</bean>
```

This has the additional benefit of enabling the database configuration to be externalised using property placeholders.

A transaction manager is then configured to manage the outermost DataSource:

```xml
<bean id="txManager"
A `mybatis-spring SqlSessionFactoryBean` then wraps that same `DataSource`:

```xml
<bean id="sqlSessionFactory" class="org.mybatis.spring.SqlSessionFactoryBean">
    <property name="dataSource" ref="dataSource"/>
    <property name="configLocation" value="/META-INF/SqlMapConfig.xml"/>
    <property name="mapperLocations" value="classpath*:META-INF/mappers/**/*.xml"/>
</bean>
```

The camel-mybatis component is then configured with that factory:

```xml
<bean id="mybatis" class="org.apache.camel.component.mybatis.MyBatisComponent">
    <property name="sqlSessionFactory" ref="sqlSessionFactory"/>
</bean>
```

Finally, a transaction policy is defined over the top of the transaction manager, which can then be used as usual:

```xml
<bean id="PROPAGATION_REQUIRED" class="org.apache.camel.spring.spi.SpringTransactionPolicy">
    <property name="transactionManager" ref="txManager"/>
    <property name="propagationBehaviorName" value="PROPAGATION_REQUIRED"/>
</bean>
```

```
<camelContext id="my-model-context" xmlns="http://camel.apache.org/schema/spring">
    <route id="insertModel">
        <from uri="direct:insert"/>
        <transacted ref="PROPAGATION_REQUIRED"/>
        <to uri="mybatis:myModel.insert?statementType=Insert"/>
    </route>
</camelContext>
```

### 224.7. SEE ALSO

- Configuring Camel
- Component

- Getting Started
CHAPTER 225. NAGIOS COMPONENT

Available as of Camel version 2.3

The Nagios component allows you to send passive checks to Nagios.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-nagios</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

225.1. URI FORMAT

```
nagios://host[:port][?Options]
```

Camel provides two abilities with the Nagios component. You can send passive check messages by sending a message to its endpoint. Camel also provides a EventNotifier which allows you to send notifications to Nagios.

225.2. OPTIONS

The Nagios component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration (advanced)</td>
<td>To use a shared NagiosConfiguration</td>
<td></td>
<td>NagiosConfiguration</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Nagios endpoint is configured using URI syntax:

```
nagios:host:port
```

with the following path and query parameters:

225.2.1. Path Parameters (2 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td><strong>Required</strong> This is the address of the Nagios host where checks should be send.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td><strong>Required</strong> The port number of the host.</td>
<td></td>
<td>int</td>
</tr>
</tbody>
</table>

### 225.2.2. Query Parameters (7 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectionTimeout (producer)</td>
<td>Connection timeout in millis.</td>
<td>5000</td>
<td>int</td>
</tr>
<tr>
<td>sendSync (producer)</td>
<td>Whether or not to use synchronous when sending a passive check. Setting it to false will allow Camel to continue routing the message and the passive check message will be send asynchronously.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>timeout (producer)</td>
<td>Sending timeout in millis.</td>
<td>5000</td>
<td>int</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>encryption (security)</td>
<td>To specify an encryption method.</td>
<td></td>
<td>Encryption</td>
</tr>
<tr>
<td>encryptionMethod (security)</td>
<td>Deprecated To specify an encryption method.</td>
<td></td>
<td>NagiosEncryption Method</td>
</tr>
<tr>
<td>password (security)</td>
<td>Password to be authenticated when sending checks to Nagios.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 225.3. SENDING MESSAGE EXAMPLES

You can send a message to Nagios where the message payload contains the message. By default it will be **OK** level and use the CamelContext name as the service name. You can overrule these values using headers as shown above.

For example we send the **Hello Nagios** message to Nagios as follows:

```java
template.sendBody("direct:start", "Hello Nagios");
from("direct:start").to("nagios:127.0.0.1:5667?password=secret").to("mock:result");
```
To send a **CRITICAL** message you can send the headers such as:

```java
Map headers = new HashMap();
headers.put(NagiosConstants.LEVEL, "CRITICAL");
headers.put(NagiosConstants.HOST_NAME, "myHost");
headers.put(NagiosConstants.SERVICE_NAME, "myService");
template.sendBodyAndHeaders("direct:start", "Hello Nagios", headers);
```

### 225.4. USING NAGIOSEVENTNOTIFIER

The *Nagios* component also provides an EventNotifer which you can use to send events to Nagios. For example we can enable this from Java as follows:

```java
NagiosEventNotifier notifier = new NagiosEventNotifier();
notifier.getConfiguration().setHost("localhost");
notifier.getConfiguration().setPort(5667);
notifier.getConfiguration().setPassword("password");

CamelContext context = ...
context.getManagementStrategy().addEventNotifier(notifier);
return context;
```

In Spring XML it's just a matter of defining a Spring bean with the type `EventNotifier` and Camel will pick it up as documented here: [Advanced configuration of CamelContext using Spring](#).

CHAPTER 226. NATS COMPONENT

Available as of Camel version 2.17

NATS is a fast and reliable messaging platform.

Maven users will need to add the following dependency to their pom.xml for this component.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-nats</artifactId>
  <version>x.y.z</version>
</dependency>
```

226.1. URI FORMAT

nats:servers[?options]

Where servers represents the list of NATS servers.

226.2. OPTIONS

The Nats component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>useGlobalSslContext Parameters (security)</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Nats endpoint is configured using URI syntax:

```
nats:servers
```

with the following path and query parameters:

226.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
</table>
## servers

**Required** URLs to one or more NAT servers. Use comma to separate URLs when specifying multiple servers.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>servers</td>
<td>Required URLs to one or more NAT servers. Use comma to separate URLs when specifying multiple servers.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 226.2.2. Query Parameters (22 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>flushConnection</td>
<td>Define if we want to flush connection or not</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>flushTimeout</td>
<td>Set the flush timeout</td>
<td>1000</td>
<td>int</td>
</tr>
<tr>
<td>maxReconnectAttempts</td>
<td>Max reconnection attempts</td>
<td>3</td>
<td>int</td>
</tr>
<tr>
<td>noRandomizeServers</td>
<td>Whether or not randomizing the order of servers for the connection attempts</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>pedantic</td>
<td>Whether or not running in pedantic mode (this affects performance)</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>pingInterval</td>
<td>Ping interval to be aware if connection is still alive (in milliseconds)</td>
<td>4000</td>
<td>int</td>
</tr>
<tr>
<td>reconnect</td>
<td>Whether or not using reconnection feature</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>reconnectTimeWait</td>
<td>Waiting time before attempts reconnection (in milliseconds)</td>
<td>2000</td>
<td>int</td>
</tr>
<tr>
<td>topic</td>
<td>Required The name of topic we want to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>verbose</td>
<td>Whether or not running in verbose mode</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------------</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>maxMessages</td>
<td>Stop receiving messages from a topic we are subscribing to after maxMessages</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>poolSize</td>
<td>Consumer pool size</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>queueName</td>
<td>The Queue name if we are using nats for a queue configuration</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>replySubject</td>
<td>the subject to which subscribers should send response</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>secure</td>
<td>Set secure option indicating TLS is required</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>ssl</td>
<td>Whether or not using SSL</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sslContextParameters</td>
<td>To configure security using SSLContextParameters</td>
<td></td>
<td>SSLContextParameters</td>
</tr>
<tr>
<td>tlsDebug</td>
<td>TLS Debug, it will add additional console output</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 226.3. HEADERS
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel NatsMessage Timestamp</td>
<td>long</td>
<td>The timestamp of a consumed message.</td>
</tr>
<tr>
<td>Camel NatsSubscriptionId</td>
<td>Integer</td>
<td>The subscription ID of a consumer.</td>
</tr>
</tbody>
</table>

**Producer example:**

```java
from("direct:send").to("nats://localhost:4222?topic=test");
```

**Consumer example:**

```java
from("nats://localhost:4222?topic=test&maxMessages=5&queueName=test").to("mock:result");
```
The `netty` component in Camel is a socket communication component, based on the Netty project. Netty is a NIO client server framework which enables quick and easy development of network applications such as protocol servers and clients. Netty greatly simplifies and streamlines network programming such as TCP and UDP socket server.

This camel component supports both producer and consumer endpoints.

The Netty component has several options and allows fine-grained control of a number of TCP/UDP communication parameters (buffer sizes, keepAlives, tcpNoDelay etc) and facilitates both In-Only and In-Out communication on a Camel route.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-netty</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 227.1. URI FORMAT

The URI scheme for a netty component is as follows:

- `netty:tcp://localhost:99999/[?options]`
- `netty:udp://remotehost:99999/[?options]`

This component supports producer and consumer endpoints for both TCP and UDP.

You can append query options to the URI in the following format, `?option=value&option=value&...`

### 227.2. OPTIONS

The Netty component supports 4 options which are listed below.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>configuration</strong> (advanced)</td>
<td>To use the NettyConfiguration as configuration when creating endpoints.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>maximumPoolSize</strong> (advanced)</td>
<td>The core pool size for the ordered thread pool, if its in use. The default value is 16.</td>
<td>16</td>
<td>int</td>
</tr>
<tr>
<td><strong>useGlobalSslContext Parameters</strong> (security)</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>resolveProperty Placeholders</strong> (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Netty endpoint is configured using URI syntax:

```
netty:protocol:host:port
```

with the following path and query parameters:

### 227.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>protocol</strong></td>
<td>Required The protocol to use which can be tcp or udp.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>host</strong></td>
<td>Required The hostname. For the consumer the hostname is localhost or 0.0.0.0 For the producer the hostname is the remote host to connect to</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>port</strong></td>
<td>Required The host port number</td>
<td></td>
<td>int</td>
</tr>
</tbody>
</table>

### 227.2.2. Query Parameters (67 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>disconnect</strong> (common)</td>
<td>Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------</td>
</tr>
<tr>
<td>keepAlive</td>
<td>Setting to ensure socket is not closed due to inactivity</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>reuseAddress</td>
<td>Setting to facilitate socket multiplexing</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>sync</td>
<td>Setting to set endpoint as one-way or request-response</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>tcpNoDelay</td>
<td>Setting to improve TCP protocol performance</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>broadcast</td>
<td>Setting to choose Multicast over UDP</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>clientMode</td>
<td>If the clientMode is true, netty consumer will connect the address as a TCP client.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backlog</td>
<td>Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be If this option is not configured, then the backlog depends on OS setting.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>bossCount</td>
<td>When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>bossPool</td>
<td>To use a explicit org.jboss.netty.channel.socket.nio.BossPool as the boss thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own boss pool with 1 core thread.</td>
<td></td>
<td>BossPool</td>
</tr>
<tr>
<td>channelGroup</td>
<td>To use a explicit ChannelGroup.</td>
<td></td>
<td>ChannelGroup</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td>disconnectOnNoReply (consumer)</td>
<td>If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a customExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>maxChannelMemorySize (consumer)</td>
<td>The maximum total size of the queued events per channel when using orderedThreadPoolExecutor. Specify 0 to disable.</td>
<td>104857 60</td>
<td>long</td>
</tr>
<tr>
<td>maxTotalMemorySize (consumer)</td>
<td>The maximum total size of the queued events for this pool when using orderedThreadPoolExecutor. Specify 0 to disable.</td>
<td>209715 200</td>
<td>long</td>
</tr>
<tr>
<td>nettyServerBootstrapFactory (consumer)</td>
<td>To use a custom NettyServerBootstrapFactory</td>
<td></td>
<td>NettyServerBootstrapFactory</td>
</tr>
<tr>
<td>networkInterface (consumer)</td>
<td>When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>noReplyLogLevel (consumer)</td>
<td>If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>orderedThreadPoolExecutor (consumer)</td>
<td>Whether to use ordered thread pool, to ensure events are processed orderly on the same channel. See details at the netty javadoc of org.jboss.netty.handler.execution.OrderedMemoryAwareThreadPoolExecutor for more details.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>serverClosedChannelExceptionCaughtLogLevel (consumer)</td>
<td>If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.</td>
<td>DEBU</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------</td>
</tr>
<tr>
<td>serverExceptionCaughtLog Level (consumer)</td>
<td>If the server (NettyConsumer) catches an exception then its logged using this logging level.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>serverPipelineFactory (consumer)</td>
<td>To use a custom ServerPipelineFactory</td>
<td></td>
<td>ServerPipelineFactory</td>
</tr>
<tr>
<td>workerCount (consumer)</td>
<td>When netty works on nio mode, it uses default workerCount parameter from Netty, which is cpu_core_threads2. User can use this operation to override the default workerCount from Netty</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>workerPool (consumer)</td>
<td>To use a explicit org.jboss.netty.channel.socket.nio.WorkerPool as the worker thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own worker pool with 2 x cpu count core threads.</td>
<td>WorkerPool</td>
<td></td>
</tr>
<tr>
<td>connectTimeout (producer)</td>
<td>Time to wait for a socket connection to be available. Value is in millis.</td>
<td>10000</td>
<td>long</td>
</tr>
<tr>
<td>requestTimeout (producer)</td>
<td>Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty’s ReadTimeoutHandler to trigger the timeout.</td>
<td>long</td>
<td></td>
</tr>
<tr>
<td>clientPipelineFactory (producer)</td>
<td>To use a custom ClientPipelineFactory</td>
<td></td>
<td>ClientPipelineFactory</td>
</tr>
<tr>
<td>lazyChannelCreation (producer)</td>
<td>Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>producerPoolEnabled (producer)</td>
<td>Whether producer pool is enabled or not. Important: Do not turn this off, as the pooling is needed for handling concurrency and reliable request-reply.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>producerPoolMaxActive (producer)</td>
<td>Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>producerPoolMaxIdle (producer)</td>
<td>Sets the cap on the number of idle instances in the pool.</td>
<td>100</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>producerPoolMin Idle (producer)</td>
<td>Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.</td>
<td>30000</td>
<td>long</td>
</tr>
<tr>
<td>producerPoolMinIdle (producer)</td>
<td>Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>udpConnectionlessSending (producer)</td>
<td>This option supports connection less ud send which is a real fire and forget. A connected ud send receive the PortUnreachableException if no one is listen on the receiving port.</td>
<td></td>
<td>boolean</td>
</tr>
<tr>
<td>useChannelBuffer (producer)</td>
<td>If the useChannelBuffer is true, netty producer will turn the message body into ChannelBuffer before sending it out.</td>
<td></td>
<td>boolean</td>
</tr>
<tr>
<td>bootstrapConfiguration (advanced)</td>
<td>To use a custom configured NettyServerBootstrapConfiguration for configuring this endpoint.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>options (advanced)</td>
<td>Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>receiveBufferSize (advanced)</td>
<td>The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.</td>
<td>65536</td>
<td>long</td>
</tr>
<tr>
<td>receiveBufferSizePredictor (advanced)</td>
<td>Configures the buffer size predictor. See details at Jetty documentation and this mail thread.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>sendBufferSize (advanced)</td>
<td>The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.</td>
<td>65536</td>
<td>long</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td></td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>transferExchange (advanced)</td>
<td>Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>allowDefaultCodec (codec)</td>
<td>The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>autoAppendDelimiter (codec)</td>
<td>Whether or not to auto append missing end delimiter when sending using the textline codec.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>decoder (codec)</td>
<td>Deprecated A custom ChannelHandler class that can be used to perform special marshalling of inbound payloads. Must override org.jboss.netty.channel.ChannelUpStreamHandler.</td>
<td>ChannelHandler</td>
<td></td>
</tr>
<tr>
<td>decoderMaxLengthLength (codec)</td>
<td>The max line length to use for the textline codec.</td>
<td>1024</td>
<td>int</td>
</tr>
<tr>
<td>decoders (codec)</td>
<td>A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with so Camel knows it should lookup.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>delimiter (codec)</td>
<td>The delimiter to use for the textline codec. Possible values are LINE and NULL.</td>
<td>LINE</td>
<td>TextLineDelimiter</td>
</tr>
<tr>
<td>encoder (codec)</td>
<td>Deprecated A custom ChannelHandler class that can be used to perform special marshalling of outbound payloads. Must override org.jboss.netty.channel.ChannelDownStreamHandler.</td>
<td>ChannelHandler</td>
<td></td>
</tr>
<tr>
<td>encoders (codec)</td>
<td>A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with so Camel knows it should lookup.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>encoding (codec)</td>
<td>The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>textline (codec)</td>
<td>Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>enabledProtocols (security)</td>
<td>Which protocols to enable when using SSL</td>
<td>TLSv1, TLSv1.1, TLSv1.2</td>
<td>String</td>
</tr>
<tr>
<td>keyStoreFile (security)</td>
<td>Client side certificate keystore to be used for encryption</td>
<td></td>
<td>File</td>
</tr>
<tr>
<td>keyStoreFormat (security)</td>
<td>Keystore format to be used for payload encryption. Defaults to JKS if not set</td>
<td>JKS</td>
<td>String</td>
</tr>
<tr>
<td>keyStoreResource (security)</td>
<td>Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>needClientAuth (security)</td>
<td>Configures whether the server needs client authentication when using SSL.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>passphrase (security)</td>
<td>Password setting to use in order to encrypt/decrypt payloads sent using SSH</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>securityProvider (security)</td>
<td>Security provider to be used for payload encryption. Defaults to SunX509 if not set.</td>
<td>SunX509</td>
<td>String</td>
</tr>
<tr>
<td>ssl (security)</td>
<td>Setting to specify whether SSL encryption is applied to this endpoint</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sslClientCertHeaders (security)</td>
<td>When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sslContextParameters (security)</td>
<td>To configure security using SSLContextParameters</td>
<td></td>
<td>SSLContextParameters</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
--- | --- | --- | ---
sslHandler (security) | Reference to a class that could be used to return an SSL Handler | | SslHandler
trustStoreFile (security) | Server side certificate keystore to be used for encryption | | File
trustStoreResource (security) | Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems. | | String

### 227.3. REGISTRY BASED OPTIONS
Codec Handlers and SSL Keystores can be enlisted in the Registry, such as in the Spring XML file. The values that could be passed in, are the following:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>passphrase</td>
<td>password setting to use in order to encrypt/decrypt payloads sent using SSH</td>
</tr>
<tr>
<td>keyStoreFormat</td>
<td>keystore format to be used for payload encryption. Defaults to &quot;JKS&quot; if not set</td>

</tbody>
</table>
**Name** | **Description**
--- | ---
sslHandler | Reference to a class that could be used to return an SSL Handler
encoder | A custom ChannelHandler class that can be used to perform special marshalling of outbound payloads. Must override org.jboss.netty.channel.ChannelDownStreamHandler.
encoders | A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.
decoder | A custom ChannelHandler class that can be used to perform special marshalling of inbound payloads. Must override org.jboss.netty.channel.ChannelUpStreamHandler.
decoders | A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.

**Important:** Read below about using non shareable encoders/decoders.

### 227.3.1. Using non shareable encoders or decoders

If your encoders or decoders is not shareable (eg they have the @Shareable class annotation), then your encoder/decoder must implement the org.apache.camel.component.netty.ChannelHandlerFactory interface, and return a new instance in the newChannelHandler method. This is to ensure the encoder/decoder can safely be used. If this is not the case, then the Netty component will log a WARN when an endpoint is created.

The Netty component offers a org.apache.camel.component.netty.ChannelHandlerFactories factory class, that has a number of commonly used methods.

### 227.4. SENDING MESSAGES TO/FROM A NETTY ENDPOINT

#### 227.4.1. Netty Producer

In Producer mode, the component provides the ability to send payloads to a socket endpoint using either TCP or UDP protocols (with optional SSL support).

The producer mode supports both one-way and request–response based operations.

#### 227.4.2. Netty Consumer

In Consumer mode, the component provides the ability to:

- listen on a specified socket using either TCP or UDP protocols (with optional SSL support),
- receive requests on the socket using text/xml, binary and serialized object based payloads and
- send them along on a route as message exchanges.
The consumer mode supports both one-way and request-response based operations.

### 227.5. HEADERS

The following headers are filled for the exchanges created by the Netty consumer:

<table>
<thead>
<tr>
<th>Header key</th>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NettyConstants.NETTY_CHANNELHANDLER_CONTEXT</td>
<td>org.jboss.netty.channel.ChannelHandlerContext</td>
<td><code>ChannelHandlerContext</code> instance associated with the connection received by netty.</td>
</tr>
<tr>
<td>NettyConstants.NETTY_MESSAGEEVENT</td>
<td>org.jboss.netty.channel.MessageEvent</td>
<td><code>MessageEvent</code> instance associated with the connection received by netty.</td>
</tr>
<tr>
<td>NettyConstants.NETTY_REMOTEADDRESS</td>
<td>java.net.SocketAddress</td>
<td>Remote address of the incoming socket connection.</td>
</tr>
</tbody>
</table>
### 227.6. USAGE SAMPLES

**227.6.1. A UDP Netty endpoint using Request-Reply and serialized object payload**

```java
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("netty:udp://localhost:5155?sync=true")
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    Poetry poetry = (Poetry) exchange.getIn().getBody();
                    poetry.setPoet("Dr. Sarojini Naidu");
                    exchange.getOut().setBody(poetry);
                }
            })
    }
};
```

**227.6.2. A TCP based Netty consumer endpoint using One-way communication**

```java
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("netty:tcp://localhost:5150")
            .to("mock:result");
    }
};
```

**227.6.3. An SSL/TCP based Netty consumer endpoint using Request-Reply communication**

Using the JSSE Configuration Utility

As of Camel 2.9, the Netty component supports SSL/TLS configuration through the **Camel JSSE Configuration Utility**. This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate...
how to use the utility with the Netty component.

Programmatic configuration of the component

```java
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("keyPassword");

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

NettyComponent nettyComponent = getContext().getComponent("netty", NettyComponent.class);
nettyComponent.setSslContextParameters(scp);
```

Spring DSL based configuration of endpoint

```xml
<camel:sslContextParameters
   id="sslContextParameters">
  <camel:keyManagers
     keyPassword="keyPassword">
    <camel:keyStore
       resource="/users/home/server/keystore.jks"
       password="keystorePassword"/>
  </camel:keyManagers>
</camel:sslContextParameters>

<to uri="netty:tcp://localhost:5150?sync=true&ssl=true&sslContextParameters=#sslContextParameters"/>
```

Using Basic SSL/TLS configuration on the Jetty Component

```java
JndiRegistry registry = new JndiRegistry(createJndiContext());
registry.bind("password", "changeit");
registry.bind("ksf", new File("src/test/resources/keystore.jks");
registry.bind("tsf", new File("src/test/resources/keystore.jks");

context.createRegistry(registry);
context.addRoutes(new RouteBuilder() {
    public void configure() {
        String netty_ssl_endpoint =
            "netty:tcp://localhost:5150?sync=true&ssl=true&passphrase=#password"
            + "&keyStoreFile=#ksf&trustStoreFile=#tsf";
        String return_string =
            "When You Go Home, Tell Them Of Us And Say,"
            + "For Your Tomorrow, We Gave Our Today."
            + ";

        from(netty_ssl_endpoint)
        .process(new Processor() { 
            public void process(Exchange exchange) throws Exception {
```
Getting access to SSLSession and the client certificate

Available as of Camel 2.12

You can get access to the `javax.net.ssl.SSLSession` if you eg need to get details about the client certificate. When `ssl=true` then the Netty component will store the `SSLSession` as a header on the Camel Message as shown below:

```java
SSLSession session = exchange.getIn().getHeader(NettyConstants.NETTY_SSL_SESSION, SSLSession.class);
java.security.cert.X509Certificate cert = session.getPeerCertificateChain()[0];
Principal principal = cert.getSubjectDN();
```

Remember to set `needClientAuth=true` to authenticate the client, otherwise `SSLSession` cannot access information about the client certificate, and you may get an exception `javax.net.ssl.SSLPeerUnverifiedException: peer not authenticated`. You may also get this exception if the client certificate is expired or not valid etc.

TIP

The option `sslClientCertHeaders` can be set to `true` which then enriches the Camel Message with headers having details about the client certificate. For example the subject name is readily available in the header `CamelNettySSLClientCertSubjectName`.

227.6.4. Using Multiple Codecs

In certain cases it may be necessary to add chains of encoders and decoders to the netty pipeline. To add multiple codecs to a camel netty endpoint the ‘encoders’ and ‘decoders’ uri parameters should be used. Like the ‘encoder’ and ‘decoder’ parameters they are used to supply references (to lists of ChannelUpstreamHandlers and ChannelDownstreamHandlers) that should be added to the pipeline. Note that if encoders is specified then the encoder param will be ignored, similarly for decoders and the decoder param.

INFO: Read further above about using non shareable encoders/decoders.

The lists of codecs need to be added to the Camel’s registry so they can be resolved when the endpoint is created.

Spring’s native collections support can be used to specify the codec lists in an application context

The bean names can then be used in netty endpoint definitions either as a comma separated list or contained in a List e.g.

or via spring.

227.7. CLOSING CHANNEL WHEN COMPLETE
When acting as a server you sometimes want to close the channel when, for example, a client conversion is finished. You can do this by simply setting the endpoint option `disconnect=true`.

However you can also instruct Camel on a per message basis as follows. To instruct Camel to close the channel, you should add a header with the key `CamelNettyCloseChannelWhenComplete` set to a boolean `true` value.

For instance, the example below will close the channel after it has written the bye message back to the client:

```java
from("netty:tcp://localhost:8080").process(new Processor() {
    public void process(Exchange exchange) throws Exception {
        String body = exchange.getIn().getBody(String.class);
        exchange.getOut().setBody("Bye " + body);
        // some condition which determines if we should close
        if (close) {
            exchange.getOut().setHeader(NettyConstants.NETTY_CLOSE_CHANNEL_WHEN_COMPLETE, true);
        }
    }
});
```

### 227.8. ADDING CUSTOM CHANNEL PIPELINE FACTORIES TO GAIN COMPLETE CONTROL OVER A CREATED PIPELINE

**Available as of Camel 2.5**

Custom channel pipelines provide complete control to the user over the handler/interceptor chain by inserting custom handler(s), encoder(s) & decoder(s) without having to specify them in the Netty Endpoint URL in a very simple way.

In order to add a custom pipeline, a custom channel pipeline factory must be created and registered with the context via the context registry (JNDIRegistry, or the camel-spring ApplicationContextRegistry etc).

A custom pipeline factory must be constructed as follows:

- A Producer linked channel pipeline factory must extend the abstract class `ClientPipelineFactory`.

- A Consumer linked channel pipeline factory must extend the abstract class `ServerPipelineFactory`.

- The classes should override the `getPipeline()` method in order to insert custom handler(s), encoder(s) and decoder(s). Not overriding the `getPipeline()` method creates a pipeline with no handlers, encoders or decoders wired to the pipeline.

The example below shows how `ServerChannelPipeline` factory may be created

**Using custom pipeline factory**

```java
public class SampleServerChannelPipelineFactory extends ServerPipelineFactory {
    private int maxLineSize = 1024;

    public ChannelPipeline getPipeline() throws Exception {
```
The custom channel pipeline factory can then be added to the registry and instantiated/utilized on a camel route in the following way:

```java
ChannelPipeline channelPipeline = Channels.pipeline();

channelPipeline.addLast("encoder-SD", new StringEncoder(CharsetUtil.UTF_8));
channelPipeline.addLast("decoder-DELIM", new DelimiterBasedFrameDecoder(maxLineSize,
true, Delimiters.lineDelimiter()));
channelPipeline.addLast("decoder-SD", new StringDecoder(CharsetUtil.UTF_8));
// here we add the default Camel ServerChannelHandler for the consumer, to allow Camel to route the message etc.
channelPipeline.addLast("handler", new ServerChannelHandler(consumer));

return channelPipeline;
}
```

The custom channel pipeline factory can then be added to the registry and instantiated/utilized on a camel route in the following way:

```java
Registry registry = camelContext.getRegistry();
serverPipelineFactory = new TestServerChannelPipelineFactory();
registry.bind("spf", serverPipelineFactory);
context.addRoutes(new RouteBuilder() {
    public void configure() {
        String netty_ssl_endpoint = "netty:tcp://localhost:5150?serverPipelineFactory=#spf"
        String return_string = "When You Go Home, Tell Them Of Us And Say,
                        + "For Your Tomorrow, We Gave Our Today."

        from(netty_ssl_endpoint)
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    exchange.getOut().setBody(return_string);
                }
            });
    }
});
```

### 227.9. REUSING NETTY BOSS AND WORKER THREAD POOLS

**Available as of Camel 2.12**

Netty has two kind of thread pools: boss and worker. By default each Netty consumer and producer has their private thread pools. If you want to reuse these thread pools among multiple consumers or producers then the thread pools must be created and enlisted in the Registry.

For example using Spring XML we can create a shared worker thread pool using the `NettyWorkerPoolBuilder` with 2 worker threads as shown below:

```xml
<bean id="poolBuilder" class="org.apache.camel.component.netty.NettyWorkerPoolBuilder">
    <property name="workerCount" value="2"/>
</bean>

<bean/>
```

<--- the shared worker thread pool -->

Then in the Camel routes we can refer to this worker pools by configuring the `workerPool` option in the `URI` as shown below:

```xml
<route>
  <to uri="log:result"/>
  ...
</route>
```

And if we have another route we can refer to the shared worker pool:

```xml
<route>
  <to uri="log:result"/>
  ...
</route>
```

i. and so forth.

### 227.10. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
- Netty HTTP
- MINA
CHAPTER 228. NETTY HTTP COMPONENT (DEPRECATED)

Available as of Camel version 2.12

The netty-http component is an extension to Netty component to facilitate HTTP transport with Netty.

This camel component supports both producer and consumer endpoints.

WARNING
This component is deprecated. You should use Netty4 HTTP.

INFO: Stream. Netty is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream once. If you find a situation where the message body appears to be empty or you need to access the data multiple times (eg: doing multicasting, or redelivery error handling) you should use Stream caching or convert the message body to a String which is safe to be re-read multiple times. Notice Netty4 HTTP reads the entire stream into memory using io.netty.handler.codec.http.HttpObjectAggregator to build the entire full http message. But the resulting message is still a stream based message which is readable once.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-netty-http</artifactId>
    <version>x.x.x</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

228.1. URI FORMAT

The URI scheme for a netty component is as follows

```
netty-http:http://localhost:8080/?options
```

You can append query options to the URI in the following format, ?option=value&option=value&...

INFO: Query parameters vs endpoint options You may be wondering how Camel recognizes URI query parameters and endpoint options. For example you might create endpoint URI as follows - netty-http:http://example.com?myParam=myValue&compression=true. In this example myParam is the HTTP parameter, while compression is the Camel endpoint option. The strategy used by Camel in such situations is to resolve available endpoint options and remove them from the URI. It means that for the discussed example, the HTTP request sent by Netty HTTP producer to the endpoint will look as follows - http://example.com?myParam=myValue, because compression endpoint option will be resolved and removed from the target URL. Keep also in mind that you cannot specify endpoint options using dynamic headers (like CamelHttpQuery). Endpoint options can be specified only at the endpoint URI definition level (like to or from DSL elements).
228.2. HTTP OPTIONS

INFO: A lot more options. Important: This component inherits all the options from Netty. So make sure to look at the Netty documentation as well. Notice that some options from Netty is not applicable when using this Netty HTTP component, such as options related to UDP transport.

The Netty HTTP component supports 7 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>nettyHttpBinding</td>
<td>To use a custom org.apache.camel.component.netty.http.NettyHttpBinding for binding to/from Netty and Camel Message API.</td>
<td></td>
<td>NettyHttpBinding</td>
</tr>
<tr>
<td>configuration</td>
<td>To use the NettyConfiguration as configuration when creating endpoints.</td>
<td></td>
<td>NettyHttpConfiguration</td>
</tr>
<tr>
<td>headerFilterStrategy</td>
<td>To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>useGlobalSslContextParameters</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>maximumPoolSize</td>
<td>The core pool size for the ordered thread pool, if its in use. The default value is 16.</td>
<td>16</td>
<td>int</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Netty HTTP endpoint is configured using URI syntax:

```
netty-http:protocol:host:port/path
```

with the following path and query parameters:

228.2.1. Path Parameters (4 parameters):  

...
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol</td>
<td><strong>Required</strong> The protocol to use which is either http or https</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td><strong>Required</strong> The local hostname such as localhost, or 0.0.0.0 when being a consumer. The remote HTTP server hostname when using producer.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>The host port number</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>path</td>
<td>Resource path</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 228.2.2. Query Parameters (78 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeEndpoint</td>
<td>If the option is true, the producer will ignore the Exchange.HTTP_URI header, and use the endpoint’s URI for request. You may also set the throwExceptionOnFailure to be false to let the producer send all the fault response back. The consumer working in the bridge mode will skip the gzip compression and WWW URL form encoding (by adding the Exchange.SKIP_GZIP_ENCODING and Exchange.SKIP_WWW_FORM_URLENCODED headers to the consumed exchange).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>disconnect</td>
<td>Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>keepAlive</td>
<td>Setting to ensure socket is not closed due to inactivity</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>reuseAddress</td>
<td>Setting to facilitate socket multiplexing</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>sync</td>
<td>Setting to set endpoint as one-way or request-response</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>tcpNoDelay</td>
<td>Setting to improve TCP protocol performance</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
--- | --- | --- | ---
**bridgeErrorHandler** *(consumer)* | Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored. | false | boolean

**matchOnUriPrefix** *(consumer)* | Whether or not Camel should try to find a target consumer by matching the URI prefix if no exact match is found. | false | boolean

**send503whenSus pended** *(consumer)* | Whether to send back HTTP status code 503 when the consumer has been suspended. If the option is false then the Netty Acceptor is unbound when the consumer is suspended, so clients cannot connect anymore. | true | boolean

**backlog** *(consumer)* | Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be if this option is not configured, then the backlog depends on OS setting. | int

**bossCount** *(consumer)* | When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty | 1 | int

**bossPool** *(consumer)* | To use a explicit org.jboss.netty.channel.socket.nio.BossPool as the boss thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own boss pool with 1 core thread. | BossPool

**channelGroup** *(consumer)* | To use a explicit ChannelGroup. | ChannelGroup

**chunkedMaxLength** *(consumer)* | Value in bytes the max content length per chunked frame received on the Netty HTTP server. | 1048576 | int

**compression** *(consumer)* | Allow using gzip/deflate for compression on the Netty HTTP server if the client supports it from the HTTP headers. | false | boolean
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>disableStreamCache</td>
<td>Determines whether or not the raw input stream from Netty HttpRequest getContent() is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Netty raw stream.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>disconnectOnNoReply</td>
<td>If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>httpMethodRestrict</td>
<td>To disable HTTP methods on the Netty HTTP consumer. You can specify multiple separated by comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>mapHeaders</td>
<td>If this option is enabled, then during binding from Netty to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the org.apache.camel.component.netty.http.NettyHttpMessage message with the method getHttpRequest() that returns the Netty HTTP request org.jboss.netty.handler.codec.http.HttpRequest instance.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>maxChannelMemorySize</td>
<td>The maximum total size of the queued events per channel when using orderedThreadPoolExecutor. Specify 0 to disable.</td>
<td>10485760</td>
<td>long</td>
</tr>
<tr>

<tr>
<td>orderedThreadPoolExecutor (consumer)</td>
<td>Whether to use ordered thread pool, to ensure events are processed orderly on the same channel. See details at the netty javadoc of org.jboss.netty.handler.execution.OrderedMemoryAwareThreadPoolExecutor for more details.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>serverClosedChannelExceptionCaughtLogLevel (consumer)</td>
<td>If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.</td>
<td>DEBU G</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>serverExceptionCaughtLogLevel (consumer)</td>
<td>If the server (NettyConsumer) catches an exception then its logged using this logging level.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>serverPipelineFactory (consumer)</td>
<td>To use a custom ServerPipelineFactory</td>
<td>ServerPipelineFactory</td>
<td></td>
</tr>
<tr>
<td>traceEnabled (consumer)</td>
<td>Specifies whether to enable HTTP TRACE for this Netty HTTP consumer. By default TRACE is turned off.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
**Name** | **Description** | **Default** | **Type**
--- | --- | --- | ---
urlDecodeHeaders (consumer) | If this option is enabled, then during binding from Netty to Camel Message then the header values will be URL decoded (e.g. `%20` will be a space character). Notice this option is used by the default `org.apache.camel.component.netty.http.NettyHttpBinding` and therefore if you implement a custom `org.apache.camel.component.netty.http.NettyHttpBinding` then you would need to decode the headers accordingly to this option. | false | boolean
workerCount (consumer) | When netty works on nio mode, it uses default `workerCount` parameter from Netty, which is `cpu_core_threads2`. User can use this operation to override the default `workerCount` from Netty | int | 
workerPool (consumer) | To use an explicit `org.jboss.netty.channel.socket.nio.WorkerPool` as the worker thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own worker pool with 2 x cpu count core threads. | WorkerPool | 
connectTimeout (producer) | Time to wait for a socket connection to be available. Value is in millis. | 10000 | long
requestTimeout (producer) | Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so e.g. 30000 is 30 seconds. The `requestTimeout` is using Netty’s `ReadTimeoutHandler` to trigger the timeout. | long | 
throwExceptionOnFailure (producer) | Option to disable throwing the `HttpOperationFailedException` in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code. | true | boolean
clientPipelineFactory (producer) | To use a custom `ClientPipelineFactory` | ClientPipelineFactory | 
lazyChannelCreation (producer) | Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started. | true | boolean
okStatusCodeRange (producer) | The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included. The default range is 200-299 | 200-299 | String

</tbody>
</table>

### 228.3. MESSAGE HEADERS

The following headers can be used on the producer to control the HTTP request.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel HttpMethod</td>
<td>String</td>
<td>Allow to control what HTTP method to use such as GET, POST, TRACE etc. The type can also be a <code>org.jboss.netty.handler.codec.http.HttpMethod</code> instance.</td>
</tr>
<tr>
<td>Camel HttpQuery</td>
<td>String</td>
<td>Allows to provide URI query parameters as a <code>String</code> value that overrides the endpoint configuration. Separate multiple parameters using the &amp; sign. For example: <code>foo=bar&amp;beer=yes</code>.</td>
</tr>
<tr>
<td>Camel HttpPath</td>
<td>String</td>
<td>Camel 2.13.1/2.12.4: Allows to provide URI context-path and query parameters as a <code>String</code> value that overrides the endpoint configuration. This allows to reuse the same producer for calling same remote http server, but using a dynamic context-path and query parameters.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>String</td>
<td>To set the content-type of the HTTP body. For example: <code>text/plain; charset=UTF-8</code>.</td>
</tr>
</tbody>
</table>
The following headers is provided as meta-data when a route starts from an Netty HTTP endpoint:

The description in the table takes offset in a route having: `from("netty-http:http:0.0.0:8080/myapp")` ...

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelHttpResponseCode</td>
<td>int</td>
<td>Allows to set the HTTP Status code to use. By default 200 is used for success, and 500 for failure.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelHttpMethod</td>
<td>String</td>
<td>The HTTP method used, such as GET, POST, TRACE etc.</td>
</tr>
<tr>
<td>CamelHttpUrl</td>
<td>String</td>
<td>The URL including protocol, host and port, etc</td>
</tr>
<tr>
<td>CamelHttpUri</td>
<td>String</td>
<td>The URI without protocol, host and port, etc</td>
</tr>
<tr>
<td>CamelHttpQuery</td>
<td>String</td>
<td>Any query parameters, such as <code>foo=bar&amp;beer=yes</code></td>
</tr>
<tr>
<td>CamelHttpRawQuery</td>
<td>String</td>
<td>Camel 2.13.0: Any query parameters, such as <code>foo=bar&amp;beer=yes</code>. Stored in the raw form, as they arrived to the consumer (i.e. before URL decoding).</td>
</tr>
<tr>
<td>CamelHttpPath</td>
<td>String</td>
<td>Additional context-path. This value is empty if the client called the context-path <code>/myapp</code>. If the client calls <code>/myapp/mystuff</code>, then this header value is <code>/mystuff</code>. In other words its the value after the context-path configured on the route endpoint.</td>
</tr>
<tr>
<td>CamelHttpCharacterEncoding</td>
<td>String</td>
<td>The charset from the content-type header.</td>
</tr>
</tbody>
</table>
### 228.4. ACCESS TO NETTY TYPES

This component uses the `org.apache.camel.component.netty.http.NettyHttpMessage` as the message implementation on the Exchange. This allows end users to get access to the original Netty request/response instances if needed, as shown below. Mind that the original response may not be accessible at all times.

```java
org.jboss.netty.handler.codec.http.HttpRequest request =
    exchange.getIn(NettyHttpMessage.class).getHttpRequest();
```

### 228.5. EXAMPLES

In the route below we use Netty HTTP as a HTTP server, which returns back a hardcoded "Bye World" message.

```java
from("netty-http:http://0.0.0.0:8080/foo")
    .transform().constant("Bye World");
```

And we can call this HTTP server using Camel also, with the ProducerTemplate as shown below:

```java
String out = template.requestBody("netty-http:http://localhost:8080/foo", "Hello World", String.class);  
System.out.println(out);
```

And we get back "Bye World" as the output.

### 228.6. HOW DO I LET NETTY MATCH WILDCARDS

By default Netty HTTP will only match on exact uri’s. But you can instruct Netty to match prefixes. For example

```java
from("netty-http:http://0.0.0.0:8123/foo").to("mock:foo");
```

In the route above Netty HTTP will only match if the uri is an exact match, so it will match if you enter `http://0.0.0.0:8123/foo` but not match if you do `http://0.0.0.0:8123/foo/bar`.

So if you want to enable wildcard matching you do as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelHttpAuthentication</td>
<td>String</td>
<td>If the user was authenticated using HTTP Basic then this header is added with the value Basic.</td>
</tr>
<tr>
<td>ContentType</td>
<td>String</td>
<td>The content type if provided. For example: <code>text/plain; charset=&quot;UTF-8&quot;</code>.</td>
</tr>
</tbody>
</table>
So now Netty matches any endpoints with starts with `foo`.

To match any endpoint you can do:

```java
from("netty-http:http://0.0.0.0:8123?matchOnUriPrefix=true").to("mock:foo");
```

## 228.7. USING MULTIPLE ROUTES WITH SAME PORT

In the same CamelContext you can have multiple routes from Netty HTTP that shares the same port (e.g. a `org.jboss.netty.bootstrap.ServerBootstrap` instance). Doing this requires a number of bootstrap options to be identical in the routes, as the routes will share the same `org.jboss.netty.bootstrap.ServerBootstrap` instance. The instance will be configured with the options from the first route created.

The options the routes must be identical configured is all the options defined in the `org.apache.camel.component.netty.NettyServerBootstrapConfiguration` configuration class. If you have configured another route with different options, Camel will throw an exception on startup, indicating the options is not identical. To mitigate this ensure all options is identical.

Here is an example with two routes that share the same port.

**Two routes sharing the same port**

```java
from("netty-http:http://0.0.0.0:{{port}}/foo")
  .to("mock:foo")
  .transform().constant("Bye World");

from("netty-http:http://0.0.0.0:{{port}}/bar")
  .to("mock:bar")
  .transform().constant("Bye Camel");
```

And here is an example of a mis configured 2nd route that do not have identical `org.apache.camel.component.netty.NettyServerBootstrapConfiguration` option as the 1st route. This will cause Camel to fail on startup.

**Two routes sharing the same port, but the 2nd route is misconfigured and will fail on starting**

```java
from("netty-http:http://0.0.0.0:{{port}}/foo")
  .to("mock:foo")
  .transform().constant("Bye World");

// we cannot have a 2nd route on same port with SSL enabled, when the 1st route is NOT
from("netty-http:http://0.0.0.0:{{port}}/bar?ssl=true")
  .to("mock:bar")
  .transform().constant("Bye Camel");
```

### 228.7.1. Reusing same server bootstrap configuration with multiple routes

By configuring the common server bootstrap option in an single instance of a `org.apache.camel.component.netty.NettyServerBootstrapConfiguration` type, we can use the `bootstrapConfiguration` option on the Netty HTTP consumers to refer and reuse the same options.
across all consumers.

<bean id="nettyHttpBootstrapOptions"
class="org.apache.camel.component.netty.NettyServerBootstrapConfiguration">
  <property name="backlog" value="200" />
  <property name="connectTimeout" value="20000" />
  <property name="workerCount" value="16" />
</bean>

And in the routes you refer to this option as shown below

<route>
  <from uri="netty-http:http://0.0.0.0:{port}/foo?
  bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

<route>
  <from uri="netty-http:http://0.0.0.0:{port}/bar?
  bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

<route>
  <from uri="netty-http:http://0.0.0.0:{port}/beer?
  bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

228.7.2. Reusing same server bootstrap configuration with multiple routes across multiple bundles in OSGi container

See the Netty HTTP Server Example for more details and example how to do that.

228.8. USING HTTP BASIC AUTHENTICATION

The Netty HTTP consumer supports HTTP basic authentication by specifying the security realm name to use, as shown below

<route>
  <from uri="netty-http:http://0.0.0.0:{port}/foo?securityConfiguration.realm=karaf"/>
  ...
</route>

The realm name is mandatory to enable basic authentication. By default the JAAS based authenticator is used, which will use the realm name specified (karaf in the example above) and use the JAAS realm and the JAAS \{{LoginModule}}s of this realm for authentication.

End user of Apache Karaf / ServiceMix has a karaf realm out of the box, and hence why the example above would work out of the box in these containers.

228.8.1. Specifying ACL on web resources
The `org.apache.camel.component.netty.http.SecurityConstraint` allows to define constraints on web resources. And the `org.apache.camel.component.netty.http.SecurityConstraintMapping` is provided out of the box, allowing to easily define inclusions and exclusions with roles.

For example as shown below in the XML DSL, we define the constraint bean:

```xml
<bean id="constraint" class="org.apache.camel.component.netty.http.SecurityConstraintMapping">
  <!-- inclusions defines url -> roles restrictions -->
  <!-- a * should be used for any role accepted (or even no roles) -->
  <property name="inclusions">
    <map>
      <entry key="/" value="*"/>
      <entry key="/admin/" value="admin"/>
      <entry key="/guest/" value="admin,guest"/>
    </map>
  </property>
  <!-- exclusions is used to define public urls, which requires no authentication -->
  <property name="exclusions">
    <set>
      <value>/public/*</value>
    </set>
  </property>
</bean>
```

The constraint above is defined so that

- access to /* is restricted and any role is accepted (also if user has no roles)
- access to /admin/* requires the admin role
- access to /guest/* requires the admin or guest role
- access to /public/* is an exclusion which means no authentication is needed, and is therefore public for everyone without logging in

To use this constraint we just need to refer to the bean id as shown below:

```xml
<route>
  <from uri="netty-http:http://0.0.0.0:{port}/foo?matchOnUriPrefix=true&securityConfiguration.realm=karaf&securityConfiguration.securityConstraint=#constraint"/>
  ...
</route>
```

CHAPTER 229. NETTY4 COMPONENT

Available as of Camel version 2.14

The netty4 component in Camel is a socket communication component, based on the Netty project version 4.
Netty is a NIO client server framework which enables quick and easy development of
netwServerlnitializerFactoryork applications such as protocol servers and clients.
Netty greatly simplifies and streamlines network programming such as TCP and UDP socket server.

This camel component supports both producer and consumer endpoints.

The Netty component has several options and allows fine-grained control of a number of TCP/UDP
communication parameters (buffer sizes, keepAlives, tcpNoDelay etc) and facilitates both In-Only and
In-Out communication on a Camel route.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-netty4</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

229.1. URI FORMAT

The URI scheme for a netty component is as follows

```
netty4:tcp://localhost:99999[?options]
netty4:udp://remotehost:99999[/?options]
```

This component supports producer and consumer endpoints for both TCP and UDP.

You can append query options to the URI in the following format, ?option=value&option=value&...

229.2. OPTIONS

The Netty4 component supports 5 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>maximumPoolSize</td>
<td>The thread pool size for the EventExecutorGroup if its in use. The default value is 16.</td>
<td>16</td>
<td>int</td>
</tr>
<tr>
<td>configuration</td>
<td>To use the NettyConfiguration as configuration when creating endpoints.</td>
<td></td>
<td>NettyConfiguration</td>
</tr>
<tr>
<td>executorService</td>
<td>To use the given EventExecutorGroup</td>
<td></td>
<td>EventExecutorGroup</td>
</tr>
</tbody>
</table>
The Netty4 endpoint is configured using URI syntax:

```
netty4:protocol:host:port
```

with the following path and query parameters:

### 229.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol</td>
<td><strong>Required</strong> The protocol to use which can be tcp or udp.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td><strong>Required</strong> The hostname. For the consumer the hostname is localhost or 0.0.0.0 For the producer the hostname is the remote host to connect to</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td><strong>Required</strong> The host port number</td>
<td></td>
<td>int</td>
</tr>
</tbody>
</table>

### 229.2.2. Query Parameters (72 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>disconnect</td>
<td>Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>keepAlive</td>
<td>Setting to ensure socket is not closed due to inactivity</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>reuseAddress</td>
<td>Setting to facilitate socket multiplexing</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>reuseChannel (common)</td>
<td>This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key link NettyConstants.NETTY_CHANNEL which allows you to obtain the channel during routing and use it as well.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sync (common)</td>
<td>Setting to set endpoint as one-way or request-response</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>tcpNoDelay (common)</td>
<td>Setting to improve TCP protocol performance</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>broadcast (consumer)</td>
<td>Setting to choose Multicast over UDP</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>clientMode (consumer)</td>
<td>If the clientMode is true, netty consumer will connect the address as a TCP client.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>reconnect (consumer)</td>
<td>Used only in clientMode in consumer, the consumer will attempt to reconnect on disconnection if this is enabled</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>reconnectInterval (consumer)</td>
<td>Used if reconnect and clientMode is enabled. The interval in milli seconds to attempt reconnection</td>
<td>10000</td>
<td>int</td>
</tr>
<tr>
<td>backlog (consumer)</td>
<td>Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be if this option is not configured, then the backlog depends on OS setting.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><strong>bossCount</strong> (consumer)</td>
<td>When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td><strong>bossGroup</strong> (consumer)</td>
<td>Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint</td>
<td></td>
<td>EventLoopGroup</td>
</tr>
<tr>
<td><strong>disconnectOnNoReply</strong> (consumer)</td>
<td>If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>exceptionHandler</strong> (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td><strong>exchangePattern</strong> (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td><strong>nettyServerBootstrapFactory</strong> (consumer)</td>
<td>To use a custom NettyServerBootstrapFactory</td>
<td></td>
<td>NettyServerBootstrapFactory</td>
</tr>
<tr>
<td><strong>networkInterface</strong> (consumer)</td>
<td>When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>noReplyLogLevel</strong> (consumer)</td>
<td>If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td><strong>serverClosedChannelExceptionCaughtLogLevel</strong> (consumer)</td>
<td>If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.</td>
<td>DEBUG</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td><strong>serverExceptionHandler</strong> (consumer)</td>
<td>If the server (NettyConsumer) catches an exception then its logged using this logging level.</td>
<td>WARN</td>
<td>LoggingLevel</td>

<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>usingExecutorService (consumer)</td>
<td>Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>connectTimeout (producer)</td>
<td>Time to wait for a socket connection to be available. Value is in millis.</td>
<td>10000</td>
<td>int</td>
</tr>
<tr>
<td>requestTimeout (producer)</td>
<td>Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.</td>
<td></td>
<td>long</td>
</tr>
<tr>
<td>clientInitializerFactory (producer)</td>
<td>To use a custom ClientInitializerFactory</td>
<td></td>
<td>ClientInitializerFactory</td>
</tr>
<tr>
<td>correlationManager (producer)</td>
<td>To use a custom correlation manager to manage how request and reply messages are mapped when using request/reply with the netty producer. This should only be used if you have a way to map requests together with replies such as if there is correlation ids in both the request and reply messages. This can be used if you want to multiplex concurrent messages on the same channel (aka connection) in netty. When doing this you must have a way to correlate the request and reply messages so you can store the right reply on the inflight Camel Exchange before its continued routed. We recommend extending the TimeoutCorrelationManagerSupport when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well. See also the producerPoolEnabled option for more details.</td>
<td></td>
<td>NettyCamelState CorrelationManager</td>

### 229.3. REGISTRY BASED OPTIONS

Codec Handlers and SSL Keystores can be enlisted in the Registry, such as in the Spring XML file. The values that could be passed in, are the following:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>trustStoreResource (security)</td>
<td>Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

- **trustStoreResource**:  
  - **Description**: Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.
  - **Default**: String

- **trustStoreFile**:  
  - **Description**: Client side certificate keystore to be used for encryption.
  - **Default**: String

- **trustStoreResource**:  
  - **Description**: Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.
  - **Default**: String

- **sslHandler**:  
  - **Description**: Reference to a class that could be used to return an SSL Handler.

- **encoder**:  
  - **Description**: A custom ChannelHandler class that can be used to perform special marshalling of outbound payloads. Must override io.netty.channel.ChannelInboundHandlerAdapter.

- **passphrase**:  
  - **Description**: Password setting to use in order to encrypt/decrypt payloads sent using SSH.

- **keyStoreFormat**:  
  - **Description**: Keystore format to be used for payload encryption. Defaults to "JKS" if not set.

- **securityProvider**:  
  - **Description**: Security provider to be used for payload encryption. Defaults to "SunX509" if not set.

- **keyStoreFile**:  
  - **Description**: Client side certificate keystore to be used for encryption.
  - **Default**: String

- **trustStoreFile**:  
  - **Description**: Server side certificate keystore to be used for encryption.
  - **Default**: String

- **keyStoreResource**:  
  - **Description**: Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with "classpath:\", "file:\", or "http:\" to load the resource from different systems.
  - **Default**: String

- **trustStoreResource**:  
  - **Description**: Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with "classpath:\", "file:\", or "http:\" to load the resource from different systems.
  - **Default**: String
## 229.3.1. Using non shareable encoders or decoders

If your encoders or decoders is not shareable (eg they have the @Shareable class annotation), then your encoder/decoder must implement the `org.apache.camel.component.netty.ChannelHandlerFactory` interface, and return a new instance in the `newChannelHandler` method. This is to ensure the encoder/decoder can safely be used. If this is not the case, then the Netty component will log a WARN when an endpoint is created.

The Netty component offers a `org.apache.camel.component.netty.ChannelHandlerFactories` factory class, that has a number of commonly used methods.

## 229.4. SENDING MESSAGES TO/FROM A NETTY ENDPOINT

### 229.4.1. Netty Producer

In Producer mode, the component provides the ability to send payloads to a socket endpoint using either TCP or UDP protocols (with optional SSL support).

The producer mode supports both one-way and request-response based operations.

### 229.4.2. Netty Consumer

In Consumer mode, the component provides the ability to:

- listen on a specified socket using either TCP or UDP protocols (with optional SSL support),
- receive requests on the socket using text/xml, binary and serialized object based payloads and
- send them along on a route as message exchanges.

The consumer mode supports both one-way and request-response based operations.

## 229.5. EXAMPLES
229.5.1. A UDP Netty endpoint using Request-Reply and serialized object payload

```java
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("netty4:udp://localhost:5155?sync=true")
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    Poetry poetry = (Poetry) exchange.getIn().getBody();
                    poetry.setPoet("Dr. Sarojini Naidu");
                    exchange.getOut().setBody(poetry);
                }
            }
    }
};
```

229.5.2. A TCP based Netty consumer endpoint using One-way communication

```java
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("netty4:tcp://localhost:5150")
            .to("mock:result");
    }
};
```

229.5.3. An SSL/TCP based Netty consumer endpoint using Request-Reply communication

Using the JSSE Configuration Utility

As of Camel 2.9, the Netty component supports SSL/TLS configuration through the Camel JSSE Configuration Utility. This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the Netty component.

Programmatic configuration of the component

```java
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("keyPassword");

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

NettyComponent nettyComponent = getContext().getComponent("netty4", NettyComponent.class);
nettyComponent.setSslContextParameters(scp);
```

Spring DSL based configuration of endpoint

...
Getting access to SSLSession and the client certificate

You can get access to the `javax.net.ssl.SSLSession` if you need to get details about the client certificate. When `ssl=true` then the Netty4 component will store the `SSLSession` as a header on the Camel Message as shown below:

```java
SSLSession session = exchange.getIn().getHeader(NettyConstants.NETTY_SSL_SESSION, SSLSession.class);
// get the first certificate which is client certificate
javax.security.cert.X509Certificate cert = session.getPeerCertificateChain()[0];
Principal principal = cert.getSubjectDN();
```

Remember to set `needClientAuth=true` to authenticate the client, otherwise `SSLSession` cannot access information about the client certificate, and you may get an exception.
javax.net.ssl.SSLPeerUnverifiedException: peer not authenticated. You may also get this exception if the client certificate is expired or not valid etc.

TIP

The option sslClientCertHeaders can be set to true which then enriches the Camel Message with headers having details about the client certificate. For example the subject name is readily available in the header CamelNettySSLClientCertSubjectName.

229.5.4. Using Multiple Codecs

In certain cases it may be necessary to add chains of encoders and decoders to the netty pipeline. To add multiple codecs to a camel netty endpoint the ‘encoders’ and ‘decoders’ uri parameters should be used. Like the ‘encoder’ and ‘decoder’ parameters they are used to supply references (to lists of ChannelUpstreamHandlers and ChannelDownstreamHandlers) that should be added to the pipeline. Note that if encoders is specified then the encoder param will be ignored, similarly for decoders and the decoder param.

NOTE

Read further above about using non shareable encoders/decoders.

The lists of codecs need to be added to the Camel’s registry so they can be resolved when the endpoint is created.

```java
ChannelHandlerFactory lengthDecoder = ChannelHandlerFactories.newLengthFieldBasedFrameDecoder(1048576, 0, 4, 0, 4);

StringDecoder stringDecoder = new StringDecoder();
registry.bind("length-decoder", lengthDecoder);
registry.bind("string-decoder", stringDecoder);

LengthFieldPrepender lengthEncoder = new LengthFieldPrepender(4);
StringEncoder stringEncoder = new StringEncoder();
registry.bind("length-encoder", lengthEncoder);
registry.bind("string-encoder", stringEncoder);

List<ChannelHandler> decoders = new ArrayList<ChannelHandler>();
decoders.add(lengthDecoder);
decoders.add(stringDecoder);

List<ChannelHandler> encoders = new ArrayList<ChannelHandler>();
encoders.add(lengthEncoder);
encoders.add(stringEncoder);

registry.bind("encoders", encoders);
registry.bind("decoders", decoders);
```

Spring’s native collections support can be used to specify the codec lists in an application context.

```xml
<util:list id="decoders" list-class="java.util.LinkedList">
  <bean class="org.apache.camel.component.netty4.ChannelHandlerFactories" factory-method="newLengthFieldBasedFrameDecoder">
    <constructor-arg value="1048576"/>
  </bean>
</util:list>
```
The bean names can then be used in netty endpoint definitions either as a comma separated list or contained in a List e.g.

```xml
<route>
  <from uri="direct:multiple-codec"/>
  <to uri="netty4:tcp://localhost:{port}?encoders=#encoders&sync=false"/>
</route>
```

Or via XML.

```xml
<cAMELcontext id="multiple-netty-codecs-context" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:multiple-codec"/>
    <to uri="netty4:tcp://localhost:{port}?encoders=#encoders&sync=false"/>
  </route>
</camelContext>
```

### 229.6. CLOSING CHANNEL WHEN COMPLETE

When acting as a server you sometimes want to close the channel when, for example, a client conversion constructor-arg value="0"/>
  <constructor-arg value="4"/>
  </bean>
  <bean class="io.netty.handler.codec.string.StringDecoder"/>
</util:list>

```xml
<util:list id="encoders" list-class="java.util.LinkedList">
  <bean class="io.netty.handler.codec.LengthFieldPrepender">
    <constructor-arg value="4"/>
  </bean>
  <bean class="io.netty.handler.codec.string.StringEncoder"/>
</util:list>
```

```xml
<bean id="length-encoder" class="io.netty.handler.codec.LengthFieldPrepender">
  <constructor-arg value="4"/>
</bean>
```

```xml
<bean id="string-encoder" class="io.netty.handler.codec.string.StringEncoder"/>
```

```xml
<bean id="length-decoder" class="org.apache.camel.component.netty4.ChannelHandlerFactories" factory-method="newLengthFieldBasedFrameDecoder">
  <constructor-arg value="1048576"/>
  <constructor-arg value="0"/>
  <constructor-arg value="4"/>
  <constructor-arg value="0"/>
  <constructor-arg value="4"/>
</bean>
```

```xml
<bean id="string-decoder" class="io.netty.handler.codec.string.StringDecoder"/>
```

The bean names can then be used in netty endpoint definitions either as a comma separated list or contained in a List e.g.

```java
from("direct:multiple-codec").to("netty4:tcp://localhost:{port}?encoders=#encoders&sync=false");
```

```java
from("netty4:tcp://localhost:{port}?decoders=#length-decoder,#string-decoder&sync=false").to("mock:multiple-codec");
```
When acting as a server you sometimes want to close the channel when, for example, a client conversion is finished.
You can do this by simply setting the endpoint option `disconnect=true`.

However you can also instruct Camel on a per message basis as follows.
To instruct Camel to close the channel, you should add a header with the key `CamelNettyCloseChannelWhenComplete` set to a boolean `true` value.
For instance, the example below will close the channel after it has written the bye message back to the client:

```java
from("netty4:tcp://localhost:8080").process(new Processor() {
    public void process(Exchange exchange) throws Exception {
        String body = exchange.getIn().getBody(String.class);
        exchange.getOut().setBody("Bye " + body);
        // some condition which determines if we should close
        if (close) {
            exchange.getOut().setHeader(NettyConstants.NETTY_CLOSE_CHANNEL_WHEN_COMPLETE, true);
        }
    }
});
```

Adding custom channel pipeline factories to gain complete control over a

### 229.7. CUSTOM PIPELINE

Custom channel pipelines provide complete control to the user over the handler/interceptor chain by inserting custom handler(s), encoder(s) & decoders without having to specify them in the Netty Endpoint URL in a very simple way.

In order to add a custom pipeline, a custom channel pipeline factory must be created and registered with the context via the context registry (JNDIRegistry, or the camel-spring ApplicationContextRegistry etc).

A custom pipeline factory must be constructed as follows

- A Producer linked channel pipeline factory must extend the abstract class `ClientPipelineFactory`.
- A Consumer linked channel pipeline factory must extend the abstract class `ServerInitializerFactory`.
- The classes should override the `initChannel()` method in order to insert custom handler(s), encoder(s) and decoder(s). Not overriding the `initChannel()` method creates a pipeline with no handlers, encoders or decoders wired to the pipeline.

The example below shows how `ServerInitializerFactory` factory may be created

### 229.7.1. Using custom pipeline factory

```java
public class SampleServerInitializerFactory extends ServerInitializerFactory {
    private int maxLineSize = 1024;

    protected void initChannel(Channel ch) throws Exception {
        ChannelPipeline channelPipeline = ch.pipeline();
    }
}"
```
The custom channel pipeline factory can then be added to the registry and instantiated/utilized on a camel route in the following way:

```java
Registry registry = camelContext.getRegistry();
ServerInitializerFactory factory = new TestServerInitializerFactory();
registry.bind("spf", factory);
context.addRoutes(new RouteBuilder() {
    public void configure() {
        String netty_ssl_endpoint = "netty4:tcp://localhost:5150?serverInitializerFactory=#spf"
        String return_string = "When You Go Home, Tell Them Of Us And Say,"
        + "For Your Tomorrow, We Gave Our Today."

        from(netty_ssl_endpoint)
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    exchange.getOut().setBody(return_string);
                }
            });
    }
});
```

229.8. REUSING NETTY BOSS AND WORKER THREAD POOLS

Netty has two kind of thread pools: boss and worker. By default each Netty consumer and producer has their private thread pools. If you want to reuse these thread pools among multiple consumers or producers then the thread pools must be created and enlisted in the Registry.

For example using Spring XML we can create a shared worker thread pool using the `NettyWorkerPoolBuilder` with 2 worker threads as shown below:

```xml
<l use the worker pool builder to help create the shared thread pool -->
<bean id="poolBuilder" class="org.apache.camel.component.netty.NettyWorkerPoolBuilder">
    <property name="workerCount" value="2"/>
</bean>

<l the shared worker thread pool -->
<bean id="sharedPool" class="org.jboss.netty.channel.socket.nio.WorkerPool"
    factory-bean="poolBuilder" factory-method="build" destroy-method="shutdown">
</bean>
```

Then in the Camel routes we can refer to this worker pools by configuring the `workerPool` option in the `URI` as shown below:

```xml
<route>
  <from uri="netty4:tcp://localhost:5021?textline=true&amp;sync=true&amp;workerPool=#sharedPool&amp;usingExecutorService=false"/>
  <to uri="log:result"/>
  ...
</route>
```

And if we have another route we can refer to the shared worker pool:

```xml
<route>
  <from uri="netty4:tcp://localhost:5022?textline=true&amp;sync=true&amp;workerPool=#sharedPool&amp;usingExecutorService=false"/>
  <to uri="log:result"/>
  ...
</route>
```

and so forth.

### 229.9. MULTIPLEXING CONCURRENT MESSAGES OVER A SINGLE CONNECTION WITH REQUEST/REPLY

When using Netty for request/reply messaging via the netty producer then by default each message is sent via a non-shared connection (pooled). This ensures that replies are automatic being able to map to the correct request thread for further routing in Camel. In other words correlation between request/reply messages happens out-of-the-box because the replies comes back on the same connection that was used for sending the request; and this connection is not shared with others. When the response comes back, the connection is returned back to the connection pool, where it can be reused by others.

However if you want to multiplex concurrent request/responses on a single shared connection, then you need to turn off the connection pooling by setting `producerPoolEnabled=false`. Now this means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement `NettyCamelStateCorrelationManager` as correlation manager and configure it via the `correlationManager=#myManager` option.

**NOTE**

We recommend extending the `TimeoutCorrelationManagerSupport` when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well.

### 229.10. SEE ALSO
- Netty HTTP
- MINA
CHAPTER 230. NETTY4 HTTP COMPONENT

Available as of Camel version 2.14

The netty4-http component is an extension to Netty4 component to facilitate HTTP transport with Netty4.

This camel component supports both producer and consumer endpoints.

INFO: Stream. Netty is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream once. If you find a situation where the message body appears to be empty or you need to access the data multiple times (eg: doing multicasting, or redelivery error handling) you should use Stream caching or convert the message body to a String which is safe to be re-read multiple times. Notice Netty4 HTTP reads the entire stream into memory using io.netty.handler.codec.http.HttpObjectAggregator to build the entire full http message. But the resulting message is still a stream based message which is readable once.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-netty4-http</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

230.1. URI FORMAT

The URI scheme for a netty component is as follows

```text
netty4-http:http://localhost:8080/[?options]
```

You can append query options to the URI in the following format, ?option=value&option=value&…

INFO: Query parameters vs endpoint options You may be wondering how Camel recognizes URI query parameters and endpoint options. For example you might create endpoint URI as follows - netty4-http:http://example.com?myParam=myValue&compression=true. In this example myParam is the HTTP parameter, while compression is the Camel endpoint option. The strategy used by Camel in such situations is to resolve available endpoint options and remove them from the URI. It means that for the discussed example, the HTTP request sent by Netty HTTP producer to the endpoint will look as follows - http://example.com?myParam=myValue, because compression endpoint option will be resolved and removed from the target URL. Keep also in mind that you cannot specify endpoint options using dynamic headers (like CamelHttpQuery). Endpoint options can be specified only at the endpoint URI definition level (like to or from DSL elements).

230.2. HTTP OPTIONS

INFO: A lot more options. Important: This component inherits all the options from Netty4. So make sure to look at the Netty4 documentation as well. Notice that some options from Netty4 is not applicable when using this Netty4 HTTP component, such as options related to UDP transport.

The Netty4 HTTP component supports 8 options which are listed below.
### Name | Description | Default | Type
--- | --- | --- | ---
nettyHttpBinding (advanced) | To use a custom org.apache.camel.component.netty4.http.NettyHttp Binding for binding to/from Netty and Camel Message API. | NettyHttpBinding |  
configuration (common) | To use the NettyConfiguration as configuration when creating endpoints. | NettyHttpConfiguration |  
headerFilterStrategy (advanced) | To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers. | HeaderFilterStrategy |  
useGlobalSslContext Parameters (security) | Enable usage of global SSL context parameters. | false | boolean 
maximumPoolSize (advanced) | The thread pool size for the EventExecutorGroup if its in use. The default value is 16. | 16 | int 
executorService (advanced) | To use the given EventExecutorGroup | EventExecutorGroup |  
resolveProperty Placeholders (advanced) | Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders. | true | boolean 

The Netty4 HTTP endpoint is configured using URI syntax:

```
netty4-http:protocol:host:port/path
```

with the following path and query parameters:

#### 230.2.1. Path Parameters (4 parameters):

### Name | Description | Default | Type
--- | --- | --- | ---
protocol | **Required** The protocol to use which is either http or https |  | String
## host

**Required** The local hostname such as localhost, or 0.0.0.0 when being a consumer. The remote HTTP server hostname when using producer.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>host</strong></td>
<td></td>
<td></td>
<td><strong>String</strong></td>
</tr>
</tbody>
</table>

## port

The host port number

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>port</strong></td>
<td>The host port number</td>

### 230.2.2. Query Parameters (79 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>bridgeEndpoint</strong> (common)</td>
<td>If the option is true, the producer will ignore the Exchange.HTTP_URI header, and use the endpoint’s URI for request. You may also set the throwExceptionOnFailure to be false to let the producer send all the fault response back. The consumer working in the bridge mode will skip the gzip compression and WWW URL form encoding (by adding the Exchange.SKIP_GZIP_ENCODING and Exchange.SKIP_WWW_FORM_URLENCODED headers to the consumed exchange).</td>
<td>false</td>
<td><strong>boolean</strong></td>
</tr>
<tr>
<td><strong>disconnect</strong> (common)</td>
<td>Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.</td>
<td>false</td>
<td><strong>boolean</strong></td>
</tr>
<tr>
<td><strong>keepAlive</strong> (common)</td>
<td>Setting to ensure socket is not closed due to inactivity</td>
<td>true</td>
<td><strong>boolean</strong></td>
</tr>
<tr>
<td><strong>reuseAddress</strong> (common)</td>
<td>Setting to facilitate socket multiplexing</td>
<td>true</td>
<td><strong>boolean</strong></td>
</tr>
<tr>
<td><strong>reuseChannel</strong> (common)</td>
<td>This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key link NettyConstantsNETTY_CHANNEL which allows you to obtain the channel during routing and use it as well.</td>
<td>false</td>
<td><strong>boolean</strong></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>

<td>Setting to set endpoint as one-way or request-response</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>tcpNoDelay (common)</td>
<td>Setting to improve TCP protocol performance</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>matchOnUriPrefix (consumer)</td>
<td>Whether or not Camel should try to find a target consumer by matching the URI prefix if no exact match is found.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>send503whenSuspended (consumer)</td>
<td>Whether to send back HTTP status code 503 when the consumer has been suspended. If the option is false then the Netty Acceptor is unbound when the consumer is suspended, so clients cannot connect anymore.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>backlog (consumer)</td>
<td>Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be if this option is not configured, then the backlog depends on OS setting.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>bossCount (consumer)</td>
<td>When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>bossGroup (consumer)</td>
<td>Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint</td>
<td>EventLoopGroup</td>
<td></td>
</tr>
<tr>
<td>chunkedMaxContentLength (consumer)</td>
<td>Value in bytes the max content length per chunked frame received on the Netty HTTP server.</td>
<td>1048576</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>

<tr>
<td>compression (consumer)</td>
<td>Allow using gzip/deflate for compression on the Netty HTTP server if the client supports it from the HTTP headers.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>disconnectOnNoReply (consumer)</td>
<td>If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>httpMethodRestrict (consumer)</td>
<td>To disable HTTP methods on the Netty HTTP consumer. You can specify multiple separated by comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>mapHeaders (consumer)</td>
<td>If this option is enabled, then during binding from Netty to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the org.apache.camel.component.netty.http.NettyHttpMessage message with the method getHttpRequest() that returns the Netty HTTP request io.netty.handler.codec.http.HttpRequest instance.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>maxHeaderSize (consumer)</td>
<td>The maximum length of all headers. If the sum of the length of each header exceeds this value, a io.netty.handler.codec.TooLongFrameException will be raised.</td>
<td>8192</td>
<td>int</td>
</tr>
<tr>
<td>nettyServerBootstrapFactory (consumer)</td>
<td>To use a custom NettyServerBootstrapFactory</td>
<td></td>
<td>NettyServerBootstrapFactory</td>
</tr>
<tr>
<td>nettySharedHttpServer (consumer)</td>
<td>To use a shared Netty HTTP server. See Netty HTTP Server Example for more details.</td>
<td></td>
<td>NettySharedHttpServer</td>
</tr>
<tr>
<td>Name</td>

<td>If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td><code>serverClosedChannelExceptionCaughtLogLevel</code> <em>(consumer)</em></td>
<td>If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.</td>
<td>DEBU</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td><code>serverExceptionCaughtLogLevel</code> <em>(consumer)</em></td>
<td>If the server (NettyConsumer) catches an exception then its logged using this logging level.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td><code>serverInitializerFactory</code> <em>(consumer)</em></td>
<td>To use a custom ServerInitializerFactory</td>
<td></td>
<td>ServerInitializerFactory</td>
</tr>
<tr>
<td><code>traceEnabled</code> <em>(consumer)</em></td>
<td>Specifies whether to enable HTTP TRACE for this Netty HTTP consumer. By default TRACE is turned off.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>urlDecoders</code> <em>(consumer)</em></td>
<td>If this option is enabled, then during binding from Netty to Camel Message then the header values will be URL decoded (eg %20 will be a space character. Notice this option is used by the default org.apache.camel.component.netty.http.NettyHttpBinding and therefore if you implement a custom org.apache.camel.component.netty4.http.NettyHttpBinding then you would need to decode the headers accordingly to this option.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>usingExecutorService</code> <em>(consumer)</em></td>
<td>Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>connectTimeout</code> <em>(producer)</em></td>
<td>Time to wait for a socket connection to be available. Value is in millis.</td>
<td>10000</td>
<td>int</td>
</tr>
<tr>
<td><code>cookieHandler</code> <em>(producer)</em></td>
<td>Configure a cookie handler to maintain a HTTP session</td>
<td></td>
<td>CookieHandler</td>
</tr>
<tr>
<td><code>requestTimeout</code> <em>(producer)</em></td>
<td>Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty’s ReadTimeoutHandler to trigger the timeout.</td>
<td></td>
<td>long</td>
</tr>
<tr>

<tr>
<td>throwExceptionOnFailure</td>
<td>Option to disable throwing the HttpOperationFailedException in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>clientInitializerFactory</td>
<td>To use a custom ClientInitializerFactory</td>
<td></td>
<td>ClientInitializer Factory</td>
</tr>
<tr>
<td>lazyChannelCreation</td>
<td>Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>okStatusCodeRange</td>
<td>The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included. The default range is 200-299</td>
<td>200-299</td>
<td>String</td>
</tr>
<tr>
<td>producerPoolEnabled</td>
<td>Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement NettyCamelStateCorrelationManager as correlation manager and configure it via the correlationManager option. See also the correlationManager option for more details.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>producerPoolMaxActive</td>
<td>Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>producerPoolMaxIdle</td>
<td>Sets the cap on the number of idle instances in the pool.</td>
<td>100</td>
<td>int</td>
</tr>
<tr>
<td>producerPoolMinEvictable</td>
<td>Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.</td>
<td>300000</td>
<td>long</td>
</tr>
<tr>
<td>Name</td>

<tr>
<td>producerPoolMinIdle (producer)</td>
<td>Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>useRelativePath (producer)</td>
<td>Sets whether to use a relative path in HTTP requests.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>allowSerializedHeaders (advanced)</td>
<td>Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>bootstrapConfiguration (advanced)</td>
<td>To use a custom configured NettyServerBootstrapConfiguration for configuring this endpoint.</td>
<td></td>
<td>NettyServerBootstrapConfiguration</td>
</tr>
<tr>
<td>channelGroup (advanced)</td>
<td>To use an explicit ChannelGroup.</td>
<td></td>
<td>ChannelGroup</td>
</tr>
<tr>
<td>configuration (advanced)</td>
<td>To use a custom configured NettyHttpConfiguration for configuring this endpoint.</td>
<td></td>
<td>NettyHttpConfiguration</td>
</tr>
<tr>
<td>disableStreamCache (advanced)</td>
<td>Determines whether or not the raw input stream from Netty HttpRequest/getContent() or HttpResonse/getContent() is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Netty raw stream. Also Netty will auto-close the Netty stream when the Netty HTTP server/HTTP client is done processing, which means that if the asynchronous routing engine is in use then any asynchronous thread that may continue routing the org.apache.camel.Exchange may not be able to read the Netty stream, because Netty has closed it.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>headerFilterStrategy (advanced)</td>
<td>To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
---|---|---|---
**nativeTransport** *(advanced)* | Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: [http://netty.io/wiki/native-transports.html](http://netty.io/wiki/native-transports.html) | false | boolean
**nettyHttpBinding** *(advanced)* | To use a custom `org.apache.camel.component.netty4.http.NettyHttpBinding` for binding to/from Netty and Camel Message API. | NettyHttpBinding |
**options** *(advanced)* | Allows to configure additional netty options using `option. as prefix. For example option.child.keepAlive=false` to set the netty option `child.keepAlive=false`. See the Netty documentation for possible options that can be used. | Map |
**receiveBufferSize** *(advanced)* | The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes. | 65536 | int |
**receiveBufferSize Predictor** *(advanced)* | Configures the buffer size predictor. See details at Jetty documentation and this mail thread. | int |
**sendBufferSize** *(advanced)* | The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes. | 65536 | int |
**synchronous** *(advanced)* | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean |
**transferException** *(advanced)* | If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the `HttpOperationFailedException`. The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk. | false | boolean |

### 230.3. MESSAGE HEADERS
The following headers can be used on the producer to control the HTTP request.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel HttpMethod</td>
<td>String</td>
<td>Allow to control what HTTP method to use such as GET, POST, TRACE etc. The type can also be a <code>io.netty.handler.codec.http.HttpMethod</code> instance.</td>
</tr>
<tr>
<td>Camel HttpQuery</td>
<td>String</td>
<td>Allows to provide URI query parameters as a <code>String</code> value that overrides the endpoint configuration. Separate multiple parameters using the &amp; sign. For example: <code>foo=bar&amp;beer=yes</code>.</td>
</tr>
<tr>
<td>Camel HttpPath</td>
<td>String</td>
<td>Allows to provide URI context-path and query parameters as a <code>String</code> value that overrides the endpoint configuration. This allows to reuse the same producer for calling same remote http server, but using a dynamic context-path and query parameters.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>String</td>
<td>To set the content-type of the HTTP body. For example: <code>text/plain; charset=&quot;UTF-8&quot;</code>.</td>
</tr>
<tr>
<td>Camel HttpResponseCode</td>
<td>int</td>
<td>Allows to set the HTTP Status code to use. By default 200 is used for success, and 500 for failure.</td>
</tr>
</tbody>
</table>

The following headers is provided as meta-data when a route starts from an Netty4 HTTP endpoint:

The description in the table takes offset in a route having: `from("netty4-http:http:0.0.0:8080/myapp")` ...

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel HttpMethod</td>
<td>String</td>
<td>The HTTP method used, such as GET, POST, TRACE etc.</td>
</tr>
<tr>
<td>Camel HttpUrl</td>
<td>String</td>
<td>The URL including protocol, host and port, etc: <code>http://0.0.0:8080/myapp</code></td>
</tr>
<tr>
<td>Camel HttpUri</td>
<td>String</td>
<td>The URI without protocol, host and port, etc: <code>/myapp</code></td>
</tr>
<tr>
<td>Camel HttpQuery</td>
<td>String</td>
<td>Any query parameters, such as <code>foo=bar&amp;beer=yes</code></td>
</tr>
</tbody>
</table>
### 230.4. ACCESS TO NETTY TYPES

This component uses the `org.apache.camel.component.netty4.http.NettyHttpMessage` as the message implementation on the Exchange. This allows end users to get access to the original Netty request/response instances if needed, as shown below. Mind that the original response may not be accessible at all times.

```java
io.netty.handler.codec.http.HttpRequest request =
   exchange.getIn(NettyHttpMessage.class).getHttpRequest();
```

### 230.5. EXAMPLES

In the route below we use Netty4 HTTP as a HTTP server, which returns back a hardcoded "Bye World" message.

```java
from("netty4-http:http://0.0.0.0:8080/foo")
   .transform().constant("Bye World");
```

And we can call this HTTP server using Camel also, with the ProducerTemplate as shown below:
And we get back "Bye World" as the output.

### 230.6. HOW DO I LET NETTY MATCH WILDCARDS

By default Netty4 HTTP will only match on exact uri’s. But you can instruct Netty to match prefixes. For example

```java
from("netty4-http:http://0.0.0.0:8123/foo").to("mock:foo");
```

In the route above Netty4 HTTP will only match if the uri is an exact match, so it will match if you enter `http://0.0.0.0:8123/foo` but not match if you do `http://0.0.0.0:8123/foo/bar`.

So if you want to enable wildcard matching you do as follows:

```java
from("netty4-http:http://0.0.0.0:8123/foo?matchOnUriPrefix=true").to("mock:foo");
```

So now Netty matches any endpoints with starts with `foo`.

To match **any** endpoint you can do:

```java
from("netty4-http:http://0.0.0.0:8123?matchOnUriPrefix=true").to("mock:foo");
```

### 230.7. USING MULTIPLE ROUTES WITH SAME PORT

In the same CamelContext you can have multiple routes from Netty4 HTTP that shares the same port (eg a `io.netty.bootstrap.ServerBootstrap` instance). Doing this requires a number of bootstrap options to be identical in the routes, as the routes will share the same `io.netty.bootstrap.ServerBootstrap` instance. The instance will be configured with the options from the first route created.

The options the routes must be identical configured is all the options defined in the `org.apache.camel.component.netty4.NettyServerBootstrapConfiguration` configuration class. If you have configured another route with different options, Camel will throw an exception on startup, indicating the options is not identical. To mitigate this ensure all options is identical.

Here is an example with two routes that share the same port.

**Two routes sharing the same port**

```java
from("netty4-http:http://0.0.0.0:{{port}}/foo")
  .to("mock:foo")
  .transform().constant("Bye World");

from("netty4-http:http://0.0.0.0:{{port}}/bar")
  .to("mock:bar")
  .transform().constant("Bye Camel");
```

And here is an example of a mis configured 2nd route that do not have identical `org.apache.camel.component.netty4.NettyServerBootstrapConfiguration` option as the 1st route. This will cause Camel to fail on startup.
Two routes sharing the same port, but the 2nd route is misconfigured and will fail on starting

```
from("netty4-http:http://0.0.0.0:{{port}}/foo")
  .to("mock:foo")
  .transform().constant("Bye World");

// we cannot have a 2nd route on same port with SSL enabled, when the 1st route is NOT
from("netty4-http:http://0.0.0.0:{{port}}/bar?ssl=true")
  .to("mock:bar")
  .transform().constant("Bye Camel");
```

230.7.1. Reusing same server bootstrap configuration with multiple routes

By configuring the common server bootstrap option in an single instance of a `org.apache.camel.component.netty4.NettyServerBootstrapConfiguration` type, we can use the `bootstrapConfiguration` option on the Netty4 HTTP consumers to refer and reuse the same options across all consumers.

```
<bean id="nettyHttpBootstrapOptions"
  class="org.apache.camel.component.netty4.NettyServerBootstrapConfiguration">
  <property name="backlog" value="200"/>
  <property name="connectionTimeout" value="20000"/>
  <property name="workerCount" value="16"/>
</bean>
```

And in the routes you refer to this option as shown below

```
<route>
  <from uri="netty4-http:http://0.0.0.0:{{port}}/foo?
  bootstrapConfiguration=#nettyHttpBootstrapOptions"/>

  ...
</route>

<route>
  <from uri="netty4-http:http://0.0.0.0:{{port}}/bar?
  bootstrapConfiguration=#nettyHttpBootstrapOptions"/>

  ...
</route>

<route>
  <from uri="netty4-http:http://0.0.0.0:{{port}}/beer?
  bootstrapConfiguration=#nettyHttpBootstrapOptions"/>

  ...
</route>
```

230.7.2. Reusing same server bootstrap configuration with multiple routes across multiple bundles in OSGi container

See the Netty HTTP Server Example for more details and example how to do that.

230.8. USING HTTP BASIC AUTHENTICATION
The Netty HTTP consumer supports HTTP basic authentication by specifying the security realm name
to use, as shown below

```xml
<route>
  <from uri="netty4-http:http://0.0.0.0:{port}/foo?securityConfiguration.realm=karaf"/>
  ...
</route>
```

The realm name is mandatory to enable basic authentication. By default the JAAS based authenticator
is used, which will use the realm name specified (karaf in the example above) and use the JAAS realm
and the JAAS \{{LoginModule}}s of this realm for authentication.

End user of Apache Karaf / ServiceMix has a karaf realm out of the box, and hence why the example
above would work out of the box in these containers.

### 230.8.1. Specifying ACL on web resources

The `org.apache.camel.component.netty4.http.SecurityConstraint` allows to define constrains on web
resources. And the `org.apache.camel.component.netty.http.SecurityConstraintMapping` is provided
out of the box, allowing to easily define inclusions and exclusions with roles.

For example as shown below in the XML DSL, we define the constraint bean:

```xml
<bean id="constraint" class="org.apache.camel.component.netty4.http.SecurityConstraintMapping">
  <!-- inclusions defines url -> roles restrictions -->
  <!-- a * should be used for any role accepted (or even no roles) -->
  <property name="inclusions">
    <map>
      <entry key="/" value="*"/>
      <entry key="/admin/" value="admin"/>
      <entry key="/guest/" value="admin,guest"/>
    </map>
  </property>
  <!-- exclusions is used to define public urls, which requires no authentication -->
  <property name="exclusions">
    <set>
      <value>/public/</value>
    </set>
  </property>
</bean>
```

The constraint above is define so that

- access to /* is restricted and any roles is accepted (also if user has no roles)
- access to /admin/* requires the admin role
- access to /guest/* requires the admin or guest role
- access to /public/* is an exclusion which means no authentication is needed, and is therefore
  public for everyone without logging in

To use this constraint we just need to refer to the bean id as shown below:

```xml
<route>
```

CHAPTER 230. NETTY4 HTTP COMPONENT
<from uri="netty4-http:http://0.0.0.0:{{port}}/foo?matchOnUriPrefix=true&securityConfiguration.realm=karaf&securityConfiguration.securityConstraint=#constraint"/>

...</route>

- Component
- Endpoint
- Getting Started
- Netty
- Netty HTTP Server Example
- Jetty
CHAPTER 231. OGNL LANGUAGE

Available as of Camel version 1.1

Camel allows OGNL to be used as an Expression or Predicate the DSL or Xml Configuration.

You could use OGNL to create an Predicate in a Message Filter or as an Expression for a Recipient List.

You can use OGNL dot notation to invoke operations. If you for instance have a body that contains a POJO that has a `getFamilyName` method then you can construct the syntax as follows:

```
"request.body.familyName"
// or
"getRequest().getBody().getFamilyName()"
```

231.1. OGNL OPTIONS

The OGNL language supports 1 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trim</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to trim the value to remove leading and trailing whitespaces and line breaks</td>
</tr>
</tbody>
</table>

231.2. VARIABLES

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>this</td>
<td>Exchange</td>
<td>the Exchange is the root object</td>
</tr>
<tr>
<td>exchange</td>
<td>Exchange</td>
<td>the Exchange object</td>
</tr>
<tr>
<td>exception</td>
<td>Throwable</td>
<td>the Exchange exception (if any)</td>
</tr>
<tr>
<td>exchangeld</td>
<td>String</td>
<td>the exchange id</td>
</tr>
<tr>
<td>fault</td>
<td>Message</td>
<td>the Fault message (if any)</td>
</tr>
<tr>
<td>request</td>
<td>Message</td>
<td>the exchange.in message</td>
</tr>
</tbody>
</table>
231.3. SAMPLES

For example you could use OGNL inside a Message Filter in XML

```xml
<route>
  <from uri="seda:foo"/>
  <filter>
    <ognl>request.headers.foo == 'bar'</ognl>
    <to uri="seda:bar"/>
  </filter>
</route>
```

And the sample using Java DSL:

```java
from("seda:foo").filter().ognl("request.headers.foo == 'bar'").to("seda:bar");
```

231.4. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as "classpath:" , "file:" or "http:".

This is done using the following syntax: "resource:scheme:location", eg to refer to a file on the classpath you can do:

```java
.setHeader("myHeader").ognl("resource:classpath:myognl.txt")
```

231.5. DEPENDENCIES

To use OGNL in your camel routes you need to add the a dependency on camel-ognl which implements the OGNL language.
If you use Maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ognl</artifactId>
  <version>x.x.x</version>
</dependency>
```

Otherwise, you’ll also need OGNL.
CHAPTER 232. OLINGO2 COMPONENT

Available as of Camel version 2.14

The Olingo2 component utilizes Apache Olingo version 2.0 APIs to interact with OData 2.0 compliant services. A number of popular commercial and enterprise vendors and products support the OData protocol. A sample list of supporting products can be found on the OData website.

The Olingo2 component supports reading feeds, delta feeds, entities, simple and complex properties, links, counts, using custom and OData system query parameters. It supports updating entities, properties, and association links. It also supports submitting queries and change requests as a single OData batch operation.

The component supports configuring HTTP connection parameters and headers for OData service connection. This allows configuring use of SSL, OAuth2.0, etc. as required by the target OData service.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-olingo2</artifactId>
  <version>${camel-version}</version>
</dependency>
```

232.1. URI FORMAT

```
olingo2://endpoint/<resource-path>?[options]
```

232.2. OLINGO2 OPTIONS

The Olingo2 component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>To use the shared configuration</td>
<td></td>
<td>Olingo2Configurations</td>
</tr>
<tr>
<td>(common)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>useGlobalSslContext Parameters</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>(security)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Olingo2 endpoint is configured using URI syntax:

```
olingo2:apiName/methodName
```
with the following path and query parameters:

### 232.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiName</td>
<td>Required What kind of operation to perform</td>
<td></td>
<td>Olingo2ApiName</td>
</tr>
<tr>
<td>methodName</td>
<td>Required What sub operation to use for the selected operation</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 232.2.2. Query Parameters (14 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectTimeout</td>
<td>HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds)</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td>contentType</td>
<td>Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpAsyncClientBuilder</td>
<td>Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely</td>
<td></td>
<td>HttpAsyncClientBuilder</td>
</tr>
<tr>
<td>httpClientBuilder</td>
<td>Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely</td>
<td></td>
<td>HttpClientBuilder</td>
</tr>
<tr>
<td>httpHeaders</td>
<td>Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>inBody</td>
<td>Sets the name of a parameter to be passed in the exchange In Body</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>proxy</td>
<td>HTTP proxy server configuration</td>
<td></td>
<td>HttpHost</td>
</tr>
<tr>
<td>serviceUri</td>
<td>Target OData service base URI, e.g. <a href="http://services.odata.org/OData/OData.svc">http://services.odata.org/OData/OData.svc</a></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------------</td>
</tr>
<tr>
<td>socketTimeout (common)</td>
<td>HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds)</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td>sslContextParameters (common)</td>
<td>To configure security using SSLContextParameters</td>
<td>SSLContextParameters</td>
<td></td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 232.3. PRODUCER ENDPOINTS

Producer endpoints can use endpoint names and options listed next. Producer endpoints can also use a special option inBody that in turn should contain the name of the endpoint option whose value will be contained in the Camel Exchange In message. The inBody option defaults to data for endpoints that take that option.

### 232.4. ENDPOINT OPTIONS

Any of the endpoint options can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format CamelOlingo2.<option>. Note that the inBody option overrides message header, i.e. the endpoint option inBody=option would override a CamelOlingo2.option header. In addition, query parameters can be specified.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Object</td>
<td>Data with appropriate type used to create or modify the OData resource</td>
</tr>
</tbody>
</table>
**keyPredicate**

String

Key predicate to create a parameterized OData resource endpoint. Useful for create/update operations where the key predicate value is dynamically provided in a header.

**queryParameters**

java.util.Map<String, String>

OData system options and custom query options. For more information see OData 2.0 URI Conventions.

**resourcePath**

String

OData resource path, may or may not contain key predicate.

**endpointHttpHeaders**

java.util.Map<String, String>

Dynamic HTTP Headers to be sent to the endpoint.

**responseHttpHeaders**

java.util.Map<String, String>

Dynamic HTTP Response Headers from the endpoint.

Note that the resourcePath option can either in specified in the URI as a part of the URI path, as an endpoint option ?resourcePath=<resource-path> or as a header value CamelOlingo2.resourcePath. The OData entity key predicate can either be a part of the resource path, e.g. Manufacturers('1'), where '1' is the key predicate, or be specified separately with resource path Manufacturers and keyPredicate option '1'.

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Options</th>
<th>HTTP Method</th>
<th>Result Body Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>batch</td>
<td>data, endpointHttpHeaders</td>
<td>POST with multipart/mixed batch request</td>
<td>java.util.List&lt;org.apache.camel.component.oolingo2.api.batch.Olingo2BatchResponse&gt;</td>
</tr>
<tr>
<td>create</td>
<td>data, resourcePath, endpointHttpHeaders</td>
<td>POST</td>
<td>org.apache.oolingo.odata2.api.ep.entry.ODataEntry for new entries org.apache.oolingo.odata2.api.commons.HttpStatusCodes for other OData resources</td>
</tr>
<tr>
<td>Endpoint</td>
<td>Options</td>
<td>HTTP Method</td>
<td>Result Body Type</td>
</tr>
<tr>
<td>----------</td>
<td>---------</td>
<td>-------------</td>
<td>------------------</td>
</tr>
<tr>
<td>delete</td>
<td>resourcePath, endpointHttpHeaders</td>
<td>DELETE</td>
<td>org.apache.olio.odata2.api.commons.HttpStatusCodes</td>
</tr>
<tr>
<td>merge</td>
<td>data, resourcePath, endpointHttpHeaders</td>
<td>MERGE</td>
<td>org.apache.olio.odata2.api.commons.HttpStatusCodes</td>
</tr>
<tr>
<td>patch</td>
<td>data, resourcePath, endpointHttpHeaders</td>
<td>PATCH</td>
<td>org.apache.olio.odata2.api.commons.HttpStatusCodes</td>
</tr>
<tr>
<td>read</td>
<td>queryParams, resourcePath, endpointHttpHeaders</td>
<td>GET</td>
<td>Depends on OData resource being queried as described next</td>
</tr>
<tr>
<td>update</td>
<td>data, resourcePath, endpointHttpHeaders</td>
<td>PUT</td>
<td>org.apache.olio.odata2.api.commons(HttpStatusCodes)</td>
</tr>
</tbody>
</table>

### 232.5. ENDPOINT HTTP HEADERS (SINCE 2.20)

The component level configuration property `httpHeaders` supplies static HTTP header information. However, some systems require dynamic header information to be passed to and received from the endpoint. A sample use case would be systems that require dynamic security tokens. The `endpointHttpHeaders` and `responseHttpHeaders` endpoint properties provide this capability. Set
headers that need to be passed to the endpoint in the `CamelOlingo2.endpointHttpHeaders` property and the response headers will be returned in a `CamelOlingo2.responseHttpHeaders` property. Both properties are of the type `java.util.Map<String, String>`.

## 232.6. ODATA RESOURCE TYPE MAPPING

The result of `read` endpoint and data type of `data` option depends on the OData resource being queried, created or modified.

<table>
<thead>
<tr>
<th>OData Resource Type</th>
<th>Resource URI from resourcePath and keyPredicate</th>
<th>In or Out Body Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Entity data model</td>
<td>$metadata</td>
<td>org.apache.olingo.odata2.api.edm.Edm</td>
</tr>
<tr>
<td>OData feed</td>
<td>&lt;entity-set&gt;(&lt;key-predicate&gt;)</td>
<td>org.apache.olingo.odata2.api.ep.feed.ODataFeed</td>
</tr>
<tr>
<td>OData entry</td>
<td>&lt;entity-set&gt;(&lt;key-predicate&gt;)</td>
<td>org.apache.olingo.odata2.api.ep.entry.ODataEntry for Out body (response) java.util.Map&lt;String, Object&gt; for In body (request)</td>
</tr>
<tr>
<td>Simple property</td>
<td>&lt;entity-set&gt;(&lt;key-predicate&gt;)/&lt;simple-property&gt;</td>
<td>Appropriate Java data type as described by Olingo EdmProperty</td>
</tr>
<tr>
<td>OData Resource Type</td>
<td>Resouce URI from resourcePath and keyPredicate</td>
<td>In or Out Body Type</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Simple property value</td>
<td><code>&lt;entity-set&gt;(&lt;key-predicate&gt;)/&lt;simple-property&gt;$value</code></td>
<td>Appropriate Java data type as described by Olingo EdmProperty</td>
</tr>
<tr>
<td>Complex property</td>
<td><code>&lt;entity-set&gt;(&lt;key-predicate&gt;)/&lt;complex-property&gt;</code></td>
<td><code>java.util.Map&lt;String, Object&gt;</code></td>
</tr>
<tr>
<td>Zero or one association link</td>
<td><code>&lt;entity-set&gt;(&lt;key-predicate&gt;)/$link/&lt;one-to-one-entity-set-property&gt;</code></td>
<td>String for response <code>java.util.Map&lt;String, Object&gt;</code> with key property names and values for request</td>
</tr>
</tbody>
</table>
232.7. CONSUMER ENDPOINTS

Only the **read** endpoint can be used as a consumer endpoint. Consumer endpoints can use **Scheduled Poll Consumer Options** with a **consumer**. prefix to schedule endpoint invocation. By default consumer endpoints that return an array or collection will generate one exchange per element, and their routes will be executed once for each exchange. This behavior can be disabled by setting the endpoint property `consumer.splitResult=false`.

232.8. MESSAGE HEADERS

Any URI option can be provided in a message header for producer endpoints with a **CamelOlingo2**. prefix.

232.9. MESSAGE BODY

All result message bodies utilize objects provided by the underlying **Apache Olingo 2.0 API** used by the Olingo2Component. Producer endpoints can specify the option name for incoming message body in the **inBody** endpoint URI parameter. For endpoints that return an array or collection, a consumer endpoint will map every element to distinct messages, unless `consumer.splitResult` is set to **false**.

232.10. USE CASES

The following route reads top 5 entries from the Manufacturer feed ordered by ascending Name property.
The following route reads Manufacturer entry using the key property value in incoming ID header.

```
from("direct:...")
  .setHeader("CamelOlingo2.$top", "5")
  .to("olingo2://read/Manufacturers?orderBy=Name%20asc");
```

The following route creates Manufacturer entry using the java.util.Map<String, Object> in body message.

```
from("direct:...")
  .setHeader("CamelOlingo2.keyPredicate", header("id"))
  .to("olingo2://read/Manufacturers");
```

The following route polls Manufacturer delta feed every 30 seconds. The bean blah updates the bean paramsBean to add an updated !deltatoken property with the value returned in the ODataDeltaFeed result. Since the initial delta token is not known, the consumer endpoint will produce an ODataFeed value the first time, and ODataDeltaFeed on subsequent polls.

```
from("olingo2://read/Manufacturers?
  queryParams=#paramsBean&consumer.timeUnit=SECONDS&consumer.delay=30")
  .to("bean:blah");
```
The Olingo4 component utilizes Apache Olingo version 4.0 APIs to interact with OData 4.0 compliant service. Since version 4.0 OData is OASIS standard and number of popular open source and commercial vendors and products support this protocol. A sample list of supporting products can be found on the OData website.

The Olingo4 component supports reading entity sets, entities, simple and complex properties, counts, using custom and OData system query parameters. It supports updating entities and properties. It also supports submitting queries and change requests as a single OData batch operation.

The component supports configuring HTTP connection parameters and headers for OData service connection. This allows configuring use of SSL, OAuth2.0, etc. as required by the target OData service.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-olingo4</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 233.1. URI FORMAT

olingo4://endpoint/<resource-path>?[options]

### 233.2. OLINGO4 OPTIONS

The Olingo4 component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>To use the shared configuration</td>
<td></td>
<td>Olingo4Configuration</td>
</tr>
<tr>
<td>(common)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>useGlobalSslContextParameters</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>(security)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Olingo4 endpoint is configured using URI syntax:

```
olingo4:apiName/methodName
```
with the following path and query parameters:

### 233.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiName</td>
<td><strong>Required</strong> What kind of operation to perform</td>
<td></td>
<td>Olingo4ApiName</td>
</tr>
<tr>
<td>methodName</td>
<td><strong>Required</strong> What sub operation to use for the selected operation</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 233.2.2. Query Parameters (14 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectTimeout</td>
<td>HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds)</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td>contentType</td>
<td>Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpAsyncClientBuilder</td>
<td>Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely</td>
<td></td>
<td>HttpAsyncClientBuilder</td>
</tr>
<tr>
<td>httpClientBuilder</td>
<td>Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely</td>
<td></td>
<td>HttpClientBuilder</td>
</tr>
<tr>
<td>httpHeaders</td>
<td>Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>inBody</td>
<td>Sets the name of a parameter to be passed in the exchange In Body</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>proxy</td>
<td>HTTP proxy server configuration</td>
<td></td>
<td>HttpHost</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
--- | --- | --- | ---
**serviceUri** *(common)* | Target OData service base URI, e.g. http://services.odata.org/OData/OData.svc | | String
**socketTimeout** *(common)* | HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds) | 30000 | int
**sslContextParameters** *(common)* | To configure security using SSLContextParameters | | SSLContextParameters
**bridgeErrorHandler** *(consumer)* | Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored. | false | boolean
**exceptionHandler** *(consumer)* | To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored. | | ExceptionHandler
**exchangePattern** *(consumer)* | Sets the exchange pattern when the consumer creates an exchange. | | ExchangePattern
**synchronous** *(advanced)* | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

## 233.3. PRODUCER ENDPOINTS

Producer endpoints can use endpoint names and options listed next. Producer endpoints can also use a special option **inBody** that in turn should contain the name of the endpoint option whose value will be contained in the Camel Exchange In message. The **inBody** option defaults to **data** for endpoints that take that option.

Any of the endpoint options can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelOlingo4.<option>**. Note that the **inBody** option overrides message header, i.e. the endpoint option inBody=option would override a CamelOlingo4.option header. In addition, query parameters can be specified

Note that the resourcePath option can either in specified in the URI as a part of the URI path, as an endpoint option ?resourcePath=<resource-path> or as a header value CamelOlingo4.resourcePath. The OData entity key predicate can either be a part of the resource path, e.g. **Manufacturers('1')**, where `'1'` is the key predicate, or be specified separately with resource path **Manufacturers** and keyPredicate option `'1'`. 
<table>
<thead>
<tr>
<th>Endpoint Options</th>
<th>HTTP Method</th>
<th>Result Body Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>batch</td>
<td>POST with multipart/mixed batch request</td>
<td>java.util.List&lt;org.apache.camel.component.olingo4.api.batch.Olingo4BatchResponse&gt;</td>
</tr>
<tr>
<td>read</td>
<td>GET</td>
<td>Depends on OData resource being queried as described next</td>
</tr>
</tbody>
</table>
The component level configuration property `httpHeaders` supplies static HTTP header information. However, some systems require dynamic header information to be passed to and received from the endpoint. A sample use case would be systems that require dynamic security tokens. The `endpointHttpHeaders` and `responseHttpHeaders` endpoint properties provide this capability. Set headers that need to be passed to the endpoint in the `CamelOlingo4.endpointHttpHeaders` property and the response headers will be returned in a `CamelOlingo4.responseHttpHeaders` property. Both properties are of the type `java.util.Map<String, String>`.

**233.5. ODATA RESOURCE TYPE MAPPING**

The result of `read` endpoint and data type of `data` option depends on the OData resource being queried, created or modified.

<table>
<thead>
<tr>
<th>OData Resource Type</th>
<th>Resource URI from resourcePath and keyPredicate</th>
<th>In or Out Body Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Entity data model</td>
<td><code>$metadata</code></td>
<td>org.apache.olingocommons.api.edm.Edm</td>

<tr>
<td>OData entity</td>
<td>&lt;entity-set&gt;(&lt;key-predicate&gt;)</td>
<td>org.apache.olingo.client.api.domain.ClientEntity for Out body (response) java.util.Map&lt;String, Object&gt; for In body (request)</td>
</tr>
<tr>
<td>Simple property</td>
<td>&lt;entity-set&gt;(&lt;key-predicate&gt;/&lt;simple-property&gt;)</td>
<td>org.apache.olingo.client.api.domain.ClientPrimitiveValue</td>
</tr>
<tr>
<td>Simple property value</td>
<td>&lt;entity-set&gt;(&lt;key-predicate&gt;/&lt;simple-property&gt;/$value)</td>
<td>org.apache.olingo.client.api.domain.ClientPrimitiveValue</td>
</tr>
<tr>
<td>Complex property</td>
<td>&lt;entity-set&gt;(&lt;key-predicate&gt;/&lt;complex-property&gt;)</td>
<td>org.apache.olingo.client.api.domain.ClientComplexValue</td>
</tr>
<tr>
<td>Count</td>
<td>&lt;resource-uri&gt;$count</td>
<td>java.lang.Long</td>
</tr>
</tbody>
</table>

### 233.6. CONSUMER ENDPOINTS
Only the read endpoint can be used as a consumer endpoint. Consumer endpoints can use Scheduled Poll Consumer Options with a consumer. prefix to schedule endpoint invocation. By default consumer endpoints that return an array or collection will generate one exchange per element, and their routes will be executed once for each exchange. This behavior can be disabled by setting the endpoint property consumer.splitResult=false.

233.7. MESSAGE HEADERS

Any URI option can be provided in a message header for producer endpoints with a CamelOlingo4. prefix.

233.8. MESSAGE BODY

All result message bodies utilize objects provided by the underlying Apache Olingo 4.0 API used by the Olingo4Component. Producer endpoints can specify the option name for incoming message body in the inBody endpoint URI parameter. For endpoints that return an array or collection, a consumer endpoint will map every element to distinct messages, unless consumer.splitResult is set to false.

233.9. USE CASES

The following route reads top 5 entries from the People entity ordered by ascending FirstName property.

```java
from("direct:...")
    .setHeader("CamelOlingo4.$top", "5")
    .to("olingo4://read/People?orderBy=FirstName%20asc");
```

The following route reads Airports entity using the key property value in incoming id header.

```java
from("direct:...")
    .setHeader("CamelOlingo4.keyPredicate", header("id"))
    .to("olingo4://read/Airports");
```

The following route creates People entity using the ClientEntity in body message.

```java
from("direct:....")
    .to("olingo4://create/People");
```
CHAPTER 234. OPENSHEET COMPONENT (DEPRECATED)

Available as of Camel version 2.14

The openshift component is a component for managing your OpenShift applications.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openshift</artifactId>
  <version>x.x.x</version>
<!-- use the same version as your Camel core version -->
</dependency>
```

234.1. URI FORMAT

`openshift:clientId[?options]`

You can append query options to the URI in the following format, `?option=value&option=value&…`

234.2. OPTIONS

The OpenShift component supports 5 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>username (security)</td>
<td>The username to login to openshift server.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>password (security)</td>
<td>The password for login to openshift server.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>domain (common)</td>
<td>Domain name. If not specified then the default domain is used.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>server (common)</td>
<td>Url to the openshift server. If not specified then the default value from the local openshift configuration file /.openshift/express.conf is used. And if that fails as well then openshift.redhat.com is used.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The OpenShift endpoint is configured using URI syntax:

`openshift:clientId`
with the following path and query parameters:

### 234.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>clientId</td>
<td>Required The client id</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 234.2.2. Query Parameters (26 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>domain</td>
<td>Domain name. If not specified then the default domain is used.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>password</td>
<td>Required The password for login to openshift server.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>server</td>
<td>Url to the openshift server. If not specified then the default value from the local openshift configuration file /.openshift/express.conf is used. And if that fails as well then openshift.redhat.com is used.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>username</td>
<td>Required The username to login to openshift server.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------</td>
<td>--------------</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>pollStrategy</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td>application</td>
<td>The application name to start, stop, restart, or get the state.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>mode</td>
<td>Whether to output the message body as a pojo or json. For pojo the message is a List type.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>operation</td>
<td>The operation to perform which can be: list, start, stop, restart, and state. The list operation returns information about all the applications in json format. The state operation returns the state such as: started, stopped etc. The other operations does not return any value.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffIdleThreshold</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffMultiplier</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>delay</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td>greedy (scheduler)</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay (scheduler)</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel (scheduler)</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>scheduledExecutorService (scheduler)</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td>ScheduledExecutorService</td>
<td></td>
</tr>
<tr>
<td>scheduler (scheduler)</td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollConsumer</td>
</tr>
<tr>
<td>schedulerProperties (scheduler)</td>
<td>To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.</td>
<td>Map</td>
<td></td>
</tr>
<tr>
<td>startScheduler (scheduler)</td>
<td>Whether the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>timeUnit (scheduler)</td>
<td>Time unit for initialDelay and delay options.</td>
<td>MILLIESCONDS TimeUnit</td>
<td></td>
</tr>
<tr>
<td>useFixedDelay (scheduler)</td>
<td>Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 234.3. EXAMPLES

#### 234.3.1. Listing all applications

```java
// sending route
from("direct:apps")
  .to("openshift:myClient?username=foo&password=secret&operation=list");
  .to("log:apps");
```

In this case the information about all the applications is returned as pojo. If you want a json response, then set mode=json.
234.3.2. Stopping an application

```java
// stopping the foobar application
from("direct:control")
  .to("openshift:myClient?username=foo&password=secret&operation=stop&application=foobar");
```

In the example above we stop the application named foobar.

Polling for gear state changes

The consumer is used for polling state changes in gears. Such as when a new gear is added/removed/ or
its lifecycle is changed, eg started, or stopped etc.

```java
// trigger when state changes on our gears
from("openshift:myClient?username=foo&password=secret&delay=30s")
  .log("Event ${header.CamelOpenShiftEventType} on application ${body.name} changed state to
       ${header.CamelOpenShiftEventNewState}");
```

When the consumer emits an Exchange then the body contains the `com.openshift.client.IApplication`
as the message body. And the following headers is included.

<table>
<thead>
<tr>
<th>Header</th>
<th>May be null</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelOpenShiftEventType</td>
<td>No</td>
<td>The type of the event which can be one of: added, removed or changed.</td>
</tr>
<tr>
<td>CamelOpenShiftEventOldState</td>
<td>Yes</td>
<td>The old state, when the event type is changed.</td>
</tr>
<tr>
<td>CamelOpenShiftEventNewState</td>
<td>No</td>
<td>The new state, for any of the event types</td>
</tr>
</tbody>
</table>

234.4. SEE ALSO

- Configuring Camel
- Component
- Endpoint
• Getting Started
CHAPTER 235. OPENShift BUILD CONFIG COMPONENT

Available as of Camel version 2.17

The OpenShift Build Config component is one of Kubernetes Components which provides a producer to execute kubernetes build config operations.

235.1. COMPONENT OPTIONS

The OpenShift Build Config component has no options.

235.2. ENDPOINT OPTIONS

The OpenShift Build Config endpoint is configured using URI syntax:

```
openshift-build-configs:masterUrl
```

with the following path and query parameters:

235.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterUrl</td>
<td>Required Kubernetes Master url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

235.2.2. Query Parameters (19 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion (producer)</td>
<td>The Kubernetes API Version to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>dnsDomain (producer)</td>
<td>The dns domain, used for ServiceCall EIP</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>kubernetesClient (producer)</td>
<td>Default KubernetesClient to use if provided</td>
<td></td>
<td>KubernetesClient</td>
</tr>
<tr>
<td>operation (producer)</td>
<td>Producer operation to do on Kubernetes</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>portName (producer)</td>
<td>The port name, used for ServiceCall EIP</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>connectionTimeout (advanced)</td>
<td>Connection timeout in milliseconds to use when making requests to the Kubernetes API server.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td><code>synchronous</code></td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>caCertData</code></td>
<td>The CA Cert Data</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>caCertFile</code></td>
<td>The CA Cert File</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>clientCertData</code></td>
<td>The Client Cert Data</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>clientCertFile</code></td>
<td>The Client Cert File</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>clientKeyAlgo</code></td>
<td>The Key Algorithm used by the client</td>
<td></td>

<td>Password to connect to Kubernetes</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>trustCerts</code></td>
<td>Define if the certs we used are trusted anyway or not</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><code>username</code></td>
<td>Username to connect to Kubernetes</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
CHAPTER 236. OPENSHEET BUILDS COMPONENT

Available as of Camel version 2.17

The Kubernetes Builds component is one of Kubernetes Components which provides a producer to execute kubernetes build operations.

236.1. COMPONENT OPTIONS

The Openshift Builds component has no options.

236.2. ENDPOINT OPTIONS

The Openshift Builds endpoint is configured using URI syntax:

```
openshift-builds:masterUrl
```

with the following path and query parameters:

236.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterUrl</td>
<td>Required Kubernetes Master url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

236.2.2. Query Parameters (19 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>

<td>Define if the certs we used are trusted anyway or not</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>username</td>
<td>Username to connect to Kubernetes</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

236.3. OPENSTACK COMPONENT

Available as of Camel 2.19

The **openstack** component is a component for managing your OpenStack applications.
Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

<table>
<thead>
<tr>
<th>OpenStack service</th>
<th>Camel Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OpenStack Cinder</td>
<td>openstack-cinder</td>
<td>Component to maintain OpenStack cinder.</td>
</tr>
<tr>
<td>OpenStack Glance</td>
<td>openstack-glance</td>
<td>Component to maintain OpenStack glance.</td>
</tr>
<tr>
<td>OpenStack Keystone</td>
<td>openstack-keystone</td>
<td>Component to maintain OpenStack keystone.</td>
</tr>
<tr>
<td>OpenStack Neutron</td>
<td>openstack-neutron</td>
<td>Component to maintain OpenStack neutron.</td>
</tr>
<tr>
<td>OpenStack Nova</td>
<td>openstack-nova</td>
<td>Component to maintain OpenStack nova.</td>
</tr>
<tr>
<td>OpenStack Swift</td>
<td>openstack-swift</td>
<td>Component to maintain OpenStack swift.</td>
</tr>
</tbody>
</table>
CHAPTER 237. OPENSTACK CINDER COMPONENT

Available as of Camel version 2.19

The openstack-cinder component allows messages to be sent to an OpenStack block storage services.

237.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

```
pom.xml

<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-openstack</artifactId>
    <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

237.2. URI FORMAT

```
openstack-cinder://hosturl[?options]
```

You can append query options to the URI in the following format `?options=value&option2=value&...`

237.3. URI OPTIONS

The OpenStack Cinder component has no options.

The OpenStack Cinder endpoint is configured using URI syntax:

```
openstack-cinder:host
```

with the following path and query parameters:

237.3.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required OpenStack host url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

237.3.2. Query Parameters (9 parameters):
### Name | Description |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code> (Producer)</td>
<td>OpenStack API version</td>
</tr>
<tr>
<td><code>config</code> (Producer)</td>
<td>OpenStack configuration</td>
</tr>
<tr>
<td><code>domain</code> (Producer)</td>
<td>Authentication domain</td>
</tr>
<tr>
<td><code>operation</code> (Producer)</td>
<td>The operation to do</td>
</tr>
<tr>
<td><code>password</code> (Producer)</td>
<td>Required OpenStack password</td>
</tr>
<tr>
<td><code>project</code> (Producer)</td>
<td>Required The project ID</td>
</tr>
<tr>
<td><code>subsystem</code> (Producer)</td>
<td>Required OpenStack Cinder subsystem</td>
</tr>
<tr>
<td><code>username</code> (Producer)</td>
<td>Required OpenStack username</td>
</tr>
<tr>
<td><code>synchronous</code> (Advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code></td>
<td>V3</td>
<td>String</td>
</tr>
<tr>
<td><code>config</code></td>
<td></td>
<td>Config</td>
</tr>
<tr>
<td><code>domain</code></td>
<td>default</td>
<td>String</td>
</tr>
<tr>
<td><code>operation</code></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>password</code></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>project</code></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>subsystem</code></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>username</code></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>synchronous</code></td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

#### 237.4. USAGE

You can use following settings for each subsystem:

#### 237.5. VOLUMES

##### 237.5.1. Operations you can perform with the Volume producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>create</code></td>
<td>Create new volume.</td>
</tr>
<tr>
<td><code>get</code></td>
<td>Get the volume.</td>
</tr>
<tr>
<td><code>getAll</code></td>
<td>Get all volumes.</td>
</tr>
<tr>
<td><code>getAllTypes</code></td>
<td>Get volume types.</td>
</tr>
</tbody>
</table>
### Operation

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>update</strong></td>
<td>Update the volume.</td>
</tr>
<tr>
<td><strong>delete</strong></td>
<td>Delete the volume.</td>
</tr>
</tbody>
</table>

---

#### 237.5.2. Message headers evaluated by the Volume producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>operation</strong></td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td><strong>ID</strong></td>
<td>String</td>
<td>ID of the volume.</td>
</tr>
<tr>
<td><strong>name</strong></td>
<td>String</td>
<td>The volume name.</td>
</tr>
<tr>
<td><strong>description</strong></td>
<td>String</td>
<td>Volume description.</td>
</tr>
<tr>
<td><strong>size</strong></td>
<td>Integer</td>
<td>Size of volume.</td>
</tr>
<tr>
<td><strong>volumeType</strong></td>
<td>String</td>
<td>Volume type.</td>
</tr>
<tr>
<td><strong>imageRef</strong></td>
<td>String</td>
<td>ID of image.</td>
</tr>
<tr>
<td><strong>snapshotId</strong></td>
<td>String</td>
<td>ID of snapshot.</td>
</tr>
<tr>
<td><strong>isBootable</strong></td>
<td>Boolean</td>
<td>Is bootable.</td>
</tr>
</tbody>
</table>

If you need more precise volume settings you can create new object of the type `org.openstack4j.model.storage.block.Volume` and send in the message body.

---

#### 237.6. SNAPSHOTS

### 237.6.1. Operations you can perform with the Snapshot producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>create</strong></td>
<td>Create new snapshot.</td>
</tr>
</tbody>
</table>
### Operation Description

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get</td>
<td>Get the snapshot.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all snapshots.</td>
</tr>
<tr>
<td>update</td>
<td>Get update the snapshot.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the snapshot.</td>
</tr>
</tbody>
</table>

#### 237.6.2. Message headers evaluated by the Snapshot producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the server.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The server name.</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>The snapshot description.</td>
</tr>
<tr>
<td>VolumeId</td>
<td>String</td>
<td>The Volume ID.</td>
</tr>
<tr>
<td>force</td>
<td>Boolean</td>
<td>Force.</td>
</tr>
</tbody>
</table>

If you need more precise server settings you can create new object of the type `org.openstack4j.model.storage.block.VolumeSnapshot` and send in the message body.

#### 237.7. SEE ALSO

- Configuring Camel
- Component
- Endpoint

- openstack Component
CHAPTER 238. OPENSTACK GLANCE COMPONENT

Available as of Camel version 2.19

The openstack-glance component allows messages to be sent to an OpenStack image services.

238.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

238.2. URI FORMAT

```
openstack-glance://hosturl[?options]
```

You can append query options to the URI in the following format `?options=value&option2=value&...`

238.3. URI OPTIONS

The OpenStack Glance component has no options.

The OpenStack Glance endpoint is configured using URI syntax:

```
openstack-glance:host
```

with the following path and query parameters:

238.3.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required OpenStack host url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

238.3.2. Query Parameters (8 parameters):
<table>
<thead>
<tr>
<th>Name (producer)</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>OpenStack API version</td>
<td>V3</td>
<td>String</td>
</tr>
<tr>
<td>config</td>
<td>OpenStack configuration</td>
<td></td>
<td>Config</td>
</tr>
<tr>
<td>domain</td>
<td>Authentication domain</td>
<td>default</td>
<td>String</td>
</tr>
<tr>
<td>operation</td>
<td>The operation to do</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>password</td>
<td>Required OpenStack password</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>project</td>
<td>Required The project ID</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>username</td>
<td>Required OpenStack username</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 238.4. USAGE

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reserve</td>
<td>Reserve image.</td>
</tr>
<tr>
<td>create</td>
<td>Create new image.</td>
</tr>
<tr>
<td>update</td>
<td>Update image.</td>
</tr>
<tr>
<td>upload</td>
<td>Upload image.</td>
</tr>
<tr>
<td>get</td>
<td>Get the image.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all image.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the image.</td>
</tr>
</tbody>
</table>

#### 238.4.1. Message headers evaluated by the Glance producer
<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the flavor.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The flavor name.</td>
</tr>
<tr>
<td>diskFormat</td>
<td>org.openstack4j.model.image.DiskFormat</td>
<td>The number of flavor VCPU.</td>
</tr>
<tr>
<td>containerFormat</td>
<td>org.openstack4j.model.image.ContainerFormat</td>
<td>Size of RAM.</td>
</tr>
<tr>
<td>owner</td>
<td>String</td>
<td>Image owner.</td>
</tr>
<tr>
<td>isPublic</td>
<td>Boolean</td>
<td>Is public.</td>
</tr>
<tr>
<td>minRam</td>
<td>Long</td>
<td>Minimum ram.</td>
</tr>
<tr>
<td>minDisk</td>
<td>Long</td>
<td>Minimum disk.</td>
</tr>
<tr>
<td>size</td>
<td>Long</td>
<td>Size.</td>
</tr>
<tr>
<td>checksum</td>
<td>String</td>
<td>Checksum.</td>
</tr>
<tr>
<td>properties</td>
<td>Map</td>
<td>Image properties.</td>
</tr>
</tbody>
</table>

238.5. SEE ALSO

- Configuring Camel
- Component
• Endpoint
• Getting Started
• openstack Component
The openstack-keystone component allows messages to be sent to an OpenStack identity services.

The openstack-keystone component supports only Identity API v3!

239.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where ${camel-version} must be replaced by the actual version of Camel.

239.2. URI FORMAT

`openstack-keystone://hosturl[?options]`

You can append query options to the URI in the following format `?options=value&option2=value&…`

239.3. URI OPTIONS

The OpenStack Keystone component has no options.

The OpenStack Keystone endpoint is configured using URI syntax:

`openstack-keystone:host`

with the following path and query parameters:

239.3.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required OpenStack host url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

239.3.2. Query Parameters (8 parameters):
### Name | Description | Default | Type
---|---|---|---
`config` (producer) | OpenStack configuration | | Config
`domain` (producer) | Authentication domain | default | String
`operation` (producer) | The operation to do | | String
`password` (producer) | Required OpenStack password | | String
`project` (producer) | Required The project ID | | String
`subsystem` (producer) | Required OpenStack Keystone subsystem | | String
`username` (producer) | Required OpenStack username | | String
`synchronous` (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

### 239.4. USAGE
You can use following settings for each subsystem:

### 239.5. DOMAINS

#### 239.5.1. Operations you can perform with the Domain producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>create</code></td>
<td>Create new domain.</td>
</tr>
<tr>
<td><code>get</code></td>
<td>Get the domain.</td>
</tr>
<tr>
<td><code>getAll</code></td>
<td>Get all domains.</td>
</tr>
<tr>
<td><code>update</code></td>
<td>Update the domain.</td>
</tr>
<tr>
<td><code>delete</code></td>
<td>Delete the domain.</td>
</tr>
</tbody>
</table>
239.5.2. Message headers evaluated by the Domain producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the domain.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The domain name.</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Domain description.</td>
</tr>
</tbody>
</table>

If you need more precise domain settings you can create new object of the type `org.openstack4j.model.identity.v3.Domain` and send in the message body.

239.6. GROUPS

239.6.1. Operations you can perform with the Group producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new group.</td>
</tr>
<tr>
<td>get</td>
<td>Get the group.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all groups.</td>
</tr>
<tr>
<td>update</td>
<td>Update the group.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the group.</td>
</tr>
<tr>
<td>addUserToGroup</td>
<td>Add the user to the group.</td>
</tr>
<tr>
<td>checkUserGroup</td>
<td>Check whether is the user in the group.</td>
</tr>
<tr>
<td>removeUserFromGroup</td>
<td>Remove the user from the group.</td>
</tr>
</tbody>
</table>

239.6.2. Message headers evaluated by the Group producer
If you need more precise group settings you can create a new object of the type `org.openstack4j.model.identity.v3.Group` and send it in the message body.

### 239.7. PROJECTS

#### 239.7.1. Operations you can perform with the Project producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new project.</td>
</tr>
<tr>
<td>get</td>
<td>Get the project.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all projects.</td>
</tr>
<tr>
<td>update</td>
<td>Update the project.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the project.</td>
</tr>
</tbody>
</table>

#### 239.7.2. Message headers evaluated by the Project producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>Header</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>--------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the project.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The project name.</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Project description.</td>
</tr>
<tr>
<td>domainId</td>
<td>String</td>
<td>ID of the domain.</td>
</tr>
<tr>
<td>parentId</td>
<td>String</td>
<td>The parent project ID.</td>
</tr>
</tbody>
</table>

If you need more precise project settings you can create new object of the type `org.openstack4j.model.identity.v3.Project` and send in the message body.

### 239.8. REGIONS

#### 239.8.1. Operations you can perform with the Region producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new region.</td>
</tr>
<tr>
<td>get</td>
<td>Get the region.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all regions.</td>
</tr>
<tr>
<td>update</td>
<td>Update the region.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the region.</td>
</tr>
</tbody>
</table>

#### 239.8.2. Message headers evaluated by the Region producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the region.</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Region description.</td>
</tr>
</tbody>
</table>
If you need more precise region settings you can create new object of the type `org.openstack4j.model.identity.v3.Region` and send in the message body.

### 239.9. USERS

#### 239.9.1. Operations you can perform with the User producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new user.</td>
</tr>
<tr>
<td>get</td>
<td>Get the user.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all users.</td>
</tr>
<tr>
<td>update</td>
<td>Update the user.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the user.</td>
</tr>
</tbody>
</table>

#### 239.9.2. Message headers evaluated by the User producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the user.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The user name.</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>User description.</td>
</tr>
<tr>
<td>domainId</td>
<td>String</td>
<td>ID of the domain.</td>
</tr>
<tr>
<td>password</td>
<td>String</td>
<td>User’s password.</td>
</tr>
<tr>
<td>email</td>
<td>String</td>
<td>User’s email.</td>
</tr>
</tbody>
</table>

If you need more precise user settings you can create new object of the type `org.openstack4j.model.identity.v3.User` and send in the message body.

### 239.10. SEE ALSO

- Configuring Camel

• Endpoint
• Getting Started
• openstack Component
CHAPTER 240. OPENSTACK NEUTRON COMPONENT

Available as of Camel version 2.19

The openstack-neutron component allows messages to be sent to an OpenStack network services.

240.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

```
pom.xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

240.2. URI FORMAT

```
openstack-neutron://hosturl[?options]
```

You can append query options to the URI in the following format `?options=value&option2=value&...`

240.3. URI OPTIONS

The OpenStack Neutron component has no options.

The OpenStack Neutron endpoint is configured using URI syntax:

```
openstack-neutron:host
```

with the following path and query parameters:

240.3.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required OpenStack host url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

240.3.2. Query Parameters (9 parameters):
### Name | Description | Default | Type
---|---|---|---
apiVersion (producer) | OpenStack API version | V3 | String
config (producer) | OpenStack configuration | | Config
domain (producer) | Authentication domain | default | String
operation (producer) | The operation to do | | String
password (producer) | Required OpenStack password | | String
project (producer) | Required The project ID | | String
subsystem (producer) | Required OpenStack Neutron subsystem | | String
username (producer) | Required OpenStack username | | String
synchronous (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

### 240.4. USAGE

You can use following settings for each subsystem:

### 240.5. NETWORKS

#### 240.5.1. Operations you can perform with the Network producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new network.</td>
</tr>
<tr>
<td>get</td>
<td>Get the network.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all networks.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the network.</td>
</tr>
</tbody>
</table>
240.5.2. Message headers evaluated by the Network producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the network.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The network name.</td>
</tr>
<tr>
<td>tenantId</td>
<td>String</td>
<td>Tenant ID.</td>
</tr>
<tr>
<td>adminStateUp</td>
<td>Boolean</td>
<td>AdminStateUp header.</td>
</tr>
<tr>
<td>networkType</td>
<td>org.openstack4j.model.network.NetworkType</td>
<td>Network type.</td>
</tr>
<tr>
<td>physicalNetwork</td>
<td>String</td>
<td>Physical network.</td>
</tr>
<tr>
<td>segmentId</td>
<td>String</td>
<td>Segment ID.</td>
</tr>
<tr>
<td>isShared</td>
<td>Boolean</td>
<td>Is shared.</td>
</tr>
<tr>
<td>isRouterExternal</td>
<td>Boolean</td>
<td>Is router external.</td>
</tr>
</tbody>
</table>

If you need more precise network settings you can create new object of the type `org.openstack4j.model.network.Network` and send in the message body.

240.6. SUBNETS

240.6.1. Operations you can perform with the Subnet producer
### 240.6.2. Message headers evaluated by the Subnet producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the subnet.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>networkId</td>
<td>String</td>
<td>Network ID.</td>
</tr>
<tr>
<td>enableDHCp</td>
<td>Boolean</td>
<td>Enable DHCP.</td>
</tr>
<tr>
<td>gateway</td>
<td>String</td>
<td>Gateway.</td>
</tr>
</tbody>
</table>

If you need more precise subnet settings you can create new object of the type `org.openstack4j.model.network.Subnet` and send in the message body.

### 240.7. PORTS

#### 240.7.1. Operations you can perform with the Port producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new port.</td>
</tr>
<tr>
<td>get</td>
<td>Get the port.</td>
</tr>
</tbody>
</table>
### Operation

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getAll</td>
<td>Get all ports.</td>
</tr>
<tr>
<td>update</td>
<td>Update the port.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the port.</td>
</tr>
</tbody>
</table>

### Message headers evaluated by the Port producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The port name.</td>
</tr>
<tr>
<td>networkId</td>
<td>String</td>
<td>Network ID.</td>
</tr>
<tr>
<td>tenantId</td>
<td>String</td>
<td>Tenant ID.</td>
</tr>
<tr>
<td>deviceId</td>
<td>String</td>
<td>Device ID.</td>
</tr>
<tr>
<td>macAddress</td>
<td>String</td>
<td>MAC address.</td>
</tr>
</tbody>
</table>

### ROUTERS

### Operations you can perform with the Router producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new router.</td>
</tr>
<tr>
<td>get</td>
<td>Get the router.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all routers.</td>
</tr>
<tr>
<td>update</td>
<td>Update the router.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the router.</td>
</tr>
<tr>
<td>Operation</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>attachInterface</td>
<td>Attach an interface.</td>
</tr>
<tr>
<td>detachInterface</td>
<td>Detach an interface.</td>
</tr>
</tbody>
</table>

### 240.8.2. Message headers evaluated by the Port producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The router name.</td>
</tr>
<tr>
<td>routerId</td>
<td>String</td>
<td>Router ID.</td>
</tr>
<tr>
<td>subnetId</td>
<td>String</td>
<td>Subnet ID.</td>
</tr>
<tr>
<td>portId</td>
<td>String</td>
<td>Port ID.</td>
</tr>
<tr>
<td>interfaceType</td>
<td><code>org.openstack4j.model.network.AttachInterfaceType</code></td>
<td>Interface type.</td>
</tr>
<tr>
<td>tenantId</td>
<td>String</td>
<td>Tenant ID.</td>
</tr>
</tbody>
</table>

### 240.9. SEE ALSO

- Configuring Camel
- Component

- openstack Component
241. OPENSTACK NOVA COMPONENT

Available as of Camel version 2.19

The openstack-nova component allows messages to be sent to an OpenStack compute services.

241.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

241.2. URI FORMAT

`openstack-nova://hosturl[?options]`

You can append query options to the URI in the following format `?options=value&option2=value&...`

241.3. URI OPTIONS

The OpenStack Nova component has no options.

The OpenStack Nova endpoint is configured using URI syntax:

`openstack-nova:host`

with the following path and query parameters:

241.3.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required OpenStack host url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

241.3.2. Query Parameters (9 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion (producer)</td>
<td>OpenStack API version</td>
<td>V3</td>
<td>String</td>
</tr>
<tr>
<td>config (producer)</td>
<td>OpenStack configuration</td>
<td></td>
<td>Config</td>
</tr>
<tr>
<td>domain (producer)</td>
<td>Authentication domain</td>
<td>default</td>
<td>String</td>
</tr>
<tr>
<td>operation (producer)</td>
<td>The operation to do</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>password (producer)</td>
<td>Required OpenStack password</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>project (producer)</td>
<td>Required The project ID</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>subsystem (producer)</td>
<td>Required OpenStack Nova subsystem</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>username (producer)</td>
<td>Required OpenStack username</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 241.4. USAGE

You can use following settings for each subsystem:

### 241.5. FLAVORS

#### 241.5.1. Operations you can perform with the Flavor producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new flavor.</td>
</tr>
<tr>
<td>get</td>
<td>Get the flavor.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all flavors.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the flavor.</td>
</tr>
</tbody>
</table>
241.5.2. Message headers evaluated by the Flavor producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the flavor.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The flavor name.</td>
</tr>
<tr>
<td>VCPU</td>
<td>Integer</td>
<td>The number of flavor VCPU.</td>
</tr>
<tr>
<td>RAM</td>
<td>Integer</td>
<td>Size of RAM.</td>
</tr>
<tr>
<td>Disk</td>
<td>Integer</td>
<td>Size of disk.</td>
</tr>
<tr>
<td>Swap</td>
<td>Integer</td>
<td>Size of swap.</td>
</tr>
<tr>
<td>RxtxFactor</td>
<td>Integer</td>
<td>Rxtx Factor.</td>
</tr>
</tbody>
</table>

If you need more precise flavor settings you can create new object of the type `org.openstack4j.model.compute.Flavor` and send in the message body.

241.6. SERVERS

241.6.1. Operations you can perform with the Server producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new server.</td>
</tr>
<tr>
<td>createSnapshot</td>
<td>Create snapshot of the server.</td>
</tr>
<tr>
<td>get</td>
<td>Get the server.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all servers.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the server.</td>
</tr>
<tr>
<td>action</td>
<td>Perform an action on the server.</td>
</tr>
</tbody>
</table>
241.6.2. Message headers evaluated by the Server producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>ID</td>
<td>String</td>
<td>ID of the server.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The server name.</td>
</tr>
<tr>
<td>ImageId</td>
<td>String</td>
<td>The Image ID.</td>
</tr>
<tr>
<td>FlavorId</td>
<td>String</td>
<td>The ID of flavor which will be used.</td>
</tr>
<tr>
<td>KeypairName</td>
<td>String</td>
<td>The Keypair name.</td>
</tr>
<tr>
<td>NetworkId</td>
<td>String</td>
<td>The network ID.</td>
</tr>
<tr>
<td>AdminPassword</td>
<td>String</td>
<td>Admin password of the new server.</td>
</tr>
<tr>
<td>action</td>
<td>org.openstack4j.model.compute.Action</td>
<td>An action to perform.</td>
</tr>
</tbody>
</table>

If you need more precise server settings you can create new object of the type org.openstack4j.model.compute.ServerCreate and send in the message body.

241.7. KEYPAIRS

241.7.1. Operations you can perform with the Keypair producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new keypair.</td>
</tr>
<tr>
<td>get</td>
<td>Get the keypair.</td>
</tr>
</tbody>
</table>
### Operation

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getAll</code></td>
<td>Get all keypairs.</td>
</tr>
<tr>
<td><code>delete</code></td>
<td>Delete the keypair.</td>
</tr>
</tbody>
</table>

#### 241.7.2. Message headers evaluated by the Keypair producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>operation</code></td>
<td><code>String</code></td>
<td>The operation to perform.</td>
</tr>
<tr>
<td><code>name</code></td>
<td><code>String</code></td>
<td>The keypair name.</td>
</tr>
</tbody>
</table>

CHAPTER 242. OPENSTACK SWIFT COMPONENT

Available as of Camel version 2.19

The openstack-swift component allows messages to be sent to an OpenStack object storage services.

242.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

242.2. URI FORMAT

```
openstack-swift://hosturl[?options]
```

You can append query options to the URI in the following format `?options=value&option2=value&...`

242.3. URI OPTIONS

The OpenStack Swift component has no options.

The OpenStack Swift endpoint is configured using URI syntax:

```
openstack-swift:host
```

with the following path and query parameters:

242.3.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required OpenStack host url</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

242.3.2. Query Parameters (9 parameters):
### Name | Description | Default | Type
--- | --- | --- | ---
apiVersion (producer) | OpenStack API version | V3 | String
config (producer) | OpenStack configuration | | Config
domain (producer) | Authentication domain | default | String
operation (producer) | The operation to do | | String
password (producer) | Required OpenStack password | | String
project (producer) | Required The project ID | | String
subsystem (producer) | Required OpenStack Swift subsystem | | String
username (producer) | Required OpenStack username | | String
synchronous (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

#### 242.4. USAGE

You can use following settings for each subsystem:

#### 242.5. CONTAINERS

#### 242.5.1. Operations you can perform with the Container producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new container.</td>
</tr>
<tr>
<td>get</td>
<td>Get the container.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all containers.</td>
</tr>
<tr>
<td>update</td>
<td>Update the container.</td>
</tr>
</tbody>
</table>
## 242.5.2. Message headers evaluated by the Volume producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The container name.</td>
</tr>
<tr>
<td>X-Container-Meta-Map</td>
<td>Map</td>
<td>Container metadata prefix.</td>
</tr>
<tr>
<td>X-Versions-Location</td>
<td>String</td>
<td>Versions location.</td>
</tr>
<tr>
<td>X-Container-Read</td>
<td>String</td>
<td>ACL - container read.</td>
</tr>
<tr>
<td>X-Container-Write</td>
<td>String</td>
<td>ACL - container write.</td>
</tr>
<tr>
<td>limit</td>
<td>Integer</td>
<td>List options - limit.</td>
</tr>
<tr>
<td>marker</td>
<td>String</td>
<td>List options - marker.</td>
</tr>
<tr>
<td>end_marker</td>
<td>String</td>
<td>List options - end marker.</td>
</tr>
<tr>
<td>delimiter</td>
<td>Character</td>
<td>List options - delimiter.</td>
</tr>
<tr>
<td>path</td>
<td>String</td>
<td>List options - path.</td>
</tr>
</tbody>
</table>

If you need more precise container settings you can create new object of the type `org.openstack4j.model.storage.object.options.CreateUpdateContainerOptions` (in case of create or update operation) or `org.openstack4j.model.storage.object.options.ContainerListOptions` for listing containers and send in the message body.
242.6. OBJECTS

242.6.1. Operations you can perform with the Object producer

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Create new object.</td>
</tr>
<tr>
<td>get</td>
<td>Get the object.</td>
</tr>
<tr>
<td>getAll</td>
<td>Get all objects.</td>
</tr>
<tr>
<td>update</td>
<td>Get update the object.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete the object.</td>
</tr>
<tr>
<td>getMetadata</td>
<td>Get metadata.</td>
</tr>
<tr>
<td>createUpdateMetadata</td>
<td>Create/update metadata.</td>
</tr>
</tbody>
</table>

242.6.2. Message headers evaluated by the Object producer

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform.</td>
</tr>
<tr>
<td>containerName</td>
<td>String</td>
<td>The container name.</td>
</tr>
<tr>
<td>objectName</td>
<td>String</td>
<td>The object name.</td>
</tr>
</tbody>
</table>

CHAPTER 243. OPENTRACING COMPONENT

Available as of Camel 2.19

IMPORTANT

Starting with Camel 2.21, it will be necessary to use an OpenTracing complaint tracer that is compatible with OpenTracing Java API version 0.31 or higher.

The camel-opentracing component is used for tracing and timing incoming and outgoing Camel messages using OpenTracing.

Events (spans) are captured for incoming and outgoing messages being sent to/from Camel.

See the OpenTracing website for a list of supported tracers.

243.1. CONFIGURATION

The configuration properties for the OpenTracing tracer are:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>excludePatterns</td>
<td></td>
<td>Sets exclude pattern(s) that will disable tracing for Camel messages that matches the pattern. The content is a Set&lt;String&gt; where the key is a pattern. The pattern uses the rules from Intercept.</td>
</tr>
</tbody>
</table>

There are three ways in which an OpenTracing tracer can be configured to provide distributed tracing for a Camel application:

243.1.1. Explicit

Include the camel-opentracing component in your POM, along with any specific dependencies associated with the chosen OpenTracing compliant Tracer.

To explicitly configure OpenTracing support, instantiate the OpenTracingTracer and initialize the camel context. You can optionally specify a Tracer, or alternatively it can be implicitly discovered using the Registry or ServiceLoader.

```java
OpenTracingTracer ottracer = new OpenTracingTracer();
// By default it uses a Noop Tracer, but you can override it with a specific OpenTracing implementation.
otracer.setTracer(...);
// And then initialize the context
otracer.init(camelContext);
```

To use OpenTracingTracer in XML, all you need to do is to define the OpenTracing tracer beans. Camel will automatically discover and use them.

```xml
<bean id="tracer" class="..."/>
<bean id="otracer" class="org.apache.camel.opentracing.OpenTracingTracer">
  <property name="tracer" ref="tracer"/>
</bean>
```
243.1.2. Spring Boot

If you are using Spring Boot then you can add the camel-opentracing-starter dependency, and turn on OpenTracing by annotating the main class with `@CamelOpenTracing`.

The Tracer will be implicitly obtained from the camel context’s Registry, or the ServiceLoader, unless a Tracer bean has been defined by the application.

243.1.3. Java Agent

The third approach is to use a Java Agent to automatically configure the OpenTracing support.

Include the camel-opentracing component in your POM, along with any specific dependencies associated with the chosen OpenTracing compliant Tracer.

The OpenTracing Java Agent is associated with the following dependency:

```xml
<dependency>
  <groupId>io.opentracing.contrib</groupId>
  <artifactId>opentracing-agent</artifactId>
</dependency>
```

The Tracer used will be implicitly loaded from the camel context Registry or using the ServiceLoader.

How this agent is used will be specific to how you execute your application. Service2 in the camel-example-opentracing downloads the agent into a local folder and then uses the exec-maven-plugin to launch the service with the -javaagent command line option.

243.2. EXAMPLE

You can find an example demonstrating the three ways to configure OpenTracing here: camel-example-opentracing
CHAPTER 244. OPTAPLANNER COMPONENT

Available as of Camel version 2.13

The optaplanner: component solves the planning problem contained in a message with OptaPlanner. For example: feed it an unsolved Vehicle Routing problem and it solves it.

The component supports consumer as BestSolutionChangedEvent listener and producer for processing Solution and ProblemFactChange.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-optaplanner</artifactId>
    <version>x.x.x</version><!-- use the same version as your Camel core version -->
</dependency>
```

244.1. URI FORMAT

optaplanner:solverConfig[?options]

The solverConfig is the classpath-local URI of the solverConfig, for example /org/foo/barSolverConfig.xml.

You can append query options to the URI in the following format, ?option=value&option=value&...

244.2. OPTAPLANNER OPTIONS

The OptaPlanner component has no options.

The OptaPlanner endpoint is configured using URI syntax:

```java
optaplanner:configFile
```

with the following path and query parameters:

244.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configFile</td>
<td>Required Specifies the location to the solver file</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

244.2.2. Query Parameters (7 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default Value</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>solverId (common)</td>
<td>Specifies the solverId to user for the solver instance key</td>
<td>DEFAULT_SOLVER</td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>async (producer)</td>
<td>Specifies to perform operations in async mode</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>threadPoolSize (producer)</td>
<td>Specifies the thread pool size to use when async is true</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 244.3. MESSAGE HEADERS

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Type</th>
<th>Context</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel OptaPlannerSolverId</td>
<td>null</td>
<td>String</td>
<td>Shared</td>
<td>Specifies the solverId to use</td>
</tr>
</tbody>
</table>
## 244.4. MESSAGE BODY

Camel takes the planning problem for the IN body, solves it and returns it on the OUT body. (since v 2.16) The IN body object supports the following use cases:

- If the body is instance of Solution, then it will be solved using the solver identified by solverId and either synchronously or asynchronously.

- If the body is instance of ProblemFactChange, then it will trigger addProblemFactChange. If the processing is asynchronously, then it will wait till isEveryProblemFactChangeProcessed before returning result.

- If the body is none of the above types, then the producer will return the best result from the solver identified by solverId

## 244.5. TERMINATION

The solving will take as long as specified in the `solverConfig`.

```xml
<solver>
  ...
  <termination>
    <!-- Terminate after 10 seconds, unless it's not feasible by then yet -->
    <terminationCompositionStyle>AND</terminationCompositionStyle>
    <secondsSpentLimit>10</secondsSpentLimit>
    <bestScoreLimit>-1hard/0soft</bestScoreLimit>
  </termination>
  ...
</solver>
```

### 244.5.1. Samples

Solve an planning problem that’s on the ActiveMQ queue with OptaPlanner:

```xml
from("activemq:My.Queue").
  .to("optaplanner:/org/foo/barSolverConfig.xml");
```

Expose OptaPlanner as a REST service:

```xml
from("cxfrs:bean:rsServer?bindingStyle=SimpleConsumer")
  .to("optaplanner:/org/foo/barSolverConfig.xml");
```
244.6. SEE ALSO

- Endpoint
- Getting Started
CHAPTER 245. PAHO COMPONENT

Available as of Camel version 2.16

Paho component provides connector for the MQTT messaging protocol using the Eclipse Paho library. Paho is one of the most popular MQTT libraries, so if you would like to integrate it with your Java project - Camel Paho connector is a way to go.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-paho</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Keep in mind that Paho artifacts are not hosted in the Maven Central, so you need to add Eclipse Paho repository to your POM xml file:

```xml
<repositories>
  <repository>
    <id>eclipse-paho</id>
    <url>https://repo.eclipse.org/content/repositories/paho-releases/</url>
    <snapshots>
      <enabled>false</enabled>
    </snapshots>
  </repository>
</repositories>
```

245.1. URI FORMAT

paho:topic[?options]

Where `topic` is the name of the topic.

245.2. OPTIONS

The Paho component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>brokerUrl</td>
<td>The URL of the MQTT broker.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientId</td>
<td>MQTT client identifier.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>connectOptions</td>
<td>Client connection options</td>
<td></td>
<td>MqttConnectOptions</td>
</tr>
</tbody>
</table>
Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

The Paho endpoint is configured using URI syntax:

```
paho:topic
```

with the following path and query parameters:

### 245.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>topic</td>
<td>Required Name of the topic</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 245.2.2. Query Parameters (14 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>autoReconnect</td>
<td>Client will automatically attempt to reconnect to the server if the connection is lost</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>brokerUrl</td>
<td>The URL of the MQTT broker.</td>
<td>tcp://localhost:1883</td>
<td>String</td>
</tr>
<tr>
<td>clientId</td>
<td>MQTT client identifier.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>connectOptions</td>
<td>Client connection options</td>
<td></td>
<td>MqtttConnectOptions</td>
</tr>
<tr>
<td>filePersistenceDirectory</td>
<td>Base directory used by the file persistence provider.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>password</td>
<td>Password to be used for authentication against the MQTT broker</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>persistence</td>
<td>Client persistence to be used - memory or file.</td>
<td>MEMO</td>
<td>PahoPersistence</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>qos (common)</td>
<td>Client quality of service level (0-2).</td>
<td>2</td>
<td>int</td>
</tr>
<tr>
<td>retained (common)</td>
<td>Retain option</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>userName (common)</td>
<td>Username to be used for authentication against the MQTT broker</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 245.3. HEADERS

The following headers are recognized by the Paho component:

<table>
<thead>
<tr>
<th>Header</th>
<th>Java constant</th>
<th>Endpoint type</th>
<th>Value type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel MqttTopic</td>
<td>PahoConstants.MQTT_TOPIC</td>
<td>Consumer</td>
<td>String</td>
<td>The name of the topic</td>
</tr>
</tbody>
</table>
Camel Paho override Topic

<table>
<thead>
<tr>
<th>Header</th>
<th>Java constant</th>
<th>Endpoint type</th>
<th>Value type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel Paho override Topic</td>
<td>PahoConstants.CAMEL_PAHO_OVERRIDE_TOPIC</td>
<td>Producer</td>
<td>String</td>
<td>Name of topic to override and send to instead of topic specified on endpoint</td>
</tr>
</tbody>
</table>

245.4. DEFAULT PAYLOAD TYPE

By default Camel Paho component operates on the binary payloads extracted out of (or put into) the MQTT message:

```java
// Receive payload
byte[] payload = (byte[]) consumerTemplate.receiveBody("paho:topic");

// Send payload
byte[] payload = "message".getBytes();
producerTemplate.sendBody("paho:topic", payload);
```

But of course Camel build-in type conversion API can perform the automatic data type transformations for you. In the example below Camel automatically converts binary payload into String (and conversely):

```java
// Receive payload
String payload = consumerTemplate.receiveBody("paho:topic", String.class);

// Send payload
String payload = "message";
producerTemplate.sendBody("paho:topic", payload);
```

245.5. SAMPLES

For example the following snippet reads messages from the MQTT broker installed on the same host as the Camel router:

```java
from("paho:some/queue")
  .to("mock:test");
```

While the snippet below sends message to the MQTT broker:

```java
from("direct:test")
  .to("paho:some/target/queue");
```

For example this is how to read messages from the remote MQTT broker:
from("paho:some/queue?brokerUrl=tcp://iot.eclipse.org:1883")
    .to("mock:test");

And here we override the default topic and set to a dynamic topic

from("direct:test")
    .setHeader(PahoConstants.CAMEL_PAHO_OVERRIDE_TOPIC, simple("${header.customerId}"))
    .to("paho:some/target/queue");
CHAPTER 246. OSGI PAX LOGGING COMPONENT

Available as of Camel version 2.6

The paxlogging component can be used in an OSGi environment to receive PaxLogging events and process them.

246.1. DEPENDENCIES

Maven users need to add the following dependency to their pom.xml

```
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-paxlogging</artifactId>
    <version>${camel-version}</version>
</dependency>
```

where ${camel-version} must be replaced by the actual version of Camel (2.6.0 or higher).

246.2. URI FORMAT

```
paxlogging:appender[?options]
```

where appender is the name of the pax appender that need to be configured in the PaxLogging service configuration.

246.3. URI OPTIONS

The OSGi PAX Logging component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bundleContext (consumer)</td>
<td>The OSGi BundleContext is automatic injected by Camel</td>
<td></td>
<td>BundleContext</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The OSGi PAX Logging endpoint is configured using URI syntax:

```
paxlogging:appender
```

with the following path and query parameters:

246.3.1. Path Parameters (1 parameters):
246.3.2. Query Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

246.4. MESSAGE BODY

The in message body will be set to the received PaxLoggingEvent.

246.5. EXAMPLE USAGE

```xml
<route>
  <from uri="paxlogging:camel"/>
  <to uri="stream:out"/>
</route>
```

Configuration:

```
log4j.rootLogger=INFO, out, osgi:VmLogAppender, osgi:camel
```
CHAPTER 247. PDF COMPONENT

Available as of Camel version 2.16

The PDF component provides the ability to create, modify or extract content from PDF documents. This component uses Apache PDFBox as underlying library to work with PDF documents.

In order to use the PDF component, Maven users will need to add the following dependency to their pom.xml:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-pdf</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

247.1. URI FORMAT

The PDF component only supports producer endpoints.

```
pdf:operation[?options]
```

247.2. OPTIONS

The PDF component has no options.

The PDF endpoint is configured using URI syntax:

```
pdf:operation
```

with the following path and query parameters:

247.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>Required Operation type</td>
<td></td>
<td>PdfOperation</td>
</tr>
</tbody>
</table>

247.2.2. Query Parameters (9 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>font (producer)</td>
<td>Font</td>
<td>Helvetica</td>
<td>PDFont</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td><code>fontSize</code> (producer)</td>
<td>Font size in pixels</td>
<td>14</td>
<td>float</td>
</tr>
<tr>
<td><code>marginBottom</code> (producer)</td>
<td>Margin bottom in pixels</td>
<td>20</td>
<td>int</td>
</tr>
<tr>
<td><code>marginLeft</code> (producer)</td>
<td>Margin left in pixels</td>
<td>20</td>
<td>int</td>
</tr>
<tr>
<td><code>marginRight</code> (producer)</td>
<td>Margin right in pixels</td>
<td>40</td>
<td>int</td>
</tr>
<tr>
<td><code>marginTop</code> (producer)</td>
<td>Margin top in pixels</td>
<td>20</td>
<td>int</td>
</tr>
<tr>
<td><code>pageSize</code> (producer)</td>
<td>Page size</td>
<td>A4</td>
<td>PDRectangle</td>
</tr>
<tr>
<td><code>textProcessingFactory</code> (producer)</td>
<td>Text processing to use. autoFormatting: Text is getting sliced by words, then max amount of words that fits in the line will be written into pdf document. With this strategy all words that doesn’t fit in the line will be moved to the new line. lineTermination: Builds set of classes for line-termination writing strategy. Text getting sliced by line termination symbol and then it will be written regardless it fits in the line or not.</td>
<td>lineTermination</td>
<td>TextProcessingFactory</td>
</tr>
<tr>
<td><code>synchronous</code> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 247.3. HEADERS

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pdf-document</code></td>
<td><strong>Mandatory</strong> header for <strong>append</strong> operation and ignored in all other operations. Expected type is <code>PDDocument</code>. Stores PDF document which will be used for append operation.</td>
</tr>
<tr>
<td><code>protection-policy</code></td>
<td>Expected type <a href="https://pdfbox.apache.org/docs/1.8.10/javadocs/org/apache/pdfbox/pdmodel/encryption/ProtectionPolicy.html">ProtectionPolicy</a>. If specified then PDF document will be encrypted with it.</td>
</tr>
<tr>
<td>Header</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>

### 247.4. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 248. POSTGRESQL EVENT COMPONENT

Available as of Camel version 2.15

This is a component for Apache Camel which allows for Producing/Consuming PostgreSQL events related to the LISTEN/NOTIFY commands added since PostgreSQL 8.3.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-pgevent</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

URI format

The pgevent component uses the following two styles of endpoint URI notation:

```
pgevent:datasource[?parameters]
pgevent://host:port/database/channel[?parameters]
```

You can append query options to the URI in the following format, `?option=value&option=value&…`

248.1. OPTIONS

The Postgresql Event component has no options.

The Postgresql Event endpoint is configured using URI syntax:

```
pgevent:host:port/database/channel
```

with the following path and query parameters:

248.1.1. Path Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>

CHAPTER 249. PGP DATAFORMAT

Available as of Camel version 2.9

The PGP Data Format integrates the Java Cryptographic Extension into Camel, allowing simple and flexible encryption and decryption of messages using Camel’s familiar marshall and unmarshal formatting mechanism. It assumes marshalling to mean encryption to cyphertext and unmarshalling to mean decryption back to the original plaintext. This data format implements only symmetric (shared-key) encryption and decryption.

249.1. PGPDATAFORMAT OPTIONS

The PGP dataformat supports 15 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyUserId</td>
<td>String</td>
<td></td>
<td>The user ID of the key in the PGP keyring used during encryption. Can also be only a part of a user ID. For example, if the user ID is Test User then you can use the part Test User or to address the user ID.</td>
</tr>
<tr>
<td>signatureKeyIdUser</td>
<td>String</td>
<td></td>
<td>User ID of the key in the PGP keyring used for signing (during encryption) or signature verification (during decryption). During the signature verification process the specified User ID restricts the public keys from the public keyring which can be used for the verification. If no User ID is specified for the signature verification then any public key in the public keyring can be used for the verification. Can also be only a part of a user ID. For example, if the user ID is Test User then you can use the part Test User or to address the User ID.</td>
</tr>
<tr>
<td>password</td>
<td>String</td>
<td></td>
<td>Password used when opening the private key (not used for encryption).</td>
</tr>
<tr>
<td>signaturePassword</td>
<td>String</td>
<td></td>
<td>Password used when opening the private key used for signing (during encryption).</td>
</tr>
<tr>
<td>keyFileName</td>
<td>String</td>
<td></td>
<td>Filename of the keyring; must be accessible as a classpath resource (but you can specify a location in the file system by using the file: prefix).</td>
</tr>
<tr>
<td>signatureKeyFileName</td>
<td>String</td>
<td></td>
<td>Filename of the keyring to use for signing (during encryption) or for signature verification (during decryption); must be accessible as a classpath resource (but you can specify a location in the file system by using the file: prefix).</td>
</tr>
<tr>
<td>signatureKeyRing</td>
<td>String</td>
<td></td>
<td>Keyring used for signing/verifying as byte array. You can not set the signatureKeyFileName and signatureKeyRing at the same time.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>armored</td>
<td>false</td>
<td>Boolean</td>
<td>This option will cause PGP to base64 encode the encrypted text, making it available for copy/paste, etc.</td>
</tr>
<tr>
<td>integrity</td>
<td>true</td>
<td>Boolean</td>
<td>Adds an integrity check/sign into the encryption file. The default value is true.</td>
</tr>
<tr>
<td>provider</td>
<td>String</td>
<td></td>
<td>Java Cryptography Extension (JCE) provider, default is Bouncy Castle (BC). Alternatively you can use, for example, the IAIK JCE provider; in this case the provider must be registered beforehand and the Bouncy Castle provider must not be registered beforehand. The Sun JCE provider does not work.</td>
</tr>
<tr>
<td>algorithm</td>
<td>Integer</td>
<td></td>
<td>Symmetric key encryption algorithm; possible values are defined in org.bouncycastle.bcpg.SymmetricKeyAlgorithmTags; for example 2 ( = TRIPLE DES), 3 ( = CAST5), 4 ( = BLOWFISH), 6 ( = DES), 7 ( = AES_128). Only relevant for encrypting.</td>
</tr>
<tr>
<td>compressionAlgorithm</td>
<td>Integer</td>
<td></td>
<td>Compression algorithm; possible values are defined in org.bouncycastle.bcpg.CompressionAlgorithmTags; for example 0 ( = UNCOMPRESSED), 1 ( = ZIP), 2 ( = ZLIB), 3 ( = BZIP2). Only relevant for encrypting.</td>
</tr>
<tr>
<td>hashAlgorithm</td>
<td>Integer</td>
<td></td>
<td>Signature hash algorithm; possible values are defined in org.bouncycastle.bcpg.HashAlgorithmTags; for example 2 ( = SHA1), 8 ( = SHA256), 9 ( = SHA384), 10 ( = SHA512), 11 ( = SHA224). Only relevant for signing.</td>
</tr>
<tr>
<td>signatureVerificationOption</td>
<td>String</td>
<td></td>
<td>Controls the behavior for verifying the signature during unmarshaling. There are 4 values possible: optional: The PGP message may or may not contain signatures; if it does contain signatures, then a signature verification is executed. required: The PGP message must contain at least one signature; if this is not the case an exception (PGPException) is thrown. A signature verification is executed. ignore: Contained signatures in the PGP message are ignored; no signature verification is executed. no_signature_allowed: The PGP message must not contain a signature; otherwise an exception (PGPException) is thrown.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

249.2. PGPDATAFORMAT MESSAGE HEADERS
You can override the PGPDataFormat options by applying below headers into message dynamically.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel PGPDataFormatKeyFilename</td>
<td>String</td>
<td>Since Camel 2.11.0; filename of the keyring; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>Camel PGPDataFormatEncryptionKeyRing</td>
<td>byte[]</td>
<td>Since Camel 2.12.1; the encryption keyring; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>Camel PGPDataFormatKeyId</td>
<td>String</td>
<td>Since Camel 2.11.0; the User ID of the key in the PGP keyring; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>Camel PGPDataFormatKeyUserIds</td>
<td>List&lt;String&gt;</td>
<td>Since camel 2.12.2; the User IDs of the key in the PGP keyring; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>Camel PGPDataFormatKeyPassword</td>
<td>String</td>
<td>Since Camel 2.11.0; password used when opening the private key; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>Camel PGPDataFormatSignatureKeyFilename</td>
<td>String</td>
<td>Since Camel 2.11.0; filename of the signature keyring; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>CamelPGPDataFormatSignatureKeyRing</td>
<td>byte[]</td>
<td>Since Camel 2.12.1; the signature keyring; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>CamelPGPDataFormatSignatureKeyId</td>
<td>String</td>
<td>Since Camel 2.11.0; the User ID of the signature key in the PGP keyring; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>CamelPGPDataFormatSignatureKeyUserIds</td>
<td>List&lt;String&gt;</td>
<td>Since Camel 2.12.3; the User IDs of the signature keys in the PGP keyring; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>CamelPGPDataFormatSignatureKeyPassword</td>
<td>String</td>
<td>Since Camel 2.11.0; password used when opening the signature private key; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>CamelPGPDataFormatEncryptionAlgorithm</td>
<td>int</td>
<td>Since Camel 2.12.2; symmetric key encryption algorithm; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>CamelPGPDataFormatSignatureHashAlgorithm</td>
<td>int</td>
<td>Since Camel 2.12.2; signature hash algorithm; will override existing setting directly on the PGPDataFormat.</td>
</tr>
</tbody>
</table>
### 249.3. ENCRYPTING WITH PGPDATAFORMAT

The following sample uses the popular PGP format for encrypting/decrypting files using the Bouncy Castle Java libraries:

The following sample performs signing + encryption, and then signature verification + decryption. It uses the same keyring for both signing and encryption, but you can obviously use different keys:

Or using Spring:

#### 249.3.1. To work with the previous example you need the following

- A public keyring file which contains the public keys used to encrypt the data
- A private keyring file which contains the keys used to decrypt the data
- The keyring password

#### 249.3.2. Managing your keyring

To manage the keyring, I use the command line tools, I find this to be the simplest approach in managing the keys. There are also Java libraries available from [http://www.bouncycastle.org/java.html](http://www.bouncycastle.org/java.html) if you would prefer to do it that way.

---

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel PGPDataFormatCompressionAlgorithm</td>
<td>int</td>
<td>Since Camel 2.12.2; compression algorithm; will override existing setting directly on the PGPDataFormat.</td>
</tr>
<tr>
<td>Camel PGPDataFormatNumberOfEncryptionKeys</td>
<td>Integer</td>
<td>Since *Camel 2.12.3; *number of public keys used for encrypting the symmectric key, set by PGPDataFormat during encryption process</td>
</tr>
<tr>
<td>Camel PGPDataFormatNumberOfSigningKeys</td>
<td>Integer</td>
<td>Since *Camel 2.12.3; *number of private keys used for creating signatures, set by PGPDataFormat during signing process</td>
</tr>
</tbody>
</table>
Install the command line utilities on Linux

```bash
apt-get install gnupg
```

Create your keyring, entering a secure password

```bash
gpg --gen-key
```

If you need to import someone else's public key so that you can encrypt a file for them.

```bash
gpg --import <filename.key
```

The following files should now exist and can be used to run the example

```bash
ls -l ~/.gnupg/pubring.gpg ~/.gnupg/secring.gpg
```

Since Camel 2.12.2.

A PGP Data Formatter can decrypt/verify messages which have been encrypted by different public keys or signed by different private keys. Just, provide the corresponding private keys in the secret keyring, the corresponding public keys in the public keyring, and the passphrases in the passphrase accessor.

```java
Map<String, String> userId2Passphrase = new HashMap<String, String>(2);
// add passphrases of several private keys whose corresponding public keys have been used to encrypt the messages
userId2Passphrase.put("UserIdOfKey1","passphrase1"); // you must specify the exact User ID!
userId2Passphrase.put("UserIdOfKey2","passphrase2");

PGPPassphraseAccessor passphraseAccessor = new PGPPassphraseAccessorDefault(userId2Passphrase);

PGPDataFormat pgpVerifyAndDecrypt = new PGPDataFormat();
pgpVerifyAndDecrypt.setPassphraseAccessor(passphraseAccessor);
// the method getSecKeyRing() provides the secret keyring as byte array containing the private keys
pgpVerifyAndDecrypt.setEncryptionKeyRing(getSecKeyRing()); // alternatively you can use setKeyFileName(keyfileName)
// the method getPublicKeyRing() provides the public keyring as byte array containing the public keys
pgpVerifyAndDecrypt.setSignatureKeyRing((getPublicKeyRing()); // alternatively you can use setSignatureKeyFileName(signatureKeyfileName)
// it is not necessary to specify the encryption or signer User Id

from("direct:start")
...
.unmarshal(pgpVerifyAndDecrypt) // can decrypt/verify messages encrypted/signed by different private/public keys
...
```

- The functionality is especially useful to support the key exchange. If you want to exchange the private key for decrypting you can accept for a period of time messages which are either encrypted with the old or new corresponding public key. Or if the sender wants to exchange his signer private key, you can accept for a period of time, the old or new signer key.
Technical background: The PGP encrypted data contains a Key ID of the public key which was used to encrypt the data. This Key ID can be used to locate the private key in the secret keyring to decrypt the data. The same mechanism is also used to locate the public key for verifying a signature. Therefore you no longer must specify User IDs for the unmarshaling.

249.4. RESTRICTING THE SIGNER IDENTITIES DURING PGP SIGNATURE VERIFICATION

Since Camel 2.12.3.

If you verify a signature you not only want to verify the correctness of the signature but you also want check that the signature comes from a certain identity or a specific set of identities. Therefore it is possible to restrict the number of public keys from the public keyring which can be used for the verification of a signature.

Signature User IDs

```java
// specify the User IDs of the expected signer identities
List<String> expectedSigUserIds = new ArrayList<String>();
expectedSigUserIds.add("Trusted company1");
expectedSigUserIds.add("Trusted company2");

PGPDataFormat pgpVerifyWithSpecificKeysAndDecrypt = new PGPDataFormat();
pgpVerifyWithSpecificKeysAndDecrypt.setPassword("my password"); // for decrypting with private key
pgpVerifyWithSpecificKeysAndDecrypt.setKeyFileName(keyfileName);
pgpVerifyWithSpecificKeysAndDecrypt.setSignatureKeyFileName(signatureKeyfileName);
pgpVerifyWithSpecificKeysAndDecrypt.setSignatureKeyUserids(expectedSigUserIds); // if you have only one signer identity then you can also use setSignatureKeyUserId("expected Signer")
```

- If the PGP content has several signatures the verification is successful as soon as one signature can be verified.
- If you do not want to restrict the signer identities for verification then do not specify the signature key User IDs. In this case all public keys in the public keyring are taken into account.

249.5. SEVERAL SIGNATURES IN ONE PGP DATA FORMAT

Since Camel 2.12.3.

The PGP specification allows that one PGP data format can contain several signatures from different keys. Since Camel 2.13.3 it is possible to create such kind of PGP content via specifying signature User IDs which relate to several private keys in the secret keyring.

Several Signatures

```java
PGPDataFormat pgpSignAndEncryptSeveralSignerKeys = new PGPDataFormat();
pgpSignAndEncryptSeveralSignerKeys.setKeyUserid(keyUserid); // for encrypting, you can also use setKeyUserids if you want to encrypt with several keys
```
249.6. SUPPORT OF SUB-KEYS AND KEY FLAGS IN PGP DATA FORMAT MARSHALER

Since *Camel 2.12.3.*

*An OpenPGP V4 key* can have a primary key and sub-keys. The usage of the keys is indicated by the so-called *Key Flags*. For example, you can have a primary key with two sub-keys; the primary key shall only be used for certifying other keys (Key Flag 0x01), the first sub-key shall only be used for signing (Key Flag 0x02), and the second sub-key shall only be used for encryption (Key Flag 0x04 or 0x08). The PGP Data Format marshaler takes into account these Key Flags of the primary key and sub-keys in order to determine the right key for signing and encryption. This is necessary because the primary key and its sub-keys have the same User IDs.

249.7. SUPPORT OF CUSTOM KEY ACCESSORS

Since *Camel 2.13.0.*

*You can implement custom key accessors for encryption/signing.* The above PGPDDataFormat class selects in a certain predefined way the keys which should be used for signing/encryption or verifying/decryption. If you have special requirements how your keys should be selected you should use the PGPKeyAccessDataFormat class instead and implement the interfaces PGP PublicKeyAccessor and PGPSecretKeyAccessor as beans. There are default implementations DefaultPGPPublicKeyAccessor and DefaultPGPSecretKeyAccessor which cache the keys, so that not every time the keyring is parsed when the processor is called.

PGPKeyAccessDataFormat has the same options as PGPDDataFormat except password, keyFileName, encryptionKeyRing, signaturePassword, signatureKeyFileName, and signatureKeyRing.

249.8. DEPENDENCIES

To use the PGP dataformat in your camel routes you need to add the following dependency to your pom.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-crypto</artifactId>
  <version>x.x.x</version>
</dependency>
```

CHAPTER 250. PROPERTIES COMPONENT

Available as of Camel version 2.3

250.1. URI FORMAT

```
properties:key[?options]
```

Where `key` is the key for the property to lookup

250.2. OPTIONS

The Properties component supports 17 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>locations (common)</td>
<td>A list of locations to load properties. This option will override any default locations and only use the locations from this option.</td>
<td></td>
<td>List</td>
</tr>
<tr>
<td>location (common)</td>
<td>A list of locations to load properties. You can use comma to separate multiple locations. This option will override any default locations and only use the locations from this option.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>encoding (common)</td>
<td>Encoding to use when loading properties file from the file system or classpath. If no encoding has been set, then the properties files is loaded using ISO-8859-1 encoding (latin-1) as documented by link java.util.Properties.load(java.io.InputStream)</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>propertiesResolver (common)</td>
<td>To use a custom PropertiesResolver</td>
<td></td>
<td>PropertiesResolver</td>
</tr>
<tr>
<td>propertiesParser (common)</td>
<td>To use a custom PropertiesParser</td>
<td></td>
<td>PropertiesParser</td>
</tr>
<tr>
<td>cache (common)</td>
<td>Whether or not to cache loaded properties. The default value is true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>propertyPrefix (advanced)</td>
<td>Optional prefix prepended to property names before resolution.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>propertySuffix (advanced)</td>
<td>Optional suffix appended to property names before resolution.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>fallbackToAugmented Property (advanced)</td>
<td>If true, first attempt resolution of property name augmented with propertyPrefix and propertySuffix before falling back the plain property name specified. If false, only the augmented property name is searched.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>defaultFallbackEnabled (common)</td>
<td>If false, the component does not attempt to find a default for the key by looking after the colon separator.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>ignoreMissingLocation (common)</td>
<td>Whether to silently ignore if a location cannot be located, such as a properties file not found.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>prefixToken (advanced)</td>
<td>Sets the value of the prefix token used to identify properties to replace. Setting a value of null restores the default token (link link DEFAULT_PREFIX_TOKEN).</td>
<td>{{</td>
<td>String</td>
</tr>
<tr>
<td>suffixToken (advanced)</td>
<td>Sets the value of the suffix token used to identify properties to replace. Setting a value of null restores the default token (link link DEFAULT_SUFFIX_TOKEN).</td>
<td>}}</td>
<td>String</td>
</tr>
<tr>
<td>initialProperties (advanced)</td>
<td>Sets initial properties which will be used before any locations are resolved.</td>
<td></td>
<td>Properties</td>
</tr>
<tr>
<td>overrideProperties (advanced)</td>
<td>Sets a special list of override properties that take precedence and will use first, if a property exist.</td>
<td></td>
<td>Properties</td>
</tr>
<tr>
<td>systemProperties Mode (common)</td>
<td>Sets the system property mode.</td>
<td>2</td>
<td>int</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Properties endpoint is configured using URI syntax:

```
properties:key
```

with the following path and query parameters:

250.2.1. Path Parameters (1 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td><strong>Required</strong> Property key to use as placeholder</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 250.2.2. Query Parameters (6 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ignoreMissingLocation (common)</td>
<td>Whether to silently ignore if a location cannot be located, such as a properties file not found.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>locations (common)</td>
<td>A list of locations to load properties. You can use comma to separate multiple locations. This option will override any default locations and only use the locations from this option.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the default exchange pattern when creating an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### TIP

**Resolving property from Java code**

You can use the method `resolvePropertyPlaceholders` on the `CamelContext` to resolve a property from any Java code.

### 250.3. USING PROPERTYPLACEHOLDER

**Available as of Camel 2.3**
Camel now provides a new PropertiesComponent in camel-core which allows you to use property placeholders when defining Camel Endpoint URIs.

This works much like you would do if using Spring’s `<property-placeholder>` tag. However Spring have a limitation which prevents 3rd party frameworks to leverage Spring property placeholders to the fullest. See more at How do I use Spring Property Placeholder with Camel XML.

**TIP**

**Bridging Spring and Camel property placeholders**

From Camel 2.10 onwards, you can bridge the Spring property placeholder with Camel, see further below for more details.

The property placeholder is generally in use when doing:

- lookup or creating endpoints
- lookup of beans in the Registry
- additional supported in Spring XML (see below in examples)
- using Blueprint PropertyPlaceholder with Camel Properties component
- using `@PropertyInject` to inject a property in a POJO
- **Camel 2.14.1** Using default value if a property does not exists
- **Camel 2.14.1** Include out of the box functions, to lookup property values from OS environment variables, JVM system properties, or the service idiom.
- **Camel 2.14.1** Using custom functions, which can be plugged into the property component.

### 250.4. SYNTAX

The syntax to use Camel’s property placeholder is to use `{{key}}` for example `{{file.uri}}` where `file.uri` is the property key.

You can use property placeholders in parts of the endpoint URI’s which for example you can use placeholders for parameters in the URIs.

From **Camel 2.14.1** onwards you can specify a default value to use if a property with the key does not exists, eg `file.url:/some/path` where the default value is the text after the colon (eg /some/path).

**NOTE**

Do not use colon in the property key. The colon is used as a separator token when you are providing a default value, which is supported from **Camel 2.14.1** onwards.

### 250.5. PROPERTYRESOLVER

Camel provides a pluggable mechanism which allows 3rd part to provide their own resolver to lookup properties. Camel provides a default implementation `org.apache.camel.component.properties.DefaultPropertiesResolver` which is capable of loading properties from the file system, classpath or Registry. You can prefix the locations with either:
250.6. DEFINING LOCATION

The PropertiesResolver need to know a location(s) where to resolve the properties. You can define 1 to many locations. If you define the location in a single String property you can separate multiple locations with comma such as:

```java
pc.setLocation("com/mycompany/myprop.properties,com/mycompany/other.properties");
```

Available as of Camel 2.19.0

You can set which location can be discarded if missing by by setting the optional attribute, which is false by default, i.e:

```java
pc.setLocations(
  "com/mycompany/override.properties;optional=true"
  "com/mycompany/defaults.properties");
```

250.7. USING SYSTEM AND ENVIRONMENT VARIABLES IN LOCATIONS

Available as of Camel 2.7

The location now supports using placeholders for JVM system properties and OS environments variables.

For example:

```java
location=file:${karaf.home}/etc/foo.properties
```

In the location above we defined a location using the file scheme using the JVM system property with key karaf.home.

To use an OS environment variable instead you would have to prefix with env:

```java
location=file:${env:APP_HOME}/etc/foo.properties
```

Where APP_HOME is an OS environment.

You can have multiple placeholders in the same location, such as:

```java
location=file:${env:APP_HOME}/etc/${prop.name}.properties
```

#=== Using system and environment variables to configure property prefixes and suffixes

Available as of Camel 2.12.5, 2.13.3, 2.14.0
**propertyPrefix, propertySuffix** configuration properties support using placeholders for JVM system properties and OS environments variables.

For example, if **PropertiesComponent** is configured with the following properties file:

```
dev.endpoint = result1
test.endpoint = result2
```

Then with the following route definition:

```java
PropertiesComponent pc = context.getComponent("properties", PropertiesComponent.class);
pc.setPropertyPrefix("${stage}.");
// ...
context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("direct:start").to("mock:{{endpoint}}");
    }
});
```

it is possible to change the target endpoint by changing system property `stage` either to `dev` (the message will be routed to `mock:result1`) or `test` (the message will be routed to `mock:result2`).

### 250.8. CONFIGURING IN JAVA DSL

You have to create and register the **PropertiesComponent** under the name `properties` such as:

```java
PropertiesComponent pc = new PropertiesComponent();
pc.setLocation("classpath:com/mycompany/myprop.properties");
context.addComponent("properties", pc);
```

### 250.9. CONFIGURING IN SPRING XML

Spring XML offers two variations to configure. You can define a spring bean as a **PropertiesComponent** which resembles the way done in Java DSL. Or you can use the `<propertyPlaceholder>` tag.

```xml
<bean id="properties" class="org.apache.camel.component.properties.PropertiesComponent">
    <property name="location" value="classpath:com/mycompany/myprop.properties"/>
</bean>
```

Using the `<propertyPlaceholder>` tag makes the configuration a bit more fresh such as:

```xml
<camelContext ...>
    <propertyPlaceholder id="properties" location="com/mycompany/myprop.properties"/>
</camelContext>
```

Setting the properties location through the location tag works just fine but sometime you have a number of resources to take into account and starting from Camel 2.19.0 you can set the properties location with a dedicated propertiesLocation:
TIP

Specifying the cache option inside XML
Camel 2.10 onwards supports specifying a value for the cache option both inside the Spring as well as the Blueprint XML.

250.10. USING A PROPERTIES FROM THE REGISTRY

Available as of Camel 2.4
For example in OSGi you may want to expose a service which returns the properties as a java.util.Properties object.

Then you could setup the Properties component as follows:

```xml
<propertyPlaceholder id="properties" location="ref:myProperties"/>
```

Where myProperties is the id to use for lookup in the OSGi registry. Notice we use the ref: prefix to tell Camel that it should lookup the properties for the Registry.

250.11. EXAMPLES USING PROPERTIES COMPONENT

When using property placeholders in the endpoint URIs you can either use the properties: component or define the placeholders directly in the URI. We will show example of both cases, starting with the former.

```java
// properties
cool.end=mock:result

// route
from("direct:start").to("properties:{{cool.end}}");
```

You can also use placeholders as a part of the endpoint uri:

```java
// properties
cool.foo=result

// route
from("direct:start").to("properties:mock:{{cool.foo}}");
```
In the example above the to endpoint will be resolved to `mock:result`.

You can also have properties with refer to each other such as:

```java
// properties
cool.foo = result
cool.concat = mock:{{cool.foo}}

// route
from("direct:start").to("properties:mock:{{cool.concat}}");
```

Notice how `cool.concat` refer to another property.

The `properties` component also offers you to override and provide a location in the given uri using the `locations` option:

```java
from("direct:start").to("properties:bar.end?locations=com/mycompany/bar.properties");
```

### 250.12. EXAMPLES

You can also use property placeholders directly in the endpoint uris without having to use `properties`:

```java
// properties
cool.foo = result

// route
from("direct:start").to("mock:{{cool.foo}}");
```

And you can use them in multiple wherever you want them:

```java
// properties
cool.start = direct:start
cool.showid = true
cool.result = result

// route
from("{{cool.start}}")
  .to("log:{{cool.start}}?showBodyType=false&showExchangeId={{cool.showid}}")
  .to("mock:{{cool.result}}");
```

You can also your property placeholders when using ProducerTemplate for example:

```java
template.sendBody("{{cool.start}}", "Hello World");
```

### 250.13. EXAMPLE WITH SIMPLE LANGUAGE

The Simple language now also support using property placeholders, for example in the route below:

```java
// properties
cheese.quote = Camel rocks
```
You can also specify the location in the Simple language for example:

```
// bar.properties
bar.quote=Beer tastes good
```

// route
from("direct:start")
.transform().simple("Hi ${body} do you think ${properties:cheese.quote}?");

You can also define property placeholders in the various attributes on the <camelContext> tag such as trace as shown here:

```
PropertiesComponent pc = context.getComponent("properties", PropertiesComponent.class);
pc.setCache(false);

context.addRoutes(new RouteBuilder() {
  @Override
  public void configure() throws Exception {
    from("direct:start").to("properties:cool.end");
    from("direct:foo").to("properties:mock:{{cool.result}}");
  }
});
```

```
context.start();
```

```
getMockEndpoint("mock:override").expectedMessageCount(2);
```

```
template.sendBody("direct:start", "Hello World");
template.sendBody("direct:foo", "Hello Foo");
```

250.14. ADDITIONAL PROPERTY PLACEHOLDER SUPPORTED IN SPRING XML

The property placeholders is also supported in many of the Camel Spring XML tags such as `<package>`, `<packageScan>`, `<contextScan>`, `<jmxAgent>`, `<endpoint>`, `<routeBuilder>`, `<proxy>` and the others.

The example below has property placeholder in the `<jmxAgent>` tag:

```
You can also define property placeholders in the various attributes on the `<camelContext>` tag such as trace as shown here:
```

250.15. OVERRIDING A PROPERTY SETTING USING A JVM SYSTEM PROPERTY

Available as of Camel 2.5

It is possible to override a property value at runtime using a JVM System property without the need to restart the application to pick up the change. This may also be accomplished from the command line by creating a JVM System property of the same name as the property it replaces with a new value. An example of this is given below

```
PropertiesComponent pc = context.getComponent("properties", PropertiesComponent.class);
pc.setCache(false);

System.setProperty("cool.end", "mock:override");
System.setProperty("cool.result", "override");

context.addRoutes(new RouteBuilder() {
  @Override
  public void configure() throws Exception {
    from("direct:start").to("properties:cool.end");
    from("direct:foo").to("properties:mock:{{cool.result}}");
  }
});
context.start();
```

```
getMockEndpoint("mock:override").expectedMessageCount(2);
```

```
template.sendBody("direct:start", "Hello World");
template.sendBody("direct:foo", "Hello Foo");
```
250.16. USING PROPERTY PLACEHOLDERS FOR ANY KIND OF ATTRIBUTE IN THE XML DSL

Available as of Camel 2.7

NOTE

If you use OSGi Blueprint then this only works from 2.11.1 or 2.10.5 onwards.

Previously it was only the **xs:string** type attributes in the XML DSL that support placeholders. For example often a timeout attribute would be a **xs:int** type and thus you cannot set a string value as the placeholder key. This is now possible from Camel 2.7 onwards using a special placeholder namespace.

In the example below we use the **prop** prefix for the namespace **http://camel.apache.org/schema/placeholder** by which we can use the **prop** prefix in the attributes in the XML DSLs. Notice how we use that in the Multicast to indicate that the option **stopOnException** should be the value of the placeholder with the key "stop".

In our properties file we have the value defined as

```
stop=true
```

250.17. USING BLUEPRINT PROPERTY PLACEHOLDER WITH CAMEL ROUTES

Available as of Camel 2.7

Camel supports Blueprint which also offers a property placeholder service. Camel supports convention over configuration, so all you have to do is to define the OSGi Blueprint property placeholder in the XML file as shown below:

```
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:cm="http://aries.apache.org/blueprint/xmlns/blueprint-cm/v1.0.0"
  xsi:schemaLocation="http://www.osgi.org/xmlns/blueprint/v1.0.0
  https://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd">
  <!-- OSGI blueprint property placeholder -->
  <cm:property-placeholder id="myblueprint.placeholder" persistent-id="camel.blueprint">
    <!-- list some properties as needed -->
    <cm:default-properties>
      <cm:property name="result" value="mock:result"/>
    </cm:default-properties>
  </cm:property-placeholder>
</blueprint>
```
250.17.1. Using OSGi blueprint property placeholders in Camel routes

By default Camel detects and uses OSGi blueprint property placeholder service. You can disable this by setting the attribute `useBlueprintPropertyResolver` to false on the `<camelContext>` definition.

250.17.2. About placeholder syntax

Notice how we can use the Camel syntax for placeholders {{ and }} in the Camel route, which will lookup the value from OSGi blueprint.

The blueprint syntax for placeholders is ${{}. So outside the `<camelContext>` you must use the ${} syntax. Where as inside `<camelContext>` you must use {{ and }} syntax.

OSGi blueprint allows you to configure the syntax, so you can actually align those if you want.

You can also explicit refer to a specific OSGi blueprint property placeholder by its id. For that you need to use the Camel's `<propertyPlaceholder>` as shown in the example below:
250.18. EXPLICIT REFERRING TO A OSGI BLUEPRINT PLACEHOLDER IN CAMEL

Notice how we use the blueprint scheme to refer to the OSGi blueprint placeholder by its id. This allows you to mix and match, for example you can also have additional schemes in the location. For example to load a file from the classpath you can do:

```
location="blueprint:myblueprint.placeholder,classpath:myproperties.properties"
```

Each location is separated by comma.

250.19. OVERRIDING BLUEPRINT PROPERTY PLACEHOLDERS OUTSIDE CAMELCONTEXT

Available as of Camel 2.10.4

When using Blueprint property placeholder in the Blueprint XML file, you can declare the properties directly in the XML file as shown below:

Notice that we have a `<bean>` which refers to one of the properties. And in the Camel route we refer to the other using the `{}` notation.

Now if you want to override these Blueprint properties from an unit test, you can do this as shown below:

To do this we override and implement the `useOverridePropertiesWithConfigAdmin` method. We can then put the properties we want to override on the given props parameter. And the return value must be the persistence-id of the `<cm:property-placeholder>` tag, which you define in the blueprint XML file.

250.20. USING .CFG OR .PROPERTIES FILE FOR BLUEPRINT PROPERTY PLACEHOLDERS

Available as of Camel 2.10.4

When using Blueprint property placeholder in the Blueprint XML file, you can declare the properties in a `.properties` or `.cfg` file. If you use Apache ServieMix / Karaf then this container has a convention that it loads the properties from a file in the etc directory with the naming `etc/pid.cfg`, where `pid` is the persistence-id.

For example in the blueprint XML file we have the `persistence-id="stuff"`, which mean it will load the configuration file as `etc/stuff.cfg`.

Now if you want to unit test this blueprint XML file, then you can override the `loadConfigAdminConfigurationFile` and tell Camel which file to load as shown below:

Notice that this method requires to return a `String[]` with 2 values. The 1st value is the path for the configuration file to load. The 2nd value is the persistence-id of the `<cm:property-placeholder>` tag.

The `stuff.cfg` file is just a plain properties file with the property placeholders such as:
250.21. USING .CFG FILE AND OVERRIDING PROPERTIES FOR BLUEPRINT PROPERTY PLACEHOLDERS

You can do both as well. Here is a complete example. First we have the Blueprint XML file:

And in the unit test class we do as follows:

And the `etc/stuff.cfg` configuration file contains:

```
greeting=Bye
echo=Yay
destination=mock:result
```

250.22. BRIDGING SPRING AND CAMEL PROPERTY PLACEHOLDERS

Available as of Camel 2.10

The Spring Framework does not allow 3rd party frameworks such as Apache Camel to seamless hook into the Spring property placeholder mechanism. However you can easily bridge Spring and Camel by declaring a Spring bean with the type `org.apache.camel.spring.spi.BridgePropertyPlaceholderConfigurer`, which is a Spring `org.springframework.beans.factory.config.PropertyPlaceholderConfigurer` type.

To bridge Spring and Camel you must define a single bean as shown below:

**Bridging Spring and Camel property placeholders**

You **must not** use the spring `<context:property-placeholder>` namespace at the same time; this is not possible.

After declaring this bean, you can define property placeholders using both the Spring style, and the Camel style within the `<camelContext>` tag as shown below:

**Using bridge property placeholders**

Notice how the hello bean is using pure Spring property placeholders using the `${ }` notation. And in the Camel routes we use the Camel placeholder notation with `{{ and }}`.

250.23. CLASHING SPRING PROPERTY PLACEHOLDERS WITH CAMELS SIMPLE LANGUAGE

Take notice when using Spring bridging placeholder then the spring `${ }` syntax clashes with the Simple in Camel, and therefore take care. For example:

```
<setHeader headerName="Exchange.FILE_NAME">
  <simple>{{file.rootdir}}/${in.header.CamelFileName}</simple>
</setHeader>
```

clashes with Spring property placeholders, and you should use `$simple{ }` to indicate using the Simple language in Camel.
An alternative is to configure the `PropertyPlaceholderConfigurer` with `ignoreUnresolvablePlaceholders` option to `true`.

### 250.24. OVERRIDING PROPERTIES FROM CAMEL TEST KIT

Available as of Camel 2.10

When Testing with Camel and using the `Properties` component, you may want to be able to provide the properties to be used from directly within the unit test source code. This is now possible from Camel 2.10 onwards, as the Camel test kits, eg `CamelTestSupport` class offers the following methods:

- `useOverridePropertiesWithPropertiesComponent`
- `ignoreMissingLocationWithPropertiesComponent`

So for example in your unit test classes, you can override the `useOverridePropertiesWithPropertiesComponent` method and return a `java.util.Properties` that contains the properties which should be preferred to be used.

#### 250.24.1. Providing properties from within unit test source

This can be done from any of the Camel Test kits, such as camel-test, camel-test-spring, and camel-test-blueprint.

The `ignoreMissingLocationWithPropertiesComponent` can be used to instruct Camel to ignore any locations which was not discoverable, for example if you run the unit test, in an environment that does not have access to the location of the properties.

### 250.25. USING `@PROPERTYINJECT`

Available as of Camel 2.12

Camel allows to inject property placeholders in POJOs using the `@PropertyInject` annotation which can be set on fields and setter methods.

For example you can use that with `RouteBuilder` classes, such as shown below:

```java
public class MyRouteBuilder extends RouteBuilder {

    @PropertyInject("hello")
    private String greeting;

    @Override
    public void configure() throws Exception {
        from("direct:start")
            .transform().constant(greeting)
            .to("{{result}}");
    }
}
```
Notice we have annotated the greeting field with `@PropertyInject` and define it to use the key "hello". Camel will then lookup the property with this key and inject its value, converted to a String type.

You can also use multiple placeholders and text in the key, for example we can do:

```java
@PropertyInject("Hello {{name}} how are you?")
private String greeting;
```

This will lookup the placeholder with they key "name".

You can also add a default value if the key does not exists, such as:

```java
@PropertyInject(value = "myTimeout", defaultValue = "5000")
private int timeout;
```

### 250.26. USING OUT OF THE BOX FUNCTIONS

Available as of Camel 2.14.1

The Properties component includes the following functions out of the box

- **env** - A function to lookup the property from OS environment variables
- **sys** - A function to lookup the property from Java JVM system properties
- **service** - A function to lookup the property from OS environment variables using the service naming idiom
- **service.name** - Camel 2.16.1: A function to lookup the property from OS environment variables using the service naming idiom returning the hostname part only
- **service.port** - Camel 2.16.1: A function to lookup the property from OS environment variables using the service naming idiom returning the port part only

As you can see these functions is intended to make it easy to lookup values from the environment. As they are provided out of the box, they can easily be used as shown below:

```xml
<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <route>
    <from uri="direct:start"/>
    <to uri="\{\{env:SOMENAME\}\}"/>
    <to uri="\{\{sys:MyJvmPropertyName\}\}"/>
  </route>
</camelContext>
```

You can use default values as well, so if the property does not exists, you can define a default value as shown below, where the default value is a **log:foo** and **log:bar** value.

```xml
<camelContext xmlns="http://camel.apache.org/schema/blueprint">
</camelContext>
```
The service function is for looking up a service which is defined using OS environment variables using the service naming idiom, to refer to a service location using `hostname : port`

- `NAME_SERVICE_HOST`
- `NAME_SERVICE_PORT`

In other words the service uses `SERVICE_HOST` and `SERVICE_PORT` as prefix. So if the service is named FOO, then the OS environment variables should be set as

```bash
export $FOO_SERVICE_HOST=myserver
export $FOO_SERVICE_PORT=8888
```

For example if the FOO service a remote HTTP service, then we can refer to the service in the Camel endpoint uri, and use the HTTP component to make the HTTP call:

```xml
<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <route>
    <from uri="direct:start"/>
    <to uri="http://{service:FOO}/myapp"/>
  </route>
</camelContext>
```

And we can use default values if the service has not been defined, for example to call a service on localhost, maybe for unit testing etc

```xml
<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <route>
    <from uri="direct:start"/>
    <to uri="http://{service:FOO:localhost:8080}/myapp"/>
  </route>
</camelContext>
```

## 250.27. USING CUSTOM FUNCTIONS

Available as of Camel 2.14.1

The `Properties` component allow to plugin 3rd party functions which can be used during parsing of the property placeholders. These functions are then able to do custom logic to resolve the placeholders, such as looking up in databases, do custom computations, or whatnot. The name of the function becomes the prefix used in the placeholder. This is best illustrated in the example code below

```xml
<bean id="beerFunction" class="MyBeerFunction"/>
```
NOTE
from camel 2.19.0 the location attribute (on propertyPlaceholder tag) is not more mandatory

Here we have a Camel XML route where we have defined the `<propertyPlaceholder>` to use a custom function, which we refer to be the bean id - eg the `beerFunction`. As the beer function uses "beer" as its name, then the placeholder syntax can trigger the beer function by starting with `beer:value`.

The implementation of the function is only two methods as shown below:

```java
public static final class MyBeerFunction implements PropertiesFunction {

    @Override
    public String getName() {
        return "beer";
    }

    @Override
    public String apply(String remainder) {
        return "mock:" + remainder.toLowerCase();
    }
}
```

The function must implement the `org.apache.camel.component.properties.PropertiesFunction` interface. The method `getName` is the name of the function, eg beer. And the `apply` method is where we implement the custom logic to do. As the sample code is from an unit test, it just returns a value to refer to a mock endpoint.

To register a custom function from Java code is as shown below:

```java
PropertiesComponent pc = context.getComponent("properties", PropertiesComponent.class);
pc.addFunction(new MyBeerFunction());
```

CHAPTER 251. PROTOBUF DATAFORMAT

Available as of Camel version 2.2.0
CHAPTER 252. PROTOBUF - PROTOCOL BUFFERS

"Protocol Buffers - Google’s data interchange format"

Camel provides a Data Format to serialize between Java and the Protocol Buffer protocol. The project’s site details why you may wish to choose this format over xml. Protocol Buffer is language-neutral and platform-neutral, so messages produced by your Camel routes may be consumed by other language implementations.

API Site
Protobuf Implementation
Protobuf Java Tutorial

252.1. PROTOBUF OPTIONS

The Protobuf dataformat supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instanceClass</td>
<td>String</td>
<td></td>
<td>Name of class to use when unmarshalling</td>
</tr>
<tr>
<td>contentTypeFormat</td>
<td>native</td>
<td>String</td>
<td>Defines a content type format in which protobuf message will be serialized/deserialized from/to the Java been. The format can either be native or json for either native protobuf or json fields representation. The default value is native.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

252.2. CONTENT TYPE FORMAT (STARTING FROM CAMEL 2.19)

It’s possible to parse JSON message to convert it to the protobuf format and unpars it back using native util converter. To use this option, set contentTypeFormat value to 'json' or call protobuf with second parameter. If default instance is not specified, always use native protobuf format. The sample code shows below:

```java
from("direct:marshal")
    .unmarshal()
    .protobuf("org.apache.camel.dataformat.protobuf.generated.AddressBookProtos$Person", "json")
    .to("mock:reverse");
```

252.3. PROTOBUF OVERVIEW

This quick overview of how to use Protobuf. For more detail see the complete tutorial
252.4. DEFINING THE PROTO FORMAT

The first step is to define the format for the body of your exchange. This is defined in a .proto file as so:

addressbook.proto

```proto
syntax = "proto2";

package org.apache.camel.component.protobuf;

option java_package = "org.apache.camel.component.protobuf";
option java_outer_classname = "AddressBookProtos";

message Person {
  required string name = 1;
  required int32 id = 2;
  optional string email = 3;
}

enum PhoneType {
  MOBILE = 0;
  HOME = 1;
  WORK = 2;
}

message PhoneNumber {
  required string number = 1;
  optional PhoneType type = 2 [default = HOME];
}

  repeated PhoneNumber phone = 4;
}

message AddressBook {
  repeated Person person = 1;
}
```

252.5. GENERATING JAVA CLASSES

The Protobuf SDK provides a compiler which will generate the Java classes for the format we defined in our .proto file. If your operating system is supporting by Protobuf Java code generator maven plugin, you can automate protobuf Java code generating by adding following configurations to your pom.xml:

Insert operating system and CPU architecture detection extension inside `<build>` tag of the project pom.xml or set `${os.detected.classifier}` parameter manually

```
<extensions>
  <extension>
    <groupId>kr.motd.maven</groupId>
    <artifactId>os-maven-plugin</artifactId>
    <version>1.4.1.Final</version>
  </extension>
</extensions>
```

Insert gRPC and protobuf Java code generator plugin `<plugins>` tag of the project pom.xml

-
You can also run the compiler for any additional supported languages you require manually.

```bash
protoc --java_out= ./proto/addressbook.proto
```

This will generate a single Java class named AddressBookProtos which contains inner classes for Person and AddressBook. Builders are also implemented for you. The generated classes implement com.google.protobuf.Message which is required by the serialization mechanism. For this reason it important that only these classes are used in the body of your exchanges. Camel will throw an exception on route creation if you attempt to tell the Data Format to use a class that does not implement com.google.protobuf.Message. Use the generated builders to translate the data from any of your existing domain classes.

### 252.6. JAVA DSL

You can use create the ProtobufDataFormat instance and pass it to Camel DataFormat marshal and unmarshal API like this.

```java
ProtobufDataFormat format = new ProtobufDataFormat(Person.getDefaultInstance());
from("direct:in").marshal(format);
from("direct:back").unmarshal(format).to("mock:reverse");
```

Or use the DSL protobuf() passing the unmarshal default instance or default instance class name like this.

```java
// You don't need to specify the default instance for protobuf marshaling
from("direct:marshal").marshal().protobuf();
from("direct:unmarshalA").unmarshal().protobuf("org.apache.camel.dataformat.protobuf.generated.AddressBookProtos$Person").to("mock:reverse");
from("direct:unmarshalB").unmarshal().protobuf(Person.getDefaultInstance()).to("mock:reverse");
```

### 252.7. SPRING DSL
The following example shows how to use Protobuf to unmarshal using Spring configuring the protobuf data type

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <unmarshal>
      <protobuf
        instanceClass="org.apache.camel.dataformat.protobuf.generated.AddressBookProtos$Person" />
    </unmarshal>
    <to uri="mock:result"/>
  </route>
</camelContext>
```

### 252.8. DEPENDENCIES

To use Protobuf in your camel routes you need to add the a dependency on `camel-protobuf` which implements this data format.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-protobuf</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 252.9. SEE ALSO

- Camel gRPC component
CHAPTER 253. PUBNUB COMPONENT

Available as of Camel version 2.19

Camel PubNub component can be used to communicate with the PubNub data stream network for connected devices. This component uses pubnub java library.

Use cases includes:

- Chat rooms: Sending and receiving messages
- Locations and Connected cars: dispatching taxi cabs
- Smart sensors: Receiving data from a sensor for data visualizations
- Health: Monitoring heart rate from a patient's wearable device
- Multiplayer gamings
- Interactive media: audience-participating voting system

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-pubnub</artifactId>
  <version>x.x.x</version>
</dependency>
```

253.1. URI FORMAT

```
pubnub:channel[?options]
```

Where `channel` is the PubNub channel to publish or subscribe to.

253.2. OPTIONS

The PubNub component has no options.

The PubNub endpoint is configured using URI syntax:

```
pubnub:channel
```

with the following path and query parameters:

253.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### 253.2.2. Query Parameters (14 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid</code> (common)</td>
<td>UUID to be used as a device identifier, a default UUID is generated if not passed.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>bridgeErrorHandler</code></td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>withPresence</code> (consumer)</td>
<td>Also subscribe to related presence information</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>exceptionHandler</code> (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td><code>exchangePattern</code> (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>operation</strong> (producer)</td>
<td>The operation to perform. PUBLISH: Default. Send a message to all subscribers of a channel. FIRE: allows the client to send a message to BLOCKS Event Handlers. These messages will go directly to any Event Handlers registered on the channel. HERENOW: Obtain information about the current state of a channel including a list of unique user-ids currently subscribed to the channel and the total occupancy count. WHERE NOW: Obtain information about the current list of channels to which a uuid is subscribed to. GETSTATE: Used to get key/value pairs specific to a subscriber uuid. State information is supplied as a JSON object of key/value pairs. SETSTATE: Used to set key/value pairs specific to a subscriber uuid. GETHISTORY: Fetches historical messages of a channel.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>pubnub</strong> (advanced)</td>
<td>Reference to a Pubnub client in the registry.</td>
<td></td>
<td>PubNub</td>
</tr>
<tr>
<td><strong>synchronous</strong> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>authKey</strong> (security)</td>
<td>If Access Manager is utilized, client will use this authKey in all restricted requests.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>cipherKey</strong> (security)</td>
<td>If cipher is passed, all communications to/from PubNub will be encrypted.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>publishKey</strong> (security)</td>
<td>The publish key obtained from your PubNub account. Required when publishing messages.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>secretKey</strong> (security)</td>
<td>The secret key used for message signing.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>secure</strong> (security)</td>
<td>Use SSL for secure transmission.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>subscribeKey</strong> (security)</td>
<td>The subscribe key obtained from your PubNub account. Required when subscribing to channels or listening for presence events</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

**253.3. MESSAGE HEADERS WHEN SUBSCRIBING**
### 253.4. MESSAGE BODY

The message body can contain any JSON serializable data, including: Objects, Arrays, Ints and Strings. Message data should not contain special Java V4 classes or functions as these will not serialize. String content can include any single-byte or multi-byte UTF-8.

Object serialization when sending is done automatically. Just pass the full object as the message payload. PubNub will take care of object serialization.

When receiving the message body utilize objects provided by the PubNub API.

### 253.5. EXAMPLES

#### 253.5.1. Publishing events

Default operation when producing. The following snippet publish the event generated by PojoBean to the channel iot.

```java
from("timer:mytimer")
    // generate some data as POJO.
    .bean(PojoBean.class)
    .to("pubnub:iot?publishKey=mypublishKey");
```

#### 253.5.2. Fire events aka BLOCKS Event Handlers

See [https://www.pubnub.com/blocks-catalog/](https://www.pubnub.com/blocks-catalog/) for all kind of serverless functions that can be invoked. Example of geolocation lookup

```java
from("timer:geotimer")
    .process(exchange -> exchange.getIn().setBody(new Foo("bar", "TEXT")))
    .to("pubnub:eon-maps-geolocation-input?operation=fire&publishKey=mypubkey&subscribeKey=mysubkey");
```

#### 253.5.3. Subscribing to events

The following snippet listens for events on the iot channel. If you can add the option withPresens, you will also receive channel Join, Leave asf events.

```java
from("timer:mytimer")
    .process(exchange -> exchange.getIn().setBody(new Foo("bar", "TEXT")))
    .to("pubnub:eon-maps-geolocation-input?operation=fire&publishKey=mypubkey&subscribeKey=mysubkey");
    .log("${body}");
```

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelPubNubTimeToken</td>
<td>The Timestamp for the event.</td>
</tr>
<tr>
<td>CamelPubNubChannel</td>
<td>The channel for which the message belongs.</td>
</tr>
</tbody>
</table>
from("pubnub:iot?subscribeKey=mySubscribeKey")
    .log("${body}")
    .to("mock:result");

253.5.4. Performing operations

**herenow** : Obtain information about the current state of a channel including a list of unique user-ids currently subscribed to the channel and the total occupancy count of the channel

from("direct:control")
    .to("pubnub:myChannel?publishKey=mypublishKey&subscribeKey=mySubscribeKey&operation=herenow")
    .to("mock:result");

**wherenow** : Obtain information about the current list of channels to which a uuid is subscribed

from("direct:control")
    .to("pubnub:myChannel?publishKey=mypublishKey&subscribeKey=mySubscribeKey&operation=wherenow&uuid=spyonme")
    .to("mock:result");

**setstate** : Used to set key/value pairs specific to a subscriber uuid.

from("direct:control")
    .bean(StateGenerator.class)
    .to("pubnub:myChannel?publishKey=mypublishKey&subscribeKey=mySubscribeKey&operation=setstate&uuid=myuuid");

gethistory : Fetches historical messages of a channel.

from("direct:control")
    .to("pubnub:myChannel?publishKey=mypublishKey&subscribeKey=mySubscribeKey&operation=gethistory");

There is a couple of examples in test directory that shows some of the PubNub features. They require a PubNub account, from where you can obtain a publish- and subscribe key.

The example PubNubSensorExample already contains a subscribe key provided by PubNub, so this is ready to run without a account. The example illustrates the PubNub component subscribing to a infinite stream of sensor data.

CHAPTER 254. QUARTZ COMPONENT (DEPRECATED)

Available as of Camel version 1.0

The quartz: component provides a scheduled delivery of messages using the Quartz Scheduler 1.x. Each endpoint represents a different timer (in Quartz terms, a Trigger and JobDetail).

TIP

If you are using Quartz 2.x then from Camel 2.12 onwards there is a Quartz2 component you should use.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-quartz</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

254.1. URI FORMAT

quartz://timerName?options
quartz://groupName/timerName?options
quartz://groupName/timerName?cron=expression
quartz://timerName?cron=expression

The component uses either a CronTrigger or a SimpleTrigger. If no cron expression is provided, the component uses a simple trigger. If no groupName is provided, the quartz component uses the Camel group name.

You can append query options to the URI in the following format, ?option=value&option=value&...

254.2. OPTIONS

The Quartz component supports 8 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>factory (advanced)</td>
<td>To use the custom SchedulerFactory which is used to create the Scheduler.</td>
<td></td>
<td>SchedulerFactory</td>
</tr>
<tr>
<td>scheduler (advanced)</td>
<td>To use the custom configured Quartz scheduler, instead of creating a new Scheduler.</td>
<td></td>
<td>Scheduler</td>
</tr>
<tr>
<td>properties (consumer)</td>
<td>Properties to configure the Quartz scheduler.</td>
<td></td>
<td>Properties</td>
</tr>
</tbody>
</table>
The Quartz endpoint is configured using URI syntax:

```
quartz:groupName/timerName
```

with the following path and query parameters:

### 254.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupName</td>
<td>The quartz group name to use. The combination of group name and timer name should be unique.</td>
<td>Camel</td>
<td>String</td>
</tr>
<tr>
<td>timerName</td>
<td>Required The quartz timer name to use. The combination of group name and timer name should be unique.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 254.2.2. Query Parameters (13 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>cron (consumer)</td>
<td>Specifies a cron expression to define when to trigger.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>deleteJob (consumer)</td>
<td>If set to true, then the trigger automatically delete when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both deleteJob and pauseJob set to true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>fireNow (consumer)</td>
<td>Whether to fire the scheduler asap when its started using the simple trigger (this option does not support cron)</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>pauseJob (consumer)</td>
<td>If set to true, then the trigger automatically pauses when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both deleteJob and pauseJob set to true.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>startDelayedSeconds (consumer)</td>
<td>Seconds to wait before starting the quartz scheduler.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>stateful (consumer)</td>
<td>Uses a Quartz StatefulJob instead of the default job.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>usingFixedCamelContextName (consumer)</td>
<td>If it is true, JobDataMap uses the CamelContext name directly to reference the CamelContext, if it is false, JobDataMap uses use the CamelContext management name which could be changed during the deploy time.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
exceptionHandler (consumer) | To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored. | ExceptionHandler

exchangePattern (consumer) | Sets the exchange pattern when the consumer creates an exchange. | ExchangePattern

jobParameters (advanced) | To configure additional options on the job. | Map

synchronous (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false, boolean

triggerParameters (advanced) | To configure additional options on the trigger. | Map

When using a StatefulJob, the JobDataMap is re-persisted after every execution of the job, thus preserving state for the next execution.

INFO: Running in OSGi and having multiple bundles with quartz routes if you run in OSGi such as Apache ServiceMix, or Apache Karaf, and have multiple bundles with Camel routes that start from Quartz endpoints, then make sure if you assign an id to the <camelContext> that this id is unique, as this is required by the QuartzScheduler in the OSGi container. If you do not set any id on <camelContext> then a unique id is auto assigned, and there is no problem.

### 254.3. CONFIGURING QUARTZ.PROPERTIES FILE

By default Quartz will look for a quartz.properties file in the org/quartz directory of the classpath. If you are using WAR deployments this means just drop the quartz.properties in WEB-INF/classes/org/quartz.

However the Camel Quartz component also allows you to configure properties:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>properties</td>
<td>null</td>
<td>Properties</td>
<td>Camel 2.4: You can configure a java.util.Properties instance.</td>
</tr>
<tr>
<td>propertiesFile</td>
<td>null</td>
<td>String</td>
<td>Camel 2.4: File name of the properties to load from the classpath</td>
</tr>
</tbody>
</table>
To do this you can configure this in Spring XML as follows

```xml
<bean id="quartz" class="org.apache.camel.component.quartz.QuartzComponent">
  <property name="propertiesFile" value="com/mycompany/myquartz.properties"/>
</bean>
```

### 254.4. ENABLING QUARTZ SCHEDULER IN JMX

You need to configure the quartz scheduler properties to enable JMX. That is typically setting the option "org.quartz.scheduler.jmx.export" to a `true` value in the configuration file.

From Camel 2.13 onwards Camel will automatic set this option to true, unless explicit disabled.

### 254.5. STARTING THE QUARTZ SCHEDULER

This is an example:

```xml
<bean id="quartz" class="org.apache.camel.component.quartz.QuartzComponent">
  <property name="startDelayedSeconds" value="5"/>
</bean>
```

### 254.6. CLUSTERING

Available as of Camel 2.4

If you use Quartz in clustered mode, e.g. the JobStore is clustered. Then from Camel 2.4 onwards the Quartz component will not pause/remove triggers when a node is being stopped/shutdown. This allows the trigger to keep running on the other nodes in the cluster.

**Note:** When running in clustered node no checking is done to ensure unique job name/group for endpoints.

### 254.7. MESSAGE HEADERS

Camel adds the getters from the Quartz Execution Context as header values. The following headers are added:

- calendar
- fireTime
- jobDetail
- jobInstanceId
- jobRuntime
- triggerName
- mergedJobDataMap
- nextFireTime
- previousFireTime
- refireCount
- result
- scheduledFiretime
- scheduler
- trigger
- triggerGroup

The `fireTime` header contains the `java.util.Date` of when the exchange was fired.

### 254.8. USING CRON TRIGGERS

Quartz supports Cron-like expressions for specifying timers in a handy format. You can use these expressions in the cron URI parameter; though to preserve valid URI encoding we allow + to be used instead of spaces. Quartz provides a little tutorial on how to use cron expressions.

For example, the following will fire a message every five minutes starting at 12pm (noon) to 6pm on weekdays:
from("quartz://myGroup/myTimerName?cron=0+0/5+12-18+?+*+MON-FRI").to("activemq:Totally.Rocks");

which is equivalent to using the cron expression

0 0/5 12-18 ? * MON-FRI

The following table shows the URI character encodings we use to preserve valid URI syntax:

<table>
<thead>
<tr>
<th>URI Character</th>
<th>Cron character</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Space</td>
</tr>
</tbody>
</table>

254.9. SPECIFYING TIME ZONE

Available as of Camel 2.8.1

The Quartz Scheduler allows you to configure time zone per trigger. For example to use a timezone of your country, then you can do as follows:

quartz://groupName/timerName?cron=0+0/5+12-18+?+*+MON-FRI&trigger.timeZone=Europe/Stockholm

The timeZone value is the values accepted by java.util.TimeZone.

In Camel 2.8.0 or older versions you would have to provide your custom String to java.util.TimeZone Type Converter to be able configure this from the endpoint uri.

From Camel 2.8.1 onwards we have included such a Type Converter in the camel-core.

254.10. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
- Quartz2
- Timer
CHAPTER 255. QUARTZ2 COMPONENT

Available as of Camel version 2.12

The quartz2: component provides a scheduled delivery of messages using the Quartz Scheduler 2.x. Each endpoint represents a different timer (in Quartz terms, a Trigger and JobDetail).

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-quartz2</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

NOTE: Quartz 2.x API is not compatible with Quartz 1.x. If you need to remain on old Quartz 1.x, please use the old Quartz component instead.

255.1. URI FORMAT

```
quartz2://timerName?options
quartz2://groupName/timerName?options
quartz2://groupName/timerName?cron=expression
quartz2://timerName?cron=expression
```

The component uses either a CronTrigger or a SimpleTrigger. If no cron expression is provided, the component uses a simple trigger. If no groupName is provided, the quartz component uses the Camel group name.

You can append query options to the URI in the following format, ?option=value&option=value&...

255.2. OPTIONS

The Quartz2 component supports 11 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>autoStartScheduler (scheduler)</td>
<td>Whether or not the scheduler should be auto started. This option is default true</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>startDelayedSeconds (scheduler)</td>
<td>Seconds to wait before starting the quartz scheduler.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>prefixJobNameWithEndpointId (consumer)</td>
<td>Whether to prefix the quartz job with the endpoint id. This option is default false.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------------</td>
</tr>
<tr>
<td>enableJmx</td>
<td>Whether to enable Quartz JMX which allows to manage the Quartz scheduler from JMX. This option is default true</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>properties</td>
<td>Properties to configure the Quartz scheduler.</td>
<td></td>
<td>Properties</td>
</tr>
<tr>
<td>propertiesFile</td>
<td>File name of the properties to load from the classpath</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>prefixInstanceName</td>
<td>Whether to prefix the Quartz Scheduler instance name with the CamelContext name. This is enabled by default, to let each CamelContext use its own Quartz scheduler instance by default. You can set this option to false to reuse Quartz scheduler instances between multiple CamelContext’s.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>interruptJobsOnShutdown</td>
<td>Whether to interrupt jobs on shutdown which forces the scheduler to shutdown quicker and attempt to interrupt any running jobs. If this is enabled then any running jobs can fail due to being interrupted.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>schedulerFactory</td>
<td>To use the custom SchedulerFactory which is used to create the Scheduler.</td>
<td></td>
<td>SchedulerFactory</td>
</tr>
<tr>
<td>scheduler</td>
<td>To use the custom configured Quartz scheduler, instead of creating a new Scheduler.</td>
<td></td>
<td>Scheduler</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Quartz2 endpoint is configured using URI syntax:

```
quartz2:groupName/triggerName
```

with the following path and query parameters:

### 255.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupName</td>
<td>The quartz group name to use. The combination of group name and timer name should be unique.</td>
<td>Camel</td>
<td>String</td>
</tr>
</tbody>
</table>
### Required
The quartz timer name to use. The combination of group name and timer name should be unique.

### Query Parameters (19 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>triggerName</td>
<td></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>cron (consumer)</td>
<td>Specifies a cron expression to define when to trigger.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>deleteJob (consumer)</td>
<td>If set to true, then the trigger automatically delete when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both deleteJob and pauseJob set to true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>durableJob (consumer)</td>
<td>Whether or not the job should remain stored after it is orphaned (no triggers point to it).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>pauseJob (consumer)</td>
<td>If set to true, then the trigger automatically pauses when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both deleteJob and pauseJob set to true.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>recoverableJob (consumer)</td>
<td>Instructs the scheduler whether or not the job should be re-executed if a 'recovery' or 'fail-over' situation is encountered.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>stateful (consumer)</td>
<td>Uses a Quartz PersistJobDataAfterExecution and DisallowConcurrentExecution instead of the default job.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>---------</td>
<td>-----------------</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>customCalendar (advanced)</td>
<td>Specifies a custom calendar to avoid specific range of date</td>
<td></td>
<td>Calendar</td>
</tr>
<tr>
<td>jobParameters (advanced)</td>
<td>To configure additional options on the job.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>prefixJobNameWithEndpointId (advanced)</td>
<td>Whether the job name should be prefixed with endpoint id</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>triggerParameters (advanced)</td>
<td>To configure additional options on the trigger.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>usingFixedCamelContextName (advanced)</td>
<td>If it is true, JobDataMap uses the CamelContext name directly to reference the CamelContext, if it is false, JobDataMap uses the CamelContext management name which could be changed during the deploy time.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>autoStartScheduler (scheduler)</td>
<td>Whether or not the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>fireNow (scheduler)</td>
<td>If it is true will fire the trigger when the route is start when using SimpleTrigger.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>startDelayedSeconds (scheduler)</td>
<td>Seconds to wait before starting the quartz scheduler.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>triggerStartDelay (scheduler)</td>
<td>In case of scheduler has already started, we want the trigger start slightly after current time to ensure endpoint is fully started before the job kicks in.</td>
<td>500</td>
<td>long</td>
</tr>
</tbody>
</table>

For example, the following routing rule will fire two timer events to the `mock:results` endpoint:
When using `stateful=true`, the `JobDataMap` is re-persisted after every execution of the job, thus preserving state for the next execution.

INFO: Running in OSGi and having multiple bundles with quartz routes if you run in OSGi such as Apache ServiceMix, or Apache Karaf, and have multiple bundles with Camel routes that start from Quartz2 endpoints, then make sure if you assign an `id` to the `<camelContext>` that this id is unique, as this is required by the `QuartzScheduler` in the OSGi container. If you do not set any `id` on `<camelContext>` then a unique id is auto assigned, and there is no problem.

255.3. CONFIGURING QUARTZ.PROPERTIES FILE

By default Quartz will look for a `quartz.properties` file in the `org/quartz` directory of the classpath. If you are using WAR deployments this means just drop the quartz.properties in `WEB-INF/classes/org/quartz`.

However the Camel Quartz2 component also allows you to configure properties:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>properties</td>
<td>null</td>
<td>Properties</td>
<td>You can configure a <code>java.util.Properties</code> instance.</td>
</tr>
<tr>
<td>propertiesFile</td>
<td>null</td>
<td>String</td>
<td>File name of the properties to load from the classpath</td>
</tr>
</tbody>
</table>

To do this you can configure this in Spring XML as follows

```xml
<bean id="quartz2" class="org.apache.camel.component.quartz2.QuartzComponent">
    <property name="propertiesFile" value="com/mycompany/myquartz.properties"/>
</bean>
```

255.4. ENABLING QUARTZ SCHEDULER IN JMX

You need to configure the quartz scheduler properties to enable JMX. That is typically setting the option "org.quartz.scheduler.jmx.export" to a `true` value in the configuration file.

From Camel 2.13 onwards Camel will automatic set this option to true, unless explicit disabled.

255.5. STARTING THE QUARTZ SCHEDULER

The Quartz2 component offers an option to let the Quartz scheduler be started delayed, or not auto started at all.

This is an example:
255.6. CLUSTERING

If you use Quartz in clustered mode, e.g. the JobStore is clustered. Then the Quartz2 component will not pause/remove triggers when a node is being stopped/shutdown. This allows the trigger to keep running on the other nodes in the cluster.

Note: When running in clustered node no checking is done to ensure unique job name/group for endpoints.

255.7. MESSAGE HEADERS

Camel adds the getters from the Quartz Execution Context as header values. The following headers are added: calendar, fireTime, jobDetail, jobInstance, jobRunTime, mergedJobDataMap, nextFireTime, previousFireTime, refireCount, result, scheduledFireTime, scheduler, trigger, triggerName, triggerGroup.

The fireTime header contains the java.util.Date of when the exchange was fired.

255.8. USING CRON TRIGGERS

Quartz supports Cron-like expressions for specifying timers in a handy format. You can use these expressions in the cron URI parameter; though to preserve valid URI encoding we allow + to be used instead of spaces.

For example, the following will fire a message every five minutes starting at 12pm (noon) to 6pm on weekdays:

```xml
from("quartz2://myGroup/myTimerName?cron=0+0/5+12-18+?+*+MON-FRI")
  .to("activemq:Totally.Rocks");
```

which is equivalent to using the cron expression

```text
0 0/5 12-18 ? * MON-FRI
```

The following table shows the URI character encodings we use to preserve valid URI syntax:

<table>
<thead>
<tr>
<th>URI Character</th>
<th>Cron character</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Space</td>
</tr>
</tbody>
</table>

255.9. SPECIFYING TIME ZONE

The Quartz Scheduler allows you to configure time zone per trigger. For example to use a timezone of your country, then you can do as follows:

```xml
<bean id="quartz2" class="org.apache.camel.component.quartz2.QuartzComponent">
  <property name="startDelayedSeconds" value="5"/>
</bean>
```
quartz2://groupName/timerName?cron=0+0/5+12-18+?+++MON-FRI&trigger.timeZone=Europe/Stockholm

The timeZone value is the values accepted by java.util.TimeZone.

### 255.10. USING QUARTZSCHEDULDPOLLCONSUMERSCHEDULER

The Quartz2 component provides a Polling Consumer scheduler which allows to use cron based scheduling for Polling Consumer such as the File and FTP consumers.

For example to use a cron based expression to poll for files every 2nd second, then a Camel route can be define simply as:

```camel
from("file:inbox?scheduler=quartz2&scheduler.cron=0/2+*+*+*+*+")
.to("bean:process");
```

Notice we define the `scheduler=quartz2` to instruct Camel to use the Quartz2 based scheduler. Then we use `scheduler.xxx` options to configure the scheduler. The Quartz2 scheduler requires the cron option to be set.

The following options is supported:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quartzScheduler</td>
<td>null</td>
<td>org.quartz.Scheduler</td>
<td>To use a custom Quartz scheduler. If none configure then the shared scheduler from the Quartz2 component is used.</td>
</tr>
<tr>
<td>cron</td>
<td>null</td>
<td>String</td>
<td>Mandatory: To define the cron expression for triggering the polls.</td>
</tr>
<tr>
<td>triggerId</td>
<td>null</td>
<td>String</td>
<td>To specify the trigger id. If none provided then an UUID is generated and used.</td>
</tr>
<tr>
<td>triggerGroup</td>
<td>QuartzScheduledPollConsumerScheduler</td>
<td>String</td>
<td>To specify the trigger group.</td>
</tr>
<tr>
<td>timeZone</td>
<td>Default</td>
<td>TimeZone</td>
<td>The time zone to use for the CRON trigger.</td>
</tr>
</tbody>
</table>

**Important:** Remember configuring these options from the endpoint URIs must be prefixed with `scheduler..`. For example to configure the trigger id and group:
There is also a CRON scheduler in Spring, so you can use the following as well:

```java
from("file:inbox?scheduler=spring&scheduler.cron=0/2+*+*+*+*")
  .to("bean:process");
```

```java
from("file:inbox?scheduler=quartz2&scheduler.cron=0/2+*+*+*+*+*
&scheduler.triggerId=myId&scheduler.triggerGroup=myGroup")
  .to("bean:process");
```
CHAPTER 256. RABBITMQ COMPONENT

Available as of Camel version 2.12

The `rabbitmq:` component allows you produce and consume messages from RabbitMQ instances. Using the RabbitMQ AMQP client, this component offers a pure RabbitMQ approach over the generic AMQP component.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rabbitmq</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

256.1. URI FORMAT

The old syntax is deprecated:

```
rabbitmq://hostname[:port]/exchangeName?[options]
```

Instead the hostname and port is configured on the component level, or can be provided as uri query parameters instead.

The new syntax is:

```
rabbitmq:exchangeName?[options]
```

Where `hostname` is the hostname of the running rabbitmq instance or cluster. Port is optional and if not specified then defaults to the RabbitMQ client default (5672). The exchange name determines which exchange produced messages will sent to. In the case of consumers, the exchange name determines which exchange the queue will bind to.

256.2. OPTIONS

The RabbitMQ component supports 49 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hostname</code></td>
<td>The hostname of the running RabbitMQ instance or cluster.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>portNumber</code></td>
<td>Port number for the host with the running rabbitmq instance or cluster.</td>
<td>5672</td>
<td>int</td>
</tr>
<tr>
<td><code>username</code></td>
<td>Username in case of authenticated access</td>
<td>guest</td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>password</strong> (security)</td>
<td>Password for authenticated access</td>
<td>guest</td>
<td>String</td>
</tr>
<tr>
<td><strong>vhost</strong> (common)</td>
<td>The vhost for the channel</td>
<td>/</td>
<td>String</td>
</tr>
<tr>
<td><strong>addresses</strong> (common)</td>
<td>If this option is set, camel-rabbitmq will try to create connection based on the setting of option addresses. The addresses value is a string which looks like server1:12345, server2:12345</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>connectionFactory</strong> (common)</td>
<td>To use a custom RabbitMQ connection factory. When this option is set, all connection options (connectionTimeout, requestedChannelMax...) set on URI are not used</td>
<td></td>
<td>ConnectionFactor</td>
</tr>
<tr>
<td><strong>threadPoolSize</strong> (consumer)</td>
<td>The consumer uses a Thread Pool Executor with a fixed number of threads. This setting allows you to set that number of threads.</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td><strong>autoDetectConnectionFactory</strong> (advanced)</td>
<td>Whether to auto-detect looking up RabbitMQ connection factory from the registry. When enabled and a single instance of the connection factory is found then it will be used. An explicit connection factory can be configured on the component or endpoint level which takes precedence.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>connectionTimeout</strong> (advanced)</td>
<td>Connection timeout</td>
<td>60000</td>
<td>int</td>
</tr>
<tr>
<td><strong>requestedChannelMax</strong> (advanced)</td>
<td>Connection requested channel max (max number of channels offered)</td>
<td>0</td>
<td>int</td>
</tr>
<tr>
<td><strong>requestedFrameMax</strong> (advanced)</td>
<td>Connection requested frame max (max size of frame offered)</td>
<td>0</td>
<td>int</td>
</tr>
<tr>
<td><strong>requestedHeartbeat</strong> (advanced)</td>
<td>Connection requested heartbeat (heart-beat in seconds offered)</td>
<td>60</td>
<td>int</td>
</tr>
<tr>
<td><strong>automaticRecoveryEnabled</strong> (advanced)</td>
<td>Enables connection automatic recovery (uses connection implementation that performs automatic recovery when connection shutdown is not initiated by the application)</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>networkRecoveryInterval</strong> (advanced)</td>
<td>Network recovery interval in milliseconds (interval used when recovering from network failure)</td>
<td>5000</td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>topologyRecoveryEnabled (advanced)</td>
<td>Enables connection topology recovery (should topology recovery be performed)</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>prefetchEnabled (consumer)</td>
<td>Enables the quality of service on the RabbitMQConsumer side. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>prefetchSize (consumer)</td>
<td>The maximum amount of content (measured in octets) that the server will deliver, 0 if unlimited. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>prefetchCount (consumer)</td>
<td>The maximum number of messages that the server will deliver, 0 if unlimited. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>prefetchGlobal (consumer)</td>
<td>If the settings should be applied to the entire channel rather than each consumer You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>channelPoolMaxSize (producer)</td>
<td>Get maximum number of opened channel in pool</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>channelPoolMaxWait (producer)</td>
<td>Set the maximum number of milliseconds to wait for a channel from the pool</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>requestTimeout (advanced)</td>
<td>Set timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds)</td>
<td>20000</td>
<td>long</td>
</tr>
<tr>
<td>requestTimeoutCheckerInterval (advanced)</td>
<td>Set requestTimeoutCheckerInterval for inOut exchange</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>transferException (advanced)</td>
<td>When true and an InOut Exchange failed on the consumer side send the caused Exception back in the response</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>publisherAcknowledgements (producer)</td>
<td>When true, the message will be published with publisher acknowledgements turned on</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>---------</td>
<td>------</td>
</tr>
<tr>
<td>publisher Acknowledgments Timeout (producer)</td>
<td>The amount of time in milliseconds to wait for a basic.ack response from RabbitMQ server</td>
<td></td>
<td>long</td>
</tr>
<tr>
<td>guaranteedDeliveries (producer)</td>
<td>When true, an exception will be thrown when the message cannot be delivered (basic.return) and the message is marked as mandatory. PublisherAcknowledgement will also be activated in this case. See also publisher acknowledgements - When will messages be confirmed.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>mandatory (producer)</td>
<td>This flag tells the server how to react if the message cannot be routed to a queue. If this flag is set, the server will return an unroutable message with a Return method. If this flag is zero, the server silently drops the message. If the header is present rabbitmq.MANDATORY it will override this option.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>immediate (producer)</td>
<td>This flag tells the server how to react if the message cannot be routed to a queue consumer immediately. If this flag is set, the server will return an undeliverable message with a Return method. If this flag is zero, the server will queue the message, but with no guarantee that it will ever be consumed. If the header is present rabbitmq.IMMEDIATE it will override this option.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>args (advanced)</td>
<td>Specify arguments for configuring the different RabbitMQ concepts, a different prefix is required for each: Exchange: arg.exchange. Queue: arg.queue. Binding: arg.binding. For example to declare a queue with message ttl argument: <code>http://localhost:5672/exchange/queueargs=arg.queue.x-message-ttl=60000</code></td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>clientProperties (advanced)</td>
<td>Connection client properties (client info used in negotiating with the server)</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>sslProtocol (security)</td>
<td>Enables SSL on connection, accepted value are true, TLS and ‘SSLv3`</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>trustManager (security)</td>
<td>Configure SSL trust manager, SSL should be enabled for this option to be effective</td>
<td></td>
<td>TrustManager</td>
</tr>
<tr>
<td>autoAck (consumer)</td>
<td>If messages should be auto acknowledged</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>autoDelete</td>
<td>If it is true, the exchange will be deleted when it is no longer in use</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>durable</td>
<td>If we are declaring a durable exchange (the exchange will survive a server restart)</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exclusive</td>
<td>Exclusive queues may only be accessed by the current connection, and are deleted when that connection closes.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>passive</td>
<td>Passive queues depend on the queue already to be available at RabbitMQ.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>skipQueueDeclare</td>
<td>If true the producer will not declare and bind a queue. This can be used for directing messages via an existing routing key.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>skipQueueBind</td>
<td>If true the queue will not be bound to the exchange after declaring it</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>skipExchangeDeclare</td>
<td>This can be used if we need to declare the queue but not the exchange</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>declare</td>
<td>If the option is true, camel declare the exchange and queue name and bind them together. If the option is false, camel won’t declare the exchange and queue name on the server.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>deadLetterExchange</td>
<td>The name of the dead letter exchange</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>deadLetterQueue</td>
<td>The name of the dead letter queue</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>deadLetterRoutingKey</td>
<td>The routing key for the dead letter exchange</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>deadLetterExchangeType</td>
<td>The type of the dead letter exchange</td>
<td>direct</td>
<td>String</td>
</tr>
<tr>
<td>allowNullHeaders</td>
<td>Allow pass null values to header</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

true  boolean

The RabbitMQ endpoint is configured using URI syntax:

```
rabbitmq:exchangeName
```

with the following path and query parameters:

### 256.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>exchangeName</td>
<td>Required The exchange name determines which exchange produced messages will sent to. In the case of consumers, the exchange name determines which exchange the queue will bind to.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 256.2.2. Query Parameters (61 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>addresses</td>
<td>If this option is set, camel-rabbitmq will try to create connection based on the setting of option addresses. The addresses value is a string which looks like server1:12345, server2:12345</td>
<td></td>
<td>Address[]</td>
</tr>
<tr>
<td>autoDelete</td>
<td>If it is true, the exchange will be deleted when it is no longer in use</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>connectionFactory</td>
<td>To use a custom RabbitMQ connection factory. When this option is set, all connection options (connectionTimeout, requestedChannelMax...) set on URI are not used</td>
<td></td>
<td>ConnectionFactory</td>
</tr>
<tr>
<td>deadLetterExchange</td>
<td>The name of the dead letter exchange</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>deadLetterExchangeType</td>
<td>The type of the dead letter exchange</td>
<td>direct</td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>deadLetterQueue</td>
<td>The name of the dead letter queue</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>deadLetterRoutingKey</td>
<td>The routing key for the dead letter exchange</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>declare</td>
<td>If the option is true, camel declare the exchange and queue name and bind them together. If the option is false, camel won’t declare the exchange and queue name on the server.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>durable</td>
<td>If we are declaring a durable exchange (the exchange will survive a server restart)</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exchangeType</td>
<td>The exchange type such as direct or topic.</td>
<td>direct</td>
<td>String</td>
</tr>
<tr>
<td>exclusive</td>
<td>Exclusive queues may only be accessed by the current connection, and are deleted when that connection closes.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>hostname</td>
<td>The hostname of the running rabbitmq instance or cluster.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>passive</td>
<td>Passive queues depend on the queue already to be available at RabbitMQ.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>portNumber</td>
<td>Port number for the host with the running rabbitmq instance or cluster. Default value is 5672.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>queue</td>
<td>The queue to receive messages from</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>routingKey</td>
<td>The routing key to use when binding a consumer queue to the exchange. For producer routing keys, you set the header rabbitmq.ROUTING_KEY.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>skipExchangeDeclare</td>
<td>This can be used if we need to declare the queue but not the exchange</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>skipQueueBind</td>
<td>If true the queue will not be bound to the exchange after declaring it</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>skipQueueDeclare</td>
<td>If true the producer will not declare and bind a queue. This can be used for directing messages via an existing routing key.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>

<tr>
<td>trustManager (security)</td>
<td>Configure SSL trust manager, SSL should be enabled for this option to be effective</td>
<td></td>
<td>TrustManager</td>
</tr>
<tr>
<td>username (security)</td>
<td>Username in case of authenticated access</td>
<td>guest</td>
<td>String</td>
</tr>
</tbody>
</table>

### 256.3. USING CONNECTION FACTORY

To connect to RabbitMQ you can setup a `ConnectionFactory` (same as with JMS) with the login details such as:

```xml
<bean id="rabbitConnectionFactory" class="com.rabbitmq.client.ConnectionFactory">
    <property name="host" value="localhost"/>
    <property name="port" value="5672"/>
    <property name="username" value="camel"/>
    <property name="password" value="bugs bunny"/>
</bean>
```
And then refer to the connection factory in the endpoint uri as shown below:

```xml
<camelContext>
  <route>
    <from uri="direct:rabbitMQEx2"/>
    <to uri="rabbitmq:ex2?connectionFactory=#rabbitConnectionFactory"/>
  </route>
</camelContext>
```

From Camel 2.21 onwards the `ConnectionFactory` is auto-detected by default, so you can just do

```xml
<camelContext>
  <route>
    <from uri="direct:rabbitMQEx2"/>
    <to uri="rabbitmq:ex2"/>
  </route>
</camelContext>
```

### 256.4. MESSAGE HEADERS

The following headers are set on exchanges when consuming messages.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rabbitmq.OUTGOING_KEY</td>
<td>The routing key that was used to receive the message, or the routing key that will be used when producing a message</td>
</tr>
<tr>
<td>rabbitmq.EXCHANGE_NAME</td>
<td>The exchange the message was received from</td>
</tr>
<tr>
<td>rabbitmq.DELIVERY_TAG</td>
<td>The rabbitmq delivery tag of the received message</td>
</tr>
<tr>
<td>rabbitmq.REDELIVERED_TAG</td>
<td>Whether the message is a redelivered</td>
</tr>
</tbody>
</table>
### Property | Value
---|---
**rabbit mq.REQUEUE** | **Camel 2.14.2**: This is used by the consumer to control rejection of the message. When the consumer is complete processing the exchange, and if the exchange failed, then the consumer is going to reject the message from the RabbitMQ broker. The value of this header controls this behavior. If the value is false (by default) then the message is discarded/dead-lettered. If the value is true, then the message is re-queued.

The following headers are used by the producer. If these are set on the camel exchange then they will be set on the RabbitMQ message.

### Property | Value
---|---
**rabbit mq.RROUTING KEY** | The routing key that will be used when sending the message

**rabbit mq.EXCHANGE_NAME** | The exchange the message was received from

**rabbit mq.EXCHANGE_OVERRIDE_NAME** | **Camel 2.21**: Used for force sending the message to this exchange instead of the endpoint configured name on the producer

**rabbit mq.CONTENT_TYPE** | The contentType to set on the RabbitMQ message

**rabbit mq.PRIORITY** | The priority header to set on the RabbitMQ message
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rabbit mq.CORRELATIONID</td>
<td>The correlationId to set on the RabbitMQ message</td>
</tr>
<tr>
<td>rabbit mq.MESSAGE_ID</td>
<td>The message id to set on the RabbitMQ message</td>
</tr>
<tr>
<td>rabbit mq.DELIVERY_MODE</td>
<td>If the message should be persistent or not</td>
</tr>
<tr>
<td>rabbit mq.USERID</td>
<td>The userId to set on the RabbitMQ message</td>
</tr>
<tr>
<td>rabbit mq.CLUSTERID</td>
<td>The clusterId to set on the RabbitMQ message</td>
</tr>
<tr>
<td>rabbit mq.REPLY_TO</td>
<td>The replyTo to set on the RabbitMQ message</td>
</tr>
<tr>
<td>rabbit mq.CONTENT_ENCODING</td>
<td>The contentEncoding to set on the RabbitMQ message</td>
</tr>
<tr>
<td>rabbit mq.TYYPE</td>
<td>The type to set on the RabbitMQ message</td>
</tr>
<tr>
<td>rabbit mq.EXPIRATION</td>
<td>The expiration to set on the RabbitMQ message</td>
</tr>
<tr>
<td>Property</td>
<td>Value</td>
</tr>
<tr>
<td>----------</td>
<td>-------</td>
</tr>
<tr>
<td>rabbitmq.TIAMP</td>
<td>The timestamp to set on the RabbitMQ message</td>
</tr>
<tr>
<td>rabbitmq.APP_ID</td>
<td>The appId to set on the RabbitMQ message</td>
</tr>
</tbody>
</table>

Headers are set by the consumer once the message is received. The producer will also set the headers for downstream processors once the exchange has taken place. Any headers set prior to production that the producer sets will be overridden.

### 256.5. MESSAGE BODY

The component will use the camel exchange in body as the rabbit mq message body. The camel exchange in object must be convertible to a byte array. Otherwise the producer will throw an exception of unsupported body type.

### 256.6. SAMPLES

To receive messages from a queue that is bound to an exchange A with the routing key B,

```java
from("rabbitmq:A?routingKey=B")
```

To receive messages from a queue with a single thread with auto acknowledge disabled.

```java
from("rabbitmq:A?routingKey=B&threadPoolSize=1&autoAck=false")
```

To send messages to an exchange called C

```java
to("rabbitmq:C")
```

Declaring a headers exchange and queue

```java
from("rabbitmq:ex?exchangeType=headers&queue=q&bindingArgs=#bindArgs")
```

and place corresponding `Map<String, Object>` with the id of "bindArgs" in the Registry.

For example declaring a method in spring

```java
@Bean(name="bindArgs")
public Map<String, Object> bindArgsBuilder() {
    return Collections.singletonMap("foo", "bar");
}
```

### 256.6.1. Issue when routing between exchanges (in Camel 2.20.x or older)
If you for example want to route messages from one Rabbit exchange to another as shown in the example below with foo → bar:

```java
from("rabbitmq:foo")
  .to("rabbitmq:bar")
```

Then beware that Camel will route the message to itself, eg foo → foo. So why is that? This is because the consumer that receives the message (eg from) provides the message header `rabbitmq.EXCHANGE_NAME` with the name of the exchange, eg `foo`. And when the Camel producer is sending the message to `bar` then the header `rabbitmq.EXCHANGE_NAME` will override this and instead send the message to `foo`.

To avoid this you need to either:

- Remove the header:

```java
from("rabbitmq:foo")
  .removeHeader("rabbitmq.EXCHANGE_NAME")
  .to("rabbitmq:bar")
```

- Or turn on `bridgeEndpoint` mode on the producer:

```java
from("rabbitmq:foo")
  .to("rabbitmq:bar?bridgeEndpoint=true")
```

From Camel 2.21 onwards this has been improved so you can easily route between exchanges. The header `rabbitmq.EXCHANGE_NAME` is not longer used by the producer to override the destination exchange. Instead a new header `rabbitmq.EXCHANGE_OVERRIDE_NAME` can be used to send to a different exchange. For example to send to cheese exchange you can do

```java
from("rabbitmq:foo")
  .setHeader("rabbitmq.EXCHANGE_OVERRIDE_NAME", constant("cheese"))
  .to("rabbitmq:bar")
```
CHAPTER 257. REACTIVE STREAMS COMPONENT

Available as of Camel version 2.19

The **reactive-streams**: component allows you to exchange messages with reactive stream processing libraries compatible with the **reactive streams** standard.

The component supports backpressure and has been tested using the **reactive streams technology compatibility kit (TCK)**.

The Camel module provides a **reactive-streams** component that allows users to define incoming and outgoing streams within Camel routes, and a direct client API that allows using Camel endpoints directly into any external reactive framework.

Camel uses an internal implementation of the reactive streams **Publisher** and **Subscriber**, so it’s not tied to any specific framework. The following reactive frameworks have been used in the integration tests: Reactor Core 3, RxJava 2.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-reactive-streams</artifactId>
    <version>x.x.x</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

257.1. URI FORMAT

```
reactive-streams://stream?[options]
```

Where **stream** is a logical stream name used to bind Camel routes to the external stream processing systems.

257.2. OPTIONS

The Reactive Streams component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>internalEngine Configuration</td>
<td>Configures the internal engine for Reactive Streams.</td>
<td></td>
<td>ReactiveStreamsEngine Configuration</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>backpressureStrategy</td>
<td>The backpressure strategy to use when pushing events to a slow subscriber.</td>
<td>BUFFER</td>
<td>ReactiveStreamsBackpressureStrategy</td>
</tr>
</tbody>
</table>

1697
The Reactive Streams endpoint is configured using URI syntax:

```
reactive-streams:stream
```

with the following path and query parameters:

### 257.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>stream</td>
<td>Name of the stream channel used by the endpoint to exchange messages.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 257.2.2. Query Parameters (10 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>(consumer)</td>
<td>mean any exceptions occurred while the consumer is trying to pickup</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>incoming messages, or the likes, will now be processed as a message and</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>handled by the routing Error Handler. By default the consumer will use the</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>logged at WARN or ERROR level and ignored.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>concurrentConsumers</td>
<td>Number of threads used to process exchanges in the Camel route.</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>exchangesRefillLowWatermark (consumer)</td>
<td>Set the low watermark of requested exchanges to the active subscription as percentage of the maxInflightExchanges. When the number of pending items from the upstream source is lower than the watermark, new items can be requested to the subscription. If set to 0, the subscriber will request items in batches of maxInflightExchanges, only after all items of the previous batch have been processed. If set to 1, the subscriber can request a new item each time an exchange is processed (chatty). Any intermediate value can be used.</td>
<td>0.25</td>
<td>double</td>
</tr>
<tr>
<td>forwardOnComplete (consumer)</td>
<td>Determines if onComplete events should be pushed to the Camel route.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>forwardOnError (consumer)</td>
<td>Determines if onError events should be pushed to the Camel route. Exceptions will be set as message body.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>maxInflightExchanges (consumer)</td>
<td>Maximum number of exchanges concurrently being processed by Camel. This parameter controls backpressure on the stream. Setting a non-positive value will disable backpressure.</td>
<td>128</td>
<td>Integer</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>backpressureStrategy (producer)</td>
<td>The backpressure strategy to use when pushing events to a slow subscriber.</td>
<td></td>
<td>ReactiveStreamsBackpressureStrategy</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 257.3. USAGE

The library is aimed to support all the communication modes needed by an application to interact with Camel data:

- **Get** data from Camel routes (In-Only from Camel)
- **Send** data to Camel routes (In-Only towards Camel)
- **Request** a transformation to a Camel route (In-Out towards Camel)
- **Process** data flowing from a Camel route using a reactive processing step (In-Out from Camel)

## 257.4. GETTING DATA FROM CAMEL

In order to subscribe to data flowing from a Camel route, exchanges should be redirected to a named stream, like in the following snippet:

```java
from("timer:clock")
  .setBody().header(Exchange.TIMER_COUNTER)
  .to("reactive-streams:numbers");
```

Routes can also be written using the XML DSL.

In the example, an unbounded stream of numbers is associated to the name `numbers`. The stream can be accessed using the `CamelReactiveStreams` utility class.

```java
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Getting a stream of exchanges
Publisher<Exchange> exchanges = camel.fromStream("numbers");

// Getting a stream of Integers (using Camel standard conversion system)
Publisher<Integer> numbers = camel.fromStream("numbers", Integer.class);
```

The stream can be used easily with any reactive streams compatible library. Here is an example of how to use it with **RxJava 2** (although any reactive framework can be used to process events).

```java
Flowable.fromPublisher(integers)
  .doOnNext(System.out::println)
  .subscribe();
```

The example prints all numbers generated by Camel into **System.out**.

### 257.4.1. Getting data from Camel using the direct API

For short Camel routes and for users that prefer defining the whole processing flow using functional constructs of the reactive framework (without using the Camel DSL at all), streams can also be defined using Camel URIs.

```java
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Get a stream from all the files in a directory
Publisher<String> files = camel.from("file:folder", String.class);

// Use the stream in RxJava2
Flowable.fromPublisher(files)
  .doOnNext(System.out::println)
  .subscribe();
```
257.5. SENDING DATA TO CAMEL

When an external library needs to push events into a Camel route, the Reactive Streams endpoint must be set as consumer.

```java
from("reactive-streams:elements")
    .to("log:INFO");
```

A handle to the `elements` stream can be obtained from the `CamelReactiveStreams` utility class.

```java
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);
Subscriber<String> elements = camel.streamSubscriber("elements", String.class);
```

The subscriber can be used to push events to the Camel route that consumes from the `elements` stream.

Here is an example of how to use it with RxJava 2 (although any reactive framework can be used to publish events).

```java
Flowable.interval(1, TimeUnit.SECONDS)
    .map(i -> "Item " + i)
    .subscribe(elements);
```

String items are generated every second by RxJava in the example and they are pushed into the Camel route defined above.

257.5.1. Sending data to Camel using the direct API

Also in this case, the direct API can be used to obtain a Camel subscriber from an endpoint URI.

```java
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Send two strings to the "seda:queue" endpoint
Flowable.just("hello", "world")
    .subscribe(camel.subscriber("seda:queue", String.class));
```

257.6. REQUEST A TRANSFORMATION TO CAMEL

Routes defined in some Camel DSL can be used within a reactive stream framework to perform a specific transformation (the same mechanism can be also used to eg. just send data to a http endpoint and continue).

The following snippet shows how RxJava functional code can request the task of loading and marshalling files to Camel.

```java
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Process files starting from their names
Flowable.just(new File("file1.txt"), new File("file2.txt"))
    .flatMap(file -> camel.toStream("readAndMarshal", String.class))
```
In order to work, a route like the following should be defined in the Camel context:

```java
from("reactive-streams:readAndMarshal")
.marshall() // ... other details
```

### 257.6.1. Request a transformation to Camel using the direct API

An alternative approach consists in using the URI endpoints directly in the reactive flow:

```java
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Process files starting from their names
Flowable.just(new File("file1.txt"), new File("file2.txt"))
.flatMap(file -> camel.to("direct:process", String.class))
// Camel output will be converted to String
// other steps
.subscribe();
```

When using the `to()` method instead of the `toStream`, there is no need to define the route using "reactive-streams:" endpoints (although they are used under the hood).

In this case, the Camel transformation can be just:

```java
from("direct:process")
.marshall() // ... other details
```

### 257.7. PROCESS CAMEL DATA INTO THE REACTIVE FRAMEWORK

While a reactive streams Publisher allows exchanging data in a unidirectional way, Camel routes often use a in-out exchange pattern (eg. to define REST endpoints and, in general, where a reply is needed for each request).

In these circumstances, users can add a reactive processing step to the flow, to enhance a Camel route or to define the entire transformation using the reactive framework.

For example, given the following route:

```java
from("timer:clock")
.setBody().header(Exchange.TIMER_COUNTER)
.to("direct:reactive")
.log("Continue with Camel route... n=${body}");
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);
```

A reactive processing step can be associated to the "direct:reactive" endpoint:

```java
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

camel.process("direct:reactive", Integer.class, items ->
Flowable.fromPublisher(items) // RxJava2
.map(n -> -n)); // make every number negative
```
Data flowing in the Camel route will be processed by the external reactive framework then continue the processing flow inside Camel.

This mechanism can also be used to define a In-Out exchange in a completely reactive way.

```java
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);
// requires a rest-capable Camel component
camel.process("rest:get:orders", exchange ->
Flowable.fromPublisher(exchange)
.flatMap(ex -> allOrders())); // retrieve orders asynchronously
```

See Camel examples (camel-example-reactive-streams) for details.

### 257.8. ADVANCED TOPICS

#### 257.8.1. Controlling Backpressure (producer side)

When routing Camel exchanges to an external subscriber, backpressure is handled by an internal buffer that caches exchanges before delivering them. If the subscriber is slower than the exchange rate, the buffer may become too big. In many circumstances this must be avoided.

Considering the following route:

```java
from("jms:queue")
.to("reactive-streams:flow");
```

If the JMS queue contains a high number of messages and the Subscriber associated with the flow stream is too slow, messages are dequeued from JMS and appended to the buffer, possibly causing a "out of memory" error. To avoid such problems, a `ThrottlingInflightRoutePolicy` can be set in the route.

```java
ThrottlingInflightRoutePolicy policy = new ThrottlingInflightRoutePolicy();
policy.setMaxInflightExchanges(10);
from("jms:queue")
.routePolicy(policy)
.to("reactive-streams:flow");
```

The policy limits the maximum number of active exchanges (and so the maximum size of the buffer), keeping it lower than the threshold (10 in the example). When more than 10 messages are in flight, the route is suspended, waiting for the subscriber to process them.

With this mechanism, the subscriber controls the route suspension/resume automatically, through backpressure. When multiple subscribers are consuming items from the same stream, the slowest one controls the route status automatically.

In other circumstances, eg. when using a http consumer, the route suspension makes the http service unavailable, so using the default configuration (no policy, unbounded buffer) should be preferable. Users should try to avoid memory issues by limiting the number of requests to the http service (eg. scaling out).

In contexts where a certain amount of data loss is acceptable, setting a backpressure strategy other than `BUFFER` can be a solution for dealing with fast sources.
When the **LATEST** backpressure strategy is used, only the last exchange received from the route is kept by the publisher, while older data is discarded (other options are available).

### 257.8.2. Controlling Backpressure (consumer side)

When Camel consumes items from a reactive-streams publisher, the maximum number of inflight exchanges can be set as endpoint option.

The subscriber associated with the consumer interacts with the publisher to keep the number of messages in the route lower than the threshold.

An example of backpressure-aware route:

```java
from("reactive-streams:numbers?maxInflightExchanges=10")
.to("direct:endpoint");
```

The number of items that Camel requests to the source publisher (through the reactive streams backpressure mechanism) is always lower than **10**. Messages are processed by a single thread in the Camel side.

The number of concurrent consumers (threads) can also be set as endpoint option (**concurrentConsumers**). When using 1 consumer (the default), the order of items in the source stream is maintained. When this value is increased, items will be processed concurrently by multiple threads (so not preserving the order).

### 257.9. CAMEL REACTIVE STREAMS STARTER

A starter module is available to spring-boot users. When using the starter, the **CamelReactiveStreamsService** can be directly injected into Spring components.

To use the starter, add the following to your spring boot pom.xml file:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-reactive-streams-starter</artifactId>
  <version>${camel.version}</version>
</dependency>
```

### 257.10. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 258. REACTOR COMPONENT

Available as of Camel version 2.20

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-reactor</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 259. REF COMPONENT

Available as of Camel version 1.2

The `ref:` component is used for lookup of existing endpoints bound in the Registry.

### 259.1. URI FORMAT

```text
ref:someName[?options]
```

Where `someName` is the name of an endpoint in the Registry (usually, but not always, the Spring registry). If you are using the Spring registry, `someName` would be the bean ID of an endpoint in the Spring registry.

### 259.2. REF OPTIONS

The Ref component has no options.

The Ref endpoint is configured using URI syntax:

```text
ref:name
```

with the following path and query parameters:

#### 259.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required Name of endpoint to lookup in the registry.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

#### 259.2.2. Query Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bridgeErrorHandler</code> (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### 259.3. RUNTIME LOOKUP

This component can be used when you need dynamic discovery of endpoints in the Registry where you can compute the URI at runtime. Then you can look up the endpoint using the following code:

```java
// lookup the endpoint
String myEndpointRef = "bigspenderOrder";
Endpoint endpoint = context.getEndpoint("ref:" + myEndpointRef);

Producer producer = endpoint.createProducer();
Exchange exchange = producer.createExchange();
exchange.getIn().setBody(payloadToSend);
// send the exchange
producer.process(exchange);
```

And you could have a list of endpoints defined in the Registry such as:

```xml
<camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring">
  <endpoint id="normalOrder" url="activemq:order.slow"/>
  <endpoint id="bigspenderOrder" url="activemq:order.high"/>
</camelContext>
```

### 259.4. SAMPLE

In the sample below we use the `ref:` in the URI to reference the endpoint with the spring ID, `endpoint2`:

You could, of course, have used the `ref` attribute instead:

```xml
<to ref="endpoint2"/>
```

Which is the more common way to write it.
CHAPTER 260. REST COMPONENT

Available as of Camel version 2.14

The rest component allows to define REST endpoints (consumer) using the Rest DSL and plugin to other Camel components as the REST transport.

From Camel 2.18 onwards the rest component can also be used as a client (producer) to call REST services.

260.1. URI FORMAT

```
rest://method:path:[uriTemplate]?[options]
```

260.2. URI OPTIONS

The REST component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>componentName</td>
<td>The Camel Rest component to use for the REST transport, such as restlet, spark-rest. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a <code>org.apache.camel.spi.RestConsumerFactory</code> (consumer) or <code>org.apache.camel.spi.RestProducerFactory</code> (producer) is registered in the registry. If either one is found, then that is being used.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>apiDoc</td>
<td>The swagger api doc resource to use. The resource is loaded from classpath by default and must be in Json format.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td>Host and port of HTTP service to use (override host in swagger schema)</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The REST endpoint is configured using URI syntax:

```
rest:method:path:[uriTemplate]
```

with the following path and query parameters:
### 260.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>method</td>
<td>Required HTTP method to use.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>path</td>
<td>Required The base path</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>uriTemplate</td>
<td>The uri template</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 260.2.2. Query Parameters (15 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>componentName</td>
<td>The Camel Rest component to use for the REST transport, such as restlet, spark-rest. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumes</td>
<td>Media type such as: ‘text/xml’, or ‘application/json’ this REST service accepts. By default we accept all kinds of types.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>inType</td>
<td>To declare the incoming POJO binding type as a FQN class name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>outType</td>
<td>To declare the outgoing POJO binding type as a FQN class name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>produces</td>
<td>Media type such as: ‘text/xml’, or ‘application/json’ this REST service returns.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>routeId</td>
<td>Name of the route this REST services creates</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### 260.3. SUPPORTED REST COMPONENTS

The following components support rest consumer (Rest DSL):

- camel-coap
- camel-netty-http
- camel-netty4-http
- camel-jetty
- camel-restlet
- camel-servlet
- camel-spark-rest
The following components support rest producer:

- camel-http
- camel-http4
- camel-netty4-http
- camel-jetty
- camel-restlet
- camel-undertow

260.4. PATH AND URITEMplate SYNTAX

The path and uriTemplate option is defined using a REST syntax where you define the REST context path using support for parameters.

TIP: If no uriTemplate is configured then path option works the same way. It does not matter if you configure only path or if you configure both options. Though configuring both a path and uriTemplate is a more common practice with REST.

The following is a Camel route using a a path only

```camel
from("rest:get:hello")
.transform().constant("Bye World");
```

And the following route uses a parameter which is mapped to a Camel header with the key "me".

```camel
from("rest:get:hello/{me}")
.transform().simple("Bye ${header.me}");
```

The following examples have configured a base path as "hello" and then have two REST services configured using uriTemplates.

```camel
from("rest:get:hello/{me}")
.transform().simple("Hi ${header.me}");
from("rest:get:hello:french/{me}")
.transform().simple("Bonjour ${header.me}");
```

260.5. REST PRODUCER EXAMPLES

You can use the rest component to call REST services like any other Camel component.

For example to call a REST service on using `hello/{me}` you can do

```camel
from("direct:start")
.to("rest:get:hello/{me}");
```
And then the dynamic value `{me}` is mapped to Camel message with the same name. So to call this REST service you can send an empty message body and a header as shown:

```java
template.sendBodyAndHeader("direct:start", null, "me", "Donald Duck");
```

The Rest producer needs to know the hostname and port of the REST service, which you can configure using the host option as shown:

```java
from("direct:start")
  .to("rest:get:hello/{me}?host=myserver:8080/foo");
```

Instead of using the host option, you can configure the host on the `restConfiguration` as shown:

```java
restConfiguration().host("myserver:8080/foo");
from("direct:start")
  .to("rest:get:hello/{me}");
```

You can use the `producerComponent` to select which Camel component to use as the HTTP client, for example to use http4 you can do:

```java
restConfiguration().host("myserver:8080/foo").producerComponent("http4");
from("direct:start")
  .to("rest:get:hello/{me}");
```

### 260.6. REST PRODUCER BINDING

The REST producer supports binding using JSON or XML like the rest-dsl does. For example to use jetty with json binding mode turned on you can configure this in the rest configuration:

```java
restConfiguration().component("jetty").host("localhost").port(8080).bindingMode(RestBindingMode.json);
from("direct:start")
  .to("rest:post:user");
```

Then when calling the REST service using rest producer it will automatic bind any POJOs to json before calling the REST service:

```java
UserPojo user = new UserPojo();
user.setId(123);
user.setName("Donald Duck");
template.sendBody("direct:start", user);
```

In the example above we send a POJO instance `UserPojo` as the message body. And because we have turned on JSON binding in the rest configuration, then the POJO will be marshalled from POJO to JSON before calling the REST service.
However if you want to also perform binding for the response message (eg what the REST service send back as response) you would need to configure the `outType` option to specify what is the classname of the POJO to unmarshal from JSON to POJO.

For example if the REST service returns a JSON payload that binds to `com.foo.MyResponsePojo` you can configure this as shown:

```java
restConfiguration().component("jetty").host("localhost").port(8080).bindingMode(RestBindingMode.json);
from("direct:start")
.to("rest:post:user?outType=com.foo.MyResponsePojo");
```

**IMPORTANT**

You must configure `outType` option if you want POJO binding to happen for the response messages received from calling the REST service.

260.7. MORE EXAMPLES

See Rest DSL which offers more examples and how you can use the Rest DSL to define those in a nicer RESTful way.

There is a `camel-example-servlet-rest-tomcat` example in the Apache Camel distribution, that demonstrates how to use the Rest DSL with SERVLET as transport that can be deployed on Apache Tomcat, or similar web containers.

260.8. SEE ALSO

- Rest DSL
- SERVLET
CHAPTER 261. REST SWAGGER COMPONENT

Available as of Camel version 2.19

The rest-swagger configures rest producers from Swagger (Open API) specification document and delegates to a component implementing the RestProducerFactory interface. Currently known working components are:

- http
- http4
- netty4-http
- restlet
- jetty
- undertow

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rest-swagger</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

261.1. URI FORMAT

```
rest-swagger:[specificationPath#]operationId
```

Where operationId is the ID of the operation in the Swagger specification, and specificationPath is the path to the specification. If the specificationPath is not specified it defaults to swagger.json. The lookup mechanism uses Camels ResourceHelper to load the resource, which means that you can use CLASSPATH resources (classpath:my-specification.json), files (file:/some/path.json), the web (http://api.example.com/swagger.json) or reference a bean (ref:nameOfBean) or use a method of a bean (bean:nameOfBean.methodName) to get the specification resource, failing that Swagger’s own resource loading support.

This component does not act as a HTTP client, it delegates that to another component mentioned above. The lookup mechanism searches for a single component that implements the RestProducerFactory interface and uses that. If the CLASSPATH contains more than one, then the property componentName should be set to indicate which component to delegate to.

Most of the configuration is taken from the Swagger specification but the option exists to override those by specifying them on the component or on the endpoint. Typically you would just need to override the host or basePath if those differ from the specification.

NOTE

The host parameter should contain the absolute URI containing scheme, hostname and port number, for instance: https://api.example.com
With **componentName** you specify what component is used to perform the requests, this named component needs to be present in the Camel context and implement the required *RestProducerFactory* interface — as do the components listed at the top.

If you do not specify the **componentName** at either component or endpoint level, CLASSPATH is searched for a suitable delegate. There should be only one component present on the CLASSPATH that implements the *RestProducerFactory* interface for this to work.

This component’s endpoint URI is lenient which means that in addition to message headers you can specify REST operation’s parameters as endpoint parameters, these will be constant for all subsequent invocations so it makes sense to use this feature only for parameters that are indeed constant for all invocations — for example API version in path such as `/api/7.2/users/{id}`.

### 261.2. OPTIONS

The REST Swagger component supports 7 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>basePath</strong></td>
<td>API basePath, for example /v2. Default is unset, if set overrides the value present in Swagger specification.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>componentName</strong></td>
<td>Name of the Camel component that will perform the requests. The component must be present in Camel registry and it must implement RestProducerFactory service provider interface. If not set CLASSPATH is searched for single component that implements RestProducerFactory SPI. Can be overridden in endpoint configuration.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>consumes</strong></td>
<td>What payload type this component capable of consuming. Could be one type, like application/json or multiple types as application/json, application/xml; q=0.5 according to the RFC7231. This equates to the value of Accept HTTP header. If set overrides any value found in the Swagger specification. Can be overridden in endpoint configuration</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>host</strong></td>
<td>Scheme hostname and port to direct the HTTP requests to in the form of <a href="https://hostname:port">https://hostname:port</a>. Can be configured at the endpoint, component or in the corresponding REST configuration in the Camel Context. If you give this component a name (e.g. petstore) that REST configuration is consulted first, rest-swagger next, and global configuration last. If set overrides any value found in the Swagger specification, RestConfiguration. Can be overridden in endpoint configuration.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>produces (producer)</td>
<td>What payload type this component is producing. For example application/json according to the RFC7231. This equates to the value of Content-Type HTTP header. If set overrides any value present in the Swagger specification. Can be overridden in endpoint configuration.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>specificationUri (producer)</td>
<td>Path to the Swagger specification file. The scheme, host base path are taken from this specification, but these can be overridden with properties on the component or endpoint level. If not given the component tries to load swagger.json resource. Note that the host defined on the component and endpoint of this Component should contain the scheme, hostname and optionally the port in the URI syntax (i.e. <a href="https://api.example.com:8080">https://api.example.com:8080</a>). Can be overridden in endpoint configuration.</td>
<td></td>
<td>URI</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The REST Swagger endpoint is configured using URI syntax:

```
rest-swagger:specificationUri#operationId
```

with the following path and query parameters:

### 261.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>specificationUri</td>
<td>Path to the Swagger specification file. The scheme, host base path are taken from this specification, but these can be overridden with properties on the component or endpoint level. If not given the component tries to load swagger.json resource. Note that the host defined on the component and endpoint of this Component should contain the scheme, hostname and optionally the port in the URI syntax (i.e. <a href="https://api.example.com:8080">https://api.example.com:8080</a>). Overrides component configuration.</td>
<td>swagger.json</td>
<td>URI</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>operationId</td>
<td>Required ID of the operation from the Swagger specification.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

**261.2.2. Query Parameters (6 parameters):**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>basePath</td>
<td>API basePath, for example /v2. Default is unset, if set overrides the value present in Swagger specification and in the component configuration.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>componentName</td>
<td>Name of the Camel component that will perform the requests. The component must be present in Camel registry and it must implement RestProducerFactory service provider interface. If not set CLASSPATH is searched for single component that implements RestProducerFactory SPI. Overrides component configuration.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumes</td>
<td>What payload type this component capable of consuming. Could be one type, like application/json or multiple types as application/json, application/xml; q=0.5 according to the RFC7231. This equates to the value of Accept HTTP header. If set overrides any value found in the Swagger specification and in the component configuration</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td>Scheme hostname and port to direct the HTTP requests to in the form of <a href="https://hostname:port">https://hostname:port</a>. Can be configured at the endpoint, component or in the corresponding REST configuration in the Camel Context. If you give this component a name (e.g. petstore) that REST configuration is consulted first, rest-swagger next, and global configuration last. If set overrides any value found in the Swagger specification, RestConfiguration. Overrides all other configuration.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>produces</td>
<td>What payload type this component is producing. For example application/json according to the RFC7231. This equates to the value of Content-Type HTTP header. If set overrides any value present in the Swagger specification. Overrides all other configuration.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### 261.3. EXAMPLE: PETSTORE

Checkout the example in the **camel-example-rest-swagger** project in the **examples** directory.

For example if you wanted to use the **PetStore** provided REST API simply reference the specification URI and desired operation id from the Swagger specification or download the specification and store it as **swagger.json** (in the root) of CLASSPATH that way it will be automaticaly used. Let’s use the **Undertow** component to perform all the requests and Camels excelent support for Spring Boot.

Here are our dependencies defined in Maven POM file:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-undertow-starter</artifactId>
</dependency>

<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rest-swagger-starter</artifactId>
</dependency>
```

Start by defining the **Undertow** component and the **RestSwaggerComponent**:

```java
@Bean
public Component petstore(CamelContext camelContext, UndertowComponent undertow) {
    RestSwaggerComponent petstore = new RestSwaggerComponent(camelContext);
    petstore.setSpecificationUri("http://petstore.swagger.io/v2/swagger.json");
    petstore.setDelegate(undertow);

    return petstore;
}
```

**NOTE**

Support in Camel for Spring Boot will auto create the **UndertowComponent** Spring bean, and you can configure it using **application.properties** (or **application.yml**) using prefix **camel.component.undertow**. We are defining the **petstore** component here in order to have a named component in the Camel context that we can use to interact with the PetStore REST API, if this is the only **rest-swagger** component used we might configure it in the same manner (using **application.properties**).

Now in our application we can simply use the **ProducerTemplate** to invoke PetStore REST methods:
@Autowired
ProducerTemplate template;

String getPetJsonById(int petId) {
    return template.requestBodyAndHeaders("petstore:getPetById", null, "petId", petId);
}
CHAPTER 262. RESTLET COMPONENT

Available as of Camel version 2.0

The Restlet component provides Restlet based endpoints for consuming and producing RESTful resources.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-restlet</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

262.1. URI FORMAT

restlet:restletUrl[?options]

Format of restletUrl:

```
protocol://hostname[:port]/resourcePattern
```

Restlet promotes decoupling of protocol and application concerns. The reference implementation of Restlet Engine supports a number of protocols. However, we have tested the HTTP protocol only. The default port is port 80. We do not automatically switch default port based on the protocol yet.

You can append query options to the URI in the following format, `?option=value&option=value&…`

INFO: It seems Restlet is case sensitive in understanding headers. For example to use content-type, use Content-Type, and for location use Location and so on.

WARNING

We have received a report about drop in performance in camel-restlet in Camel 2.14.0 and 2.14.1. We have reported this to the Restlet team in issue 996. To remedy the issue then from Camel 2.14.2 onwards you can set synchronous=true as option on the endpoint uris, Or set it on the RestletComponent as a global option so all endpoints inherit this option.

262.2. OPTIONS

The Restlet component supports 22 options which are listed below.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>controllerDaemon (consumer)</td>
<td>Indicates if the controller thread should be a daemon (not blocking JVM exit).</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>controllerSleepTimeMs (consumer)</td>
<td>Time for the controller thread to sleep between each control.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>headerFilterStrategy (filter)</td>
<td>To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>inboundBufferSize (consumer)</td>
<td>The size of the buffer when reading messages.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>maxConnectionsPerHost (common)</td>
<td>Maximum number of concurrent connections per host (IP address).</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>maxThreads (consumer)</td>
<td>Maximum threads that will service requests.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>lowThreads (consumer)</td>
<td>Number of worker threads determining when the connector is considered overloaded.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>maxTotalConnections (common)</td>
<td>Maximum number of concurrent connections in total.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>minThreads (consumer)</td>
<td>Minimum threads waiting to service requests.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>outboundBufferSize (consumer)</td>
<td>The size of the buffer when writing messages.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>persistingConnections (consumer)</td>
<td>Indicates if connections should be kept alive after a call.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>pipeliningConnections (consumer)</td>
<td>Indicates if pipelining connections are supported.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>threadMaxIdleTimeMs (consumer)</td>
<td>Time for an idle thread to wait for an operation before being collected.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>useForwardedForHeader (consumer)</td>
<td>Lookup the X-Forwarded-For header supported by popular proxies and caches and uses it to populate the Request.getClientAddresses() method result. This information is only safe for intermediary components within your local network. Other addresses could easily be changed by setting a fake header and should not be trusted for serious security checks.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>reuseAddress (consumer)</td>
<td>Enable/disable the SO_REUSEADDR socket option. See java.io.ServerSocket.reuseAddress property for additional details.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>maxQueued (consumer)</td>
<td>Maximum number of calls that can be queued if there aren’t any worker thread available to service them. If the value is '0', then no queue is used and calls are rejected if no worker thread is immediately available. If the value is '-1', then an unbounded queue is used and calls are never rejected.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>disableStreamCache (consumer)</td>
<td>Determines whether or not the raw input stream from Restlet is cached or not (Camel will read the stream into a in memory/overflow to file, Stream caching) cache. By default Camel will cache the Restlet input stream to support reading it multiple times to ensure Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultRestletBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>port (consumer)</td>
<td>To configure the port number for the restlet consumer routes. This allows to configure this once to reuse the same port for these consumers.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>synchronous (producer)</td>
<td>Whether to use synchronous Restlet Client for the producer. Setting this option to true can yield faster performance as it seems the Restlet synchronous Client works better.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>enabledConverters (advanced)</td>
<td>A list of converters to enable as full class name or simple class name. All the converters automatically registered are enabled if empty or null</td>
<td></td>
<td>List</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
---|---|---|---
useGlobalSslContext Parameters (security) | Enable usage of global SSL context parameters. | false | boolean
resolveProperty Placeholders (advanced) | Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders. | true | boolean

The Restlet endpoint is configured using URI syntax:

```
restlet:protocol:host:port/uriPattern
```

with the following path and query parameters:

#### 262.2.1. Path Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol</td>
<td><strong>Required</strong> The protocol to use which is http or https</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td><strong>Required</strong> The hostname of the restlet service</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td><strong>Required</strong> The port number of the restlet service</td>
<td>80</td>
<td>int</td>
</tr>
<tr>
<td>uriPattern</td>
<td>The resource pattern such as /customer/id</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

#### 262.2.2. Query Parameters (18 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>restletMethod (common)</td>
<td>On a producer endpoint, specifies the request method to use. On a consumer endpoint, specifies that the endpoint consumes only restletMethod requests.</td>
<td>GET</td>
<td>Method</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>restletMethods</td>
<td>Specify one or more methods separated by commas (e.g. restletMethods=post,put) to be serviced by a restlet consumer endpoint. If both restletMethod and restletMethods options are specified, the restletMethod setting is ignored. The possible methods are: ALL, CONNECT, DELETE, GET, HEAD, OPTIONS, PATCH, POST, PUT, TRACE</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>disableStreamCache</td>
<td>Determines whether or not the raw input stream from Restlet is cached or not (Camel will read the stream into a in memory/overflow to file, Stream caching) cache. By default Camel will cache the Restlet input stream to support reading it multiple times to ensure Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultRestletBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>restletUriPatterns</td>
<td><strong>Deprecated</strong> Specify one ore more URI templates to be serviced by a restlet consumer endpoint, using the notation to reference a List in the Camel Registry. If a URI pattern has been defined in the endpoint URI, both the URI pattern defined in the endpoint and the restletUriPatterns option will be honored.</td>
<td></td>
<td>List</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------------</td>
</tr>
<tr>
<td>connectTimeout</td>
<td>The Client will give up connection if the connection is timeout, 0 for unlimited wait.</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td>cookieHandler</td>
<td>Configure a cookie handler to maintain a HTTP session</td>
<td></td>
<td>CookieHandler</td>
</tr>
<tr>
<td>socketTimeout</td>
<td>The Client socket receive timeout, 0 for unlimited wait.</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td>throwExceptionOnFailure</td>
<td>Whether to throw exception on a producer failure. If this option is false then the http status code is set as a message header which can be checked if it has an error value.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>autoCloseStream</td>
<td>Whether to auto close the stream representation as response from calling a REST service using the restlet producer. If the response is streaming and the option streamRepresentation is enabled then you may want to auto close the InputStream from the streaming response to ensure the input stream is closed when the Camel Exchange is done being routed. However if you need to read the stream outside a Camel route, you may need to not auto close the stream.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>streamRepresentation</td>
<td>Whether to support stream representation as response from calling a REST service using the restlet producer. If the response is streaming then this option can be enabled to use an java.io.InputStream as the message body on the Camel Message body. If using this option you may want to enable the autoCloseStream option as well to ensure the input stream is closed when the Camel Exchange is done being routed. However if you need to read the stream outside a Camel route, you may need to not auto close the stream.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>headerFilterStrategy</td>
<td>To use a custom HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>restletBinding</td>
<td>To use a custom RestletBinding to bind between Restlet and Camel message.</td>
<td></td>
<td>RestletBinding</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### 262.3. MESSAGE HEADERS

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>content-type</td>
<td>String</td>
<td>Specifies the content type, which can be set on the OUT message by the application/processor. The value is the <code>content-type</code> of the response message. If this header is not set, the content type is based on the object type of the OUT message body. In Camel 2.3 onward, if the Content-Type header is specified in the Camel IN message, the value of the header determine the content type for the Restlet request message. Otherwise, it is defaulted to &quot;application/x-www-form-urlencoded&quot;. Prior to release 2.3, it is not possible to change the request content type default.</td>
</tr>
<tr>
<td>Camel AcceptContentType</td>
<td>String</td>
<td>Since Camel 2.9.3, 2.10.0: The HTTP Accept request header.</td>
</tr>
<tr>
<td>Camel HttpMethod</td>
<td>String</td>
<td>The HTTP request method. This is set in the IN message header.</td>
</tr>
<tr>
<td>Camel HttpQuery</td>
<td>String</td>
<td>The query string of the request URI. It is set on the IN message by <code>DefaultRestletBinding</code> when the restlet component receives a request.</td>
</tr>
<tr>
<td>Camel HttpResponseMessage</td>
<td>String or Integer</td>
<td>The response code can be set on the OUT message by the application/processor. The value is the response code of the response message. If this header is not set, the response code is set by the restlet runtime engine.</td>
</tr>
<tr>
<td>Camel HttpUri</td>
<td>String</td>
<td>The HTTP request URI. This is set in the IN message header.</td>
</tr>
<tr>
<td>Camel RestletLogin</td>
<td>String</td>
<td>Login name for basic authentication. It is set on the IN message by the application and gets filtered before the restlet request header by Camel.</td>
</tr>
</tbody>
</table>
### Camel RESTlet Component

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel RestletPassword</td>
<td>String</td>
<td>Password name for basic authentication. It is set on the IN message by the application and gets filtered before the restlet request header by Camel.</td>
</tr>
<tr>
<td>Camel RestletRequest</td>
<td>Request</td>
<td>Camel 2.8: The org.restlet.Request object which holds all request details.</td>
</tr>
<tr>
<td>Camel RestletResponse</td>
<td>Response</td>
<td>Camel 2.8: The org.restlet.Response object. You can use this to create responses using the API from Restlet. See examples below.</td>
</tr>
<tr>
<td>org.restlet.*</td>
<td></td>
<td>Attributes of a Restlet message that get propagated to Camel IN headers.</td>
</tr>
<tr>
<td>cache-control</td>
<td>String or List&lt;CacheDirective&gt;</td>
<td>Camel 2.11: User can set the cache-control with the String value or the List of CacheDirective of Restlet from the camel message header.</td>
</tr>
</tbody>
</table>

#### 262.4. MESSAGE BODY

Camel will store the restlet response from the external server on the OUT body. All headers from the IN message will be copied to the OUT message, so that headers are preserved during routing.

#### 262.5. SAMPLES

##### 262.5.1. Restlet Endpoint with Authentication

The following route starts a restlet consumer endpoint that listens for POST requests on http://localhost:8080. The processor creates a response that echoes the request body and the value of the id header.

The restletRealm setting in the URI query is used to look up a Realm Map in the registry. If this option is specified, the restlet consumer uses the information to authenticate user logins. Only authenticated requests can access the resources. In this sample, we create a Spring application context that serves as a registry. The bean ID of the Realm Map should match the restletRealmRef.

The following sample starts a direct endpoint that sends requests to the server on http://localhost:8080 (that is, our restlet consumer endpoint).

That is all we need. We are ready to send a request and try out the restlet component:
The sample client sends a request to the `direct:start-auth` endpoint with the following headers:

- **CamelRestletLogin** (used internally by Camel)
- **CamelRestletPassword** (used internally by Camel)
- **id** (application header)

**NOTE**

`org.apache.camel.restlet.auth.login` and `org.apache.camel.restlet.auth.password` will not be propagated as Restlet header.

The sample client gets a response like the following:

```
received [<order foo='1'/>] as an order id = 89531
```

### 262.5.2. Single restlet endpoint to service multiple methods and URI templates (deprecated)

This functionality is **deprecated** so do NOT use!

It is possible to create a single route to service multiple HTTP methods using the `restletMethods` option. This snippet also shows how to retrieve the request method from the header:

In addition to servicing multiple methods, the next snippet shows how to create an endpoint that supports multiple URI templates using the `restletUriPatterns` option. The request URI is available in the header of the IN message as well. If a URI pattern has been defined in the endpoint URI (which is not the case in this sample), both the URI pattern defined in the endpoint and the `restletUriPatterns` option will be honored.

The `restletUriPatterns=#uriTemplates` option references the `<List<String>` bean defined in the Spring XML configuration.

```
<util:list id="uriTemplates">
  <value>/users/{username}</value>
  <value>/atom/collection/{id}/component/{cid}</value>
</util:list>
```

### 262.5.3. Using Restlet API to populate response

**Available as of Camel 2.8**

You may want to use the `org.restlet.Response` API to populate the response. This gives you full access to the Restlet API and fine grained control of the response. See the route snippet below where we generate the response from an inlined Camel Processor:

**Generating response using Restlet Response API**

### 262.5.4. Configuring max threads on component

To configure the max threads options you must do this on the component, such as:
262.5.5. Using the Restlet servlet within a webapp

Available as of Camel 2.8

There are three possible ways to configure a Restlet application within a servlet container and using the subclassed SpringServerServlet enables configuration within Camel by injecting the Restlet Component.

Use of the Restlet servlet within a servlet container enables routes to be configured with relative paths in URIs (removing the restrictions of hard-coded absolute URIs) and for the hosting servlet container to handle incoming requests (rather than have to spawn a separate server process on a new port).

To configure, add the following to your camel-context.xml;

```xml
<camelContext>
  <route id="RS_RestletDemo">
    <from uri="restlet:/demo/{id}" />
    <transform>
      <simple>Request type : ${header.CamelHttpMethod} and ID : ${header.id}</simple>
    </transform>
  </route>
</camelContext>

<bean id="RestletComponent" class="org.restlet.Component" />

<bean id="RestletComponentService" class="org.apache.camel.component.restlet.RestletComponent">
  <constructor-arg index="0">
    <ref bean="RestletComponent" />
  </constructor-arg>
</bean>
```

And add this to your web.xml;

```xml
<!-- Restlet Servlet -->
< servlet>
  <servlet-name>RestletServlet</servlet-name>
  <servlet-class>org.restlet.ext.spring.SpringServerServlet</servlet-class>
  <init-param>
    <param-name>org.restlet.component</param-name>
    <param-value>RestletComponent</param-value>
  </init-param>
</ servlet>

< servlet-mapping>
  <servlet-name>RestletServlet</servlet-name>
  <url-pattern>/rs/*</url-pattern>
</ servlet-mapping>
```

You will then be able to access the deployed route at http://localhost:8080/mywebapp/rs/demo/1234 where;
localhost:8080 is the server and port of your servlet container
mywebapp is the name of your deployed webapp
Your browser will then show the following content:

"Request type : GET and ID : 1234"

You will need to add dependency on the Spring extension to restlet which you can do in your Maven pom.xml file:

```xml
<dependency>
  <groupId>org.restlet.jee</groupId>
  <artifactId>org.restlet.ext.spring</artifactId>
  <version>${restlet-version}</version>
</dependency>
```

And you would need to add dependency on the restlet maven repository as well:

```xml
<repository>
  <id>maven-restlet</id>
  <name>Public online Restlet repository</name>
  <url>http://maven.restlet.org</url>
</repository>
```
CHAPTER 263. RIBBON COMPONENT

Available as of Camel version 2.18

The ribbon component provides use of Netflix Ribbon for client side load balancing.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ribbon</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

This component helps applying load balancing feature at the client side when using ServiceCall EIP.

263.1. CONFIGURATION

- **Programmatic**

  ```java
  RibbonConfiguration configuration = new RibbonConfiguration();
  configuration.addProperties("ServerListRefreshInterval", "250");

  RibbonLoadBalancer loadBalancer = new RibbonLoadBalancer(configuration);
  ```

  ```java
  from("direct:start")
  .serviceCall()
  .name("myService")
  .loadBalancer(loadBalancer)
  .consulServiceDiscovery()
  .end()
  .to("mock:result");
  ```

- **Spring Boot**

  ```java
  application.properties
  ```

  ```java
  camel.cloud.ribbon.properties[ServerListRefreshInterval] = 250
  ```

  ```java
  from("direct:start")
  .serviceCall()
  .name("myService")
  .ribbonLoadBalancer()
  .consulServiceDiscovery()
  .end()
  .to("mock:result");
  ```

- **XML**

  ```xml
  <route>
  ```
263.2. SEE ALSO

- ServiceCall EIP
CHAPTER 264. RMI COMPONENT

Available as of Camel version 1.0

The rmi: component binds Exchanges to the RMI protocol (JRMP).

Since this binding is just using RMI, normal RMI rules still apply regarding what methods can be invoked. This component supports only Exchanges that carry a method invocation from an interface that extends the Remote interface. All parameters in the method should be either Serializable or Remote objects.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-rmi</artifactId>
    <version>x.x.x</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

264.1. URI FORMAT

For example:

```text
rmi://rmi-registry-host:rmi-registry-port/registry-path[?options]
```

You can append query options to the URI in the following format, ?option=value&option=value&…

264.2. OPTIONS

The RMI component has no options.

The RMI endpoint is configured using URI syntax:

```text
rmi:hostname:port/name
```

with the following path and query parameters:

264.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname</td>
<td>Hostname of RMI server</td>
<td>hostname</td>
<td>String</td>
</tr>
<tr>
<td>name</td>
<td>Required Name to use when binding to RMI server</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>port</td>
<td>Port number of RMI server</td>
<td>1099</td>
<td>int</td>
</tr>
</tbody>
</table>
264.2.2. Query Parameters (6 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>method (common)</td>
<td>You can set the name of the method to invoke.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>remoteInterfaces (common)</td>
<td>To specific the remote interfaces.</td>
<td></td>
<td>List</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

264.3. USING

To call out to an existing RMI service registered in an RMI registry, create a route similar to the following:

```java
from("pojo:foo").to("rmi://localhost:1099/foo");
```

To bind an existing camel processor or service in an RMI registry, define an RMI endpoint as follows:

```java
RmiEndpoint endpoint= (RmiEndpoint) endpoint("rmi://localhost:1099/bar");
endpoint.setRemoteInterfaces(ISay.class);
from(endpoint).to("pojo:bar");
```

Note that when binding an RMI consumer endpoint, you must specify the Remote interfaces exposed.

In XML DSL you can do as follows from Camel 2.7 onwards:

```xml
<camel:route>
  <from url="rmi://localhost:37541/helloServiceBean?
```
264.4. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 265. ROUTEBOX COMPONENT (DEPRECATED)

Available as of Camel version 2.6

Routebox subject for change

The routebox component enables the creation of specialized endpoints that offer encapsulation and a strategy based indirection service to a collection of camel routes hosted in an automatically created or user injected camel context.

Routebox endpoints are camel endpoints that may be invoked directly on camel routes. The routebox endpoint performs the following key functions

- encapsulation - acts as a blackbox, hosting a collection of camel routes stored in an inner camel context. The inner context is fully under the control of the routebox component and is JVM bound.

- strategy based indirection - direct payloads sent to the routebox endpoint along a camel route to specific inner routes based on a user defined internal routing strategy or a dispatch map.

- exchange propagation - forward exchanges modified by the routebox endpoint to the next segment of the camel route.

The routebox component supports both consumer and producer endpoints.

Producer endpoints are of two flavors

- Producers that send or dispatch incoming requests to a external routebox consumer endpoint

- Producers that directly invoke routes in an internal embedded camel context thereby not sending requests to an external consumer.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-routebox</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

265.1. THE NEED FOR A CAMEL ROUTEBOX ENDPOINT

The routebox component is designed to ease integration in complex environments needing

- a large collection of routes and

- involving a wide set of endpoint technologies needing integration in different ways

In such environments, it is often necessary to craft an integration solution by creating a sense of layering among camel routes effectively organizing them into

- Coarse grained or higher level routes - aggregated collection of inner or lower level routes exposed as Routebox endpoints that represent an integration focus area. For example
### Focus Area

<table>
<thead>
<tr>
<th>Department Focus</th>
<th>Coarse grained Route Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>HR routes, Sales routes etc</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Supply chain &amp; B2B Focus</th>
<th>Coarse grained Route Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shipping routes, Fulfillment routes, 3rd party services etc</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Technology Focus</th>
<th>Coarse grained Route Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database routes, JMS routes, Scheduled batch routes etc</td>
<td></td>
</tr>
</tbody>
</table>

- Fine grained routes - routes that execute a singular and specific business and/or integration pattern.

Requests sent to Routebox endpoints on coarse grained routes can then delegate requests to inner fine grained routes to achieve a specific integration objective, collect the final inner result, and continue to progress to the next step along the coarse-grained route.

#### 265.2. URI FORMAT

```
routebox:routeboxname[?options]
```

You can append query options to the URI in the following format, `?option=value&option=value&...`

#### 265.3. OPTIONS

The RouteBox component has no options.

The RouteBox endpoint is configured using URI syntax:

```
routebox:routeboxName
```

with the following path and query parameters:

**265.3.1. Path Parameters (1 parameters):**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeboxName</td>
<td>Required Logical name for the routebox (eg like a queue name)</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

**265.3.2. Query Parameters (17 parameters):**
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>dispatchMap</td>
<td>A string representing a key in the Camel Registry matching an object value of the type HashMap. The HashMap key should contain strings that can be matched against the value set for the exchange header ROUTE_DISPATCH_KEY. The HashMap value should contain inner route consumer URI's to which requests should be directed.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>dispatchStrategy</td>
<td>To use a custom RouteboxDispatchStrategy which allows to use custom dispatching instead of the default.</td>
<td></td>
<td>RouteboxDispatchStrategy</td>
</tr>
<tr>
<td>forkContext</td>
<td>Whether to fork and create a new inner CamelContext instead of reusing the same CamelContext.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>innerProtocol</td>
<td>The Protocol used internally by the Routebox component. Can be Direct or SEDA. The Routebox component currently offers protocols that are JVM bound.</td>
<td>direct</td>
<td>String</td>
</tr>
<tr>
<td>queueSize</td>
<td>Create a fixed size queue to receive requests.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>pollInterval</td>
<td>The timeout used when polling from seda. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>threads</td>
<td>Number of threads to be used by the routebox to receive requests.</td>
<td>20</td>
<td>int</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
</tbody>
</table>
### 265.4. SENDING/RECEIVING MESSAGES TO/FROM THE ROUTEBOX

Before sending requests it is necessary to properly configure the routebox by loading the required URI parameters into the Registry as shown below. In the case of Spring, if the necessary beans are declared correctly, the registry is automatically populated by Camel.

#### 265.4.1. Step 1: Loading inner route details into the Registry

```java
@Override
protected JndiRegistry createRegistry() throws Exception {
    JndiRegistry registry = new JndiRegistry(createJndiContext());

    // Wire the routeDefinitions & dispatchStrategy to the outer camelContext where the routebox is
```
265.4.2. Step 2: Optional use of a Dispatch Strategy instead of a Dispatch Map

Using a dispatch Strategy involves implementing the interface
org.apache.camel.component.routebox.strategy.RouteboxDispatchStrategy as shown in the example below.

```
List<RouteBuilder> routes = new ArrayList<RouteBuilder>();
registry.bind("registry", createInnerRegistry());
registry.bind("routes", routes);

// Wire a dispatch map to registry
HashMap<String, String> map = new HashMap<String, String>();
map.put("addToCatalog", "seda:addToCatalog");
map.put("findBook", "seda:findBook");
registry.bind("map", map);

// Alternatively wiring a dispatch strategy to the registry
registry.bind("strategy", new SimpleRouteDispatchStrategy());
```

```
private JndiRegistry createInnerRegistry() throws Exception {
  JndiRegistry innerRegistry = new JndiRegistry(createJndiContext());
  BookCatalog catalogBean = new BookCatalog();
  innerRegistry.bind("library", catalogBean);

  return innerRegistry;
}
```

```
public class SimpleRouteDispatchStrategy implements RouteboxDispatchStrategy {

  /* (non-Javadoc)
   * @see org.apache.camel.component.routebox.strategy.RouteboxDispatchStrategy#selectDestinationUri(java.util.List, org.apache.camel.Exchange)
   */
  public URI selectDestinationUri(List<URI> activeDestinations, Exchange exchange) {
    URI dispatchDestination = null;

    String operation = exchange.getIn().getHeader("ROUTE_DISPATCH_KEY", String.class);
    for (URI destination : activeDestinations) {
      if (destination.toASCIIString().equalsIgnoreCase("seda:" + operation)) {
        dispatchDestination = destination;
        break;
      }
    }
  }
```
265.4.3. Step 2: Launching a routebox consumer

When creating a route consumer, note that the # entries in the routeboxUri are matched to the created inner registry, routebuilder list and dispatchStrategy/dispatchMap in the CamelContext Registry. Note that all routebuilders and associated routes are launched in the routebox created inner context.

```java
private String routeboxUri = "routebox:multipleRoutes?
innerRegistry=#registry&routeBuilders=#routes&dispatchMap=#map";

public void testRouteboxRequests() throws Exception {
    CamelContext context = createCamelContext();
    template = new DefaultProducerTemplate(context);
    template.start();

    context.addRoutes(new RouteBuilder() {
        public void configure() {
            from(routeboxUri)
                .to("log:Routes operation performed?showAll=true");
        }
    });
    context.start();

    // Now use the ProducerTemplate to send the request to the routebox
    template.requestBodyAndHeader(routeboxUri, book,
        "ROUTE_DISPATCH_KEY", "addToCatalog");
}
```

265.4.4. Step 3: Using a routebox producer

When sending requests to the routebox, it is not necessary for producers do not need to know the inner route endpoint URI and they can simply invoke the Routebox URI endpoint with a dispatch strategy or dispatchMap as shown below.

It is necessary to set a special exchange Header called ROUTE_DISPATCH_KEY (optional for Dispatch Strategy) with a key that matches a key in the dispatch map so that the request can be sent to the correct inner route.

```java
from("direct:sendToStrategyBasedRoutebox")
    .to("routebox:multipleRoutes?
        innerRegistry=#registry&routeBuilders=#routes&dispatchStrategy=#strategy")
    .to("log:Routes operation performed?showAll=true");

from ("direct:sendToMapBasedRoutebox")
    .setHeader("ROUTE_DISPATCH_KEY", constant("addToCatalog"))
    .to("routebox:multipleRoutes?
        innerRegistry=#registry&routeBuilders=#routes&dispatchMap=#map")
    .to("log:Routes operation performed?showAll=true");
```
CHAPTER 266. RSS COMPONENT

Available as of Camel version 2.0

The rss: component is used for polling RSS feeds. Camel will default poll the feed every 60th seconds.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rss</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Note: The component currently only supports polling (consuming) feeds.

**NOTE**

Camel-rss internally uses a patched version of ROME hosted on ServiceMix to solve some OSGi class loading issues.

266.1. URI FORMAT

rss:rssUri

Where rssUri is the URI to the RSS feed to poll.

You can append query options to the URI in the following format, `?option=value&option=value&...`

266.2. OPTIONS

The RSS component has no options.

The RSS endpoint is configured using URI syntax:

rss:feedUri

with the following path and query parameters:

266.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>feedUri</td>
<td>Required The URI to the feed to poll.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

266.2.2. Query Parameters (27 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bridgeErrorHandler</code> (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>feedHeader</code> (consumer)</td>
<td>Sets whether to add the feed object as a header</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>filter</code> (consumer)</td>
<td>Sets whether to use filtering or not of the entries.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>lastUpdate</code> (consumer)</td>
<td>Sets the timestamp to be used for filtering entries from the atom feeds. This options is only in conjunction with the splitEntries.</td>
<td></td>
<td>Date</td>
</tr>
<tr>
<td><code>password</code> (consumer)</td>
<td>Sets the password to be used for basic authentication when polling from a HTTP feed</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>sendEmptyMessageWhenIdle</code> (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>sortEntries</code> (consumer)</td>
<td>Sets whether to sort entries by published date. Only works when splitEntries = true.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>splitEntries</code> (consumer)</td>
<td>Sets whether or not entries should be sent individually or whether the entire feed should be sent as a single message</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>throttleEntries</code> (consumer)</td>
<td>Sets whether all entries identified in a single feed poll should be delivered immediately. If true, only one entry is processed per consumer.delay. Only applicable when splitEntries = true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>username</code> (consumer)</td>
<td>Sets the username to be used for basic authentication when polling from a HTTP feed</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>exceptionHandler</code> (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------</td>
<td>-------------------</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>pollStrategy</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>backoffIdleThreshold</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>backoffMultiplier</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>delay</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
</tbody>
</table>
### 266.3. EXCHANGE DATA TYPES

Camel initializes the In body on the Exchange with a ROME SyndFeed. Depending on the value of the splitEntries flag, Camel returns either a SyndFeed with one SyndEntry or a java.util.List of SyndEntries.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>splitEntries</td>
<td>true</td>
<td>A single entry from the current feed is set in the exchange.</td>
</tr>
<tr>
<td>splitEntries</td>
<td>false</td>
<td>The entire list of entries from the current feed is set in the exchange.</td>
</tr>
</tbody>
</table>

### 266.4. MESSAGE HEADERS

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel RssFeed</td>
<td>The entire SyndFeed object.</td>
</tr>
</tbody>
</table>

### 266.5. RSS DATAFORMAT
The RSS component ships with an RSS dataformat that can be used to convert between String (as XML) and ROME RSS model objects.

- marshal = from ROME SyndFeed to XML String
- unmarshal = from XML String to ROME SyndFeed

A route using the RSS dataformat will look like this: from("rss:file:src/test/data/rss20.xml?splitEntries=false&consumer.delay=1000").marshal().rss().to("mock:marshal");

The purpose of this feature is to make it possible to use Camel’s built-in expressions for manipulating RSS messages. As shown below, an XPath expression can be used to filter the RSS message. In the following example, only entries with Camel in the title will get through the filter.

```
'from("rss:file:src/test/data/rss20.xml?
    splitEntries=true&consumer.delay=100").marshal().rss().filter().xpath("//item/title[contains(.,'Camel')]").to
    ("mock:result");'
```

TIP

**Query parameters** If the URL for the RSS feed uses query parameters, this component will resolve them. For example if the feed uses `alt=rss`, then the following example will be resolved:

from("rss:http://someserver.com/feeds/posts/default?
    alt=rss&splitEntries=false&consumer.delay=1000").to("bean:rss");

### 266.6. FILTERING ENTRIES

You can filter out entries using XPath, as shown in the data format section above. You can also exploit Camel’s Bean Integration to implement your own conditions. For instance, a filter equivalent to the XPath example above would be:

```
from("rss:file:src/test/data/rss20.xml?splitEntries=true&consumer.delay=100").
    filter().method("myFilterBean", "titleContainsCamel").to("mock:result");
```

The custom bean for this would be:

```java
public static class FilterBean {
    public boolean titleContainsCamel(@Body SyndFeed feed) { SyndEntry firstEntry = (SyndEntry) feed.getEntries().get(0);
        return firstEntry.getTitle().contains("Camel");
    }
}
```

### 266.7. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
- Atom
CHAPTER 267. RSS DATAFORMAT

Available as of Camel version 2.1

The RSS component ships with an RSS dataformat that can be used to convert between String (as XML) and ROME RSS model objects.

- marshal = from ROME SyndFeed to XML String
- unmarshal = from XML String to ROME SyndFeed

A route using this would look something like this:

The purpose of this feature is to make it possible to use Camel’s lovely built-in expressions for manipulating RSS messages. As shown below, an XPath expression can be used to filter the RSS message:

**TIP**

Query parameters If the URL for the RSS feed uses query parameters, this component will understand them as well, for example if the feed uses alt=rss, then you can for example do

```java
```

267.1. OPTIONS

The RSS dataformat supports 1 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>
CHAPTER 268. SALESFORCE COMPONENT

Available as of Camel version 2.12

This component supports producer and consumer endpoints to communicate with Salesforce using Java DTOs. There is a companion maven plugin Camel Salesforce Plugin that generates these DTOs (see further below).

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-salesforce</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

NOTE

Developers wishing to contribute to the component are instructed to look at the README.md file on instructions on how to get started and setup your environment for running integration tests.

268.1. AUTHENTICATING TO SALESFORCE

The component supports three OAuth authentication flows:

- OAuth 2.0 Username-Password Flow
- OAuth 2.0 Refresh Token Flow
- OAuth 2.0 JWT Bearer Token Flow

For each of the flow different set of properties needs to be set:

Table 268.1. Properties to set for each authentication flow

<table>
<thead>
<tr>
<th>Property</th>
<th>Where to find it on Salesforce</th>
<th>Flow</th>
</tr>
</thead>
<tbody>
<tr>
<td>clientId</td>
<td>Connected App, Consumer Key</td>
<td>All flows</td>
</tr>
<tr>
<td>clientSecret</td>
<td>Connected App, Consumer Secret</td>
<td>Username-Password, Refresh Token</td>
</tr>
<tr>
<td>userName</td>
<td>Salesforce user username</td>
<td>Username-Password, JWT Bearer Token</td>
</tr>
<tr>
<td>password</td>
<td>Salesforce user password</td>
<td>Username-Password</td>
</tr>
<tr>
<td>refreshToken</td>
<td>From OAuth flow callback</td>
<td>Refresh Token</td>
</tr>
</tbody>
</table>
The component auto determines what flow you’re trying to configure, to be remove ambiguity set the `authenticationType` property.

**NOTE**

Using Username-Password Flow in production is not encouraged.

**NOTE**

The certificate used in JWT Bearer Token Flow can be a selfsigned certificate. The KeyStore holding the certificate and the private key must contain only single certificate-private key entry.

### 268.2. URI FORMAT

When used as a consumer, receiving streaming events, the URI scheme is:

```java
salesforce:topic?options
```

When used as a producer, invoking the Salesforce RSET APIs, the URI scheme is:

```java
salesforce:operationName?options
```

You can append query options to the URI in the following format, `?option=value&option=value&…`

### 268.3. PASSING IN SALESFORCE HEADERS AND FETCHING SALESFORCE RESPONSE HEADERS

With Camel 2.21 there is support to pass Salesforce headers via inbound message headers, header names that start with `Sforce` or `x-sfdc` on the Camel message will be passed on in the request, and response headers that start with `Sforce` will be present in the outbound message headers.

For example to fetch API limits you can specify:

```java
// in your Camel route set the header before Salesforce endpoint
// ...
.setHeader("Sforce-Limit-Info", constant("api-usage"))
.to("salesforce:getGlobalObjects")
.to(myProcessor);

// myProcessor will receive `Sforce-Limit-Info` header on the outbound message
class MyProcessor implements Processor {
    public void process(Exchange exchange) throws Exception {
        Message in = exchange.getIn();
```
268.4. SUPPORTED SALESFORCE APIs

The component supports the following Salesforce APIs

Producer endpoints can use the following APIs. Most of the APIs process one record at a time, the Query API can retrieve multiple Records.

268.4.1. Rest API

You can use the following for operationName:

- getVersions - Gets supported Salesforce REST API versions
- getResources - Gets available Salesforce REST Resource endpoints
- getGlobalObjects - Gets metadata for all available SObject types
- getBasicInfo - Gets basic metadata for a specific SObject type
- getDescription - Gets comprehensive metadata for a specific SObject type
- getSObject - Gets an SObject using its Salesforce Id
- createSObject - Creates an SObject
- updateSObject - Updates an SObject using Id
- deleteSObject - Deletes an SObject using Id
- getSObjectWithId - Gets an SObject using an external (user defined) id field
- upsertSObject - Updates or inserts an SObject using an external id
- deleteSObjectWithId - Deletes an SObject using an external id
- query - Runs a Salesforce SOQL query
- queryMore - Retrieves more results (in case of large number of results) using result link returned from the 'query' API
- queryAll - Runs a SOQL query. It returns the results that are deleted because of a merge or delete. Also returns the information about archived Task and Event records.
- search - Runs a Salesforce SOSL query
- limits - fetching organization API usage limits
- recent - fetching recent items
- approval - submit a record or records (batch) for approval process
- approvals - fetch a list of all approval processes
composite - submit up to 25 possibly related REST requests and receive individual responses
composite-tree - create up to 200 records with parent-child relationships (up to 5 levels) in one go
composite-batch - submit a composition of requests in batch
getBlobField - Retrieves the specified blob field from an individual record.
apexCall - Executes a user defined APEX REST API call.

For example, the following producer endpoint uses the upsertSObject API, with the sObjectIdName parameter specifying 'Name' as the external id field. The request message body should be an SObject DTO generated using the maven plugin. The response message will either be null if an existing record was updated, or CreateSObjectResult with an id of the new record, or a list of errors while creating the new object.

...to("salesforce:upsertSObject?sObjectIdName=Name")...

268.4.2. Rest Bulk API

Producer endpoints can use the following APIs. All Job data formats, i.e. xml, csv, zip/xml, and zip/csv are supported. The request and response have to be marshalled/unmarshalled by the route. Usually the request will be some stream source like a CSV file, and the response may also be saved to a file to be correlated with the request.

You can use the following for operationName:

createJob - Creates a Salesforce Bulk Job
getJob - Gets a Job using its Salesforce Id
closeJob - Closes a Job
abortJob - Aborts a Job
createBatch - Submits a Batch within a Bulk Job
getBatch - Gets a Batch using Id
getAllBatches - Gets all Batches for a Bulk Job Id
getRequest - Gets Request data (XML/CSV) for a Batch
getResults - Gets the results of the Batch when its complete
createBatchQuery - Creates a Batch from an SOQL query
getQueryResultIds - Gets a list of Result Ids for a Batch Query
getQueryResult - Gets results for a Result Id
getRecentReports - Gets up to 200 of the reports you most recently viewed by sending a GET request to the Report List resource.
- **getReportDescription** - Retrieves the report, report type, and related metadata for a report, either in a tabular or summary or matrix format.

- **executeSyncReport** - Runs a report synchronously with or without changing filters and returns the latest summary data.

- **executeAsyncReport** - Runs an instance of a report asynchronously with or without filters and returns the summary data with or without details.

- **getReportInstances** - Returns a list of instances for a report that you requested to be run asynchronously. Each item in the list is treated as a separate instance of the report.

- **getReportResults** - Contains the results of running a report.

For example, the following producer endpoint uses the createBatch API to create a Job Batch. The in message must contain a body that can be converted into an *InputStream* (usually UTF-8 CSV or XML content from a file, etc.) and header fields 'jobId' for the Job and 'contentType' for the Job content type, which can be XML, CSV, ZIP_XML or ZIP_CSV. The put message body will contain *BatchInfo* on success, or throw a *SalesforceException* on error.

```java
...to("salesforce:createBatchJob")..
```

### 268.4.3. Rest Streaming API

Consumer endpoints can use the following syntax for streaming endpoints to receive Salesforce notifications on create/update.

To create and subscribe to a topic

```java
from("salesforce:CamelTestTopic?
  notifyForFields=ALL&notifyForOperations=ALL&sObjectName=Merchandise__c&updateTopic=true&sObjectNameQuery=SELECT Id, Name FROM Merchandise__c")...
```

To subscribe to an existing topic

```java
from("salesforce:CamelTestTopic&sObjectName=Merchandise__c")...
```

### 268.4.4. Platform events

To emit a platform event use *createSObject* operation. And set the message body can be JSON string or InputStream with key-value data – in that case *sObjectName* needs to be set to the API name of the event, or a class that extends from AbstractDTOBase with the appropriate class name for the event.

For example using a DTO:

```java
class Order_Event__e extends AbstractDTOBase {
  @JsonProperty("OrderNumber")
  private String orderNumber;
  // ... other properties and getters/setters
}
```

```java
from("timer:tick")
  .process(exchange -> {
    final Message in = exchange.getIn();
```
Or using JSON event data:

```java
PlatformEvent event = consumer.receiveBody("salesforce:event/Order_Event__e", PlatformEvent.class);
```

To receive platform events use the consumer endpoint with the API name of the platform event prefixed with `event/` (or `/event/`), e.g.: `salesforce:events/Order_Event__e`. Processor consuming from that endpoint will receive either `org.apache.camel.component.salesforce.api.dto.PlatformEvent` object or `org.cometd.bayeux.Message` in the body depending on the `rawPayload` being `false` or `true` respectively.

For example, in the simplest form to consume one event:

```java
PlatformEvent event = consumer.receiveBody("salesforce:event/Order_Event__e", PlatformEvent.class);
```

### 268.5. EXAMPLES

#### 268.5.1. Uploading a document to a ContentWorkspace

Create the ContentVersion in Java, using a Processor instance:

```java
public class ContentProcessor implements Processor {
    public void process(Exchange exchange) throws Exception {
        Message message = exchange.getIn();

        ContentVersion cv = new ContentVersion();
        ContentWorkspace cw = getWorkspace(exchange);
        cv.setFirstPublishLocationId(cw.getId());
        cv.setTitle("test document");
        cv.setPathOnClient("test_doc.html");
        byte[] document = message.getBody(byte[].class);
        ObjectMapper mapper = new ObjectMapper();
        String enc = mapper.writeValueAsString(document, String.class);
        cv.setVersionDataURL(enc);
        message.setBody(cv);
    }

    protected ContentWorkspace getWorkSpace(Exchange exchange) {
        // Look up the content workspace somehow, maybe use enrich() to add it to a
        // header that can be extracted here
    }
}
```
268.6. USING SALESFORCE LIMITS API

With `salesforce:limits` operation you can fetch API limits from Salesforce and then act upon that data received. The result of `salesforce:limits` operation is mapped to `org.apache.camel.component.salesforce.api.dto.Limits` class and can be used in a custom processors or expressions.

For instance, consider that you need to limit the API usage of Salesforce so that 10% of daily API requests is left for other routes. The body of output message contains an instance of `org.apache.camel.component.salesforce.api.dto.Limits` object that can be used in conjunction with Content Based Router and Spring Expression Language (SpEL) to choose when to perform queries.

Notice how multiplying `1.0` with the integer value held in `body.dailyApiRequests.remaining` makes the expression evaluate as with floating point arithmetic, without it - it would end up making integral division which would result with either `0` (some API limits consumed) or `1` (no API limits consumed).

```java
from("direct:querySalesforce")
  .to("salesforce:limits")
  .choice()
  .when(spel("#{1.0 * body.dailyApiRequests.remaining / body.dailyApiRequests.max < 0.1}"))
    .to("salesforce:query?...")
  .otherwise()
    .setBody(constant("Used up Salesforce API limits, leaving 10% for critical routes"))
  .endChoice()
```

268.7. WORKING WITH APPROVALS

All the properties are named exactly the same as in the Salesforce REST API prefixed with `approval`. You can set approval properties by setting `approval.PropertyName` of the Endpoint these will be used as template – meaning that any property not present in either body or header will be taken from the Endpoint configuration. Or you can set the approval template on the Endpoint by assigning `approval` property to a reference onto a bean in the Registry.

You can also provide header values using the same `approval.PropertyName` in the incoming message headers.

And finally body can contain one `ApprovalRequest` or an `Iterable` of `ApprovalRequest` objects to process as a batch.

The important thing to remember is the priority of the values specified in these three mechanisms:

1. value in body takes precedence before any other
2. value in message header takes precedence before template value
3. value in template is set if no other value in header or body was given

For example to send one record for approval using values in headers use:

Given a route:

```java
from("direct:example1")
  .setHeader("approval.ContextId", simple("${body['contextId']}"))
  .setHeader("approval.NextApproverIds", simple("${body['nextApproverIds']}"))
  .to("salesforce:approval?"
      + "approval.actionType=Submit"/
      + "&approval.comments=this is a test"/
      + "&approval.processDefinitionNameOrId=Test_Account_Process"/
      + "&approval.skipEntryCriteria=true");
```

You could send a record for approval using:

```java
final Map<String, String> body = new HashMap<>();
body.put("contextId", accountIds.iterator().next());
body.put("nextApproverIds", userId);
final ApprovalResult result = template.requestBody("direct:example1", body, ApprovalResult.class);
```

268.8. USING SALESFORCE RECENT ITEMS API

To fetch the recent items use `salesforce:recent` operation. This operation returns a `java.util.List` of `org.apache.camel.component.salesforce.api.dto.RecentItem` objects (List<RecentItem>) that in turn contain the `Id`, `Name` and `Attributes` (with `type` and `url` properties). You can limit the number of returned items by specifying `limit` parameter set to maximum number of records to return. For example:

```java
from("direct:fetchRecentItems")
  .to("salesforce:recent")
  .split().body()
  .log("${body.name} at ${body.attributes.url}");
```

268.9. WORKING WITH APPROVALS

All the properties are named exactly the same as in the Salesforce REST API prefixed with `approval`. You can set approval properties by setting `approval.PropertyName` of the Endpoint these will be used as template – meaning that any property not present in either body or header will be taken from the Endpoint configuration. Or you can set the approval template on the Endpoint by assigning `approval` property to a reference onto a bean in the Registry.

You can also provide header values using the same `approval.PropertyName` in the incoming message headers.

And finally body can contain one `ApprovalRequest` or an `Iterable` of `ApprovalRequest` objects to process as a batch.

The important thing to remember is the priority of the values specified in these three mechanisms:

1. value in body takes precedence before any other
2. Value in message header takes precedence before template value
3. Value in template is set if no other value in header or body was given

For example to send one record for approval using values in headers use:

Given a route:

```java
from("direct:example1")
    .setHeader("approval.ContextId", simple("${body['contextId']}"))
    .setHeader("approval.NextApproverIds", simple("${body['nextApproverIds']}"))
    .to("salesforce:approval?" + "approvalActionType=Submit" + "/&approvalComments=this is a test" + "/&approvalProcessDefinitionNameOrId=Test_Account_Process" + "/&approvalSkipEntryCriteria=true");
```

You could send a record for approval using:

```java
final Map<String, String> body = new HashMap<>();
body.put("contextId", accountIds.iterator().next());
body.put("nextApproverIds", userId);
final ApprovalResult result = template.requestBody("direct:example1", body, ApprovalResult.class);
```

### 268.10. Using Salesforce Composite API to Submit SOBJECT TREE

To create up to 200 records including parent-child relationships use `salesforce:composite-tree` operation. This requires an instance of `org.apache.camel.component.salesforce.api.dto.composite.SObjectTree` in the input message and returns the same tree of objects in the output message. The `org.apache.camel.component.salesforce.api.dto.AbstractSObjectBase` instances within the tree get updated with the identifier values (`id` property) or their corresponding `org.apache.camel.component.salesforce.api.dto.composite.SObjectNode` is populated with errors on failure.

Note that for some records operation can succeed and for some it can fail — so you need to manually check for errors.

Easiest way to use this functionality is to use the DTOs generated by the `camel-salesforce-maven-plugin`, but you also have the option of customizing the references that identify the each object in the tree, for instance primary keys from your database.

Let's look at an example:

```java
Account account = ...
Contact president = ...
Contact marketing = ...
Account anotherAccount = ...
Contact sales = ...
Asset someAsset = ...
```
268.11. USING SALESFORCE COMPOSITE API TO SUBMIT MULTIPLE REQUESTS IN A BATCH

The Composite API batch operation (composite-batch) allows you to accumulate multiple requests in a batch and then submit them in one go, saving the round trip cost of multiple individual requests. Each response is then received in a list of responses with the order preserved, so that the n-th requests response is in the n-th place of the response.

NOTE

The results can vary from API to API so the result of the request is given as a java.lang.Object. In most cases the result will be a java.util.Map with string keys and values or other java.util.Map as value. Requests made in JSON format hold some type information (i.e. it is known what values are strings and what values are numbers), so in general those will be more type friendly. Note that the responses will vary between XML and JSON, this is due to the responses from Salesforce API being different. So be careful if you switch between formats without changing the response handling code.

Let’s look at an example:

```java
// build the tree
SObjectTree request = new SObjectTree();
request.addObject(account).addChildren(president, marketing);
request.addObject(anotherAccount).addChild(sales).addChild(someAsset);

final SObjectTree response = template.requestBody("salesforce:composite-tree", tree,
SObjectTree.class);
final Map<Boolean, List<SObjectNode>> result = response.allNodes()
    .collect(Collectors.groupingBy(SObjectNode::hasErrors));

final List<SObjectNode> withErrors = result.get(true);
final List<SObjectNode> succeeded = result.get(false);

final String firstId = succeeded.get(0).getId();
final String acountId = ...
final SObjectBatch batch = new SObjectBatch("38.0");
final Account updates = new Account();
updates.setName("NewName");
batch.addUpdate("Account", accountId, updates);

final Account newAccount = new Account();
newAccount.setName("Account created from Composite batch API");
batch.addCreate(newAccount);

batch.addGet("Account", accountId, "Name", "BillingPostalCode");

batch.addDelete("Account", accountId);

final SObjectBatchResponse response = template.requestBody("salesforce:composite-batch?
format=JSON", batch, SObjectBatchResponse.class);

boolean hasErrors = response.hasErrors(); // if any of the requests has resulted in either 4xx or 5xx
```
268.12. USING SALESFORCE COMPOSITE API TO SUBMIT MULTIPLE CHAINED REQUESTS

The **composite** operation allows submitting up to 25 requests that can be chained together, for instance identifier generated in previous request can be used in subsequent request. Individual requests and responses are linked with the provided `reference`.

**NOTE**

Composite API supports only JSON payloads.

**NOTE**

As with the batch API the results can vary from API to API so the result of the request is given as a `java.lang.Object`. In most cases the result will be a `java.util.Map` with string keys and values or other `java.util.Map` as value. Requests made in JSON format hold some type information (i.e. it is known what values are strings and what values are numbers), so in general those will be more type friendly.

Lets look at an example:

```java
SOBJECTComposite composite = new SOBJECTComposite("38.0", true);

// first insert operation via an external id
final Account updateAccount = new TestAccount();
updateAccount.setName("Salesforce");
updateAccount.setBillingStreet("Landmark @ 1 Market Street");
```
updateAccount.setBillingCity("San Francisco");
updateAccount.setBillingState("California");
updateAccount.setIndustry(Account_IndustryEnum.TECHNOLOGY);
composite.addUpdate("Account", "001xx000003DpAAG", updateAccount, "UpdatedAccount");

final Contact newContact = new TestContact();
newContact.setLastName("John Doe");
newContact.setPhone("1234567890");
composite.addCreate(newContact, "NewContact");

final AccountContactJunction__c junction = new AccountContactJunction__c();
junction.setAccount__c("001xx000003DpAAG");
junction.setContactId__c("@{NewContact.id}");
composite.addCreate(junction, "JunctionRecord");

final SObjectCompositeResponse response = template.requestBody("salesforce:composite?format=JSON", composite, SObjectCompositeResponse.class);
final List<SObjectCompositeResult> results = response.getCompositeResponse();

final SObjectCompositeResult accountUpdateResult = results.stream().filter(r -> "UpdatedAccount".equals(r.getReferenceId())).findFirst().get()
final int statusCode = accountUpdateResult.getHttpStatusCode(); // should be 200
final Map<String, ?> accountUpdateBody = accountUpdateResult.getBody();

268.13. CAMEL SALESFORCE MAVEN PLUGIN

This Maven plugin generates DTOs for the Camel Salesforce.

268.14. OPTIONS

The Salesforce component supports 29 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>authenticationType</td>
<td>Explicit authentication method to be used, one of USERNAME_PASSWORD, REFRESH_TOKEN or JWT. Salesforce component can auto-determine the authentication method to use from the properties set, set this property to eliminate any ambiguity.</td>
<td></td>
<td>AuthenticationType</td>
</tr>
<tr>
<td>loginConfig</td>
<td>All authentication configuration in one nested bean, all properties set there can be set directly on the component as well</td>
<td></td>
<td>SalesforceLoginConfig</td>
</tr>
<tr>
<td>instanceUrl</td>
<td>URL of the Salesforce instance used after authentication, by default received from Salesforce on successful authentication</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------</td>
<td>-----------------</td>
</tr>
<tr>
<td>loginUrl</td>
<td><strong>Required</strong> URL of the Salesforce instance used for authentication, by default set to <a href="https://login.salesforce.com">https://login.salesforce.com</a></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientId</td>
<td><strong>Required</strong> OAuth Consumer Key of the connected app configured in the Salesforce instance setup. Typically a connected app needs to be configured but one can be provided by installing a package.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clientSecret</td>
<td>OAuth Consumer Secret of the connected app configured in the Salesforce instance setup.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>keystore</td>
<td>KeyStore parameters to use in OAuth JWT flow. The KeyStore should contain only one entry with private key and certificate. Salesforce does not verify the certificate chain, so this can easily be a selfsigned certificate. Make sure that you upload the certificate to the corresponding connected app.</td>
<td></td>
<td>KeyStoreParameters</td>
</tr>
<tr>
<td>refreshToken</td>
<td>Refresh token already obtained in the refresh token OAuth flow. One needs to setup a web application and configure a callback URL to receive the refresh token, or configure using the builtin callback at <a href="https://login.salesforce.com/services/oauth2/success">https://login.salesforce.com/services/oauth2/success</a> or <a href="https://test.salesforce.com/services/oauth2/success">https://test.salesforce.com/services/oauth2/success</a> and then retrieve the refresh_token from the URL at the end of the flow. Note that in development organizations Salesforce allows hosting the callback web application at localhost.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>userName</td>
<td>Username used in OAuth flow to gain access to access token. It’s easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>password</td>
<td>Password used in OAuth flow to gain access to access token. It’s easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows. Make sure that you append security token to the end of the password if using one.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>lazyLogin</strong> (security)</td>
<td>If set to true prevents the component from authenticating to Salesforce with the start of the component. You would generally set this to the (default) false and authenticate early and be immediately aware of any authentication issues.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>config</strong> (common)</td>
<td>Global endpoint configuration - use to set values that are common to all endpoints</td>
<td></td>
<td>SalesforceEndpointConfig</td>
</tr>
<tr>
<td><strong>httpClientProperties</strong> (common)</td>
<td>Used to set any properties that can be configured on the underlying HTTP client. Have a look at properties of SalesforceHttpClient and the Jetty HttpClient for all available options.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td><strong>longPollingTransportProperties</strong> (common)</td>
<td>Used to set any properties that can be configured on the LongPollingTransport used by the BayeuxClient (CometD) used by the streaming api</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td><strong>sslContextParameters</strong> (security)</td>
<td>SSL parameters to use, see SSLContextParameters class for all available options.</td>
<td></td>
<td>SSLContextParameters</td>
</tr>
<tr>
<td><strong>useGlobalSslContextParameters</strong> (security)</td>
<td>Enable usage of global SSL context parameters</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>httpProxyHost</strong> (proxy)</td>
<td>Hostname of the HTTP proxy server to use.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>httpProxyPort</strong> (proxy)</td>
<td>Port number of the HTTP proxy server to use.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>httpProxyUsername</strong> (security)</td>
<td>Username to use to authenticate against the HTTP proxy server.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>httpProxyPassword</strong> (security)</td>
<td>Password to use to authenticate against the HTTP proxy server.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>isHttpProxySocks4</strong> (proxy)</td>
<td>If set to true the configures the HTTP proxy to use as a SOCKS4 proxy.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>isHttpProxySecure</strong> (security)</td>
<td>If set to false disables the use of TLS when accessing the HTTP proxy.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
The Salesforce endpoint is configured using URI syntax:

```
salesforce:operationName:topicName
```

with the following path and query parameters:

### 268.14.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>operationName</td>
<td>The operation to use</td>
<td></td>
<td>OperationName</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>topicName</td>
<td>The name of the topic to use</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 268.14.2. Query Parameters (44 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apexMethod (common)</td>
<td>APEX method name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>apexQueryParam (common)</td>
<td>Query params for APEX method</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>apexUrl (common)</td>
<td>APEX method URL</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>apiVersion (common)</td>
<td>Salesforce API version, defaults to SalesforceEndpointConfig.DEFAULT_VERSION</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>backoffIncrement (common)</td>
<td>Backoff interval increment for Streaming connection restart attempts for failures beyond CometD auto-reconnect.</td>
<td></td>
<td>long</td>
</tr>
<tr>
<td>batchId (common)</td>
<td>Bulk API Batch ID</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>contentType (common)</td>
<td>Bulk API content type, one of XML, CSV, ZIP_XML, ZIP_CSV</td>
<td></td>
<td>ContentType</td>
</tr>
<tr>
<td>defaultReplayId (common)</td>
<td>Default replayId setting if no value is found in link initialReplayIdMap</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>format (common)</td>
<td>Payload format to use for Salesforce API calls, either JSON or XML, defaults to JSON</td>
<td></td>
<td>PayloadFormat</td>
</tr>
<tr>
<td>httpClient (common)</td>
<td>Custom Jetty Http Client to use to connect to Salesforce.</td>
<td></td>
<td>SalesforceHttpClient</td>
</tr>
<tr>
<td>includeDetails (common)</td>
<td>Include details in Salesforce1 Analytics report, defaults to false.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>initialReplayIdMap (common)</td>
<td>Replay IDs to start from per channel name.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>instanceId (common)</td>
<td>Salesforce1 Analytics report execution instance ID</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------------</td>
</tr>
<tr>
<td><code>jobId</code> (common)</td>
<td>Bulk API Job ID</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>limit</code> (common)</td>
<td>Limit on number of returned records. Applicable to some of the API, check the Salesforce documentation.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td><code>maxBackoff</code> (common)</td>
<td>Maximum backoff interval for Streaming connection restart attempts for failures beyond CometD auto-reconnect.</td>
<td></td>
<td>long</td>
</tr>
<tr>
<td><code>notFoundBehaviour</code> (common)</td>
<td>Sets the behaviour of 404 not found status received from Salesforce API. Should the body be set to NULL link NotFoundBehaviourNULL or should a exception be signaled on the exchange link NotFoundBehaviourEXCEPTION - the default.</td>
<td></td>
<td>NotFoundBehaviour</td>
</tr>
<tr>
<td><code>notifyForFields</code> (common)</td>
<td>Notify for fields, options are ALL, REFERENCED, SELECT, WHERE</td>
<td></td>
<td>NotifyForFieldsEnum</td>
</tr>
<tr>
<td><code>notifyForOperationCreate</code> (common)</td>
<td>Notify for create operation, defaults to false (API version = 29.0)</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><code>notifyForOperationDelete</code> (common)</td>
<td>Notify for delete operation, defaults to false (API version = 29.0)</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><code>notifyForOperations</code> (common)</td>
<td>Notify for operations, options are ALL, CREATE, EXTENDED, UPDATE (API version 29.0)</td>
<td></td>
<td>NotifyForOperationsEnum</td>
</tr>
<tr>
<td><code>notifyForOperationUndelete</code> (common)</td>
<td>Notify for un-delete operation, defaults to false (API version = 29.0)</td>

<td>Whether to update an existing Push Topic when using the Streaming API, defaults to false</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### bridgeErrorHandler (consumer)

 Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.

<table>
<thead>
<tr>
<th>Name</th>

<td>The replayId value to use when subscribing</td>
<td></td>
<td>Long</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

For obvious security reasons it is recommended that the clientId, clientSecret, userName and password fields be not set in the pom.xml. The plugin should be configured for the rest of the properties, and can be executed using the following command:

```
mvn camel-salesforce:generate -DcamelSalesforce.clientId=<clientid> -DcamelSalesforce.clientSecret=<clientsecret> -DcamelSalesforce.userName=<username> -DcamelSalesforce.password=<password>
```

The generated DTOs use Jackson and XStream annotations. All Salesforce field types are supported. Date and time fields are mapped to Joda DateTime, and picklist fields are mapped to generated Java Enumerations.

CHAPTER 269. SAP COMPONENT

The SAP component is a package consisting of a suite of ten different SAP components. There are remote function call (RFC) components that support the sRFC, tRFC, and qRFC protocols; and there are IDoc components that facilitate communication using messages in IDoc format. The component uses the SAP Java Connector (SAP JCo) library to facilitate bidirectional communication with SAP and the SAP IDoc library to facilitate the transmission of documents in the Intermediate Document (IDoc) format.

269.1. OVERVIEW

Dependencies

Maven users need to add the following dependency to their pom.xml file to use this component:

```
<dependency>
  <groupId>org.fusesource</groupId>
  <artifactId>camel-sap</artifactId>
  <version>x.x.x</version>
<dependency>
```

Additional platform restrictions for the SAP component

Because the SAP component depends on the third-party JCo 3.0 and IDoc 3.0 libraries, it can only be installed on the platforms that these libraries support. For more details about the platform restrictions, see Red Hat JBoss Fuse Supported Configurations.

SAP JCo and SAP IDoc libraries

A prerequisite for using the SAP component is that the SAP Java Connector (SAP JCo) libraries and the SAP IDoc library are installed into the lib/ directory of the Java runtime. You must make sure that you download the appropriate set of SAP libraries for your target operating system from the SAP Service Marketplace.

The names of the library files vary depending on the target operating system, as shown in Table 269.1, “Required SAP Libraries”.

<table>
<thead>
<tr>
<th>SAP Component</th>
<th>Linux and UNIX</th>
<th>Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAP JCo 3</td>
<td>sapjco3.jar</td>
<td>sapjco3.jar</td>
</tr>
<tr>
<td></td>
<td>libsapjco3.so</td>
<td>sapjco3.dll</td>
</tr>
<tr>
<td>SAP IDoc</td>
<td>sapidoc3.jar</td>
<td>sapidoc3.jar</td>
</tr>
</tbody>
</table>

Deploying in a Fuse OSGi Container

You can install the SAP JCo libraries and the SAP IDoc library into the JBoss Fuse OSGi container as follows:
1. Download the SAP JCo libraries and the SAP IDoc library from the SAP Service Marketplace (http://service.sap.com/public/connectors), making sure to choose the appropriate version of the libraries for your operating system.

   **NOTE**

   You require version 3.0.11 or greater of the JCo library and version 3.0.10 or greater of the IDoc library. You must have an SAP Service Marketplace Account in order to download and use these libraries.

2. Copy the sapjco3.jar, libsapjco3.so (or sapjco3.dll on Windows), and sapidoc3.jar library files into the lib/ directory of your Fuse installation.

3. Open both the configuration properties file, etc/config.properties, and the custom properties file, etc/custom.properties, in a text editor. In the etc/config.properties file, look for the org.osgi.framework.system.packages.extra property and copy the complete property setting (this setting extends over multiple lines, with a backslash character, \, used to indicate line continuation). Now paste this setting into the etc/custom.properties file.

   You can now add the extra packages required to support the SAP libraries. In the etc/custom.properties file, add the required packages to the org.osgi.framework.system.packages.extra setting as shown:

   ```
   org.osgi.framework.system.packages.extra = \
   ... , \
   com.sap.conn.idoc, \
   com.sap.conn.idoc.jco, \
   com.sap.conn.jco, \
   com.sap.conn.jco.ext, \
   com.sap.conn.jco.monitor, \
   com.sap.conn.jco.rt, \
   com.sap.conn.jco.server
   ```

   Don’t forget to include a comma and a backslash, , \, at the end of each line preceding the new entries, so that the list is properly continued.

4. You need to restart the container for these changes to take effect.

5. You need to install the camel-sap feature in the container. In the Karaf console, enter the following command:

   ```
   JBossFuse:karaf@root> features:install camel-sap
   ```

**Deploying in a JBoss EAP container**

To deploy the SAP component in a JBoss EAP container, perform the following steps:

1. Download the SAP JCo libraries and the SAP IDoc library from the SAP Service Marketplace (http://service.sap.com/public/connectors), making sure to choose the appropriate version of the libraries for your operating system.
NOTE

You require version 3.0.11 or greater of the JCo library and version 3.0.10 or greater of the IDoc library. You must have an SAP Service Marketplace Account in order to download and use these libraries.

2. Copy the JCo library files and the IDoc library file into the appropriate subdirectory of your JBoss EAP installation. For example, if your host platform is 64-bit Linux (linux-x86_64), install the library files as follows:

```bash
cp sapjco3.jar sapidoc3.jar
$JBOSS_HOME/modules/system/layers/fuse/com/sap/conn/jco/main/
mkdir -p $JBOSS_HOME/modules/system/layers/fuse/com/sap/conn/jco/main/lib/linux-x86_64
cp libsapjco3.so
$JBOSS_HOME/modules/system/layers/fuse/com/sap/conn/jco/main/lib/linux-x86_64/
```

IMPORTANT

For installing native libraries (such as libsapjco3.so) into the JBoss EAP installation, there is a standardized convention for naming the library subdirectory, which must be followed. In the case of 64-bit Linux, the subdirectory is linux-x86_64. For other platforms, see https://docs.jboss.org/author/display/MODULES/Native+Libraries.

3. Create a new file called

```xml
$JBOSS_HOME/modules/system/layers/fuse/org/wildfly/camel/extras/main/module.xml
```

and add the following content:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<module xmlns="urn:jboss:module:1.1" name="org.wildfly.camel.extras">
  <dependencies>
    <module name="org.fusesource.camel.component.sap" export="true" services="export" />
  </dependencies>
</module>
```

URI format

There are two different kinds of endpoint provided by the SAP component: the Remote Function Call (RFC) endpoints, and the Intermediate Document (IDoc) endpoints.

The URI formats for the RFC endpoints are as follows:

- `sap-srfc-destination:destinationName:rfcName`
- `sap-trfc-destination:destinationName:rfcName`
- `sap-qrfc-destination:destinationName:queueName:rfcName`
- `sap-srfc-server:servername:rfcName[?options]`
- `sap-trfc-server:servername:rfcName[?options]`

The URI formats for the IDoc endpoints are as follows:
The URI formats prefixed by sap-\textit{endpointKind}-destination are used to define destination endpoints (in other words, Camel producer endpoints) and \textit{destinationName} is the name of a specific outbound connection to an SAP instance. Outbound connections are named and configured at the component level, as described in Section 269.2.2, “Destination Configuration”.

The URI formats prefixed by sap-\textit{endpointKind}-server are used to define server endpoints (in other words, Camel consumer endpoints) and \textit{serverName} is the name of a specific inbound connection from an SAP instance. Inbound connections are named and configured at the component level, as described in the Section 269.2.3, “Server Configuration”.

The other components of an RFC endpoint URI are as follows:

\textit{rfcName}  
\textbf{(Required)} In a destination endpoint URI, is the name of the RFC invoked by the endpoint in the connected SAP instance. In a server endpoint URI, is the name of the RFC handled by the endpoint when invoked from the connected SAP instance.

\textit{queueName}  
Specifies the queue this endpoint sends an SAP request to.

The other components of an IDoc endpoint URI are as follows:

\textit{idocType}  
\textbf{(Required)} Specifies the Basic IDoc Type of an IDoc produced by this endpoint.

\textit{idocTypeExtension}  
Specifies the IDoc Type Extension, if any, of an IDoc produced by this endpoint.

\textit{systemRelease}  
Specifies the associated SAP Basis Release, if any, of an IDoc produced by this endpoint.

\textit{applicationRelease}  
Specifies the associated Application Release, if any, of an IDoc produced by this endpoint.

\textit{queueName}  
Specifies the queue this endpoint sends an SAP request to.

\textbf{Options for RFC destination endpoints}

The RFC destination endpoints (\texttt{sap-srfc-destination}, \texttt{sap-trfc-destination}, and \texttt{sap-qrfc-destination}) support the following URI options:
<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stateful</td>
<td>false</td>
<td>If true, specifies that this endpoint initiates an SAP stateful session.</td>
</tr>
<tr>
<td>transacted</td>
<td>false</td>
<td>If true, specifies that this endpoint initiates an SAP transaction.</td>
</tr>
</tbody>
</table>

### Options for RFC server endpoints

The SAP RFC server endpoints (sap-srfc-server and sap-trfc-server) support the following URI options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stateful</td>
<td>false</td>
<td>If true, specifies that this endpoint initiates an SAP stateful session.</td>
</tr>
<tr>
<td>propagateExceptions</td>
<td>false</td>
<td>(sap-trfc-server endpoint only) If true, specifies that this endpoint propagates exceptions back to the caller in SAP, instead of the exchange's exception handler</td>
</tr>
</tbody>
</table>

### Options for the IDoc List Server endpoint

The SAP IDoc List Server endpoint (sap-idoclist-server) supports the following URI options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stateful</td>
<td>false</td>
<td>If true, specifies that this endpoint initiates an SAP stateful session.</td>
</tr>
<tr>
<td>propagateExceptions</td>
<td>false</td>
<td>If true, specifies that this endpoint propagates exceptions back to the caller in SAP, instead of the exchange's exception handler</td>
</tr>
</tbody>
</table>

### Summary of the RFC and IDoc endpoints

The SAP component package provides the following RFC and IDoc endpoints:

- sap-srfc-destination
JBoss Fuse SAP Synchronous Remote Function Call Destination Camel component. This endpoint should be used in cases where Camel routes require synchronous delivery of requests to and responses from an SAP system.

NOTE

The sRFC protocol used by this component delivers requests and responses to and from an SAP system with **best effort**. In case of a communication error while sending a request, the completion status of a remote function call in the receiving SAP system remains **in doubt**.

sap-trfc-destination

JBoss Fuse SAP Transactional Remote Function Call Destination Camel component. This endpoint should be used in cases where requests must be delivered to the receiving SAP system at most once. To accomplish this, the component generates a transaction ID, tid, which accompanies every request sent through the component in a route’s exchange. The receiving SAP system records the tid accompanying a request before delivering the request; if the SAP system receives the request again with the same tid it will not deliver the request. Thus if a route encounters a communication error when sending a request through an endpoint of this component, it can retry sending the request within the same exchange knowing it will be delivered and executed only once.

NOTE

The tRFC protocol used by this component is asynchronous and does not return a response. Thus the endpoints of this component do not return a response message.

NOTE

This component does not guarantee the order of a series of requests through its endpoints, and the delivery and execution order of these requests may differ on the receiving SAP system due to communication errors and resends of a request. For guaranteed delivery order, please see the JBoss Fuse SAP Queued Remote Function Call Destination Camel component.

sap-qrfc-destination

JBoss Fuse SAP Queued Remote Function Call Destination Camel component. This component extends the capabilities of the JBoss Fuse Transactional Remote Function Call Destination camel component by adding **in order** delivery guarantees to the delivery of requests through its endpoints. This endpoint should be used in cases where a series of requests depend on each other and must be delivered to the receiving SAP system at most once and in order. The component accomplishes the at most once delivery guarantees using the same mechanisms as the JBoss Fuse SAP Transactional Remote Function Call Destination Camel component. The ordering guarantee is accomplished by serializing the requests in the order they are received by the SAP system to an **inbound queue**. Inbound queues are processed by the **QIN scheduler** within SAP. When the inbound queue is activated, the QIN Scheduler will execute the queue requests in order.

NOTE

The qRFC protocol used by this component is asynchronous and does not return a response. Thus the endpoints of this component do not return a response message.

sap-srfc-server
JBoss Fuse SAP Synchronous Remote Function Call Server Camel component. This component and its endpoints should be used in cases where a Camel route is required to synchronously handle requests from and responses to an SAP system.

**sap-trfc-server**

JBoss Fuse SAP Transactional Remote Function Call Server Camel component. This endpoint should be used in cases where the sending SAP system requires at most once delivery of its requests to a Camel route. To accomplish this, the sending SAP system generates a transaction ID, tid, which accompanies every request it sends to the component’s endpoints. The sending SAP system will first check with the component whether a given tid has been received by it before sending a series of requests associated with the tid. The component will check the list of received tids it maintains, record the sent tid if it is not in that list, and then respond to the sending SAP system, indicating whether or not the tid had already been recorded. The sending SAP system will only then send the series of requests, if the tid has not been previously recorded. This enables a sending SAP system to reliably send a series of requests once to a camel route.

**sap-idoc-destination**

JBoss Fuse SAP IDoc Destination Camel component. This endpoint should be used in cases where a Camel route is required to send a list of Intermediate Documents (IDocs) to an SAP system.

**sap-idoclist-destination**

JBoss Fuse SAP IDoc List Destination Camel component. This endpoint should be used in cases where a Camel route is required to send a list of Intermediate Documents (IDocs) to an SAP system.

**sap-qidoc-destination**

JBoss Fuse SAP Queued IDoc Destination Camel component. This component and its endpoints should be used in cases where a Camel route is required to send a list of Intermediate Documents (IDocs) to an SAP system in order.

**sap-qidoclist-destination**

JBoss Fuse SAP Queued IDoc List Destination Camel component. This component and its endpoints should be used in cases where a Camel route is required to send a list of Intermediate Documents (IDocs) to an SAP system in order.

**sap-idoclist-server**

JBoss Fuse SAP IDoc List Server Camel component. This endpoint should be used in cases where a sending SAP system requires delivery of Intermediate Document lists to a Camel route. This component uses the tRFC protocol to communicate with SAP as described in the sap-trfc-server-standalone quick start.

**SAP RFC destination endpoint**

An RFC destination endpoint supports outbound communication to SAP, which enable these endpoints to make RFC calls out to ABAP function modules in SAP. An RFC destination endpoint is configured to make an RFC call to a specific ABAP function over a specific connection to an SAP instance. An RFC destination is a logical designation for an outbound connection and has a unique name. An RFC destination is specified by a set of connection parameters called destination data.

An RFC destination endpoint will extract an RFC request from the input message of the IN-OUT exchanges it receives and dispatch that request in a function call to SAP. The response from the function call will be returned in the output message of the exchange. Since SAP RFC destination endpoints only support outbound communication, an RFC destination endpoint only supports the creation of producers.

**SAP RFC server endpoint**
An RFC server endpoint supports inbound communication from SAP, which enables ABAP applications in SAP to make RFC calls into server endpoints. An ABAP application interacts with an RFC server endpoint as if it were a remote function module. An RFC server endpoint is configured to receive an RFC call to a specific RFC function over a specific connection from an SAP instance. An RFC server is a logical designation for an inbound connection and has a unique name. An RFC server is specified by a set of connection parameters called server data.

An RFC server endpoint will handle an incoming RFC request and dispatch it as the input message of an IN-OUT exchange. The output message of the exchange will be returned as the response of the RFC call. Since SAP RFC server endpoints only support inbound communication, an RFC server endpoint only supports the creation of consumers.

**SAP IDoc and IDoc list destination endpoints**

An IDoc destination endpoint supports outbound communication to SAP, which can then perform further processing on the IDoc message. An IDoc document represents a business transaction, which can easily be exchanged with non-SAP systems. An IDoc destination is specified by a set of connection parameters called destination data.

An IDoc list destination endpoint is similar to an IDoc destination endpoint, except that the messages it handles consist of a list of IDoc documents.

**SAP IDoc list server endpoint**

An IDoc list server endpoint supports inbound communication from SAP, enabling a Camel route to receive a list of IDoc documents from an SAP system. An IDoc list server is specified by a set of connection parameters called server data.

**Meta-data repositories**

A meta-data repository is used to store the following kinds of meta-data:

**Interface descriptions of function modules**

This meta-data is used by the JCo and ABAP runtimes to check RFC calls to ensure the type-safe transfer of data between communication partners before dispatching those calls. A repository is populated with repository data. Repository data is a map of named function templates. A function template contains the meta-data describing all the parameters and their typing information passed to and from a function module and has the unique name of the function module it describes.

**IDoc type descriptions**

This meta-data is used by the IDoc runtime to ensure that the IDoc documents are correctly formatted before being sent to a communication partner. A basic IDoc type consists of a name, a list of permitted segments, and a description of the hierarchical relationship between the segments. Some additional constraints can be imposed on the segments: a segment can be mandatory or optional; and it is possible to specify a minimum/maximum range for each segment (defining the number of allowed repetitions of that segment).

SAP destination and server endpoints thus require access to a repository, in order to send and receive RFC calls and in order to send and receive IDoc documents. For RFC calls, the meta-data for all function modules invoked and handled by the endpoints must reside within the repository; and for IDoc endpoints, the meta-data for all IDoc types and IDoc type extensions handled by the endpoints must reside within the repository. The location of the repository used by a destination and server endpoint is specified in the destination data and the server data of their respective connections.

In the case of an SAP destination endpoint, the repository it uses typically resides in an SAP system and
it defaults to the SAP system it is connected to. This default requires no explicit configuration in the destination data. Furthermore, the meta-data for the remote function call that a destination endpoint makes will already exist in a repository for any existing function module that it calls. The meta-data for calls made by destination endpoints thus require no configuration in the SAP component.

On the other hand, the meta-data for function calls handled by server endpoints do not typically reside in the repository of an SAP system and must instead be provided by a repository residing in the SAP component. The SAP component maintains a map of named meta-data repositories. The name of a repository corresponds to the name of the server to which it provides meta-data.

269.2. CONFIGURATION

The SAP component maintains three maps to store destination data, server data and repository data. The destination data store and the server data store are configured on a special configuration object, SapConnectionConfiguration, which automatically gets injected into the SAP component (in the context of Blueprint XML configuration or Spring XML configuration files). The repository data store must be configured directly on the relevant SAP component.

269.2.1. Configuration Overview

Overview

The SAP component maintains three maps to store destination data, server data and repository data. The component’s property, destinationDataStore, stores destination data keyed by destination name, the property, serverDataStore, stores server data keyed by server name and the property, repositoryDataStore, stores repository data keyed by repository name. These configurations must be passed to the component during its initialization.

Example

The following example shows how to configure a sample destination data store and a sample server data store in a Blueprint XML file. The sap-configuration bean (of type SapConnectionConfiguration) will automatically be injected into any SAP component that is used in this XML file.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
  ...
  <!-- Configures the Inbound and Outbound SAP Connections -->
  <bean id="sap-configuration"
      class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
    <property name="destinationDataStore">
      <map>
        <entry key="quickstartDest" value-ref="quickstartDestinationData" />
      </map>
    </property>
    <property name="serverDataStore">
      <map>
        <entry key="quickstartServer" value-ref="quickstartServerData" />
      </map>
    </property>
  </bean>
  <!-- Configures an Outbound SAP Connection -->
  <!-- *** Please enter the connection property values for your environment *** -->
</blueprint>
```
<bean id="quickstartDestinationData"
    class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
    <property name="ashost" value="example.com" />
    <property name="sysnr" value="00" />
    <property name="client" value="000" />
    <property name="user" value="username" />
    <property name="passwd" value="passowrd" />
    <property name="lang" value="en" />
</bean>

<!-- Configures an Inbound SAP Connection -->
<!-- *** Please enter the connection property values for your environment ** -->
<bean id="quickstartServerData"
    class="org.fusesource.camel.component.sap.model.rfc.impl.ServerDataImpl">
    <property name="gwhost" value="example.com" />
    <property name="gwserv" value="3300" />
</bean>

269.2.2. Destination Configuration

Overview

The configurations for destinations are maintained in the destinationDataStore property of the SAP component. Each entry in this map configures a distinct outbound connection to an SAP instance. The key for each entry is the name of the outbound connection and is used in the destinationName component of a destination endpoint URI as described in the URI format section.

The value for each entry is a destination data configuration object - org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl - that specifies the configuration of an outbound SAP connection.

Sample destination configuration

The following Blueprint XML code shows how to configure a sample destination with the name, quickstartDest.

<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
    <!-- Create interceptor to support tRFC processing -->
    <bean id="currentProcessorDefinitionInterceptor"
        class="org.fusesource.camel.component.sap.CurrentProcessorDefinitionInterceptStrategy" />

    <!-- Configures the Inbound and Outbound SAP Connections -->
    <bean id="sap-configuration"
        class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
        <property name="destinationDataStore">
            <map>
                <entry key="quickstartDest" value-ref="quickstartDestinationData" />
            </map>
        </property>
    </bean>
</blueprint>
<map>
  <property/>
</bean>

<!-- Configures an Outbound SAP Connection -->
<!-- *** Please enter the connection property values for your environment *** -->
<bean id="quickstartDestinationData"
  class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
  <property name="ashost" value="example.com"/>
  <property name="sysnr" value="00"/>
  <property name="client" value="000"/>
  <property name="user" value="username"/>
  <property name="passwd" value="password"/>
  <property name="lang" value="en"/>
</bean>
</blueprint>

For example, after configuring the destination as shown in the preceding Blueprint XML file, you could invoke the BAPI_FLCUST_GETLIST remote function call on the quickstartDest destination using the following URI:

```
sap-srfc-destination:quickstartDest:BAPI_FLCUST_GETLIST
```

Interceptor for tRFC and qRFC destinations

The preceding sample destination configuration shows the instantiation of a CurrentProcessorDefinitionInterceptStrategy object. This object installs an interceptor in the Camel runtime, which enables the Camel SAP component to keep track of its position within a Camel route while it is handling RFC transactions. For more details, see the section called “Transactional RFC destination endpoints”.

**IMPORTANT**

This interceptor is critically important for transactional RFC destination endpoints (such as sap-trfc-destination and sap-qrfc-destination) and must be installed in the Camel runtime in order for outbound transactional RFC communication to be properly managed. The Destination RFC Transaction Handlers will issue warnings into the Camel log if the strategy is not found at runtime and in this situation the Camel runtime will need to be re-provisioned and restarted to properly manage outbound transactional RFC communication.

Logon and authentication options

The following table lists the logon and authentication options for configuring a destination in the SAP destination data store:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client</td>
<td></td>
<td>SAP client, mandatory logon parameter</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td></td>
</tr>
<tr>
<td>user</td>
<td>Logon user, logon parameter for password based authentication</td>
<td></td>
</tr>
<tr>
<td>aliasUser</td>
<td>Logon user alias, can be used instead of logon user</td>
<td></td>
</tr>
<tr>
<td>userId</td>
<td>User identity which is used for logon to the ABAP AS. Used by the JCo runtime, if the destination configuration uses SSO/assertion ticket, certificate, current user, or SNC environment for authentication. The user ID is mandatory, if neither user nor user alias is set. This ID will never be sent to the SAP backend, it will be used by the JCo runtime locally.</td>
<td></td>
</tr>
<tr>
<td>passwd</td>
<td>Logon password, logon parameter for password-based authentication</td>
<td></td>
</tr>
<tr>
<td>lang</td>
<td>Logon language, if not defined, the default user language is used</td>
<td></td>
</tr>
<tr>
<td>mysapssso2</td>
<td>Use the specified SAP Cookie Version 2 as logon ticket for SSO based authentication</td>
<td></td>
</tr>
<tr>
<td>x509cert</td>
<td>Use the specified X509 certificate for certificate based authentication</td>
<td></td>
</tr>
<tr>
<td>lcheck</td>
<td>Postpone the authentication until the first call - 1 (enable). Used in special cases only.</td>
<td></td>
</tr>
<tr>
<td>useSapGui</td>
<td>Use a visible, hidden, or do not use SAP GUI</td>
<td></td>
</tr>
<tr>
<td>codePage</td>
<td>Additional logon parameter to define the codepage that will used to convert the logon parameters. Used in special cases only</td>
<td></td>
</tr>
<tr>
<td>getsso2</td>
<td>Order a SSO ticket after logon, the obtained ticket is available in the destination attributes</td>
<td></td>
</tr>
</tbody>
</table>
### denyInitialPassword

If set to 1, using initial passwords will lead to an exception (default is 0).

### Connection options

The following table lists the **connection** options for configuring a destination in the SAP destination data store:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
</table>
| saprouter | SAP Router string for connection to systems behind a SAP Router. SAP Router string contains the chain of SAP Routers and its port numbers and has the form: 

\[/(H/<host>[/S/<port>])^+\] |
| sysnr   | System number of the SAP ABAP application server, mandatory for a direct connection |
| ashost  | SAP ABAP application server, mandatory for a direct connection |
| mhost   | SAP message server, mandatory property for a load balancing connection |
| msserv  | SAP message server port, optional property for a load balancing connection. In order to resolve the service names sapmsXXX a lookup in `etc/services` is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no look-ups are performed and no additional entries are needed. |
| gwhost  | Allows specifying a concrete gateway, which should be used for establishing the connection to an application server. If not specified the gateway on the application server is used |
**gwserv**

Should be set, when using gwhost. Allows specifying the port used on that gateway. If not specified the port of the gateway on the application server is used. In order to resolve the service names sapgwXXX a lookup in etc/services is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no lookups are performed and no additional entries are needed.

**r3name**

System ID of the SAP system, mandatory property for a load balancing connection.

**group**

Group of SAP application servers, mandatory property for a load balancing connection.

### Connection pool options

The following table lists the **connection pool** options for configuring a destination in the SAP destination data store:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>peakLimit</td>
<td>0</td>
<td>Maximum number of active outbound connections that can be created for a destination simultaneously. A value of 0 allows an unlimited number of active connections, otherwise if the value is less than the value of poolCapacity, it will be automatically increased to this value. Default setting is the value of poolCapacity, or in case of poolCapacity not being specified as well, the default is 0 (unlimited).</td>
</tr>
<tr>
<td>poolCapacity</td>
<td>1</td>
<td>Maximum number of idle outbound connections kept open by the destination. A value of 0 has the effect that there is no connection pooling (default is 1).</td>
</tr>
</tbody>
</table>
### expirationTime

Time in milliseconds after which a free connection held internally by the destination can be closed.

### expirationPeriod

Period in milliseconds after which the destination checks the released connections for expiration.

### maxGetTime

Maximum time in milliseconds to wait for a connection, if the maximum allowed number of connections has already been allocated by the application.

### Secure network connection options

The following table lists the secure network options for configuring a destination in the SAP destination data store:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sncMode</td>
<td></td>
<td>Secure network connection (SNC) mode, 0 (off) or 1 (on)</td>
</tr>
<tr>
<td>sncPartnername</td>
<td></td>
<td>SNC partner, for example: p:CN=R3, O=XYZ-INC, C=EN</td>
</tr>
<tr>
<td>sncQop</td>
<td></td>
<td>SNC level of security: 1 to 9</td>
</tr>
<tr>
<td>sncMyname</td>
<td></td>
<td>Own SNC name. Overrides environment settings</td>
</tr>
<tr>
<td>sncLibrary</td>
<td></td>
<td>Path to library that provides SNC service</td>
</tr>
</tbody>
</table>

### Repository options

The following table lists the repository options for configuring a destination in the SAP destination data store:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>repositoryDest</td>
<td></td>
<td>Specifies which destination should be used as repository.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>repositoryUser</td>
<td>If a repository destination is not set, and this property is set, it will be used as user for repository calls. This enables you to use a different user for repository look-ups.</td>
<td></td>
</tr>
<tr>
<td>repositoryPasswd</td>
<td>The password for a repository user. Mandatory, if a repository user should be used.</td>
<td></td>
</tr>
<tr>
<td>repositorySnc</td>
<td><em>(Optional)</em> If SNC is used for this destination, it is possible to turn it off for repository connections, if this property is set to 0. Default setting is the value of jco.client.snc mode. For special cases only.</td>
<td></td>
</tr>
<tr>
<td>repositoryRoundtripOptimization</td>
<td>Enable the RFC_METADATA_GET API, which provides repository data in one single round trip.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1 Activates use of RFC_METADATA_GET in ABAP System,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0 Deactivates RFC_METADATA_GET in ABAP System.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If the property is not set, the destination initially does a remote call to check whether RFC_METADATA_GET is available. If it is available, the destination will use it.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If the repository is already initialized (for example because it is used by some other destination) this property does not have any effect. Generally, this property is related to the ABAP System, and should have the same value on all destinations pointing to the same ABAP System. See note 1456826 for backend prerequisites.</td>
<td></td>
</tr>
</tbody>
</table>
Trace configuration options

The following table lists the trace configuration options for configuring a destination in the SAP destination data store:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trace</td>
<td></td>
<td>Enable/disable RFC trace (0 or 1)</td>
</tr>
<tr>
<td>cpicTrace</td>
<td></td>
<td>Enable/disable CPIC trace [0..3]</td>
</tr>
</tbody>
</table>

269.2.3. Server Configuration

Overview

The configurations for servers are maintained in the serverDataStore property of the SAP component. Each entry in this map configures a distinct inbound connection from an SAP instance. The key for each entry is the name of the outbound connection and is used in the serverName component of a server endpoint URI as described in the URI format section.

The value for each entry is a server data configuration object, org.fusesource.camel.component.sap.model.rfc.impl.ServerDataImpl, that defines the configuration of an inbound SAP connection.

Sample server configuration

The following Blueprint XML code shows how to create a sample server configuration with the name, quickstartServer.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ...>
 ...
 <!-- Configures the Inbound and Outbound SAP Connections -->
 <bean id="sap-configuration" class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
  <property name="destinationDataStore">
   <map>
    <entry key="quickstartDest" value-ref="quickstartDestinationData" />
   </map>
  </property>
  <property name="serverDataStore">
   <map>
    <entry key="quickstartServer" value-ref="quickstartServerData" />
   </map>
  </property>
 </bean>

 <!-- Configures an Outbound SAP Connection -->
 <!-- *** Please enter the connection property values for your environment *** -->
 <bean id="quickstartDestinationData" class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
  <property name="ashost" value="example.com" />
  <property name="sysnr" value="00" />
 </bean>
```
Notice how this example also configures a destination connection, `quickstartDest`, which the server uses to retrieve meta-data from a remote SAP instance. This destination is configured in the server data through the `repositoryDestination` option. If you do not configure this option, you would need to create a local meta-data repository instead (see Section 269.2.4, “Repository Configuration”).

For example, after configuring the destination as shown in the preceding Blueprint XML file, you could handle the `BAPI_FLCUST_GETLIST` remote function call from an invoking client, using the following URI:

```
sap-srfc-server:quickstartServer:BAPI_FLCUST_GETLIST
```

### Required options

The required options for the server data configuration object are, as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>gwhost</code></td>
<td></td>
<td>Gateway host on which the server connection should be registered.</td>
</tr>
<tr>
<td><code>gwserv</code></td>
<td></td>
<td>Gateway service, which is the port on which a registration can be done. In order to resolve the service names <code>sapgwXXX</code>, a lookup in <code>etc/services</code> is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no look-ups are performed and no additional entries are needed.</td>
</tr>
</tbody>
</table>
**progid**

The program ID with which the registration is done. Serves as identifier on the gateway and in the destination in the ABAP system.

**repositoryDestination**

Specifies a destination name that the server can use in order to retrieve meta-data from a meta-data repository hosted in a remote SAP server.

**connectionCount**

The number of connections that should be registered at the gateway.

---

**Secure network connection options**

The secure network connection options for the server data configuration object are, as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sncMode</td>
<td>0 (off) or 1 (on)</td>
<td>Secure network connection (SNC) mode. 0 (off) or 1 (on)</td>
</tr>
<tr>
<td>sncQop</td>
<td>1 to 9</td>
<td>SNC level of security.</td>
</tr>
<tr>
<td>sncMyname</td>
<td></td>
<td>SNC name of your server. Overrides the default SNC name. Typically something like p:CN=JCoServer, O=ACompany, C=EN.</td>
</tr>
<tr>
<td>sncLib</td>
<td></td>
<td>Path to library which provides SNC service. If this property is not provided, the value of the jco.middleware.snc_lib property is used instead</td>
</tr>
</tbody>
</table>

---

**Other options**

The other options for the server data configuration object are, as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>saprouter</td>
<td>SAP router string to use for a system protected by a firewall, which can therefore only be reached through a SAProuter, when registering the server at the gateway of that ABAP System. A typical router string is <code>/H/firewall.hostname/H/</code></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td></td>
</tr>
<tr>
<td>maxStartupDelay</td>
<td>The maximum time (in seconds) between two start-up attempts in case of failures. The waiting time is doubled from initially 1 second after each start-up failure until either the maximum value is reached or the server could be started successfully.</td>
<td></td>
</tr>
<tr>
<td>trace</td>
<td>Enable/disable RFC trace (0 or 1)</td>
<td></td>
</tr>
<tr>
<td>workerThreadCount</td>
<td>The maximum number of threads used by the server connection. If not set, the value for the connectionCount is used as the workerThreadCount. The maximum number of threads can not exceed 99.</td>
<td></td>
</tr>
<tr>
<td>workerThreadMinCount</td>
<td>The minimum number of threads used by server connection. If not set, the value for connectionCount is used as the workerThreadMinCount.</td>
<td></td>
</tr>
</tbody>
</table>

### 269.2.4. Repository Configuration

#### Overview

The configurations for repositories are maintained in the repositoryDataStore property of the SAP Component. Each entry in this map configures a distinct repository. The key for each entry is the name of the repository and this key also corresponds to the name of server to which this repository is attached.

The value of each entry is a repository data configuration object, `org.fusesource.camel.component.sap.model.rfc.impl.RepositoryDataImpl`, that defines the contents of a meta-data repository. A repository data object is a map of function template configuration objects, `org.fusesource.camel.component.sap.model.rfc.impl.FunctionTemplateImpl`. Each entry in this map specifies the interface of a function module and the key for each entry is the name of the function module specified.

Repository data example
The following code shows a simple example of configuring a meta-data repository:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >

<!-- Configures the sap-srfc-server component -->
<bean id="sap-configuration"
     class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
  <property name="repositoryDataStore">
    <map>
      <entry key="nplServer" value-ref="nplRepositoryData" />
    </map>
  </property>
</bean>

<!-- Configures a Meta-Data Repository -->
<bean id="nplRepositoryData"
     class="org.fusesource.camel.component.sap.model.rfc.impl.RepositoryDataImpl">
  <property name="functionTemplates">
    <map>
      <entry key="BOOK_FLIGHT" value-ref="bookFlightFunctionTemplate" />
    </map>
  </property>
</bean>

</blueprint>
```

**Function template properties**

The interface of a function module consists of four parameter lists by which data is transferred back and forth to the function module in an RFC call. Each parameter list consists of one or more fields, each of which is a named parameter transferred in an RFC call. The following parameter lists and exception list are supported:

- The *import parameter list* contains parameter values that are sent to a function module in an RFC call;
- The *export parameter list* contains parameter values that are returned by a function module in an RFC call;
- The *changing parameter list* contains parameter values that are sent to and returned by a function module in an RFC call;
- The *table parameter list* contains internal table values that are sent to and returned by a function module in an RFC call.
- The interface of a function module also consists of an *exception list* of ABAP exceptions that may be raised when the module is invoked in an RFC call.

A function template describes the name and type of parameters in each parameter list of a function interface and the ABAP exceptions thrown by the function. A function template object maintains five property lists of meta-data objects, as described in the following table.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameter List</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>importParameterList</td>
<td>A list of list field meta-data objects, <code>org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl</code>. Specifies the parameters that are sent in an RFC call to a function module.</td>
</tr>
<tr>
<td>changingParameterList</td>
<td>A list of list field meta-data objects, <code>org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl</code>. Specifies the parameters that sent and returned in an RFC call to and from a function module.</td>
</tr>
<tr>
<td>exportParameterList</td>
<td>A list of list field meta-data objects, <code>org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl</code>. Specifies the parameters that are returned in an RFC call from a function module.</td>
</tr>
<tr>
<td>tableParameterList</td>
<td>A list of list field meta-data objects, <code>org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl</code>. Specifies the table parameters that are sent and returned in an RFC call to and from a function module.</td>
</tr>
<tr>
<td>exceptionList</td>
<td>A list of ABAP exception meta-data objects, <code>org.fusesource.camel.component.sap.model.rfc.impl.AbapExceptionImpl</code>. Specifies the ABAP exceptions potentially raised in an RFC call of function module.</td>
</tr>
</tbody>
</table>

**Function template example**

The following example shows an outline of how to configure a function template:

```xml
<bean id="bookFlightFunctionTemplate"
     class="org.fusesource.camel.component.sap.model.rfc.impl.FunctionTemplateImpl">
  <property name="importParameterList">
    <list>
      ...
    </list>
  </property>
  <property name="changingParameterList">
    <list>
      ...
    </list>
  </property>
  <property name="exportParameterList">
    <list>
      ...
    </list>
  </property>
  <property name="tableParameterList">
    <list>
      ...
    </list>
  </property>
</bean>
```
List field meta-data properties

A list field meta-data object, \texttt{org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl}, specifies the name and type of a field in a parameter list. For an elementary parameter field (\texttt{CHAR}, \texttt{DATE}, \texttt{TIME}, \texttt{BYTE}, \texttt{NUM}, \texttt{FLOAT}, \texttt{INT}, \texttt{INT1}, \texttt{INT2}, \texttt{DECF16}, \texttt{DECF34}, \texttt{STRING}, \texttt{XSTRING}), the following table lists the configuration properties that may be set on a list field meta-data object:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>-</td>
<td>The name of the parameter field.</td>
</tr>
<tr>
<td>type</td>
<td>-</td>
<td>The parameter type of the field.</td>
</tr>
<tr>
<td>byteLength</td>
<td>-</td>
<td>The field length in bytes for a non-Unicode layout. This value depends on the parameter type. See Section 269.5, “Message Body for RFC”.</td>
</tr>
<tr>
<td>unicodeByteLength</td>
<td>-</td>
<td>The field length in bytes for a Unicode layout. This value depends on the parameter type. See Section 269.5, “Message Body for RFC”.</td>
</tr>
<tr>
<td>decimals</td>
<td>0</td>
<td>The number of decimals in field value; only required for parameter types BCD and FLOAT. See Section 269.5, “Message Body for RFC”.</td>
</tr>
<tr>
<td>optional</td>
<td>false</td>
<td>If true, the field is optional and need not be set in a RFC call.</td>
</tr>
</tbody>
</table>

Note that all elementary parameter fields require that the \texttt{name}, \texttt{type}, \texttt{byteLength} and \texttt{unicodeByteLength} properties be specified in the field meta-data object. In addition, the \texttt{BCD}, \texttt{FLOAT}, \texttt{DECF16} and \texttt{DECF34} fields require the decimal property to be specified in the field meta-data object.

For a complex parameter field of type \texttt{TABLE} or \texttt{STRUCTURE}, the following table lists the configuration properties that may be set on a list field meta-data object:
<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>-</td>
<td>The name of the parameter field</td>
</tr>
<tr>
<td>type</td>
<td>-</td>
<td>The parameter type of the field</td>
</tr>
<tr>
<td>recordMetaData</td>
<td>-</td>
<td>The meta-data for the structure or table. A record meta-data object, org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl, is passed to specify the fields in the structure or table rows.</td>
</tr>
<tr>
<td>optional</td>
<td>false</td>
<td>If true, the field is optional and need not be set in a RFC call</td>
</tr>
</tbody>
</table>

Note that all complex parameter fields require that the name, type and recordMetaData properties be specified in the field meta-data object. The value of the recordMetaData property is a record field meta-data object, org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl, which specifies the structure of a nested structure or the structure of a table row.

**Elementary list field meta-data example**

The following meta-data configuration specifies an optional, 24-digit packed BCD number parameter with two decimal places named TICKET_PRICE:

```xml
<bean class="org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl">
  <property name="name" value="TICKET_PRICE" />
  <property name="type" value="BCD" />
  <property name="byteLength" value="12" />
  <property name="unicodeByteLength" value="24" />
  <property name="decimals" value="2" />
  <property name="optional" value="true" />
</bean>
```

**Complex list field meta-data example**

The following meta-data configuration specifies a required TABLE parameter named CONNINFO with a row structure specified by the connectionInfo record meta-data object:

```xml
<bean class="org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl">
  <property name="name" value="CONNINFO" />
  <property name="type" value="TABLE" />
  <property name="recordMetaData" ref="connectionInfo" />
</bean>
```

**Record meta-data properties**

A record meta-data object,
org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl, specifies the name and contents of a nested STRUCTURE or the row of a TABLE parameter. A record meta-data object maintains a list of record field meta data objects, org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl, which specify the parameters that reside in the nested structure or table row.

The following table lists configuration properties that may be set on a record meta-data object:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>-</td>
<td>The name of the record.</td>
</tr>
<tr>
<td>recordFieldMetaData</td>
<td>-</td>
<td>The list of record field meta-data objects,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl. Specifies the fields contained within the structure.</td>
</tr>
</tbody>
</table>

**NOTE**

All properties of the record meta-data object are required.

**Record meta-data example**

The following example shows how to configure a record meta-data object:

```xml
<bean id="connectionInfo"
     class="org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl">
  <property name="name" value="CONNECTION_INFO" />
  <property name="recordFieldMetaData">
    <list>
      ...
    </list>
  </property>
</bean>
```

**Record field meta-data properties**

A record field meta-data object, org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl, specifies the name and type of a parameter field within a structure.

A record field meta-data object is similar to a parameter field meta-data object, except that the offsets of the individual field locations within the nested structure or table row must be additionally specified. The non-Unicode and Unicode offsets of an individual field must be calculated and specified from the sum of non-Unicode and Unicode byte lengths of the preceding fields in the structure or row. Note that failure to properly specify the offsets of fields in nested structures and table rows will cause the field storage of parameters in the underlying JCo and ABAP runtimes to overlap and prevent the proper transfer of values in RFC calls.
For an elementary parameter field (CHAR, DATE, BCD, TIME, BYTE, NUM, FLOAT, INT, INT1, INT2, DECF16, DECF34, STRING, XSTRING), the following table lists the configuration properties that may be set on a record field meta-data object:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>-</td>
<td>The name of the parameter field</td>
</tr>
<tr>
<td>type</td>
<td>-</td>
<td>The parameter type of the field</td>
</tr>
</tbody>
</table>
| byteLength       | -             | The field length in bytes for a non-Unicode layout. This value depends on the parameter type. See Section 269.5, “Message Body for RFC”.
| unicodeByteLength| -             | The field length in bytes for a Unicode layout. This value depends on the parameter type. See Section 269.5, “Message Body for RFC”.
| byteOffset       | -             | The field offset in bytes for non-Unicode layout. This offset is the byte location of the field within the enclosing structure. |
| unicodeByteOffset| -             | The field offset in bytes for Unicode layout. This offset is the byte location of the field within the enclosing structure. |
| decimals         | 0             | The number of decimals in field value; only required for parameter types BCD and FLOAT. See Section 269.5, “Message Body for RFC”.

For a complex parameter field of type TABLE or STRUCTURE, the following table lists the configuration properties that may be set on a record field meta-data object:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>-</td>
<td>The name of the parameter field</td>
</tr>
<tr>
<td>type</td>
<td>-</td>
<td>The parameter type of the field</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>byteOffset</td>
<td>The field offset in bytes for non-Unicode layout. This offset is the byte location of the field within the enclosing structure.</td>
<td></td>
</tr>
<tr>
<td>unicodeByteOffset</td>
<td>The field offset in bytes for Unicode layout. This offset is the byte location of the field within the enclosing structure.</td>
<td></td>
</tr>
<tr>
<td>recordMetaData</td>
<td>The meta-data for the structure or table. A record meta-data object, <code>org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl</code>, is passed to specify the fields in the structure or table rows.</td>
<td></td>
</tr>
</tbody>
</table>

**Elementary record field meta-data example**

The following meta-data configuration specifies a **DATE** field parameter named **ARRDATE** located 85 bytes into the enclosing structure in the case of a non-Unicode layout and located 170 bytes into the enclosing structure in the case of a Unicode layout:

```xml
<bean class="org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl">
  <property name="name" value="ARRDATE" />  
  <property name="type" value="DATE" />   
  <property name="byteLength" value="8" />   
  <property name="unicodeByteLength" value="16" />   
  <property name="byteOffset" value="85" />   
  <property name="unicodeByteOffset" value="170" />   
</bean>
```

**Complex record field meta-data example**

The following meta-data configuration specifies a **STRUCTURE** field parameter named **FLTINFO** with a structure specified by the **flightInfo** record meta-data object. The parameter is located at the beginning of the enclosing structure in both the case of a non-Unicode and Unicode layout.

```xml
<bean class="org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl">
  <property name="name" value="FLTINFO" />   
  <property name="type" value="STRUCTURE" />   
  <property name="byteOffset" value="0" />   
  <property name="unicodeByteOffset" value="0" />   
  <property name="recordMetaData" ref="flightInfo" />   
</bean>
```

### 269.3. MESSAGE HEADERS

The SAP component supports the following message headers:
<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelSap.scheme</td>
<td>The URI scheme of the last endpoint to process the message. Use one of the following values:</td>
</tr>
<tr>
<td></td>
<td>sap-srfc-destination</td>
</tr>
<tr>
<td></td>
<td>sap-trfc-destination</td>
</tr>
<tr>
<td></td>
<td>sap-qrfc-destination</td>
</tr>
<tr>
<td></td>

### 269.4. EXCHANGE PROPERTIES

The SAP component adds the following exchange properties:
**269.5. MESSAGE BODY FOR RFC**

**Request and response objects**

An SAP endpoint expects to receive a message with a message body containing an SAP request object and will return a message with a message body containing an SAP response object. SAP requests and responses are fixed map data structures containing named fields with each field having a predefined data type.

Note that the named fields in an SAP request and response are specific to an SAP endpoint, with each endpoint defining the parameters in the SAP request and response it will accept. An SAP endpoint provides factory methods to create the request and response objects that are specific to it.

```java
public class SAPEndpoint ... {
    ...
    public Structure getRequest() throws Exception;
    public Structure getResponse() throws Exception;
    ...
}
```

**Structure objects**

Both SAP request and response objects are represented in Java as a structure object which supports the `org.fusesource.camel.component.sap.model.rfc.Structure` interface. This interface extends both the `java.util.Map` and `org.eclipse.emf.ecore.EObject` interfaces.

```java
public interface Structure extends org.eclipse.emf.ecore.EObject,
    java.util.Map<String, Object> {
    <T> T get(Object key, Class<T> type);
}
```

The field values in a structure object are accessed through the field’s getter methods in the map interface. In addition, the structure interface provides a type-restricted method to retrieve field values.

Structure objects are implemented in the component runtime using the Eclipse Modeling Framework.
(EMF) and support that framework’s EObject interface. Instances of a structure object have attached meta-data which define and restrict the structure and contents of the map of fields it provides. This meta-data can be accessed and introspected using the standard methods provided by EMF. Please refer to the EMF documentation for further details.

**NOTE**

Attempts to get a parameter not defined on a structure object will return null. Attempts to set a parameter not defined on a structure will throw an exception as well as attempts to set the value of a parameter with an incorrect type.

As discussed in the following sections, structure objects can contain fields that contain values of the complex field types, **STRUCTURE** and **TABLE**. Note that it is unnecessary to create instances of these types and add them to the structure. Instances of these field values are created on demand if necessary when accessed in the enclosing structure.

### Field types

The fields that reside within the structure object of an SAP request or response may be either elementary or complex. An elementary field contains a single scalar value, whereas a complex field will contain one or more fields of either a elementary or complex type.

#### Elementary field types

An elementary field may be either a character, numeric, hexadecimal or string field type. The following table summarizes the types of elementary fields that may reside in a structure object:

<table>
<thead>
<tr>
<th>Field Type</th>
<th>Corresponding Java Type</th>
<th>Byte Length</th>
<th>Unicode Byte Length</th>
<th>Number Decimals Digits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR</td>

<td>ABAP Type 'decfloat16': 8-byte Decimal Floating Point Number</td>
</tr>
<tr>
<td>DECF34</td>
<td>java.math.BigDecimal</td>
<td>16</td>
<td>16</td>
<td>34</td>
<td>ABAP Type 'decfloat34': 16-byte Decimal Floating Point Number</td>
</tr>
<tr>
<td>STRING</td>
<td>java.lang.String</td>
<td>8</td>
<td>8</td>
<td>-</td>
<td>ABAP Type 'G': Variable length character string</td>
</tr>
<tr>
<td>XSTRING</td>
<td>byte[]</td>
<td>8</td>
<td>8</td>
<td>-</td>
<td>ABAP Type 'Y': Variable length byte array</td>
</tr>
</tbody>
</table>

**Character field types**

A character field contains a fixed sized character string that may use either a non-Unicode or Unicode.
character encoding in the underlying JCo and ABAP runtimes. Non-Unicode character strings encode one character per byte. Unicode characters strings are encoded in two bytes using UTF-16 encoding. Character field values are represented in Java as `java.lang.String` objects and the underlying JCo runtime is responsible for the conversion to their ABAP representation.

A character field declares its field length in its associated `byteLength` and `unicodeByteLength` properties, which determine the length of the field’s character string in each encoding system.

**CHAR**

A **CHAR** character field is a text field containing alphanumeric characters and corresponds to the ABAP type C.

**NUM**

A **NUM** character field is a numeric text field containing numeric characters only and corresponds to the ABAP type N.

**DATE**

A **DATE** character field is an 8 character date field with the year, month and day formatted as `YYYYMMDD` and corresponds to the ABAP type D.

**TIME**

A **TIME** character field is a 6 character time field with the hours, minutes and seconds formatted as `HHMMSS` and corresponds to the ABAP type T.

**Numeric field types**

A numeric field contains a number. The following numeric field types are supported:

**INT**

An **INT** numeric field is an integer field stored as a 4-byte integer value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type I. An **INT** field value is represented in Java as a `java.lang.Integer` object.

**INT2**

An **INT2** numeric field is an integer field stored as a 2-byte integer value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type S. An **INT2** field value is represented in Java as a `java.lang.Integer` object.

**INT1**

An **INT1** field is an integer field stored as a 1-byte integer value in the underlying JCo and ABAP runtimes value and corresponds to the ABAP type B. An **INT1** field value is represented in Java as a `java.lang.Integer` object.

**FLOAT**

A **FLOAT** field is a binary floating point number field stored as an 8-byte double value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type F. A **FLOAT** field declares the number of decimal digits that the field’s value contains in its associated decimal property. In the case of a **FLOAT** field, this decimal property can have a value between 1 and 15 digits. A **FLOAT** field value is represented in Java as a `java.lang.Double` object.

**BCD**

A **BCD** field is a binary coded decimal field stored as a 1 to 16 byte packed number in the underlying JCo and ABAP runtimes and corresponds to the ABAP type P. A packed number stores two decimal digits per byte. A **BCD** field declares its field length in its associated `byteLength` and `unicodeByteLength` properties. In the case of a **BCD** field, these properties can have a value between 1 and 16 bytes and both properties will have the same value. A **BCD** field declares the
number of decimal digits that the field’s value contains in its associated decimal property. In the case of a BCD field, this decimal property can have a value between 1 and 14 digits. A BCD field value is represented in Java as a `java.math.BigDecimal`.

**DECF16**

A DECF16 field is a decimal floating point stored as an 8-byte IEEE 754 decimal64 floating point value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type `decfloat16`. The value of a DECF16 field has 16 decimal digits. The value of a DECF16 field is represented in Java as `java.math.BigDecimal`.

**DECF34**

A DECF34 field is a decimal floating point stored as a 16-byte IEEE 754 decimal128 floating point value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type `decfloat34`. The value of a DECF34 field has 34 decimal digits. The value of a DECF34 field is represented in Java as `java.math.BigDecimal`.

**Hexadecimal field types**

A hexadecimal field contains raw binary data. The following hexadecimal field types are supported:

**BYTE**

A BYTE field is a fixed sized byte string stored as a byte array in the underlying JCo and ABAP runtimes and corresponds to the ABAP type X. A BYTE field declares its field length in its associated `byteLength` and `unicodeByteLength` properties. In the case of a BYTE field, these properties can have a value between 1 and 65535 bytes and both properties will have the same value. The value of a BYTE field is represented in Java as a `byte[]` object.

**String field types**

A string field references a variable length string value. The length of that string value is not fixed until runtime. The storage for the string value is dynamically created in the underlying JCo and ABAP runtimes. The storage for the string field itself is fixed and contains only a string header.

**STRING**

A STRING field refers to a character string and is stored in the underlying JCo and ABAP runtimes as an 8-byte value. It corresponds to the ABAP type G. The value of the STRING field is represented in Java as a `java.lang.String` object.

**XSTRING**

An XSTRING field refers to a byte string and is stored in the underlying JCo and ABAP runtimes as an 8-byte value. It corresponds to the ABAP type Y. The value of the STRING field is represented in Java as a `byte[]` object.

**Complex field types**

A complex field may be either a structure or table field type. The following table summarizes these complex field types.

<table>
<thead>
<tr>
<th>Field Type</th>
<th>Corresponding Java Type</th>
<th>Byte Length</th>
<th>Unicode Byte Length</th>
<th>Number Decimals</th>
<th>Description</th>
</tr>
</thead>
</table>

1799
### Structure field types

A **STRUCTURE** field contains a structure object and is stored in the underlying JCo and ABAP runtimes as an ABAP structure record. It corresponds to either an ABAP type `u` or `v`. The value of a **STRUCTURE** field is represented in Java as a structure object with the interface `org.fusesource.camel.component.sap.model.rfc.Structure`.

### Table field types

A **TABLE** field contains a table object and is stored in the underlying JCo and ABAP runtimes as an ABAP internal table. It corresponds to the ABAP type `h`. The value of the field is represented in Java by a table object with the interface `org.fusesource.camel.component.sap.model.rfc.Table`.

### Table objects

A table object is a homogeneous list data structure containing rows of structure objects with the same structure. This interface extends both the `java.util.List` and `org.eclipse.emf.ecore.EObject` interfaces.

```java
public interface Table<S extends Structure>
    extends org.eclipse.emf.ecore.EObject,
    java.util.List<S> {

    /**
     * Creates and adds table row at end of row list
     */
    S add();

    /**
     * Creates and adds table row at index in row list
     */
    S add(int index);
}
```

The list of rows in a table object are accessed and managed using the standard methods defined in the list interface. In addition the table interface provides two factory methods for creating and adding structure objects to the row list.

Table objects are implemented in the component runtime using the Eclipse Modeling Framework (EMF) and support that framework’s `EObject` interface. Instances of a table object have attached meta-data which define and restrict the structure and contents of the rows it provides. This meta-data can be...
accessed and introspected using the standard methods provided by EMF. Please refer to the EMF documentation for further details.

NOTE

Attempts to add or set a row structure value of the wrong type will throw an exception.

269.6. MESSAGE BODY FOR IDOC

IDoc message type

When using one of the IDoc Camel SAP endpoints, the type of the message body depends on which particular endpoint you are using.

For a sap-idoc-destination endpoint or a sap-qidoc-destination endpoint, the message body is of Document type:

```java
org.fusesource.camel.component.sap.model.idoc.Document
```

For a sap-idoclist-destination endpoint, a sap-qidoclist-destination endpoint, or a sap-idoclist-server endpoint, the message body is of DocumentList type:

```java
org.fusesource.camel.component.sap.model.idoc.DocumentList
```

The IDoc document model

For the Camel SAP component, an IDoc document is modelled using the Eclipse Modelling Framework (EMF), which provides a wrapper API around the underlying SAP IDoc API. The most important types in this model are:

```java
org.fusesource.camel.component.sap.model.idoc.Document
org.fusesource.camel.component.sap.model.idoc.Segment
```

The Document type represents an IDoc document instance. In outline, the Document interface exposes the following methods:

```java
// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface Document extends EObject {
    // Access the field values from the IDoc control record
    String getArchiveKey();
    void setArchiveKey(String value);
    String getClient();
    void setClient(String value);
    ...

    // Access the IDoc document contents
    Segment getRootSegment();
}
```

The following kinds of method are exposed by the Document interface:
Methods for accessing the control record

Most of the methods are for accessing or modifying field values of the IDoc control record. These methods are of the form $\textbf{AttributeName, AttributeName}$, where $\textbf{AttributeName}$ is the name of a field value (see Table 269.2, "IDoc Document Attributes").

Method for accessing the document contents

The $\texttt{getRootSegment}$ method provides access to the document contents (IDoc data records), returning the contents as a $\texttt{Segment}$ object. Each $\texttt{Segment}$ object can contain an arbitrary number of child segments, and the segments can be nested to an arbitrary degree.

Note, however, that the precise layout of the segment hierarchy is defined by the particular $\texttt{IDoc}$ type of the document. When creating (or reading) a segment hierarchy, therefore, you must be sure to follow the exact structure as defined by the IDoc type.

The $\texttt{Segment}$ type is used to access the data records of the IDoc document, where the segments are laid out in accordance with the structure defined by the document's IDoc type. In outline, the $\texttt{Segment}$ interface exposes the following methods:

```java
// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface Segment extends EObject, java.util.Map<String, Object> {
    // Returns the value of the '<em><b>Parent</b></em>' reference.
    Segment getParent();

    // Return a immutable list of all child segments
    <S extends Segment> EList<S> getChildren();

    // Returns a list of child segments of the specified segment type.
    <S extends Segment> SegmentList<S> getChildren(String segmentType);

    EList<String> getTypes();

    Document getDocument();

    String getDescription();

    String getType();

    String getDefinition();

    int getHierarchyLevel();

    String getIdocType();

    String getIdocTypeExtension();

    String getSystemRelease();

    String getApplicationRelease();

    int getNumFields();

    long getMaxOccurrence();

    long getMinOccurrence();
```
boolean isMandatory();
boolean isQualified();
int getRecordLength();
<T> T get(Object key, Class<T> type);
}

The `getChildren(String segmentType)` method is particularly useful for adding new (nested) children to a segment. It returns an object of type, `SegmentList`, which is defined as follows:

```java
// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface SegmentList<S extends Segment> extends EObject, EList<S> {
    S add();
    S add(int index);
}
```

Hence, to create a data record of `E1SCU_CRE` type, you could use Java code like the following:

```java
Segment rootSegment = document.getRootSegment();
Segment E1SCU_CRE_Segment = rootSegment.getChildren("E1SCU_CRE").add();
```

How an IDoc is related to a Document object

According to the SAP documentation, an IDoc document consists of the following main parts:

**Control record**

The control record (which contains the meta-data for the IDoc document) is represented by the attributes on the `Document` object — see Table 269.2, “IDoc Document Attributes” for details.

**Data records**

The data records are represented by the `Segment` objects, which are constructed as a nested hierarchy of segments. You can access the root segment through the `Document.getRootSegment` method.

**Status records**

In the Camel SAP component, the status records are not represented by the document model. But you do have access to the latest status value through the `status` attribute on the control record.

**Example of creating a Document instance**

For example, Example 269.1, “Creating an IDoc Document in Java” shows how to create an IDoc document with the IDoc type, `FLCUSTOMER_CREATEFROMDATA01`, using the IDoc model API in Java.

```
// Java
```
import org.fusesource.camel.component.sap.model.idoc.Document;
import org.fusesource.camel.component.sap.model.idoc.Segment;
import org.fusesource.camel.component.sap.util.IDocUtil;
import org.fusesource.camel.component.sap.model.idoc.Document;
import org.fusesource.camel.component.sap.model.idoc.DocumentList;
import org.fusesource.camel.component.sap.model.idoc.IdocFactory;
import org.fusesource.camel.component.sap.model.idoc.IdocPackage;
import org.fusesource.camel.component.sap.model.idoc.Segment;
import org.fusesource.camel.component.sap.model.idoc.SegmentChildren;
...

// Create a new IDoc instance using the modelling classes

// Get the SAP Endpoint bean from the Camel context.
// In this example, it's a 'sap-idoc-destination' endpoint.
SapTransactionalIDocDestinationEndpoint endpoint =
exchange.getContext().getEndpoint(
    "bean:SapEndpointBeanID",
    SapTransactionalIDocDestinationEndpoint.class
);

// The endpoint automatically populates some required control record attributes
Document document = endpoint.createDocument();

// Initialize additional control record attributes
document.setMessageType("FLCUSTOMER_CREATEFROMDATA");
document.setRecipientPartnerNumber("QUICKCLNT");
document.setRecipientPartnerType("LS");
document.setSenderPartnerNumber("QUICKSTART");
document.setSenderPartnerType("LS");

Segment rootSegment = document.getRootSegment();

Segment E1SCU_CRE_Segment = rootSegment.getChildren("E1SCU_CRE").add();

Segment E1BPSCUNEW_Segment =
    E1SCU_CRE_Segment.getChildren("E1BPSCUNEW").add();
E1BPSCUNEW_Segment.put("CUSTNAME", "Fred Flintstone");
E1BPSCUNEW_Segment.put("FORM", "Mr.");
E1BPSCUNEW_Segment.put("STREET", "123 Rubble Lane");
E1BPSCUNEW_Segment.put("POSTCODE", "01234");
E1BPSCUNEW_Segment.put("CITY", "Bedrock");
E1BPSCUNEW_Segment.put("COUNTR", "US");
E1BPSCUNEW_Segment.put("PHONE", "800-555-1212");
E1BPSCUNEW_Segment.put("EMAIL", "fred@bedrock.com");
E1BPSCUNEW_Segment.put("CUSTTYPE", "P");
E1BPSCUNEW_Segment.put("DISCOUNT", "005");
E1BPSCUNEW_Segment.put("LANGU", "E");

Document attributes
Table 269.2, “IDoc Document Attributes” shows the control record attributes that you can set on the Document object.

</table>

**Setting document attributes in Java**

When setting the control record attributes in Java (from Table 269.2, "IDoc Document Attributes"), the usual convention for Java bean properties is followed. That is, a `name` attribute can be accessed through the `getName` and `setName` methods, for getting and setting the attribute value. For example,
the `iDocType`, `iDocTypeExtension`, and `messageType` attributes can be set as follows on a `Document` object:

```java
// Java
document.setIDocType("FLCUSTOMER_CREATEFROMDATA01");
document.setIDocTypeExtension("$");
document.setMessageType("FLCUSTOMER_CREATEFROMDATA");
```

Setting document attributes in XML

When setting the control record attributes in XML, the attributes must be set on the `idoc:Document` element. For example, the `iDocType`, `iDocTypeExtension`, and `messageType` attributes can be set as follows:

```xml
<?xml version="1.0" encoding="ASCII"?>
<idoc:Document ... iDocType="FLCUSTOMER_CREATEFROMDATA01"
    iDocTypeExtension=""
    messageType="FLCUSTOMER_CREATEFROMDATA" ... >
    ...
</idoc:Document>
```

269.7. TRANSACTION SUPPORT

BAPI transaction model

The SAP Component supports the BAPI transaction model for outbound communication with SAP. A destination endpoint with a URL containing the transacted option set to `true` will, if necessary, initiate a stateful session on the outbound connection of the endpoint and register a Camel Synchronization object with the exchange. This synchronization object will call the BAPI service method `BAPI_TRANSACTION_COMMIT` and end the stateful session when the processing of the message exchange is complete. If the processing of the message exchange fails, the synchronization object will call the BAPI server method `BAPI_TRANSACTION_ROLLBACK` and end the stateful session.

RFC transaction model

The tRFC protocol accomplishes an AT-MOST-ONCE delivery and processing guarantee by identifying each transactional request with a unique transaction identifier (TID). A TID accompanies each request sent in the protocol. A sending application using the tRFC protocol must identify each instance of a request with a unique TID when sending the request. An application may send a request with a given TID multiple times, but the protocol ensures that the request is delivered and processed in the receiving system at most once. An application may choose to resend a request with a given TID when encountering a communication or system error when sending the request, and is thus in doubt as to whether that request was delivered and processed in the receiving system. By resenting a request when encountering an communication error, a client application using the tRFC protocol can thus ensure EXACTLY-ONCE delivery and processing guarantees for its request.

Which transaction model to use?

A BAPI transaction is an application level transaction, in the sense that it imposes ACID guarantees on the persistent data changes performed by a BAPI method or RFC function in the SAP database. An RFC transaction is a communication transaction, in the sense that it imposes delivery guarantees (AT-MOST-
ONCE, EXACTLY-ONCE, EXACTLY-ONCE-IN-ORDER) on requests to a BAPI method and/or RFC function.

Transactional RFC destination endpoints

The following destination endpoints support RFC transactions:

- sap-trfc-destination
- sap-qrfc-destination

A single Camel route can include multiple transactional RFC destination endpoints, sending messages to multiple RFC destinations and even sending messages to the same RFC destination multiple times. This implies that the Camel SAP component potentially needs to keep track of many transaction IDs (TIDs) for each Exchange object passing along a route. Now if the route processing fails and must be retried, the situation gets quite complicated. The RFC transaction semantics demand that each RFC destination along the route must be invoked using the same TID that was used the first time around (and where the TIDs for each of the destinations are distinct from each other). In other words, the Camel SAP component must keep track of which TID was used at which point along the route, and remember this information, so that the TIDs can be replayed in the correct order.

By default, Camel does not provide a mechanism that enables an Exchange to know where it is in a route. To provide such a mechanism, it is necessary to install the CurrentProcessorDefinitionInterceptStrategy interceptor into the Camel runtime. This interceptor must be installed into the Camel runtime, in order for the Camel SAP component to keep track of the TIDs in a route. For details of how to configure the interceptor, see the section called "Interceptor for tRFC and qRFC destinations".

Transactional RFC server endpoints

The following server endpoints support RFC transactions:

- sap-trfc-server

When a Camel exchange processing a transactional request encounters a processing error, Camel handles the processing error through its standard error handling mechanisms. If the Camel route processing the exchange is configured to propagate the error back to the caller, the SAP server endpoint that initiated the exchange takes note of the failure and the sending SAP system is notified of the error. The sending SAP system can then respond by sending another transaction request with the same TID to process the request again.

269.8. XML SERIALIZATION FOR RFC

Overview

SAP request and response objects support an XML serialization format which enable these objects to be serialized to and from an XML document.

XML namespace

Each RFC in a repository defines a specific XML name space for the elements which compose the serialized forms of its Request and Response objects. The form of this namespace URL is as follows:

```
http://sap.fusesource.org/rfc/<Repository Name>/<RFC Name>
```
RFC namespace URLs have a common http://sap.fusesource.org/rfc prefix followed by the name of the repository in which the RFC’s metadata is defined. The final component in the URL is the name of the RFC itself.

**Request and response XML documents**

An SAP request object will be serialized into an XML document with the root element of that document named Request and scoped by the namespace of the request’s RFC.

```xml
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Request
 xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
 ... 
</BOOK_FLIGHT:Request>
```

An SAP response object will be serialized into an XML document with the root element of that document named Response and scoped by the namespace of the response’s RFC.

```xml
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Response
 xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
 ... 
</BOOK_FLIGHT:Response>
```

**Structure fields**

Structure fields in parameter lists or nested structures are serialized as elements. The element name of the serialized structure corresponds to the field name of the structure within the enclosing parameter list, structure or table row entry it resides.

```xml
<BOOK_FLIGHT:FLTINFO
 xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
 ... 
</BOOK_FLIGHT:FLTINFO>
```

Note that the type name of the structure element in the RFC namespace will correspond to the name of the record meta data object which defines the structure, as in the following example:

```xml
<xs:schema
targetNamespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
 xmlns:xs="http://www.w3.org/2001/XMLSchema">
 ... 
<xs:complexType name="FLTINFO_STRUCTURE">
 ... 
</xs:complexType>
 ... 
</xs:schema>
```

This distinction will be important when specifying a JAXB bean to marshal and unmarshal the structure as will be seen in Section 269.12, “Example 3: Handling Requests from SAP”.

**Table fields**
Table fields in parameter lists or nested structures are serialized as elements. The element name of the serialized structure will correspond to the field name of the table within the enclosing parameter list, structure, or table row entry it resides. The table element will contain a series of row elements to hold the serialized values of the table’s row entries.

```xml
<BOOK_FLIGHT:CONNINFO
    xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
    <row ... > ... </row>
    ...
    <row ... > ... </row>
</BOOK_FLIGHT:CONNINFO>
```

Note that the type name of the table element in the RFC namespace will correspond to the name of the record meta data object which defines the row structure of the table suffixed by _TABLE. The type name of the table row element in the RFC name corresponds to the name of the record meta data object which defines the row structure of the table, as in the following example:

```xml
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Request
    xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT"
    CUSTNAME="James Legrand"
    PASSFORM="Mr"
    PASSNAME="Travelin Joe"
```

Elementary fields

Elementary fields in parameter lists or nested structures are serialized as attributes on the element of the enclosing parameter list or structure. The attribute name of the serialized field corresponds to the field name of the field within the enclosing parameter list, structure, or table row entry it resides, as in the following example:

```xml
<xs:schema
    targetNamespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT"
    xmlns:xs="http://www.w3.org/2001/XMLSchema">
    ...
    <xs:complexType name="CONNECTION_INFO_STRUCTURE_TABLE">
        <xs:sequence>
            <xs:element
                name="row"
                minOccurs="0"
                maxOccurs="unbounded"
                type="CONNECTION_INFO_STRUCTURE"/>
        </xs:sequence>
    </xs:complexType>
    <xs:complexType name="CONNECTION_INFO_STRUCTURE">
        ...
    </xs:complexType>
    ...
</xs:schema>
```

This distinction will be important when specifying a JAXB bean to marshal and unmarshal the structure as will be seen in Section 269.12, "Example 3: Handling Requests from SAP".
Date and time formats

Date and Time fields are serialized into attribute values using the following format:

```xml
yyyy-MM-dd'T'HH:mm:ss.SSSZ
```

Date fields will be serialized with only the year, month, day and timezone components set:

```xml
DEPDATE="2014-03-19T00:00:00.000-0400"
```

Time fields will be serialized with only the hour, minute, second, millisecond and timezone components set:

```xml
DEPTIME="1970-01-01T16:00:00.000-0500"
```

269.9. XML Serialization for IDoc

Overview

An IDoc message body can be serialized into an XML string format, with the help of a built-in type converter.

XML namespace

Each serialized IDoc is associated with an XML namespace, which has the following general format:

```xml
http://sap.fusesource.org/idoc/repositoryName/idocType/idocTypeExtension/systemRelease/applicationRelease
```

Both the `repositoryName` (name of the remote SAP meta-data repository) and the `idocType` (IDoc document type) are mandatory, but the other components of the namespace can be left blank. For example, you could have an XML namespace like the following:

```xml
http://sap.fusesource.org/idoc/MY_REPO/FLCUSTOMER_CREATEFROMDATA01/
```

Built-in type converter

The Camel SAP component has a built-in type converter, which is capable of converting a `Document` object or a `DocumentList` object to and from a `String` type.

For example, to serialize a `Document` object to an XML string, you can simply add the following line to a route in XML DSL:

```xml
<convertBodyTo type="java.lang.String"/>
```
You can also use this approach to a serialized XML message into a Document object. For example, given that the current message body is a serialized XML string, you can convert it back into a Document object by adding the following line to a route in XML DSL:

```xml
<convertBodyTo type="org.fusesource.camel.component.sap.model.idoc.Document"/>
```

### Sample IDoc message body in XML format

When you convert an IDoc message to a String, it is serialized into an XML document, where the root element is either idoc:Document (for a single document) or idoc:DocumentList (for a list of documents). Example 269.2, “IDoc Message Body in XML” shows a single IDoc document that has been serialized to an idoc:Document element.

#### Example 269.2. IDoc Message Body in XML

```xml
<?xml version="1.0" encoding="ASCII"?>
<idoc:Document
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:FLCUSTOMER_CREATEFROMDATA01="http://sap.fusesource.org/idoc/XXX/FLCUSTOMER_CREATEFROMDATA01/"
    xmlns:idoc="http://sap.fusesource.org/idoc"
    creationDate="2015-01-28T12:39:13.980-0500"
    iDocType="FLCUSTOMER_CREATEFROMDATA01"
    iDocTypeExtension=""
    messageType="FLCUSTOMER_CREATEFROMDATA"
    recipientPartnerNumber="QUICKCLNT"
    recipientPartnerType="LS"
    senderPartnerNumber="QUICKSTART"
    senderPartnerType="LS">
    <rootSegment xsi:type="FLCUSTOMER_CREATEFROMDATA01---:ROOT" document="/"
        <segmentChildren parent="//@rootSegment">
            <E1SCU_CRE parent="//@rootSegment" document="/"
                <segmentChildren parent="//@rootSegment/@segmentChildren/@E1SCU_CRE.0">
                    <E1BPSCUNEW parent="//@rootSegment/@segmentChildren/@E1SCU_CRE.0" document="/"
                        CUSTNAME="Fred Flintstone" FORM="Mr."
                        STREET="123 Rubble Lane"
                        POSTCODE="01234"
                        CITY="Bedrock"
                        COUNTR="US"
                        PHONE="800-555-1212"
                        EMAIL="fred@bedrock.com"
                        CUSTTYPE="P"
                        DISCOUNT="005"
                        LANGU="E"/>
                </segmentChildren>
            </E1SCU_CRE>
        </segmentChildren>
        </rootSegment>
    </idoc:Document>
```
269.10. EXAMPLE 1: READING DATA FROM SAP

Overview

This example demonstrates a route which reads FlightCustomer business object data from SAP. The route invokes the FlightCustomer BAPI method, BAPI_FLCUST_GETLIST, using an SAP synchronous RFC destination endpoint to retrieve the data.

Java DSL for route

The Java DSL for the example route is as follows:

```java
from("direct:getFlightCustomerInfo")
    .to("bean:createFlightCustomerGetListRequest")
    .to("sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST")
    .to("bean:returnFlightCustomerInfo");
```

XML DSL for route

And the Spring DSL for the same route is as follows:

```xml
<route>
  <from uri="direct:getFlightCustomerInfo"/>
  <to uri="bean:createFlightCustomerGetListRequest"/>
  <to uri="sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST"/>
  <to uri="bean:returnFlightCustomerInfo"/>
</route>
```

createFlightCustomerGetListRequest bean

The createFlightCustomerGetListRequest bean is responsible for building an SAP request object in its exchange method that is used in the RFC call of the subsequent SAP endpoint. The following code snippet demonstrates the sequence of operations to build the request object:

```java
public void create(Exchange exchange) throws Exception {
    // Get SAP Endpoint to be called from context.
    SapSynchronousRfcDestinationEndpoint endpoint =
        exchange.getContext().getEndpoint("sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST",
                                    SapSynchronousRfcDestinationEndpoint.class);

    // Retrieve bean from message containing Flight Customer name to
    // look up.
    BookFlightRequest bookFlightRequest =
        exchange.getIn().getBody(BookFlightRequest.class);

    // Create SAP Request object from target endpoint.
    Structure request = endpoint.getRequest();

    // Add Customer Name to request if set
    if (bookFlightRequest.getCustomerName() != null &&
        bookFlightRequest.getCustomerName().length() > 0) {
        request.put("CUSTOMER_NAME",
```
public void createFlightCustomerInfo(Exchange exchange) throws Exception {

// Retrieve SAP response object from body of exchange message.
Structure flightCustomerGetListResponse = exchange.getIn().getBody(Structure.class);

if (flightCustomerGetListResponse == null) {
    throw new Exception("No Flight Customer Get List Response");
}

// Check BAPI return parameter for errors
@SuppressWarnings("unchecked")
Table<Structure> bapiReturn = flightCustomerGetListResponse.get("RETURN", Table.class);
Structure bapiReturnEntry = bapiReturn.get(0);
if (bapiReturnEntry.get("TYPE", String.class) != "S") {
    String message = bapiReturnEntry.get("MESSAGE", String.class);
    throw new Exception("BAPI call failed: " + message);
}

// Get customer list table from response object.
@SuppressWarnings("unchecked")
Table<? extends Structure> customerList = flightCustomerGetListResponse.get("CUSTOMER_LIST", Table.class);

if (customerList == null || customerList.size() == 0) {
    throw new Exception("No Customer Info.");
}

// Get Flight Customer data from first row of table.
Structure customer = customerList.get(0);

// Create bean to hold Flight Customer data.
FlightCustomerInfo flightCustomerInfo = new FlightCustomerInfo();

// Get customer id from Flight Customer data and add to bean.
String customerId = customer.get("CUSTOMERID", String.class);
if (customerId != null) {
    flightCustomerInfo.setCustomerNumber(customerId);
}
269.11. EXAMPLE 2: WRITING DATA TO SAP

Overview

This example demonstrates a route which creates a FlightTrip business object instance in SAP. The route invokes the FlightTrip BAPI method, BAPI_FLTRIP_CREATE, using a destination endpoint to create the object.

Java DSL for route

The Java DSL for the example route is as follows:

```java
from("direct:createFlightTrip")
  .to("bean:createFlightTripRequest")
  .to("sap-srfc-destination:nplDest:BAPI_FLTRIP_CREATE?transacted=true")
  .to("bean:returnFlightTripResponse");
```

XML DSL for route

And the Spring DSL for the same route is as follows:

```xml
<route>
  <from uri="direct:createFlightTrip"/>
  <to uri="bean:createFlightTripRequest"/>
  <to uri="sap-srfc-destination:nplDest:BAPI_FLTRIP_CREATE?transacted=true"/>
  <to uri="bean:returnFlightTripResponse"/>
</route>
```

Transaction support

Note that the URL for the SAP endpoint has the transacted option set to true. As discussed in Section 269.7, "Transaction Support", when this option is enabled the endpoint ensures that an SAP transaction session has been initiated before invoking the RFC call. Because this endpoint’s RFC creates new data in SAP, this option is necessary to make the route’s changes permanent in SAP.

Populating request parameters

The createFlightTripRequest and returnFlightTripResponse beans are responsible for populating request parameters into the SAP request and extracting response parameters from the SAP response respectively following the same sequence of operations as demonstrated in the previous example.

269.12. EXAMPLE 3: HANDLING REQUESTS FROM SAP
Overview

This example demonstrates a route which handles a request from SAP to the BOOK_FLIGHT RFC, which is implemented by the route. In addition, it demonstrates the component’s XML serialization support, using JAXB to unmarshal and marshal SAP request objects and response objects to custom beans.

This route creates a FlightTrip business object on behalf of a travel agent, FlightCustomer. The route first unmarshals the SAP request object received by the SAP server endpoint into a custom JAXB bean. This custom bean is then multicasted in the exchange to three sub-routes, which gather the travel agent, flight connection and passenger information required to create the flight trip. The final sub-route creates the flight trip object in SAP as demonstrated in the previous example. The final sub-route also creates and returns a custom JAXB bean which is marshaled into an SAP response object and returned by the server endpoint.

Java DSL for route

The Java DSL for the example route is as follows:

```java
DataFormat jaxb = new JaxbDataFormat("org.fusesource.sap.example.jaxb");

from("sap-srfc-server:nplserver:BOOK_FLIGHT")
  .unmarshal(jaxb)
  .multicast()
  .to("direct:getFlightConnectionInfo",
   "direct:getFlightCustomerInfo",
   "direct:getPassengerInfo")
  .end()
  .to("direct:createFlightTrip")
  .marshal(jaxb);
```

XML DSL for route

And the XML DSL for the same route is as follows:

```xml
<route>
  <from uri="sap-srfc-server:nplserver:BOOK_FLIGHT"/>
  <unmarshal>
    <jaxb contextPath="org.fusesource.sap.example.jaxb"/>
  </unmarshal>
  <multicast>
    <to uri="direct:getFlightConnectionInfo"/>
    <to uri="direct:getFlightCustomerInfo"/>
    <to uri="direct:getPassengerInfo"/>
  </multicast>
  <to uri="direct:createFlightTrip"/>
  <marshal>
    <jaxb contextPath="org.fusesource.sap.example.jaxb"/>
  </marshal>
</route>
```

BookFlightRequest bean
The following listing illustrates a JAXB bean which unmarshals from the serialized form of an SAP BOOK_FLIGHT request object:

```java
@XmlElement(name="Request",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@AccessorType(XmlAccessType.FIELD)
public class BookFlightRequest {

    @XmlAttribute(name="CUSTNAME")
    private String customerName;

    @XmlAttribute(name="FLIGHTDATE")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date flightDate;

    @XmlAttribute(name="TRAVELAGENCYNUMBER")
    private String travelAgencyNumber;

    @XmlAttribute(name="DESTINATION_FROM")
    private String startAirportCode;

    @XmlAttribute(name="DESTINATION_TO")
    private String endAirportCode;

    @XmlAttribute(name="PASSFORM")
    private String passengerFormOfAddress;

    @XmlAttribute(name="PASSNAME")
    private String passengerName;

    @XmlAttribute(name="PASSBIRTH")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date passengerDateOfBirth;

    @XmlAttribute(name="CLASS")
    private String flightClass;

    ...
}
```

**BookFlightResponse bean**

The following listing illustrates a JAXB bean which marshals to the serialized form of an SAP BOOK_FLIGHT response object:

```java
@XmlElement(name="Response",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@AccessorType(XmlAccessType.FIELD)
public class BookFlightResponse {

    @XmlAttribute(name="TRIPNUMBER")
    private String tripNumber;

    @XmlAttribute(name="TICKET_PRICE")
    private BigDecimal ticketPrice;
```
@XmlAttribute(name="TICKET_TAX")
private BigDecimal ticketTax;

@XmlAttribute(name="CURRENCY")
private String currency;

@XmlAttribute(name="PASSFORM")
private String passengerFormOfAddress;

@XmlAttribute(name="PASSNAME")
private String passengerName;

@XmlAttribute(name="PASSBIRTH")
@XmlJavaTypeAdapter(DateAdapter.class)
private Date passengerDateOfBirth;

@XmlElement(name="FLTINFO")
private FlightInfo flightInfo;

@XmlElement(name="CONNINFO")
private ConnectionInfoTable connectionInfo;

...
ConnectionInfoTable bean

The following listing illustrates a JAXB bean which marshals to the serialized form of the complex table parameter, **CONNINFO**. Note that the name of the root element type of the JAXB bean corresponds to the name of the row structure type suffixed with **_TABLE** and the bean contains a list of row elements:

```java
@XmlRootElement(name="CONNINFO_TABLE",
    namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class ConnectionInfoTable {
    @XmlElement(name="row")
    List<ConnectionInfo> rows;

    ...
}
```

ConnectionInfo bean

The following listing illustrates a JAXB bean, which marshals to the serialized form of the above tables row elements:

```java
@XmlRootElement(name="CONNINFO",
    namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class ConnectionInfo {
    @XmlAttribute(name="CONNID")
    String connectionId;

    @XmlAttribute(name="AIRLINE")
    String airline;

    @XmlAttribute(name="PLANETYPE")
    String planeType;

    @XmlAttribute(name="CITYFROM")
    String cityFrom;

    @XmlAttribute(name="DEPDATE")
    private String cityTo;

    @XmlAttribute(name="ARRDATE")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date arrivalDate;

    @XmlAttribute(name="ARRTIME")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date arrivalTime;

    ...
}
```
@XmlTypeAdapter(DateAdapter.class)
Date departureDate;

@XmlAttribute(name="DEPTIME")
@XmlJavaTypeAdapter(DateAdapter.class)
Date departureTime;

@XmlAttribute(name="CITYTO")
String cityTo;

@XmlAttribute(name="ARRDATE")
@XmlJavaTypeAdapter(DateAdapter.class)
Date arrivalDate;

@XmlAttribute(name="ARRTIME")
@XmlJavaTypeAdapter(DateAdapter.class)
Date arrivalTime;

...
CHAPTER 270. SAP NETWEAVER COMPONENT

Available as of Camel version 2.12

The `sap-netweaver` integrates with the SAP NetWeaver Gateway using HTTP transports.

This camel component supports only producer endpoints.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sap-netweaver</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

270.1. URI FORMAT

The URI scheme for a sap netweaver gateway component is as follows

```
sap-netweaver:https://host:8080/path?username=foo&password=secret
```

You can append query options to the URI in the following format, `?option=value&option=value&...`

270.2. PREREQUISITES

You would need to have an account to the SAP NetWeaver system to be able to leverage this component. SAP provides a demo setup where you can requires for an account.

This component uses the basic authentication scheme for logging into SAP NetWeaver.

270.3. SAPNETWEAVER OPTIONS

The SAP NetWeaver component has no options.

The SAP NetWeaver endpoint is configured using URI syntax:

```
sap-netweaver:url
```

with the following path and query parameters:

270.3.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>Required Url to the SAP net-weaver gateway server.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

270.3.2. Query Parameters (6 parameters):
### 270.4. MESSAGE HEADERS

The following headers can be used by the producer.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelNetWeaverCommand</td>
<td>String</td>
<td><strong>Mandatory</strong>: The command to execute in MS ADO.Net Data Service format.</td>
</tr>
</tbody>
</table>

### 270.5. EXAMPLES

This example is using the flight demo example from SAP, which is available online over the internet [here](https://sapes1.sapdevcenter.com/sap/opu/odata/IWBEP/RMTSAMPLEFLIGHT_2/).

In the route below we request the SAP NetWeaver demo server using the following url:

```
https://sapes1.sapdevcenter.com/sap/opu/odata/IWBEP/RMTSAMPLEFLIGHT_2/
```

And we want to execute the following command:

```
FlightCollection(AirLineID='AA',FlightConnectionID='0017',FlightDate=datetime'2012-08-29T00%3A00%3A00')
```

To get flight details for the given flight. The command syntax is in [MS ADO.Net Data Service](https://sapes1.sapdevcenter.com/sap/opu/odata/IWBEP/RMTSAMPLEFLIGHT_2/) format.
We have the following Camel route

```java
from("direct:start")
  .setHeader(NetWeaverConstants.COMMAND, constant(command))
  .toF("sap-netweaver:%s?username=%s&password=%s", url, username, password)
  .to("log:response")
  .to("velocity:flight-info.vm")
```

Where url, username, password and command is defined as:

```java
private String username = "P1909969254";
private String password = "TODO";
private String url = 
  "https://sapes1.sapdevcenter.com/sap/opu/odata/IWBEP/RMTSAMPLEFLIGHT_2/";
private String command = 
  "FlightCollection(AirLineID='AA',FlightConnectionID='0017',FlightDate=datetime'2012-08-29T00%3A00%3A00')";
```

The password is invalid. You would need to create an account at SAP first to run the demo.

The velocity template is used for formatting the response to a basic HTML page

```html
<html>
<body>
Flight information:

<p>Airline ID: $body["AirLineID"]</p>
<p>Aircraft Type: $body["AirCraftType"]</p>
<p>Departure city: $body["FlightDetails"]["DepartureCity"]</p>
<p>Departure airport: $body["FlightDetails"]["DepartureAirPort"]</p>
<p>Destination city: $body["FlightDetails"]["DestinationCity"]</p>
<p>Destination airport: $body["FlightDetails"]["DestinationAirPort"]</p>
</body>
</html>
```

When running the application you get sample output:

```
Flight information:
Airline ID: AA
Aircraft Type: 747-400
Departure city: new york
Departure airport: JFK
Destination city: SAN FRANCISCO
Destination airport: SFO
```

270.6. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
- HTTP
CHAPTER 271. SCHEDULER COMPONENT

Available as of Camel version 2.15

The scheduler: component is used to generate message exchanges when a scheduler fires. This component is similar to the Timer component, but it offers more functionality in terms of scheduling. Also this component uses JDK ScheduledExecutorService. Where as the timer uses a JDK Timer.

You can only consume events from this endpoint.

271.1. URI FORMAT

scheduler:name[?options]

Where name is the name of the scheduler, which is created and shared across endpoints. So if you use the same name for all your timer endpoints, only one scheduler thread pool and thread will be used - but you can configure the thread pool to allow more concurrent threads.

You can append query options to the URI in the following format, ?option=value&option=value&...

Note: The IN body of the generated exchange is null. So exchange.getIn().getBody() returns null.

271.2. OPTIONS

The Scheduler component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>concurrentTasks (scheduler)</td>
<td>Number of threads used by the scheduling thread pool. Is by default using a single thread</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Scheduler endpoint is configured using URI syntax:

scheduler:name

with the following path and query parameters:

271.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required The name of the scheduler</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### 271.2.2. Query Parameters (20 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bridgeErrorHandler</code> (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default, the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>sendEmptyMessageWhenIdle</code> (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>exceptionHandler</code> (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default, the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td><code>exchangePattern</code> (consumer)</td>
<td>Sets the default exchange pattern when creating an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td><code>pollStrategy</code> (consumer)</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel. In other words the error occurred while the polling was gathering information, for instance access to a file network failed so Camel cannot access it to scan for files. The default implementation will log the caused exception at WARN level and ignore it.</td>
<td>PollingConsumerPollingStrategy</td>
<td></td>
</tr>
<tr>
<td><code>synchronous</code> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>backoffErrorThreshold</code> (scheduler)</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><code>backoffIdleThreshold</code> (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>backoffMultiplier</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>concurrentTasks</td>
<td>Number of threads used by the scheduling thread pool. Is by default using a single thread</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>delay</td>
<td>Milliseconds before the next poll. The default value is 500. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay</td>
<td>Milliseconds before the first poll starts. The default value is 1000. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>scheduledExecutorService</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool. This option allows you to share a thread pool among multiple consumers.</td>
<td></td>
<td>ScheduledExecutorService</td>
</tr>
</tbody>
</table>
Allow to plugin a custom org.apache.camel.spi.ScheduledPollConsumerScheduler to use as the scheduler for firing when the polling consumer runs. The default implementation uses the ScheduledExecutorService and there is a Quartz2, and Spring based which supports CRON expressions. Notice: If using a custom scheduler then the options for initialDelay, useFixedDelay, timeUnit, and scheduledExecutorService may not be in use. Use the text quartz2 to refer to use the Quartz2 scheduler; and use the text spring to use the Spring based; and use the text myScheduler to refer to a custom scheduler by its id in the Registry. See Quartz2 page for an example.

To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.

Whether the scheduler should be auto started.

Time unit for initialDelay and delay options.

Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.

This component is a scheduler Polling Consumer where you can find more information about the options above, and examples at the Polling Consumer page.

When the timer is fired, it adds the following information as properties to the Exchange:

The value of the name option.
### 271.5. SAMPLE

To set up a route that generates an event every 60 seconds:

```java
from("scheduler://foo?period=60s").to("bean:myBean?method=someMethodName");
```

The above route will generate an event and then invoke the `someMethodName` method on the bean called `myBean` in the Registry such as JNDI or Spring.

And the route in Spring DSL:

```xml
<route>
    <from uri="scheduler://foo?period=60s"/>
    <to uri="bean:myBean?method=someMethodName"/>
</route>
```

### 271.6. FORCING THE SCHEDULER TO TRIGGER IMMEDIATELY WHEN COMPLETED

To let the scheduler trigger as soon as the previous task is complete, you can set the option `greedy=true`. But beware then the scheduler will keep firing all the time. So use this with caution.

### 271.7. FORCING THE SCHEDULER TO BE IDLE

There can be use cases where you want the scheduler to trigger and be greedy. But sometimes you want “tell the scheduler” that there was no task to poll, so the scheduler can change into idle mode using the backoff options. To do this you would need to set a property on the exchange with the key `Exchange.SCHEDULER_POLLED_MESSAGES` to a boolean value of false. This will cause the consumer to indicate that there was no messages polled.

The consumer will otherwise as by default return 1 message polled to the scheduler, every time the consumer has completed processing the exchange.

- Quartz
CHAPTER 272. SCHEMATRON COMPONENT

Available as of Camel version 2.15

Schematron is an XML-based language for validating XML instance documents. It is used to make assertions about data in an XML document and it is also used to express operational and business rules. Schematron is an ISO Standard. The schematron component uses the leading implementation of ISO schematron. It is an XSLT based implementation. The schematron rules is run through four XSLT pipelines, which generates a final XSLT which will be used as the basis for running the assertion against the XML document. The component is written in a way that Schematron rules are loaded at the start of the endpoint (only once) this is to minimise the overhead of instantiating a Java Templates object representing the rules.

272.1. URI FORMAT

```
schematron://path?[options]
```

272.2. URI OPTIONS

The Schematron component has no options.

The Schematron endpoint is configured using URI syntax:

```
schematron:path
```

with the following path and query parameters:

272.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Required The path to the schematron rules file. Can either be in class path or location in the file system.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

272.2.2. Query Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>abort (producer)</td>
<td>Flag to abort the route and throw a schematron validation exception.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>rules (producer)</td>
<td>To use the given schematron rules instead of loading from the path</td>
<td></td>
<td>Templates</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
uriResolver
(advanced)

Set the URIResolver to be used for resolving schematron includes in the rules file.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>uriResolver</td>
<td>Set the URIResolver to be used for resolving schematron includes in the rules file.</td>
<td></td>
<td>URIResolver</td>
</tr>
</tbody>
</table>

272.3. HEADERS

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Type</th>
<th>In/Out</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelSchematronValidationStatus</td>
<td>The schematron validation status: SUCCESS / FAILED</td>
<td>String</td>
<td>IN</td>
</tr>
<tr>
<td>CamelSchematronValidationReport</td>
<td>The schematron report body in XML format. See an example below</td>
<td>String</td>
<td>IN</td>
</tr>
</tbody>
</table>

272.4. URI AND PATH SYNTAX

The following example shows how to invoke the schematron processor in Java DSL. The schematron rules file is sourced from the class path:

```xml
<from("direct:start").to("schematron://sch/schematron.sch").to("mock:result")
```

The following example shows how to invoke the schematron processor in XML DSL. The schematron rules file is sourced from the file system:

```xml
<route>
  <from uri="direct:start" />
  <to uri="schematron:///usr/local/sch/schematron.sch" />
  <log message="Schematron validation status: ${in.header.CamelSchematronValidationStatus}" />
</route>
```
TIP

Where to store schematron rules? Schematron rules can change with business requirement, as such it is recommended to store these rules somewhere in file system. When the schematron component endpoint is started, the rules are compiled into XSLT as a Java Templates Object. This is done only once to minimise the overhead of instantiating Java Templates object, which can be an expensive operation for large set of rules and given that the process goes through four pipelines of XSLT transformations. So if you happen to store the rules in the file system, in the event of an update, all you need is to restart the route or the component. No harm in storing these rules in the class path though, but you will have to build and deploy the component to pick up the changes.

272.5. SCHEMATRON RULES AND REPORT SAMPLES

Here is an example of schematron rules

```xml
<choice>
  <when>
    <simple>${in.header.CamelSchematronValidationStatus} == 'SUCCESS'</simple>
    <to uri="mock:success" />
  </when>
  <otherwise>
    <log message="Failed schematron validation" />
    <setBody>
      <header>CamelSchematronValidationReport</header>
      <to uri="mock:failure" />
    </setBody>
  </otherwise>
</choice>
</route>
```

Here is an example of schematron report:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<svrl:schematron-output xmlns:svrl="http://purl.oclc.org/dsdl/svrl"
  xmlns:iso="http://purl.oclc.org/dsdl/schematron"
  xmlns:saxon="http://saxon.sf.net/
  xmlns:schold="http://www.ascc.net/xml/schematron"
  xmlns:xhtml="http://www.w3.org/1999/xhtml"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema" schemaVersion="" title="">
  <svrl:active-pattern document="" />
  <svrl:fired-rule context="chapter"/>
</svrl:schematron-output>
```
TIP

Useful Links and resources*  Introduction to Schematron by Mulleberry technologies. An excellent document in PDF to get you started on Schematron. * Schematron official site. This contains links to other resources
CHAPTER 273. SCP COMPONENT

Available as of Camel version 2.10

The camel-jsch component supports the SCP protocol using the Client API of the Jsch project. Jsch is already used in camel by the FTP component for the sftp: protocol.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-jsch</artifactId>
    <version>x.x.x</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

273.1. URI FORMAT

```text
scp://host[:port]/destination[?options]
```

You can append query options to the URI in the following format, `?option=value&option=value&...`

The file name can be specified either in the <path> part of the URI or as a "CamelFileName" header on the message (Exchange.FILE_NAME if used in code).

273.2. OPTIONS

The SCP component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>verboseLogging</td>
<td>JSCH is verbose logging out of the box. Therefore we turn the logging down to DEBUG logging by default. But setting this option to true turns on the verbose logging again.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>resolveProperty</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Placeholders</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The SCP endpoint is configured using URI syntax:

```text
scp:host:port/directoryName
```

with the following path and query parameters:

273.2.1. Path Parameters (3 parameters):
### Name | Description | Default | Type
--- | --- | --- | ---
**host** | **Required** Hostname of the FTP server |  | String
**port** | Port of the FTP server |  | int
**directoryName** | The starting directory |  | String

#### 273.2.2. Query Parameters (20 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>disconnect</strong> (common)</td>
<td>Whether or not to disconnect from remote FTP server right after use. Disconnect will only disconnect the current connection to the FTP server. If you have a consumer which you want to stop, then you need to stop the consumer/route instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>chmod</strong> (producer)</td>
<td>Allows you to set chmod on the stored file. For example chmod=664.</td>
<td>664</td>
<td>String</td>
</tr>
<tr>
<td><strong>fileName</strong> (producer)</td>
<td>Use Expression such as File Language to dynamically set the filename. For consumers, it’s used as a filename filter. For producers, it’s used to evaluate the filename to write. If an expression is set, it take precedence over the CamelFileName header. (Note: The header itself can also be an Expression). The expression options support both String and Expression types. If the expression is a String type, it is always evaluated using the File Language. If the expression is an Expression type, the specified Expression type is used – this allows you, for instance, to use OGNL expressions. For the consumer, you can use it to filter filenames, so you can for instance consume today’s file using the File Language syntax: mydata-$date:now:yyyyMMdd.txt. The producers support the CamelOverruleFileName header which takes precedence over any existing CamelFileName header; the CamelOverruleFileName is a header that is used only once, and makes it easier as this avoids to temporary store CamelFileName and have to restore it afterwards.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>flatten (producer)</td>
<td>Flatten is used to flatten the file name path to strip any leading paths, so it’s just the file name. This allows you to consume recursively into sub-directories, but when you eg write the files to another directory they will be written in a single directory. Setting this to true on the producer enforces that any file name in CamelFileName header will be stripped for any leading paths.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>strictHostKeyChecking (producer)</td>
<td>Sets whether to use strict host key checking. Possible values are: no, yes</td>
<td>no</td>
<td>String</td>
</tr>
<tr>
<td>allow NullBody (producer)</td>
<td>Used to specify if a null body is allowed during file writing. If set to true then an empty file will be created, when set to false, and attempting to send a null body to the file component, a GenericFileWriteException of 'Cannot write null body to file.' will be thrown. If the fileExist option is set to 'Override', then the file will be truncated, and if set to append the file will remain unchanged.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>disconnectOnBatchComplete (producer)</td>
<td>Whether or not to disconnect from remote FTP server right after a Batch upload is complete. disconnectOnBatchComplete will only disconnect the current connection to the FTP server.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>connectTimeout (advanced)</td>
<td>Sets the connect timeout for waiting for a connection to be established Used by both FTPClient and JSCH</td>
<td>10000</td>
<td>int</td>
</tr>
<tr>
<td>soTimeout (advanced)</td>
<td>Sets the so timeout Used only by FTPClient</td>
<td>300000</td>
<td>int</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>timeout (advanced)</td>
<td>Sets the data timeout for waiting for reply Used only by FTPClient</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td>knownHostsFile (security)</td>
<td>Sets the known_hosts file, so that the jsch endpoint can do host key verification. You can prefix with classpath: to load the file from classpath instead of file system.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>password (security)</td>
<td>Password to use for login</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>preferredAuthentications</td>
<td>Set a comma separated list of authentications that will be used in order of preference. Possible authentication methods are defined by JCraft JSCH. Some examples include: gssapi-with-mic,publickey,keyboard-interactive,password If not specified the JSCH and/or system defaults will be used.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>privateKeyBytes</td>
<td>Set the private key bytes to that the endpoint can do private key verification. This must be used only if privateKeyFile wasn’t set. Otherwise the file will have the priority.</td>
<td></td>
<td>byte[]</td>
</tr>
<tr>
<td>privateKeyFile</td>
<td>Set the private key file to that the endpoint can do private key verification. You can prefix with classpath: to load the file from classpath instead of file system.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>privateKeyFilePassphrase</td>
<td>Set the private key file passphrase to that the endpoint can do private key verification.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>username</td>
<td>Username to use for login</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>useUserKnownHostsFile</td>
<td>If knownHostFile has not been explicit configured, then use the host file from System.getProperty(user.home) /.ssh/known_hosts</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>ciphers</td>
<td>Set a comma separated list of ciphers that will be used in order of preference. Possible cipher names are defined by JCraft JSCH. Some examples include: aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc. If not specified the default list from JSCH will be used.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 273.3. LIMITATIONS

Currently camel-jsch only supports a **Producer** (i.e. copy files to another host).

### 273.4. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 274. CAMEL SCR (DEPRECATED)

Available as of Camel 2.15

SCR stands for Service Component Runtime and is an implementation of OSGi Declarative Services specification. SCR enables any plain old Java object to expose and use OSGi services with no boilerplate code.

OSGi framework knows your object by looking at SCR descriptor files in its bundle which are typically generated from Java annotations by a plugin such as org.apache.felix:maven-scr-plugin.

Running Camel in an SCR bundle is a great alternative for Spring DM and Blueprint based solutions having significantly fewer lines of code between you and the OSGi framework. Using SCR your bundle can remain completely in Java world; there is no need to edit XML or properties files. This offers you full control over everything and means your IDE of choice knows exactly what is going on in your project.

274.1. CAMEL SCR SUPPORT

Camel-scr bundle is not included in Apache Camel versions prior 2.15.0, but the artifact itself can be used with any Camel version since 2.12.0.

org.apache.camel/camel-scr bundle provides a base class, AbstractCamelRunner, which manages a Camel context for you and a helper class, ScrHelper, for using your SCR properties in unit tests. Camel-scr feature for Apache Karaf defines all features and bundles required for running Camel in SCR bundles.

AbstractCamelRunner class ties CamelContext’s lifecycle to Service Component’s lifecycle and handles configuration with help of Camel’s PropertiesComponent. All you have to do to make a Service Component out of your java class is to extend it from AbstractCamelRunner and add the following org.apache.felix.scr.annotations on class level:

Add required annotations

```java
@Component
@References(
    @Reference(name = "camelComponent", referenceInterface = ComponentResolver.class,
    cardinality = ReferenceCardinality.MANDATORY_MULTIPLE, policy = ReferencePolicy.DYNAMIC,
    policyOption = ReferencePolicyOption.GREEDY, bind = "gotCamelComponent", unbind = "lostCamelComponent")
)
@Override
protected List<RoutesBuilder> getRouteBuilders()
{
    List<RoutesBuilder> routesBuilders = new ArrayList<>();
    routesBuilders.add(new YourRouteBuilderHere(registry));
    routesBuilders.add(new AnotherRouteBuilderHere(registry));
    return routesBuilders;
}
```

Then implement getRouteBuilders() method which returns the Camel routes you want to run:

Implement getRouteBuilders()

```java
@Override
protected List<RoutesBuilder> getRouteBuilders()
{
    List<RoutesBuilder> routesBuilders = new ArrayList<>();
    routesBuilders.add(new YourRouteBuilderHere(registry));
    routesBuilders.add(new AnotherRouteBuilderHere(registry));
    return routesBuilders;
}
```

And finally provide the default configuration with:
Default configuration in annotations

```java
@Properties({
    @Property(name = "camelContextId", value = "my-test"),
    @Property(name = "active", value = "true"),
    @Property(name = "...", value = "..."),
    ...
})
```

That's all. And if you used camel-archetype-scr to generate a project all this is already taken care of.

Below is an example of a complete Service Component class, generated by camel-archetype-scr:

CamelScrExample.java

```java
// This file was generated from org.apache.camel.archetypes/camel-archetype-scr/2.15-SNAPSHOT
package example;
import java.util.ArrayList;
import java.util.List;
import org.apache.camel.scr.AbstractCamelRunner;
import example.internal.CamelScrExampleRoute;
import org.apache.camel.RoutesBuilder;
import org.apache.camel.spi.ComponentResolver;
import org.apache.felix.scr.annotations.*
@Component(label = CamelScrExample.COMPONENT_LABEL, description = CamelScrExample.COMPONENT_DESCRIPTION, immediate = true, metatype = true)
@Properties({
    @Property(name = "camelContextId", value = "camel-scr-example"),
    @Property(name = "camelRouteId", value = "foo/timer-log"),
    @Property(name = "active", value = "true"),
    @Property(name = "from", value = "timer:foo?period=5000"),
    @Property(name = "to", value = "log:foo?showHeaders=true"),
    @Property(name = "messageOk", value = "Success: {{from}} -> {{to}}"),
    @Property(name = "messageError", value = "Failure: {{from}} -> {{to}}"),
    @Property(name = "maximumRedeliveries", value = "0"),
    @Property(name = "redeliveryDelay", value = "5000"),
    @Property(name = "backOffMultiplier", value = "2"),
    @Property(name = "maximumRedeliveryDelay", value = "60000")
})
@References({
    @Reference(name = "camelComponent", referenceInterface = ComponentResolver.class,
    cardinality = ReferenceCardinality.MANDATORY_MULTIPLE, policy = ReferencePolicy.DYNAMIC,
    policyOption = ReferencePolicyOption.GREEDY, bind = "gotCamelComponent", unbind = "lostCamelComponent")
})
public class CamelScrExample extends AbstractCamelRunner {
    public static final String COMPONENT_LABEL = "example.CamelScrExample";
    public static final String COMPONENT_DESCRIPTION = "This is the description for camel-scr-example.";
```
camel-context-id and active properties control the CamelContext’s name (defaults to "camel-runner-default") and whether it will be started or not (defaults to "false"), respectively. In addition to these you can add and use as many properties as you like. Camel’s PropertiesComponent handles recursive properties and prefixing with fallback without problem.

AbstractCamelRunner will make these properties available to your RouteBuilders with help of Camel’s PropertiesComponent and it will also inject these values into your Service Component’s and RouteBuilder’s fields when their names match. The fields can be declared with any visibility level, and many types are supported (String, int, boolean, URL, ...).

Below is an example of a RouteBuilder class generated by camel-archetype-scr:

CamelScrExampleRoute.java

```java
// This file was generated from org.apache.camel.archetypes.camel-archetype-scr/2.15-SNAPSHOT
package example.internal;

import org.apache.camel.LoggingLevel;
import org.apache.camel.builder.RouteBuilder;
import org.apache.camel.impl.SimpleRegistry;
import org.apache.commons.lang.Validate;

public class CamelScrExampleRoute extends RouteBuilder {

    SimpleRegistry registry;

    // Configured fields
    private String camelRouteId;
    private Integer maximumRedeliveries;
    private Long redeliveryDelay;
    private Double backOffMultiplier;
    private Long maximumRedeliveryDelay;

    public CamelScrExampleRoute(final SimpleRegistry registry) {
        this.registry = registry;
    }

    @Override
    public void configure() throws Exception {
        checkProperties();
        // Add a bean to Camel context registry
        registry.put("test", "bean");
    }
```

@Override
protected List<RoutesBuilder> getRouteBuilders() {
    List<RoutesBuilder> routesBuilders = new ArrayList<>();
    routesBuilders.add(new CamelScrExampleRoute(registry));
    return routesBuilders;
}
Let's take a look at `CamelScrExampleRoute` in more detail.

```
.errorHandler(defaultErrorHandler()
  .retryAttemptedLogLevel(LoggingLevel.WARN)
  .maximumRedeliveries(maximumRedeliveries)
  .redeliveryDelay(redeliveryDelay)
  .backOffMultiplier(backOffMultiplier)
  .maximumRedeliveryDelay(maximumRedeliveryDelay));

.from("{{from}}")
  .startupOrder(2)
  .routeId(camelRouteId)
  .onCompletion()
    .to("direct:processCompletion")
    .end()
  .removeHeaders("CamelHttp*")
  .to("{{to}}");

.from("direct:processCompletion")
  .startupOrder(1)
  .routeId(camelRouteId + ".completion")
  .choice()
    .when(simple("${exception} == null"))
      .log("{{messageOk}}")
    .otherwise()
      .log(LoggingLevel.ERROR, "{{messageError}}")
  .end();
}
```

```
public void checkProperties() {
  Validate.notNull(camelRouteId, "camelRouteId property is not set");
  Validate.notNull(maximumRedeliveries, "maximumRedeliveries property is not set");
  Validate.notNull(redeliveryDelay, "redeliveryDelay property is not set");
  Validate.notNull(backOffMultiplier, "backOffMultiplier property is not set");
  Validate.notNull(maximumRedeliveryDelay, "maximumRedeliveryDelay property is not set");
}
```

The values of these fields are set with values from properties by matching their names.
If you need to add some beans to CamelContext’s registry for your routes, you can do it like this.

```java
// Add a bean to Camel context registry
registry.put("test", "bean");
```

It is a good idea to check that required parameters are set and they have meaningful values before allowing the routes to start.

```java
public void checkProperties() {
    Validate.notNull(camelRouteId, "camelRouteId property is not set");
    Validate.notNull(maximumRedeliveries, "maximumRedeliveries property is not set");
    Validate.notNull(redeliveryDelay, "redeliveryDelay property is not set");
    Validate.notNull(backOffMultiplier, "backOffMultiplier property is not set");
    Validate.notNull(maximumRedeliveryDelay, "maximumRedeliveryDelay property is not set");
}
```

It is a good idea to check that required parameters are set and they have meaningful values before allowing the routes to start.

```java
from("{{from}}")
    .startupOrder(2)
    .routeId(camelRouteId)
    .onCompletion()
        .to("direct:processCompletion")
        .end()
    .removeHeaders("CamelHttp**")
    .to("{{to}}");
```

```java
from("direct:processCompletion")
    .startupOrder(1)
    .routeId(camelRouteId + ".completion")
    .choice()
        .when(simple("${exception} == null"))
            .log("{{messageOk}}")
        .otherwise()
            .log(LoggingLevel.ERROR, "{{messageError}}")
    .end();
```

Note that pretty much everything in the route is configured with properties. This essentially makes your RouteBuilder a template. SCR allows you to create more instances of your routes just by providing alternative configurations. More on this in section Using Camel SCR bundle as a template.

### 274.2. ABSTRACTCAMELRUNNER’S LIFECYCLE IN SCR

1. When component’s configuration policy and mandatory references are satisfied SCR calls `activate()`. This creates and sets up a CamelContext through the following call chain: `activate() → prepare() → createCamelContext() → setupPropertiesComponent() → configure() → setupCamelContext()`. Finally, the context is scheduled to start after a delay defined in `AbstractCamelRunner.START_DELAY` with `runWithDelay()`.

2. When Camel components (ComponentResolver services, to be exact) are registered in OSGi, SCR calls `gotCamelComponent()` which reschedules/delays the CamelContext start further.
by the same AbstractCamelRunner.START_DELAY. This in effect makes CamelContext wait until all Camel components are loaded or there is a sufficient gap between them. The same logic will tell a failed-to-start CamelContext to try again whenever we add more Camel components.

3. When Camel components are unregistered SCR calls lostCamelComponent(). This call does nothing.

4. When one of the requirements that caused the call to activate() is lost SCR will call deactivate(). This will shutdown the CamelContext.

In (non-OSGi) unit tests you should use prepare() → run() → stop() instead of activate() → deactivate() for more fine-grained control. Also, this allows us to avoid possible SCR specific operations in tests.

### 274.3. USING CAMEL-ARCHETYPE-SCR

The easiest way to create an Camel SCR bundle project is to use camel-archetype-scr and Maven.

You can generate a project with the following steps:

**Generating a project**

```bash
$ mvn archetype:generate -Dfilter=org.apache.camel.archetypes:camel-archetype-scr
```

Choose archetype:

1: local -> org.apache.camel.archetypes:camel-archetype-scr (Creates a new Camel SCR bundle project for Karaf)

Choose a number or apply filter (format: [groupId:]artifactId, case sensitive contains): : 1

Define value for property 'groupId': : example

[INFO] Using property: groupId = example

Define value for property 'artifactId': : camel-scr-example

Define value for property 'version': 1.0-SNAPSHOT: :

Define value for property 'package': example: :

[INFO] Using property: archetypeArtifactId = camel-archetype-scr

[INFO] Using property: archetypeGroupId = org.apache.camel.archetypes

Define value for property 'className': : CamelScrExample

Confirm properties configuration:

groupId: example

artifactId: camel-scr-example

version: 1.0-SNAPSHOT

package: example

archetypeArtifactId: camel-archetype-scr

archetypeGroupId: org.apache.camel.archetypes

archetypeVersion: 2.15-SNAPSHOT

className: CamelScrExample

Y: :

mvn install

Done!

Now run:

mvn install

and the bundle is ready to be deployed.
UNIT TESTING CAMEL ROUTES

Service Component is a POJO and has no special requirements for (non-OSGi) unit testing. There are however some techniques that are specific to Camel SCR or just make testing easier.

Below is an example unit test, generated by camel-archetype-scr:

```java
// This file was generated from org.apache.camel.archetypes/camel-archetype-scr/2.15-SNAPSHOT
package example;

import java.util.List;
import org.apache.camel.scr.internal.ScrHelper;
import org.apache.camel.builder.AdviceWithRouteBuilder;
import org.apache.camel.component.mock.MockComponent;
import org.apache.camel.component.mock.MockEndpoint;
import org.apache.camel.model.ModelCamelContext;
import org.apache.camel.model.RouteDefinition;
import org.junit.After;
import org.junit.Before;
import org.junit.Rule;
import org.junit.Test;
import org.junit.rules.TestName;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import org.junit.runner.RunWith;
import org.junit.runners.JUnit4;

@RunWith(JUnit4.class)
public class CamelScrExampleTest {

    Logger log = LoggerFactory.getLogger(getClass());

    @Rule
    public TestName testName = new TestName();

    CamelScrExample integration;
    ModelCamelContext context;

    @Before
    public void setUp() throws Exception {
        log.info("*******************************************************************");
        log.info("Test: " + testName.getMethodName());
        log.info("*******************************************************************");

        // Set property prefix for unit testing
        System.setProperty(CamelScrExample.PROPERTY_PREFIX, "unit");

        // Prepare the integration
        integration = new CamelScrExample();
        integration.prepare(null, ScrHelper.getScrProperties(integration.getClass().getName()));
        context = integration.getContext();

        // Disable JMX for test
        context.disableJMX();
    }
}
```
Now, let’s take a look at the interesting bits one by one.

Using property prefixing

```java
// Fake a component for test
context.addComponent("amq", new MockComponent());
}

@After
class Test {
    @Test
    public void testRoutes() throws Exception {
        // Adjust routes
        List<RouteDefinition> routes = context.getRouteDefinitions();
        routes.get(0).adviceWith(context, new AdviceWithRouteBuilder() {
            @Override
            public void configure() throws Exception {
                // Replace "from" endpoint with direct:start
                replaceFromWith("direct:start");
                // Mock and skip result endpoint
                mockEndpoints("log:*");
            }
        });
        MockEndpoint resultEndpoint = context.getEndpoint("mock:log:foo", MockEndpoint.class);
        resultEndpoint.expectedMessageCount(1); // If you want to just check the number of messages
        resultEndpoint.expectedBodiesReceived("hello"); // If you want to check the contents
        // Start the integration
        integration.run();
        // Send the test message
        context.createProducerTemplate().sendBody("direct:start", "hello");
        resultEndpoint.assertIsSatisfied();
    }
}
```

This allows you to override parts of the configuration by prefixing properties with "unit.". For example, `unit.from` overrides `from` for the unit test.

Prefixes can be used to handle the differences between the runtime environments where your routes might run. Moving the unchanged bundle through development, testing and production environments is a typical use case.
Getting test configuration from annotations

integration.prepare(null, ScrHelper.getScrProperties(integration.getClass().getName()));

Here we configure the Service Component in test with the same properties that would be used in OSGi environment.

Mocking components for test

// Fake a component for test
context.addComponent("amq", new MockComponent());

Components that are not available in test can be mocked like this to allow the route to start.

Adjusting routes for test

// Adjust routes
List<RouteDefinition> routes = context.getRouteDefinitions();

routes.get(0).adviceWith(context, new AdviceWithRouteBuilder() {
  @Override
  public void configure() throws Exception {
    // Replace "from" endpoint with direct:start
    replaceFromWith("direct:start");
    // Mock and skip result endpoint
    mockEndpoints("log:**");
  }
});

Camel’s AdviceWith feature allows routes to be modified for test.

Starting the routes

// Start the integration
integration.run();

Here we start the Service Component and along with it the routes.

Sending a test message

// Send the test message
context.createProducerTemplate().sendBody("direct:start", "hello");

Here we send a message to a route in test.

274.5. RUNNING THE BUNDLE IN APACHE KARAF
Once the bundle has been built with `mvn install` it’s ready to be deployed. To deploy the bundle on Apache Karaf perform the following steps on Karaf command line:

### Deploying the bundle in Apache Karaf

```
# Add Camel feature repository
karaf@root> features:chooseurl camel 2.15-SNAPSHOT

# Install camel-scr feature
karaf@root> features:install camel-scr

# Install commons-lang, used in the example route to validate parameters
karaf@root> osgi:install maven:commons-lang/commons-lang/2.6

# Install and start your bundle
karaf@root> osgi:install -s maven:example/camel-scr-example/1.0-SNAPSHOT

# See how it’s running
karaf@root> log:tail -n 10

Press ctrl-c to stop watching the log.
```

#### 274.5.1. Overriding the default configuration

By default, Service Component’s configuration PID equals the fully qualified name of its class. You can change the example bundle’s properties with Karaf’s `config:*` commands:

**Override a property**

```
# Override 'messageOk' property
karaf@root> config:propset -p example.CamelScrExample messageOk "This is better logging"
```

Or you can change the configuration by editing property files in Karaf’s `etc` folder.

#### 274.5.2. Using Camel SCR bundle as a template

Let’s say you have a Camel SCR bundle that implements an integration pattern that you use frequently, say, `from → to`, with success/failure logging and redelivery which also happens to be the pattern our example route implements. You probably don’t want to create a separate bundle for every instance. No worries, SCR has you covered.

Create a configuration PID for your Service Component, but add a tail with a dash and SCR will use that configuration to create a new instance of your component.

**Creating a new Service Component instance**

```
# Create a PID with a tail
karaf@root> config:edit example.CamelScrExample-anotherone

# Override some properties
karaf@root> config:propset camelContextId my-other-context
karaf@root> config:propset to "file://removeme?fileName=removetoo.txt"
```
This will start a new CamelContext with your overridden properties. How convenient.

274.6. NOTES

When designing a Service Component to be a template you typically don’t want it to start without a "tailed" configuration i.e. with the default configuration.

To prevent your Service Component from starting with the default configuration add `policy = ConfigurationPolicy.REQUIRE` to the class level `@Component` annotation.
CHAPTER 275. XML SECURITY DATAFORMAT

Available as of Camel version 2.0

The XMLSecurity Data Format facilitates encryption and decryption of XML payloads at the Document, Element, and Element Content levels (including simultaneous multi-node encryption/decryption using XPath). To sign messages using the XML Signature specification, please see the Camel XML Security component.

The encryption capability is based on formats supported using the Apache XML Security (Santuario) project. Symmetric encryption/decryption is currently supported using Triple-DES and AES (128, 192, and 256) encryption formats. Additional formats can be easily added later as needed. This capability allows Camel users to encrypt/decrypt payloads while being dispatched or received along a route.

Available as of Camel 2.9

The XMLSecurity Data Format supports asymmetric key encryption. In this encryption model a symmetric key is generated and used to perform XML content encryption or decryption. This "content encryption key" is then itself encrypted using an asymmetric encryption algorithm that leverages the recipient’s public key as the "key encryption key". Use of an asymmetric key encryption algorithm ensures that only the holder of the recipient’s private key can access the generated symmetric encryption key. Thus, only the private key holder can decode the message. The XMLSecurity Data Format handles all of the logic required to encrypt and decrypt the message content and encryption key(s) using asymmetric key encryption.

The XMLSecurity Data Format also has improved support for namespaces when processing the XPath queries that select content for encryption. A namespace definition mapping can be included as part of the data format configuration. This enables true namespace matching, even if the prefix values in the XPath query and the target xml document are not equivalent strings.

275.1. XMLSECURITY OPTIONS

The XML Security dataformat supports 12 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlCipherAlgorithm</td>
<td>TRIPEDES</td>
<td>String</td>
<td>The cipher algorithm to be used for encryption/decryption of the XML message content. The available choices are: XMLCipher.TRIPLEDES XMLCipher.AES_128 XMLCipher.AES_128_GCM XMLCipher.AES_192 XMLCipher.AES_192_GCM XMLCipher.AES_256 XMLCipher.AES_256_GCM XMLCipher.SEED_128 XMLCipher.CAMELLIA_128 XMLCipher.CAMELLIA_192 XMLCipher.CAMELLIA_256 The default value is XMLCipher.TRIPLEDES</td>
</tr>
<tr>
<td>passPhrase</td>
<td></td>
<td>String</td>
<td>A String used as passPhrase to encrypt/decrypt content. The passPhrase has to be provided. If no passPhrase is specified, a default passPhrase is used. The passPhrase needs to be put together in conjunction with the appropriate encryption algorithm. For example using TRIPLEDES the passPhrase can be a Only another 24 Byte key</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>secureTag</td>
<td></td>
<td>String</td>
<td>The XPath reference to the XML Element selected for encryption/decryption. If no tag is specified, the entire payload is encrypted/decrypted.</td>
</tr>
<tr>
<td>secureTagContents</td>
<td>false</td>
<td>Boolean</td>
<td>A boolean value to specify whether the XML Element is to be encrypted or the contents of the XML Element false = Element Level true = Element Content Level</td>
</tr>
<tr>
<td>keyCipherAlgorithm</td>
<td>RSA_OAEP</td>
<td>String</td>
<td>The cipher algorithm to be used for encryption/decryption of the asymmetric key. The available choices are: XMLCipher.RSA_v1dot5 XMLCipher.RSA_OAEP XMLCipher.RSA_OAEP_11 The default value is XMLCipher.RSA_OAEP</td>
</tr>
<tr>
<td>recipientKeyAlias</td>
<td></td>
<td>String</td>
<td>The key alias to be used when retrieving the recipient’s public or private key from a KeyStore when performing asymmetric key encryption or decryption.</td>
</tr>
<tr>
<td>keyOrTrustStoreParametersId</td>
<td></td>
<td>String</td>
<td>Refers to a KeyStore instance to lookup in the registry, which is used for configuration options for creating and loading a KeyStore instance that represents the sender’s trustStore or recipient’s keyStore.</td>
</tr>
<tr>
<td>keyPassword</td>
<td></td>
<td>String</td>
<td>The password to be used for retrieving the private key from the KeyStore. This key is used for asymmetric decryption.</td>
</tr>
<tr>
<td>digestAlgorithm</td>
<td>SHA1</td>
<td>String</td>
<td>The digest algorithm to use with the RSA OAEP algorithm. The available choices are: XMLCipher.SHA1 XMLCipher.SHA256 XMLCipher.SHA512 The default value is XMLCipher.SHA1</td>
</tr>
<tr>
<td>mgfAlgorithm</td>
<td>MGF1_SHA1</td>
<td>String</td>
<td>The MGF Algorithm to use with the RSA OAEP algorithm. The available choices are: EncryptionConstants.MGF1_SHA1 EncryptionConstants.MGF1_SHA256 EncryptionConstants.MGF1_SHA512 The default value is EncryptionConstants.MGF1_SHA1</td>
</tr>
<tr>
<td>addKeyValueForEncryptedKey</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to add the public key used to encrypt the session key as a KeyValue in the EncryptedKey structure or not.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.</td>
</tr>
</tbody>
</table>

275.1.1. Key Cipher Algorithm
As of Camel 2.12.0, the default Key Cipher Algorithm is now XMLCipher.RSA_OAEP instead of XMLCipher.RSA_v1dot5. Usage of XMLCipher.RSA_v1dot5 is discouraged due to various attacks. Requests that use RSA v1.5 as the key cipher algorithm will be rejected unless it has been explicitly configured as the key cipher algorithm.

### 275.2. MARSHAL

In order to encrypt the payload, the `marshal` processor needs to be applied on the route followed by the `secureXML()` tag.

### 275.3. UNMARSHAL

In order to decrypt the payload, the `unmarshal` processor needs to be applied on the route followed by the `secureXML()` tag.

### 275.4. EXAMPLES

Given below are several examples of how marshalling could be performed at the Document, Element, and Content levels.

#### 275.4.1. Full Payload encryption/decryption

```java
from("direct:start")
    .marshal().secureXML()
    .unmarshal().secureXML()
    .to("direct:end");
```

#### 275.4.2. Partial Payload Content Only encryption/decryption

```java
String tagXPATH = "//cheesesites/italy/cheese";
boolean secureTagContent = true;
...
from("direct:start")
    .marshal().secureXML(tagXPATH, secureTagContent)
    .unmarshal().secureXML(tagXPATH, secureTagContent)
    .to("direct:end");
```

#### 275.4.3. Partial Multi Node Payload Content Only encryption/decryption

```java
String tagXPATH = "//cheesesites/*/cheese";
boolean secureTagContent = true;
...
from("direct:start")
    .marshal().secureXML(tagXPATH, secureTagContent)
    .unmarshal().secureXML(tagXPATH, secureTagContent)
    .to("direct:end");
```

#### 275.4.4. Partial Payload Content Only encryption/decryption with choice of passPhrase(password)

```java
from("direct:start")
    .marshal().secureXML(tagXPATH, secureTagContent)
    .unmarshal().secureXML(tagXPATH, secureTagContent)
    .to("direct:end");
```
String tagXPATH = "//cheesesites/italy/cheese";
boolean secureTagContent = true;
...
String passPhrase = "Just another 24 Byte key";
from("direct:start")
.marshall().secureXML(tagXPATH, secureTagContent, passPhrase)
.unmarshall().secureXML(tagXPATH, secureTagContent, passPhrase)
.to("direct:end");

275.4.5. Partial Payload Content Only encryption/decryption with passPhrase(password) and Algorithm

import org.apache.xml.security.encryption.XMLCipher;
....
String tagXPATH = "//cheesesites/italy/cheese";
boolean secureTagContent = true;
String passPhrase = "Just another 24 Byte key";
String algorithm = XMLCipher.TRIPLEDES;
from("direct:start")
.marshall().secureXML(tagXPATH, secureTagContent, passPhrase, algorithm)
.unmarshall().secureXML(tagXPATH, secureTagContent, passPhrase, algorithm)
.to("direct:end");

275.4.6. Partial Payload Content with Namespace support

Java DSL

final Map<String, String> namespaces = new HashMap<String, String>();
namespaces.put("cust", "http://cheese.xmlsecurity.camel.apache.org/");

final KeyStoreParameters tsParameters = new KeyStoreParameters();
tsParameters.setPassword("password");
tsParameters.setResource("sender.ts");

camelContext id="springXmlSecurityDataFormatTestCamelContext"
xmlns="http://camel.apache.org/schema/spring"
xmlns:cheese="http://cheese.xmlsecurity.camel.apache.org/>

A namespace prefix that is defined as part of the camelContext definition can be re-used in context within the data format secureTag attribute of the secureXML element.

<route>
<into uri="direct://start"/>
<marshal>
  <secureXML secureTag="/cheese:cheesesites/italy"
    secureTagContents="true"/>
</marshal>
...

275.4.7. Asymmetric Key Encryption

Spring XML Sender

<!-- trust store configuration -->
<camel:keyStoreParameters id="trustStoreParams" resource="/sender.ts" password="password"/>

<camelContext id="springXmlSecurityDataFormatTestCamelContext"
  xmlns="http://camel.apache.org/schema/spring"
  xmlns:cheese="http://cheese.xmlsecurity.camel.apache.org"/>

<route>
  <from uri="direct://start"/>
  <marshal>
    <secureXML secureTag="/cheese:cheesesites/italy"
      secureTagContents="true"
      xmlCipherAlgorithm="http://www.w3.org/2001/04/xmlenc#aes128-cbc"
      keyCipherAlgorithm="http://www.w3.org/2001/04/xmlenc#rsa-1_5"
      recipientKeyAlias="recipient"
      keyOrTrustStoreParametersId="trustStoreParams"/>
  </marshal>
</route>
...

Spring XML Recipient

<!-- key store configuration -->
<camel:keyStoreParameters id="keyStoreParams" resource="/recipient.ks" password="password"/>

<camelContext id="springXmlSecurityDataFormatTestCamelContext"
  xmlns="http://camel.apache.org/schema/spring"
  xmlns:cheese="http://cheese.xmlsecurity.camel.apache.org"/>

<route>
  <from uri="direct://encrypted"/>
  <unmarshal>
    <secureXML secureTag="/cheese:cheesesites/italy"
      secureTagContents="true"
      xmlCipherAlgorithm="http://www.w3.org/2001/04/xmlenc#aes128-cbc"
      keyCipherAlgorithm="http://www.w3.org/2001/04/xmlenc#rsa-1_5"
      recipientKeyAlias="recipient"
      keyOrTrustStoreParametersId="keyStoreParams"
      keyPassword="privateKeyPassword"/>
  </unmarshal>
</route>
...

275.5. DEPENDENCIES

This data format is provided within the camel-xmlsecurity component.
CHAPTER 276. SEDA COMPONENT

Available as of Camel version 1.1

The `seda:` component provides asynchronous SEDA behavior, so that messages are exchanged on a `BlockingQueue` and consumers are invoked in a separate thread from the producer.

Note that queues are only visible within a single CamelContext. If you want to communicate across CamelContext instances (for example, communicating between Web applications), see the VM component.

This component does not implement any kind of persistence or recovery, if the VM terminates while messages are yet to be processed. If you need persistence, reliability or distributed SEDA, try using either JMS or ActiveMQ.

TIP:*Synchronous* The `Direct` component provides synchronous invocation of any consumers when a producer sends a message exchange.

276.1. URI FORMAT

```
seda:someName[?options]
```

Where `someName` can be any string that uniquely identifies the endpoint within the current CamelContext.

You can append query options to the URI in the following format: `?option=value&option=value&…`

276.2. OPTIONS

The SEDA component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>queueSize (advanced)</td>
<td>Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>concurrentConsumers (consumer)</td>
<td>Sets the default number of concurrent threads processing exchanges.</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>defaultQueueFactory (advanced)</td>
<td>Sets the default queue factory.</td>
<td></td>
<td>Exchange&gt;</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The SEDA endpoint is configured using URI syntax:

```
seda:name
```
with the following path and query parameters:

### 276.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required Name of queue</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 276.2.2. Query Parameters (16 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>size (common)</td>
<td>The maximum capacity of the SEDA queue (i.e., the number of messages it can hold).</td>
<td>214748 3647</td>
<td>int</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>concurrentConsumers (consumer)</td>
<td>Number of concurrent threads processing exchanges.</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the default exchange pattern when creating an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>limitConcurrentConsumers (consumer)</td>
<td>Whether to limit the number of concurrentConsumers to the maximum of 500. By default, an exception will be thrown if an endpoint is configured with a greater number. You can disable that check by turning this option off.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>multipleConsumers (consumer)</td>
<td>Specifies whether multiple consumers are allowed. If enabled, you can use SEDA for Publish-Subscribe messaging. That is, you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>pollTimeout (consumer)</td>
<td>The timeout used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.</td>
<td>1000</td>
<td>int</td>
</tr>
<tr>
<td>purgeWhenStopping (consumer)</td>
<td>Whether to purge the task queue when stopping the consumer/route. This allows to stop faster, as any pending messages on the queue is discarded.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>blockWhenFull (producer)</td>
<td>Whether a thread that sends messages to a full SEDA queue will block until the queue’s capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>discardIfNoConsumers (producer)</td>
<td>Whether the producer should discard the message (do not add the message to the queue), when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>failIfNoConsumers (producer)</td>
<td>Whether the producer should fail by throwing an exception, when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>timeout (producer)</td>
<td>Timeout (in milliseconds) before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable timeout by using 0 or a negative value.</td>
<td>30000</td>
<td>long</td>
</tr>
<tr>
<td>waitForTaskToComplete (producer)</td>
<td>Option to specify whether the caller should wait for the async task to complete or not before continuing. The following three options are supported: Always, Never or IfReplyExpected. The first two values are self-explanatory. The last value, IfReplyExpected, will only wait if the message is Request Reply based. The default option is IfReplyExpected.</td>
<td>IfReplyExpected</td>
<td>WaitForTaskToComplete</td>
</tr>
</tbody>
</table>
Define the queue instance which will be used by the endpoint. This option is only for rare use-cases where you want to use a custom queue instance.

**BlockingQueue**

Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).

**false**

**boolean**

### 276.3. CHOOSING BLOCKINGQUEUE IMPLEMENTATION

**Available as of Camel 2.12**

By default, the SEDA component always instantiates LinkedBlockingQueue, but you can use different implementation, you can reference your own BlockingQueue implementation, in this case the size option is not used.

```xml
<bean id="arrayQueue" class="java.util.ArrayBlockingQueue">
    <constructor-arg index="0" value="10"/>
    <constructor-arg index="1" value="true"/>
</bean>
```

Or you can reference a BlockingQueueFactory implementation, 3 implementations are provided LinkedBlockingQueueFactory, ArrayBlockingQueueFactory and PriorityBlockingQueueFactory:

```xml
<bean id="priorityQueueFactory" class="org.apache.camel.component.seda.PriorityBlockingQueueFactory">
    <property name="comparator">
        <bean class="org.apache.camel.demo.MyExchangeComparator"/>
    </property>
</bean>
```

### 276.4. USE OF REQUEST REPLY

The SEDA component supports using Request Reply, where the caller will wait for the Async route to complete. For instance:

```xml
from("mina:tcp://0.0.0.0:9876?textline=true&sync=true").to("seda:input");

from("seda:input").to("bean:processInput").to("bean:createResponse");
```

In the route above, we have a TCP listener on port 9876 that accepts incoming requests. The request is routed to the **seda:input** queue. As it is a Request Reply message, we wait for the response. When the
consumer on the `seda:input` queue is complete, it copies the response to the original message response.

**NOTE**

**until 2.2: Works only with 2 endpoints** Using Request Reply over SEDA or VM only works with 2 endpoints. You cannot chain endpoints by sending to A → B → C etc. Only between A → B. The reason is the implementation logic is fairly simple. To support 3+ endpoints makes the logic much more complex to handle ordering and notification between the waiting threads properly. This has been improved in Camel 2.3 onwards, which allows you to chain as many endpoints as you like.

### 276.5. CONCURRENT CONSUMERS

By default, the SEDA endpoint uses a single consumer thread, but you can configure it to use concurrent consumer threads. So instead of thread pools you can use:

```
from("seda:stageName?concurrentConsumers=5").process(...)
```

As for the difference between the two, note a thread pool can increase/shrink dynamically at runtime depending on load, whereas the number of concurrent consumers is always fixed.

### 276.6. THREAD POOLS

Be aware that adding a thread pool to a SEDA endpoint by doing something like:

```
from("seda:stageName").thread(5).process(...)
```

Can wind up with two BlockQueues: one from the SEDA endpoint, and one from the workqueue of the thread pool, which may not be what you want. Instead, you might wish to configure a Direct endpoint with a thread pool, which can process messages both synchronously and asynchronously. For example:

```
from("direct:stageName").thread(5).process(...)
```

You can also directly configure number of threads that process messages on a SEDA endpoint using the `concurrentConsumers` option.

### 276.7. SAMPLE

In the route below we use the SEDA queue to send the request to this async queue to be able to send a fire-and-forget message for further processing in another thread, and return a constant reply in this thread to the original caller.

Here we send a Hello World message and expects the reply to be OK.

The "Hello World" message will be consumed from the SEDA queue from another thread for further processing. Since this is from a unit test, it will be sent to a mock endpoint where we can do assertions in the unit test.

### 276.8. USING MULTIPLECONSUMERS

Available as of Camel 2.2
In this example we have defined two consumers and registered them as spring beans.

Since we have specified `multipleConsumers=true` on the seda foo endpoint we can have those two consumers receive their own copy of the message as a kind of pub-sub style messaging.

As the beans are part of an unit test they simply send the message to a mock endpoint, but notice how we can use @Consume to consume from the seda queue.

276.9. EXTRACTING QUEUE INFORMATION.

If needed, information such as queue size, etc. can be obtained without using JMX in this fashion:

```java
SedaEndpoint seda = context.getEndpoint("seda:xxxx");
int size = seda.getExchanges().size();
```

276.10. SEE ALSO

- VM
- Disruptor
- Direct
- Async
CHAPTER 277. JAVA OBJECT SERIALIZATION DATAFORMAT

Available as of Camel version 2.12

Serialization is a Data Format which uses the standard Java Serialization mechanism to unmarshal a binary payload into Java objects or to marshal Java objects into a binary blob. For example the following uses Java serialization to unmarshal a binary file then send it as an ObjectMessage to ActiveMQ

```java
from("file://foo/bar").unmarshal().serialization().to("activemq:Some.Queue");
```

277.1. OPTIONS

The Java Object Serialization dataformat supports 1 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

277.2. DEPENDENCIES

This data format is provided in camel-core so no additional dependencies is needed.
CHAPTER 278. SERVICENOW COMPONENT

Available as of Camel version 2.18

The ServiceNow component provides access to ServiceNow platform through their REST API.

NOTE

From Camel 2.18.1 the component supports multiple version of ServiceNow platform with default to Helsinki. Supported version are Table 278.1, “API Mapping” and Table 278.2, “API Mapping”

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-servicenow</artifactId>
  <version>${camel-version}</version>
</dependency>
```

278.1. URI FORMAT

```
servicenow://instanceName?[options]
```

278.2. OPTIONS

The ServiceNow component supports 14 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>instanceName</code></td>
<td>The ServiceNow instance name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>configuration</code></td>
<td>The ServiceNow default configuration</td>
<td></td>
<td>ServiceNowConfig</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td>uration</td>
</tr>
<tr>
<td><code>apiUrl</code></td>
<td>The ServiceNow REST API url</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(producer)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>userName</code></td>
<td>ServiceNow user account name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(security)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>password</code></td>
<td>ServiceNow account password</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(security)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>oauthClientId</code></td>
<td>OAuth2 ClientID</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(security)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The ServiceNow endpoint is configured using URI syntax:

```
servicenow:instanceName
```

with the following path and query parameters:

### 278.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>instanceName</td>
<td>Required The ServiceNow instance name</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 278.2.2. Query Parameters (44 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>display</strong> (producer)</td>
<td>Set this parameter to true to return only scorecards where the indicator Display field is selected. Set this parameter to all to return scorecards with any Display field value. This parameter is true by default.</td>
<td>true</td>
<td>String</td>
</tr>
<tr>
<td><strong>displayValue</strong> (producer)</td>
<td>Return the display value (true), actual value (false), or both (all) for reference fields (default: false)</td>
<td>false</td>
<td>String</td>
</tr>
<tr>
<td><strong>excludeReferenceLink</strong> (producer)</td>
<td>True to exclude Table API links for reference fields (default: false)</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>favorites</strong> (producer)</td>
<td>Set this parameter to true to return only scorecards that are favorites of the querying user.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>includeAggregates</strong> (producer)</td>
<td>Set this parameter to true to always return all available aggregates for an indicator, including when an aggregate has already been applied. If a value is not specified, this parameter defaults to false and returns no aggregates.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>includeAvailableAggregates</strong> (producer)</td>
<td>Set this parameter to true to return all available aggregates for an indicator when no aggregate has been applied. If a value is not specified, this parameter defaults to false and returns no aggregates.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>includeAvailableBreakdowns</strong> (producer)</td>
<td>Set this parameter to true to return all available breakdowns for an indicator. If a value is not specified, this parameter defaults to false and returns no breakdowns.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>includeScoreNotes</strong> (producer)</td>
<td>Set this parameter to true to return all notes associated with the score. The note element contains the note text as well as the author and timestamp when the note was added.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>includeScores</strong> (producer)</td>
<td>Set this parameter to true to return all scores for a scorecard. If a value is not specified, this parameter defaults to false and returns only the most recent score value.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>inputDisplayValue</strong> (producer)</td>
<td>True to set raw value of input fields (default: false)</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>key</strong> (producer)</td>
<td>Set this parameter to true to return only scorecards for key indicators.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td>models (producer)</td>
<td>Defines both request and response models</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>perPage (producer)</td>
<td>Enter the maximum number of scorecards each query can return. By default this value is 10, and the maximum is 100.</td>
<td>10</td>
<td>Integer</td>
</tr>
<tr>
<td>release (producer)</td>
<td>The ServiceNow release to target, default to Helsinki. See <a href="https://docs.servicenow.com">https://docs.servicenow.com</a></td>
<td>HELSINKI</td>
<td>ServiceNowRelease</td>
</tr>
<tr>
<td>requestModels (producer)</td>
<td>Defines the request model</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>resource (producer)</td>
<td>The default resource, can be overridden by header CamelServiceNowResource</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>responseModels (producer)</td>
<td>Defines the response model</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>sortBy (producer)</td>
<td>Specify the value to use when sorting results. By default, queries sort records by value.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>sortDir (producer)</td>
<td>Specify the sort direction, ascending or descending. By default, queries sort records in descending order. Use sysparm_sortdir=asc to sort in ascending order.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>suppressAutoSysField (producer)</td>
<td>True to suppress auto generation of system fields (default: false)</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>suppressPaginationHeader (producer)</td>
<td>Set this value to true to remove the Link header from the response. The Link header allows you to request additional pages of data when the number of records matching your query exceeds the query limit</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>table (producer)</td>
<td>The default table, can be overridden by header CamelServiceNowTable</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>target (producer)</td>
<td>Set this parameter to true to return only scorecards that have a target.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>topLevelOnly (producer)</td>
<td>Gets only those categories whose parent is a catalog.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>apiVersion (advanced)</td>
<td>The ServiceNow REST API version, default latest</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>

### 278.4. USAGE EXAMPLES:

#### Retrieve 10 Incidents

```java
context.addRoutes(new RouteBuilder() {
    public void configure() {
        from("direct:servicenow")
            .to("servicenow:{{env:SERVICENOW_INSTANCE}}"
                + "?userName={{env:SERVICENOW_USERNAME}}"
                + "&password={{env:SERVICENOW_PASSWORD}}"
                + "&oauthClientId={{env:SERVICENOW_OAUTH2_CLIENT_ID}}"
                + "&oauthClientSecret={{env:SERVICENOW_OAUTH2_CLIENT_SECRET}}"
            .to("mock:servicenow"));
    }
});

FluentProducerTemplate.on(context)
    .withHeader(ServiceNowConstants.RESOURCE, "table")
    .withHeader(ServiceNowConstants.ACTION, ServiceNowConstants.ACTION_RETRIEVE)
    .withHeader(ServiceNowConstants.SYSPARM_LIMIT.getId(), "10")
    .withHeader(ServiceNowConstants.TABLE, "incident")
    .withHeader(ServiceNowConstants.MODEL, Incident.class)
    .to("direct:servicenow")
    .send();
```
CHAPTER 279. SERVLET COMPONENT

Available as of Camel version 2.0

The **servlet** component provides HTTP based endpoints for consuming HTTP requests that arrive at a HTTP endpoint that is bound to a published Servlet.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-servlet</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

INFO: **Stream**. Servlet is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream **once**. If you find a situation where the message body appears to be empty or you need to access the data multiple times (eg: doing multicasting, or redelivery error handling) you should use Stream caching or convert the message body to a **String** which is safe to be read multiple times.

### 279.1. URI FORMAT

```text
servlet://relative_path[?options]
```

You can append query options to the URI in the following format, `?option=value&option=value&…`

### 279.2. OPTIONS

The Servlet component supports 8 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>servletName</td>
<td>Default name of servlet to use. The default name is CamelServlet.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(consumer)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>httpRegistry</td>
<td>To use a custom org.apache.camel.component.servlet.HttpRegistry.</td>
<td></td>
<td>HttpRegistry</td>
</tr>
<tr>
<td>(consumer)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>attachmentMultipartBinding</td>
<td>Whether to automatic bind multipart/form-data as attachments on the Camel Exchange. The options attachmentMultipartBinding=true and disableStreamCache=false cannot work together. Remove disableStreamCache to use AttachmentMultipartBinding. This is turn off by default as this may require servlet specific configuration to enable this when using Servlet’s.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
To use a custom `HttpBinding` to control the mapping between Camel message and HttpClient.

- **httpBinding** *(advanced)*
  - Description: To use a custom `HttpBinding` to control the mapping between Camel message and HttpClient.
  - Default: 
  - Type: `HttpBinding`

- **httpConfiguration** *(advanced)*
  - Description: To use the shared `HttpConfiguration` as base configuration.
  - Default: 
  - Type: `HttpConfiguration`

- **allowJavaSerializedObject** *(advanced)*
  - Description: Whether to allow Java serialization when a request uses `context-type=application/x-java-serialized-object`. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.
  - Default: `false`
  - Type: `boolean`

- **headerFilterStrategy** *(filter)*
  - Description: To use a custom `org.apache.camel.spi.HeaderFilterStrategy` to filter header to and from Camel message.
  - Default: 
  - Type: `HeaderFilterStrategy`

- **resolvePropertyPlaceholders** *(advanced)*
  - Description: Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.
  - Default: `true`
  - Type: `boolean`

The Servlet endpoint is configured using URI syntax:

```
servlet:contextPath
```

with the following path and query parameters:

### 279.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>contextPath</td>
<td>Required The context-path to use</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 279.2.2. Query Parameters (21 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>disableStreamCache (common)</td>
<td>Determines whether or not the raw input stream from Servlet is cached or not (Camel will read the stream into a in memory/overflow to file, Stream caching) cache. By default Camel will cache the Servlet input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultHttpBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times. If you use Servlet to bridge/proxy an endpoint then consider enabling this option to improve performance, in case you do not need to read the message payload multiple times. The http/http4 producer will by default cache the response body stream. If setting this option to true, then the producers will not cache the response body stream but use the response stream as-is as the message body.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>headerFilterStrategy (common)</td>
<td>To use a custom HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>httpBinding (common)</td>
<td>To use a custom HttpBinding to control the mapping between Camel message and HttpClient.</td>
<td></td>
<td>HttpBinding</td>
</tr>
<tr>
<td>async (consumer)</td>
<td>Configure the consumer to work in async mode</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>chunked (consumer)</td>
<td>If this option is false the Servlet will disable the HTTP streaming and set the content-length header on the response</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>httpMethodRestrict (consumer)</td>
<td>Used to only allow consuming if the HttpMethod matches, such as GET/POST/PUT etc. Multiple methods can be specified separated by comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------------</td>
</tr>
<tr>
<td>matchOnUriPrefix (consumer)</td>
<td>Whether or not the consumer should try to find a target consumer by matching the URI prefix if no exact match is found.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>responseBufferSize (consumer)</td>
<td>To use a custom buffer size on the javax.servlet.ServletResponse.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>servletName (consumer)</td>
<td>Name of the servlet to use</td>
<td>CamelServlet</td>
<td>String</td>
</tr>
<tr>
<td>transferException (consumer)</td>
<td>If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the HttpOperationFailedException. The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>attachmentMultipartBinding (consumer)</td>
<td>Whether to automatic bind multipart/form-data as attachments on the Camel Exchange. The options attachmentMultipartBinding=true and disableStreamCache=false cannot work together. Remove disableStreamCache to use AttachmentMultipartBinding. This is turn off by default as this may require servlet specific configuration to enable this when using Servlet's.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>eagerCheckContentAvailable (consumer)</td>
<td>Whether to eager check whether the HTTP requests has content if the content-length header is 0 or not present. This can be turned on in case HTTP clients do not send streamed data.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>optionsEnabled (consumer)</td>
<td>Specifies whether to enable HTTP OPTIONS for this Servlet consumer. By default OPTIONS is turned off.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### 279.3. MESSAGE HEADERS

Camel will apply the same Message Headers as the HTTP component.

Camel will also populate all `request.parameter` and `request.headers`. For example, if a client request has the URL, `http://myserver/myserver?orderid=123`, the exchange will contain a header named `orderid` with the value 123.

### 279.4. USAGE

You can consume only from endpoints generated by the Servlet component. Therefore, it should be used only as input into your Camel routes. To issue HTTP requests against other HTTP endpoints, use the HTTP Component.

### 279.5. PUTTING CAMEL JARS IN THE APP SERVER BOOT CLASSPATH

If you put the Camel JARs such as `camel-core`, `camel-servlet`, etc. in the boot classpath of your application server (eg usually in its `lib` directory), then mind that the servlet mapping list is now shared between multiple deployed Camel application in the app server.

Mind that putting Camel JARs in the boot classpath of the application server is generally not best practice!

So in those situations you **must** define a custom and unique servlet name in each of your Camel application, eg in the `web.xml` define:

```xml
<servlet>
  <servlet-name>MyServlet</servlet-name>
```
And in your Camel endpoints then include the servlet name as well

```
<route>
  <from url="servlet://foo?servletName=MyServlet"/>
  ...
</route>
```

From Camel 2.11 onwards Camel will detect this duplicate and fail to start the application. You can control to ignore this duplicate by setting the servlet init-parameter ignoreDuplicateServletName to true as follows:

```
<servlet>
  <servlet-name>CamelServlet</servlet-name>
  <display-name>Camel Http Transport Servlet</display-name>
  <servlet-class>org.apache.camel.component.servlet.CamelHttpTransportServlet</servlet-class>
  <init-param>
    <param-name>ignoreDuplicateServletName</param-name>
    <param-value>true</param-value>
  </init-param>
</servlet>
```

But it's strongly advised to use unique servlet-name for each Camel application to avoid this duplication clash, as well any unforeseen side-effects.

### 279.6. SAMPLE

INFO: From Camel 2.7 onwards it's easier to use Servlet in Spring web applications. See Servlet Tomcat Example for details.

In this sample, we define a route that exposes a HTTP service at http://localhost:8080/camel/services/hello.

First, you need to publish the CamelHttpTransportServlet through the normal Web Container, or OSGi Service.

Use the Web.xml file to publish the CamelHttpTransportServlet as follows:

```
<servlet>
  <servlet-name>CamelServlet</servlet-name>
  <display-name>Camel Http Transport Servlet</display-name>
  <servlet-class>org.apache.camel.component.servlet.CamelHttpTransportServlet</servlet-class>
  <init-param>
    <param-name>ignoreDuplicateServletName</param-name>
    <param-value>true</param-value>
  </init-param>
</servlet>
```

Then you can define your route as follows:

```
<route>
  <from uri="servlet://foo?servletName=MyServlet"/>
  ...
</route>
```

NOTE

Specify the relative path for camel-servlet endpoint: Since we are binding the Http transport with a published servlet, and we don’t know the servlet’s application context path, the camel-servlet endpoint uses the relative path to specify the endpoint’s URL. A client can access the camel-servlet endpoint through the servlet publish address: ("http://localhost:8080/camel/services") + RELATIVE_PATH("/hello").
279.6.1. Sample when using Spring 3.x

See Servlet Tomcat Example

279.6.2. Sample when using Spring 2.x

When using the Servlet component in a Camel/Spring application it’s often required to load the Spring ApplicationContext after the Servlet component has started. This can be accomplished by using Spring’s ContextLoaderServlet instead of ContextLoaderListener. In that case you’ll need to start ContextLoaderServlet after CamelHttpTransportServlet like this:

```xml
<web-app>
  <servlet>
    <servlet-name>CamelServlet</servlet-name>
    <servlet-class>
      org.apache.camel.component.servlet.CamelHttpTransportServlet
    </servlet-class>
    <load-on-startup>1</load-on-startup>
  </servlet>
  <servlet>
    <servlet-name>SpringApplicationContext</servlet-name>
    <servlet-class>
      org.springframework.web.context.ContextLoaderServlet
    </servlet-class>
    <load-on-startup>2</load-on-startup>
  </servlet>
</web-app>
```

279.6.3. Sample when using OSGi

From Camel 2.6.0, you can publish the CamelHttpTransportServlet as an OSGi service with help of SpringDM like this.

Then use this service in your camel route like this:

For versions prior to Camel 2.6 you can use an Activator to publish the CamelHttpTransportServlet on the OSGi platform

279.6.4. Usage with Spring-Boot

From Camel 2.19.0 onwards, the camel-servlet-starter library binds automatically all the rest endpoints under the “/camel/*” context path. The following table summarizes the additional configuration properties available in the camel-servlet-starter library. The automatic mapping of the Camel servlet can also be disabled.

<table>
<thead>
<tr>
<th>Spring-Boot Property</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>camel.component.servlet.mapping.enabled</td>
<td>true</td>
<td>Enables the automatic mapping of the servlet component into the Spring web context</td>
</tr>
<tr>
<td>camel.component.servlet.mapping.context-path</td>
<td>/camel /*</td>
<td>Context path used by the servlet component for automatic mapping</td>
</tr>
</tbody>
</table>

- Servlet Tomcat No Spring Example
- HTTP
- Jetty

### 279.8. SERVLETLISTENER COMPONENT

**Available as of Camel 2.11**

This component is used for bootstrapping Camel applications in web applications. For example beforehand people would have to find their own way of bootstrapping Camel, or rely on 3rd party frameworks such as Spring to do it.

**NOTE**

**Sidebar** This component supports Servlet 2.x onwards, which mean it works also in older web containers; which is the goal of this component. Though Servlet 2.x requires to use a web.xml file as configuration. For Servlet 3.x containers you can use annotation driven configuration to boostrap Camel using the @WebListener, and implement your own class, where you bootstrap Camel. Doing this still puts the challenge how to let end users easily configure Camel, which you get for free with the old school web.xml file.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-servletlistener</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 279.8.1. Using
You would need to chose one of the following implementations of the abstract class `org.apache.camel.component.servletlistener.CamelServletContextListener`:

- **JndiCamelServletContextListener** which uses the `JndiRegistry` to leverage JNDI for its registry.
- **SimpleCamelServletContextListener** which uses the `SimpleRegistry` to leverage a `java.util.Map` as its registry.

To use this you need to configure the `org.apache.camel.component.servletlistener.CamelServletContextListener` in the `WEB-INF/web.xml` file as shown below:

### 279.8.2. Options

The `org.apache.camel.component.servletlistener.CamelServletContextListener` supports the following options which can be configured as context-param in the web.xml file.

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propertyPlaceholder.</td>
<td>XXX</td>
<td>To configure property placeholders in Camel. You should prefix the option</td>
</tr>
<tr>
<td></td>
<td></td>
<td>with &quot;propertyPlaceholder.&quot;, for example to configure the location, use</td>
</tr>
<tr>
<td></td>
<td></td>
<td>propertyPlaceholder.location as name. You can configure all the options</td>
</tr>
<tr>
<td></td>
<td></td>
<td>from the <code>Properties</code> component.</td>
</tr>
<tr>
<td>jmx.XXX</td>
<td>X</td>
<td>To configure JMX. You should prefix the option with &quot;jmx.&quot;, for example to</td>
</tr>
<tr>
<td></td>
<td></td>
<td>disable JMX, use jmx.disabled as name. You can configure all the options</td>
</tr>
<tr>
<td></td>
<td></td>
<td>from <code>org.apache.camel.spi.ManagementAgent</code>. As well the options</td>
</tr>
<tr>
<td></td>
<td></td>
<td>mentioned on the JMX page.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>To configure the name of the CamelContext.</td>
</tr>
<tr>
<td>messageHistory</td>
<td>Boolean</td>
<td>Camel 2.12.2: Whether to enable or disable Message History (enabled by</td>
</tr>
<tr>
<td></td>
<td></td>
<td>default).</td>
</tr>
<tr>
<td>streamCache</td>
<td>Boolean</td>
<td>Whether to enable Stream caching.</td>
</tr>
<tr>
<td>trace</td>
<td>Boolean</td>
<td>Whether to enable Tracer.</td>
</tr>
<tr>
<td>delayer</td>
<td>Long</td>
<td>To set a delay value for Delay Interceptor.</td>
</tr>
<tr>
<td>handleFault</td>
<td>Boolean</td>
<td>Whether to enable handle fault.</td>
</tr>
<tr>
<td>errorHandlerRef</td>
<td>String</td>
<td>Refers to a context scoped Error Handler to be used.</td>
</tr>
</tbody>
</table>
### Option Type Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>autoStart up</td>
<td>Boolean</td>
<td>Whether to start all routes when starting Camel.</td>
</tr>
<tr>
<td>useMDCLogging</td>
<td>Boolean</td>
<td>Whether to use MDC logging.</td>
</tr>
<tr>
<td>useBreadcrumb</td>
<td>Boolean</td>
<td>Whether to use breadcrumb.</td>
</tr>
<tr>
<td>management Name Pattern</td>
<td>String</td>
<td>To set a custom naming pattern for JMX MBeans.</td>
</tr>
<tr>
<td>thread Name Pattern</td>
<td>String</td>
<td>To set a custom naming pattern for threads.</td>
</tr>
<tr>
<td>properties.XXX</td>
<td></td>
<td>To set custom properties on <code>CamelContext.getProperties</code>. This is seldom in use.</td>
</tr>
<tr>
<td>routebuilder.XXX</td>
<td></td>
<td>To configure routes to be used. See below for more details.</td>
</tr>
<tr>
<td>CamelContextLifecycle</td>
<td></td>
<td>Refers to a FQN classname of an implementation of <code>org.apache.camel.component.servletlistener.CamelContextLifecycle</code>. Which allows to execute custom code before and after CamelContext has been started or stopped. See below for further details.</td>
</tr>
<tr>
<td>XXX</td>
<td></td>
<td>To set any option on CamelContext.</td>
</tr>
</tbody>
</table>

### 279.8.3. Examples

See [Servlet Tomcat No Spring Example](#).

### 279.8.4. Accessing the created CamelContext

Available as of Camel 2.14/2.13.3/2.12.5

The created `CamelContext` is stored on the `ServletContext` as an attribute with the key "CamelContext". You can get hold of the CamelContext if you can get hold of the `ServletContext` as shown below:

```java
ServletContext sc = ...
CamelContext camel = (CamelContext) sc.getAttribute("CamelContext");
```
279.8.5. Configuring routes

You need to configure which routes to use in the web.xml file. You can do this in a number of ways, though all the parameters must be prefixed with "routeBuilder".

279.8.5.1. Using a RouteBuilder class

By default Camel will assume the param-value is a FQN classname for a Camel RouteBuilder class, as shown below:

```
<context-param>
  <param-name>routeBuilder-MyRoute</param-name>
  <param-value>org.apache.camel.component.servletlistener.MyRoute</param-value>
</context-param>
```

You can specify multiple classes in the same param-value as shown below:

```
<context-param>
  <param-name>routeBuilder-routes</param-name>
  <!-- we can define multiple values separated by comma -->
  <param-value>
    org.apache.camel.component.servletlistener.MyRoute,
    org.apache.camel.component.servletlistener.routes.BarRouteBuilder
  </param-value>
</context-param>
```

The name of the parameter does not have a meaning at runtime. It just need to be unique and start with "routeBuilder". In the example above we have "routeBuilder-routes". But you could just as well have named it "routeBuilder.foo".

279.8.5.2. Using package scanning

You can also tell Camel to use package scanning, which mean it will look in the given package for all classes of RouteBuilder types and automatic adding them as Camel routes. To do that you need to prefix the value with "packagescan:" as shown below:

```
<context-param>
  <param-name>routeBuilder-MyRoute</param-name>
  <!-- define the routes using package scanning by prefixing with packagescan: -->
  <param-value>
    packagescan:org.apache.camel.component.servletlistener.routes
  </param-value>
</context-param>
```

279.8.5.3. Using a XML file

You can also define Camel routes using XML DSL, though as we are not using Spring or Blueprint the XML file can only contain Camel route(s).

In the web.xml you refer to the XML file which can be from "classpath", "file" or a "http" url, as shown below:

```
<context-param>
</context-param>
```
And the XML file is:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!doctype camel-param>
<routes xmlns="http://camel.apache.org/schema/spring">
  <route id="foo">
    <from uri="direct:foo"/>
    <to uri="mock:foo"/>
  </route>
  <route id="bar">
    <from uri="direct:bar"/>
    <to uri="mock:bar"/>
  </route>
</routes>
```

Notice that in the XML file the root tag is `<routes>` which must use the namespace "http://camel.apache.org/schema/spring". This namespace is having the spring in the name, but that is because of historical reasons, as Spring was the first and only XML DSL back in the time. At runtime no Spring JARs is needed. Maybe in Camel 3.0 the namespace can be renamed to a generic name.

### 279.8.5.4. Configuring propert placeholders

Here is a snippet of a web.xml configuration for setting up property placeholders to load `myproperties.properties` from the classpath

```xml
<param-name>propertyPlaceholder.location</param-name>
<param-value>classpath:myproperties.properties</param-value>
</context-param>
```

For example to disable cache on properties component, you do

```xml
<param-name>propertyPlaceholder.cache</param-name>
<param-value>false</param-value>
</context-param>
```

### 279.8.5.5. Configuring JMX

Here is a snippet of a web.xml configuration for configuring JMX, such as disabling JMX.

```xml
<param-name>routeBuilder-MyRoute</param-name>
<param-value>classpath:routes/myRoutes.xml</param-value>
</context-param>
```
This component uses either JNDI or Simple as the Registry. This allows you to lookup Beans and other services in JNDI, and as well to bind and unbind your own Beans.

This is done from Java code by implementing the org.apache.camel.component.servletlistener.CamelContextLifecycle.

279.8.5.6. Using custom CamelContextLifecycle

In the code below we use the callbacks beforeStart and afterStop to enlist our custom bean in the Simple Registry, and as well to cleanup when we stop.

Then we need to register this class in the web.xml file as shown below, using the parameter name "CamelContextLifecycle". The value must be a FQN which refers to the class implementing the org.apache.camel.component.servletlistener.CamelContextLifecycle interface.

```xml
<context-param>
  <param-name>CamelContextLifecycle</param-name>
  <param-value>org.apache.camel.component.servletlistener.MyLifecycle</param-value>
</context-param>
```

As we enlisted our HelloBean Bean using the name "myBean" we can refer to this Bean in the Camel routes as shown below:

```java
public class MyBeanRoute extends RouteBuilder {
  @Override
  public void configure() throws Exception {
    from("seda:foo").routeId("foo")
      .to("bean:myBean")
      .to("mock:foo");
  }
}
```

Important: If you use org.apache.camel.component.servletlistener.JndiCamelServletContextListener then the CamelContextLifecycle must use the JndiRegistry as well. And likewise if the servlet is org.apache.camel.component.servletlistener.SimpleCamelServletContextListener then the CamelContextLifecycle must use the SimpleRegistry

CHAPTER 280. SFTP COMPONENT

Available as of Camel version 1.1

This component provides access to remote file systems over the FTP and SFTP protocols.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ftp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

For more information you can look at [FTP component](#)

280.1. URI OPTIONS

The options below are exclusive for the FTPS component.

The SFTP component has no options.

The SFTP endpoint is configured using URI syntax:

```
sftp:host:port/directoryName
```

with the following path and query parameters:

### 280.1.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required Hostname of the FTP server</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>Port of the FTP server</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>directoryName</td>
<td>The starting directory</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 280.1.2. Query Parameters (111 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td>charset (common)</td>
<td>This option is used to specify the encoding of the file. You can use this on the consumer, to specify the encodings of the files, which allow Camel to know the charset it should load the file content in case the file content is being accessed. Likewise when writing a file, you can use this option to specify which charset to write the file as well. Do mind that when writing the file Camel may have to read the message content into memory to be able to convert the data into the configured charset, so do not use this if you have big messages.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>disconnect</td>
<td>Whether or not to disconnect from remote FTP server right after use. Disconnect will only disconnect the current connection to the FTP server. If you have a consumer which you want to stop, then you need to stop the consumer/route instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>doneFileName</td>
<td>Producer: If provided, then Camel will write a 2nd done file when the original file has been written. The done file will be empty. This option configures what file name to use. Either you can specify a fixed name. Or you can use dynamic placeholders. The done file will always be written in the same folder as the original file. Consumer: If provided, Camel will only consume files if a done file exists. This option configures what file name to use. Either you can specify a fixed name. Or you can use dynamic placeholders. The done file is always expected in the same folder as the original file. Only $file.name and $file.name.noext is supported as dynamic placeholders.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
Use Expression such as File Language to dynamically set the filename. For consumers, it’s used as a filename filter. For producers, it’s used to evaluate the filename to write. If an expression is set, it take precedence over the CamelFileName header. (Note: The header itself can also be an Expression). The expression options support both String and Expression types. If the expression is a String type, it is always evaluated using the File Language. If the expression is an Expression type, the specified Expression type is used - this allows you, for instance, to use OGNL expressions. For the consumer, you can use it to filter filenames, so you can for instance consume today’s file using the File Language syntax: mydata-$date:now:yyyyMMdd.txt. The producers support the CamelOverruleFileName header which takes precedence over any existing CamelFileName header; the CamelOverruleFileName is a header that is used only once, and makes it easier as this avoids to temporary store CamelFileName and have to restore it afterwards.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileName (common)</td>
<td>Use Expression such as File Language to dynamically set the filename. For consumers, it’s used as a filename filter. For producers, it’s used to evaluate the filename to write. If an expression is set, it take precedence over the CamelFileName header. (Note: The header itself can also be an Expression). The expression options support both String and Expression types. If the expression is a String type, it is always evaluated using the File Language. If the expression is an Expression type, the specified Expression type is used - this allows you, for instance, to use OGNL expressions. For the consumer, you can use it to filter filenames, so you can for instance consume today’s file using the File Language syntax: mydata-$date:now:yyyyMMdd.txt. <td></td>
<td>String</td>
</tr>
<tr>
<td>jschLoggingLevel (common)</td>
<td>The logging level to use for JSCH activity logging. As JSCH is verbose at by default at INFO level the threshold is WARN by default.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>separator (common)</td>
<td>Sets the path separator to be used. UNIX = Uses unix style path separator Windows = Uses windows style path separator Auto = (is default) Use existing path separator in file name</td>
<td>UNIX</td>
<td>PathSeparator</td>
</tr>
<tr>
<td>fastExistsCheck (common)</td>
<td>If set this option to be true, camel-ftp will use the list file directly to check if the file exists. Since some FTP server may not support to list the file directly, if the option is false, camel-ftp will use the old way to list the directory and check if the file exists. This option also influences readLock=changed to control whether it performs a fast check to update file information or not. This can be used to speed up the process if the FTP server has a lot of files.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>delete</td>
<td>If true, the file will be deleted after it is processed successfully.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>moveFailed</td>
<td>Sets the move failure expression based on Simple language. For example, to move files into a .error subdirectory use: .error. Note: When moving the files to the fail location Camel will handle the error and will not pick up the file again.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>noop</td>
<td>If true, the file is not moved or deleted in any way. This option is good for readonly data, or for ETL type requirements. If noop=true, Camel will set idempotent=true as well, to avoid consuming the same files over and over again.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>preMove</td>
<td>Expression (such as File Language) used to dynamically set the filename when moving it before processing. For example to move in-progress files into the order directory set this value to order.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>preSort</td>
<td>When pre-sort is enabled then the consumer will sort the file and directory names during polling, that was retrieved from the file system. You may want to do this in case you need to operate on the files in a sorted order. The pre-sort is executed before the consumer starts to filter, and accept files to process by Camel. This option is default=false meaning disabled.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>recursive</td>
<td>If a directory, will look for files in all the sub-directories as well.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------</td>
</tr>
<tr>
<td>streamDownload (consumer)</td>
<td>Sets the download method to use when not using a local working directory. If set to true, the remote files are streamed to the route as they are read. When set to false, the remote files are loaded into memory before being sent into the route.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>directoryMustExist (consumer)</td>
<td>Similar to startingDirectoryMustExist but this applies during polling recursive sub directories.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>download (consumer)</td>
<td>Whether the FTP consumer should download the file. If this option is set to false, then the message body will be null, but the consumer will still trigger a Camel Exchange that has details about the file such as file name, file size, etc. It's just that the file will not be downloaded.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>ignoreFileNotFoundException PermissionError (consumer)</td>
<td>Whether to ignore when (trying to list files in directories or when downloading a file), which does not exist or due to permission error. By default when a directory or file does not exists or insufficient permission, then an exception is thrown. Setting this option to true allows to ignore that instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>inProgressRepository (consumer)</td>
<td>A pluggable in-progress repository org.apache.camel.spi.IdempotentRepository. The in-progress repository is used to account the current in progress files being consumed. By default a memory based repository is used.</td>
<td></td>
<td>String&gt;</td>
</tr>
<tr>
<td>localWorkDirectory (consumer)</td>
<td>When consuming, a local work directory can be used to store the remote file content directly in local files, to avoid loading the content into memory. This is beneficial, if you consume a very big remote file and thus can conserve memory.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>onCompletionException Handler</td>
<td>To use a custom <code>org.apache.camel.spi.ExceptionHandler</code> to handle any thrown exceptions that happens during the file on completion process where the consumer does either a commit or rollback. The default implementation will log any exception at WARN level and ignore.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>pollStrategy</td>
<td>A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollStrategy</td>
</tr>
<tr>
<td>processStrategy</td>
<td>A pluggable <code>org.apache.camel.component.file.GenericFileProcessStrategy</code> allowing you to implement your own readLock option or similar. Can also be used when special conditions must be met before a file can be consumed, such as a special ready file exists. If this option is set then the readLock option does not apply.</td>
<td></td>
<td>GenericFileProcessStrategy&lt;T&gt;</td>
</tr>
<tr>
<td>startingDirectory MustExist</td>
<td>Whether the starting directory must exist. Mind that the autoCreate option is default enabled, which means the starting directory is normally auto created if it doesn’t exist. You can disable autoCreate and enable this to ensure the starting directory must exist. Will thrown an exception if the directory doesn’t exist.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>useList</td>
<td>Whether to allow using LIST command when downloading a file. Default is true. In some use cases you may want to download a specific file and are not allowed to use the LIST command, and therefore you can set this option to false. Notice when using this option, then the specific file to download does not include meta-data information such as file size, timestamp, permissions etc, because those information is only possible to retrieve when LIST command is in use.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------------</td>
</tr>
<tr>
<td><strong>fileExist</strong></td>
<td>What to do if a file already exists with the same name. Override, which is the default, replaces the existing file. Append - adds content to the existing file. Fail - throws a GenericFileOperationException, indicating that there is already an existing file. Ignore - silently ignores the problem and does not override the existing file, but assumes everything is okay. Move - option requires to use the moveExisting option to be configured as well. The option eagerDeleteTargetFile can be used to control what to do if an moving the file, and there exists already an existing file, otherwise causing the move operation to fail. The Move option will move any existing files, before writing the target file. TryRename is only applicable if tempFileName option is in use. This allows to try renaming the file from the temporary name to the actual name, without doing any exists check. This check may be faster on some file systems and especially FTP servers.</td>
<td>Override</td>
<td>GenericFileExist</td>
</tr>
<tr>
<td><strong>flattten</strong></td>
<td>Flatten is used to flatten the file name path to strip any leading paths, so it’s just the file name. This allows you to consume recursively into sub-directories, but when you eg write the files to another directory they will be written in a single directory. Setting this to true on the producer enforces that any file name in CamelFileName header will be stripped for any leading paths.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>moveExisting</strong></td>
<td>Expression (such as File Language) used to compute file name to use when fileExist=Move is configured. To move files into a backup subdirectory just enter backup. This option only supports the following File Language tokens: file:name, file:name.ext, file:name.noext, file:onlyname, file:onlyname.noext, file:ext, and file:parent. Notice the file:parent is not supported by the FTP component, as the FTP component can only move any existing files to a relative directory based on current dir as base.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>tempFileName</strong></td>
<td>The same as tempPrefix option but offering a more fine grained control on the naming of the temporary filename as it uses the File Language.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>tempPrefix (producer)</td>
<td>This option is used to write the file using a temporary name and then, after the write is complete, rename it to the real name. Can be used to identify files being written and also avoid consumers (not using exclusive read locks) reading in progress files. Is often used by FTP when uploading big files.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>allowNullBody (producer)</td>
<td>Used to specify if a null body is allowed during file writing. If set to true then an empty file will be created, when set to false, and attempting to send a null body to the file component, a GenericFileWriteException of 'Cannot write null body to file.' will be thrown. If the fileExist option is set to 'Override', then the file will be truncated, and if set to append the file will remain unchanged.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>chmod (producer)</td>
<td>Allows you to set chmod on the stored file. For example chmod=640.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>disconnectOnBatchComplete (producer)</td>
<td>Whether or not to disconnect from remote FTP server right after a Batch upload is complete. disconnectOnBatchComplete will only disconnect the current connection to the FTP server.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>eagerDeleteTargetFile (producer)</td>
<td>Whether or not to eagerly delete any existing target file. This option only applies when you use fileExist=Override and the tempFileName option as well. You can use this to disable (set it to false) deleting the target file before the temp file is written. For example you may write big files and want the target file to exists during the temp file is being written. This ensure the target file is only deleted until the very last moment, just before the temp file is being renamed to the target filename. This option is also used to control whether to delete any existing files when fileExist=Move is enabled, and an existing file exists. If this option copyAndDeleteOnRenameFails false, then an exception will be thrown if an existing file existed, if its true, then the existing file is deleted before the move operation.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>keepLastModified (producer)</td>
<td>Will keep the last modified timestamp from the source file (if any). Will use the Exchange.FILE_LAST_MODIFIED header to locate the timestamp. This header can contain either a java.util.Date or long with the timestamp. If the timestamp exists and the option is enabled it will set this timestamp on the written file. Note: This option only applies to the file producer. You cannot use this option with any of the ftp producers.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sendNoop (producer)</td>
<td>Whether to send a noop command as a pre-write check before uploading files to the FTP server. This is enabled by default as a validation of the connection is still valid, which allows to silently re-connect to be able to upload the file. However if this causes problems, you can turn this option off.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>autoCreate (advanced)</td>
<td>Automatically create missing directories in the file's pathname. For the file consumer, that means creating the starting directory. For the file producer, it means the directory the files should be written to.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>bufferSize (advanced)</td>
<td>Write buffer sized in bytes.</td>
<td>131072</td>
<td>int</td>
</tr>
<tr>
<td>bulkRequests (advanced)</td>
<td>Specifies how many requests may be outstanding at any one time. Increasing this value may slightly improve file transfer speed but will increase memory usage.</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>compression (advanced)</td>
<td>To use compression. Specify a level from 1 to 10. Important: You must manually add the needed JSCH zlib JAR to the classpath for compression support.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>connectTimeout (advanced)</td>
<td>Sets the connect timeout for waiting for a connection to be established Used by both FTPClient and JSCH</td>
<td>10000</td>
<td>int</td>
</tr>
<tr>
<td>maximumReconnectAttempts (advanced)</td>
<td>Specifies the maximum reconnect attempts Camel performs when it tries to connect to the remote FTP server. Use 0 to disable this behavior.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>proxy (advanced)</td>
<td>To use a custom configured com.jcraft.jsch.Proxy. This proxy is used to consume/send messages from the target SFTP host.</td>
<td>Proxy</td>
<td></td>
</tr>
<tr>
<td>reconnectDelay (advanced)</td>
<td>Delay in millis Camel will wait before performing a reconnect attempt.</td>
<td>long</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>

<td>Allows you to set the serverAliveCountMax of the sftp session</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td><code>serverAliveInterval</code></td>
<td>Allows you to set the serverAliveInterval of the sftp session</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><code>soTimeout</code></td>
<td>Sets the so timeout Used only by FTPClient</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td><code>stepwise</code></td>
<td>Sets whether we should stepwise change directories while traversing file structures when downloading files, or as well when uploading a file to a directory.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td>You can disable this if you for example are in a situation where you cannot change directory on the FTP server due security reasons.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>synchronous</code></td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>throwExceptionOnConnectFailed</code></td>
<td>Should an exception be thrown if connection failed (exhausted) By default exception is not thrown and a WARN is logged. You can use this to enable exception being thrown and handle the thrown exception from the org.apache.camel.spi.PollingConsumerPollStrategy rollback method.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><code>timeout</code></td>
<td>Sets the data timeout for waiting for reply Used only by FTPClient</td>
<td>30000</td>
<td>int</td>
</tr>
<tr>
<td><code>antExclude</code></td>
<td>Ant style filter exclusion. If both antInclude and antExclude are used, antExclude takes precedence over antInclude. Multiple exclusions may be specified in comma-delimited format.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td><code>antFilterCaseSensitive</code></td>
<td>Sets case sensitive flag on ant filter</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>antInclude</code></td>
<td>Ant style filter inclusion. Multiple inclusions may be specified in comma-delimited format.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------</td>
</tr>
<tr>
<td><code>eagerMaxMessagesPerPoll</code> (filter)</td>
<td>Allows for controlling whether the limit from maxMessagesPerPoll is eager or not. If eager then the limit is during the scanning of files. Where as false would scan all files, and then perform sorting. Setting this option to false allows for sorting all files first, and then limit the poll. Mind that this requires a higher memory usage as all file details are in memory to perform the sorting.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>exclude</code> (filter)</td>
<td>Is used to exclude files, if filename matches the regex pattern (matching is case insensitive). Notice if you use symbols such as plus sign and others you would need to configure this using the RAW() syntax if configuring this as an endpoint uri. See more details at configuring endpoint uris</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>filterDirectory</code> (filter)</td>
<td>Filters the directory based on Simple language. For example to filter on current date, you can use a simple date pattern such as $date:now:yyyyMMdd</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>filterFile</code> (filter)</td>
<td>Filters the file based on Simple language. For example to filter on file size, you can use $file:size 5000</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>idempotent</code> (filter)</td>
<td>Option to use the Idempotent Consumer EIP pattern to let Camel skip already processed files. Will by default use a memory based LRUCache that holds 1000 entries. If noop=true then idempotent will be enabled as well to avoid consuming the same files over and over again.</td>
<td>false</td>
<td>Boolean</td>
</tr>
<tr>
<td><code>idempotentKey</code> (filter)</td>
<td>To use a custom idempotent key. By default the absolute path of the file is used. You can use the File Language, for example to use the file name and file size, you can do: idempotentKey=$file:name-$file:size</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>idempotentRepository</code> (filter)</td>
<td>A pluggable repository org.apache.camel.spi.IdempotentRepository which by default use MemoryMessageIdRepository if none is specified and idempotent is true.</td>
<td></td>
<td>String&gt;</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------------</td>
</tr>
<tr>
<td><code>include</code> (filter)</td>
<td>Is used to include files, if filename matches the regex pattern (matching is case in-sensitive). Notice if you use symbols such as plus sign and others you would need to configure this using the RAW() syntax if configuring this as an endpoint uri. See more details at configuring endpoint uris.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td><code>maxDepth</code> (filter)</td>
<td>The maximum depth to traverse when recursively processing a directory.</td>
<td>214748</td>
<td>int</td>
</tr>
<tr>
<td><code>maxMessagesPerPoll</code></td>
<td>To define a maximum messages to gather per poll. By default no maximum is set. Can be used to set a limit of e.g. 1000 to avoid when starting up the server that there are thousands of files. Set a value of 0 or negative to disabled it. Notice: If this option is in use then the File and FTP components will limit before any sorting. For example if you have 100000 files and use maxMessagesPerPoll=500, then only the first 500 files will be picked up, and then sorted. You can use the eagerMaxMessagesPerPoll option and set this to false to allow to scan all files first and then sort afterwards.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td><code>minDepth</code> (filter)</td>
<td>The minimum depth to start processing when recursively processing a directory. Using minDepth=1 means the base directory. Using minDepth=2 means the first sub directory.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><code>move</code> (filter)</td>
<td>Expression (such as Simple Language) used to dynamically set the filename when moving it after processing. To move files into a .done subdirectory just enter .done.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td><code>exclusiveReadLockStrategy</code> (lock)</td>
<td>Pluggable read-lock as a org.apache.camel.component.file.GenericFileExclusiveReadLockStrategy implementation.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**readLock** (lock)

Used by consumer, to only poll the files if it has exclusive read-lock on the file (i.e. the file is not in-progress or being written). Camel will wait until the file lock is granted. This option provides the build in strategies: none - No read lock is in use markerFile - Camel creates a marker file (fileName.camelLock) and then holds a lock on it. This option is not available for the FTP component changed - Changed is using file length/modification timestamp to detect whether the file is currently being copied or not. Will at least use 1 sec to determine this, so this option cannot consume files as fast as the others, but can be more reliable as the JDK IO API cannot always determine whether a file is currently being used by another process. The option readLockCheckInterval can be used to set the check frequency. fileLock - is for using java.nio.channels.FileLock. This option is not avail for the FTP component. This approach should be avoided when accessing a remote file system via a mount/share unless that file system supports distributed file locks. rename - rename is for using a try to rename the file as a test if we can get exclusive read-lock. idempotent - (only for file component) idempotent is for using a idempotentRepository as the read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. idempotent-changed - (only for file component) idempotent-changed is for using a idempotentRepository and changed as the combined read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. idempotent-rename - (only for file component) idempotent-rename is for using a idempotentRepository and rename as the combined read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. Notice: The various read locks is not all suited to work in clustered mode, where concurrent consumers on different nodes is competing for the same files on a shared file system. The markerFile using a close to atomic operation to create the empty marker file, but its not guaranteed to work in a cluster. The fileLock may work better but then the file system need to support distributed file locks, and so on. Using the idempotent read lock can support clustering if the idempotent repository supports clustering, such as Hazelcast Component or Infinispan.

</tr>
<tr>
<td>readLockCheckInterval (lock)</td>
<td>Interval in millis for the read-lock, if supported by the read lock. This interval is used for sleeping between attempts to acquire the read lock. For example when using the changed read lock, you can set a higher interval period to cater for slow writes. The default of 1 sec. may be too fast if the producer is very slow writing the file. Notice: For FTP the default readLockCheckInterval is 5000. The readLockTimeout value must be higher than readLockCheckInterval, but a rule of thumb is to have a timeout that is at least 2 or more times higher than the readLockCheckInterval. This is needed to ensure that ample time is allowed for the read lock process to try to grab the lock before the timeout was hit.</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>readLockDeleteOrphanLock Files (lock)</td>
<td>Whether or not read lock with marker files should upon startup delete any orphan read lock files, which may have been left on the file system, if Camel was not properly shutdown (such as a JVM crash). If turning this option to false then any orphaned lock file will cause Camel to not attempt to pickup that file, this could also be due another node is concurrently reading files from the same shared directory.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>readLockLogging Level (lock)</td>
<td>Logging level used when a read lock could not be acquired. By default a WARN is logged. You can change this level, for example to OFF to not have any logging. This option is only applicable for readLock of types: changed, fileLock, idempotent, idempotent-changed, idempotent-rename, rename.</td>
<td>DEBUG</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>readLockMarkerFile (lock)</td>
<td>Whether to use marker file with the changed, rename, or exclusive read lock types. By default a marker file is used as well to guard against other processes picking up the same files. This behavior can be turned off by setting this option to false. For example if you do not want to write marker files to the file systems by the Camel application.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>readLockMinAge (lock)</td>
<td>This option applied only for readLock=change. This option allows to specify a minimum age the file must be before attempting to acquire the read lock. For example use readLockMinAge=300s to require the file is at last 5 minutes old. This can speedup the changed read lock as it will only attempt to acquire files which are at least that given age.</td>

CHAPTER 281. SHIRO SECURITY COMPONENT

Available as of Camel 2.5

The shiro-security component in Camel is a security focused component, based on the Apache Shiro security project.

Apache Shiro is a powerful and flexible open-source security framework that cleanly handles authentication, authorization, enterprise session management and cryptography. The objective of the Apache Shiro project is to provide the most robust and comprehensive application security framework available while also being very easy to understand and extremely simple to use.

This camel shiro-security component allows authentication and authorization support to be applied to different segments of a camel route.

Shiro security is applied on a route using a Camel Policy. A Policy in Camel utilizes a strategy pattern for applying interceptors on Camel Processors. It offering the ability to apply cross-cutting concerns (for example, security, transactions etc) on sections/segments of a camel route.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-shiro</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

281.1. SHIRO SECURITY BASICS

To employ Shiro security on a camel route, a ShiroSecurityPolicy object must be instantiated with security configuration details (including users, passwords, roles etc). This object must then be applied to a camel route. This ShiroSecurityPolicy Object may also be registered in the Camel registry (JNDI or ApplicationContextRegistry) and then utilized on other routes in the Camel Context.

Configuration details are provided to the ShiroSecurityPolicy using an Ini file (properties file) or an Ini object. The Ini file is a standard Shiro configuration file containing user/role details as shown below:

```ini
[users]
# user 'ringo' with password 'starr' and the 'sec-level1' role
ringo = starr, sec-level1
george = harrison, sec-level2
john = lennon, sec-level3
paul = mccartney, sec-level3

[roles]
# 'sec-level3' role has all permissions, indicated by the
# wildcard '*'
sec-level3 = *

# The 'sec-level2' role can do anything with access of permission
# readonly ('*') to help
sec-level2 = zone1:*
```
281.2. INSTANTIATING A SHIROSECURITYPOLICY OBJECT

A ShiroSecurityPolicy object is instantiated as follows

```java
private final String iniResourcePath = "classpath:shiro.ini";
private final byte[] passPhrase = {
    (byte) 0x08, (byte) 0x09, (byte) 0x0A, (byte) 0x0B,
    (byte) 0x0C, (byte) 0x0D, (byte) 0x0E, (byte) 0x0F,
    (byte) 0x10, (byte) 0x11, (byte) 0x12, (byte) 0x13,
    (byte) 0x14, (byte) 0x15, (byte) 0x16, (byte) 0x17};
List<permission> permissionsList = new ArrayList<permission>();
Permission permission = new WildcardPermission("zone1:readwrite:*");
permissionsList.add(permission);
final ShiroSecurityPolicy securityPolicy =
    new ShiroSecurityPolicy(iniResourcePath, passPhrase, true, permissionsList);
```

281.3. SHIROSECURITYPOLICY OPTIONS

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iniResourcePath</td>
<td>none</td>
<td>Resource String or Ini Object</td>
<td>A mandatory Resource String for the iniResourcePath or an instance of an Ini object must be passed to the security policy. Resources can be acquired from the file system, classpath, or URLs when prefixed with &quot;file:, classpath:, or url:&quot; respectively. For e.g &quot;classpath:shiro.ini&quot;</td>
</tr>
<tr>
<td>passPhrase</td>
<td>An AES 128 based key</td>
<td>byte[]</td>
<td>A passPhrase to decrypt ShiroSecurityToken(s) sent along with Message Exchanges</td>
</tr>
<tr>
<td>alwaysAuthenticate</td>
<td>true</td>
<td>boolean</td>
<td>Setting to ensure re-authentication on every individual request. If set to false, the user is authenticated and locked such than only requests from the same user going forward are authenticated.</td>
</tr>
</tbody>
</table>
The ShiroSecurityPolicy, tests and permits incoming message exchanges containing a encrypted SecurityToken in the Message Header to proceed further following proper authentication. The SecurityToken object contains a Username/Password details that are used to determine where the user is a valid user.

```java
protected RouteBuilder createRouteBuilder() throws Exception {
```

<table>

<td>false</td>
<td>boolean</td>
<td>Camel 2.12: To use base64 encoding for the security token header, which allows transferring the header over JMS etc. This option must also be set on ShiroSecurityTokenInjector as well.</td>
</tr>
<tr>
<td>allPermissionsRequired</td>
<td>false</td>
<td>boolean</td>
<td>Camel 2.13: The default is that authorization is granted if any of the Permission Objects in the permissionsList parameter are applicable. Set this to true to require all of the Permissions to be met.</td>
</tr>
<tr>
<td>allRolesRequired</td>
<td>false</td>
<td>boolean</td>
<td>Camel 2.13: The default is that authorization is granted if any of the roles in the rolesList parameter are applicable. Set this to true to require all of the roles to be met.</td>
</tr>
</tbody>
</table>

### 281.4. APPLYING SHIRO AUTHENTICATION ON A CAMEL ROUTE

The ShiroSecurityPolicy, tests and permits incoming message exchanges containing a encrypted SecurityToken in the Message Header to proceed further following proper authentication. The SecurityToken object contains a Username/Password details that are used to determine where the user is a valid user.
281.5. APPLYING SHIRO AUTHORIZATION ON A CAMEL ROUTE

Authorization can be applied on a camel route by associating a Permissions List with the ShiroSecurityPolicy. The Permissions List specifies the permissions necessary for the user to proceed with the execution of the route segment. If the user does not have the proper permission set, the request is not authorized to continue any further.
281.6. CREATING A SHIROSECURITYTOKEN AND INJECTING IT INTO A MESSAGE EXCHANGE

A ShiroSecurityToken object may be created and injected into a Message Exchange using a Shiro Processor called ShiroSecurityTokenInjector. An example of injecting a ShiroSecurityToken using a ShiroSecurityTokenInjector in the client is shown below

```java
ShiroSecurityTokenInjector shiroSecurityTokenInjector =
    new ShiroSecurityTokenInjector(shiroSecurityToken, passPhrase);

from("direct:client").
    process(shiroSecurityTokenInjector).
    to("direct:secureEndpoint");
```

281.7. SENDING MESSAGES TO ROUTES SECURED BY A SHIROSECURITYPOLICY

Messages and Message Exchanges sent along the camel route where the security policy is applied need to be accompanied by a SecurityToken in the Exchange Header. The SecurityToken is an encrypted object that holds a Username and Password. The SecurityToken is encrypted using AES 128 bit security by default and can be changed to any cipher of your choice.

Given below is an example of how a request may be sent using a ProducerTemplate in Camel along with a SecurityToken

```java
@Test
public void testSuccessfulShiroAuthenticationWithNoAuthorization() throws Exception {
    //Incorrect password

    // TestShiroSecurityTokenInjector extends ShiroSecurityTokenInjector
    TestShiroSecurityTokenInjector shiroSecurityTokenInjector =
        new TestShiroSecurityTokenInjector(shiroSecurityToken, passPhrase);

    successEndpoint.expectedMessageCount(1);
    failureEndpoint.expectedMessageCount(0);

    template.send("direct:secureEndpoint", shiroSecurityTokenInjector);

    successEndpoint/assertIsSatisfied();
    failureEndpoint/assertIsSatisfied();
}
```

281.8. SENDING MESSAGES TO ROUTES SECURED BY A SHIROSECURITYPOLICY (MUCH EASIER FROM CAMEL 2.12 ONWARDS)

From Camel 2.12 onwards its even easier as you can provide the subject in two different ways.

281.8.1. Using ShiroSecurityToken
You can send a message to a Camel route with a header of key `ShiroSecurityConstants.SHIRO_SECURITY_TOKEN` of the type `org.apache.camel.component.shiro.security.ShiroSecurityToken` that contains the username and password. For example:

```java

template.sendBodyAndHeader("direct:secureEndpoint", "Beatle Mania", ShiroSecurityConstants.SHIRO_SECURITY_TOKEN, shiroSecurityToken);
```

You can also provide the username and password in two different headers as shown below:

```java
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(ShiroSecurityConstants.SHIRO_SECURITY_USERNAME, "ringo");
headers.put(ShiroSecurityConstants.SHIRO_SECURITY_PASSWORD, "starr");

template.sendBodyAndHeaders("direct:secureEndpoint", "Beatle Mania", headers);
```

When you use the username and password headers, then the ShiroSecurityPolicy in the Camel route will automatic transform those into a single header with key `ShiroSecurityConstants.SHIRO_SECURITY_TOKEN` with the token. Then token is either a `ShiroSecurityToken` instance, or a base64 representation as a String (the latter is when you have set `base64=true`).
CHAPTER 282. SIMPLE LANGUAGE

Available as of Camel version 1.1

The Simple Expression Language was a really simple language when it was created, but has since grown more powerful. It is primarily intended for being a really small and simple language for evaluating Expressions and Predicates without requiring any new dependencies or knowledge of XPath; so it is ideal for testing in camel-core. The idea was to cover 95% of the common use cases when you need a little bit of expression based script in your Camel routes.

However for much more complex use cases you are generally recommended to choose a more expressive and powerful language such as:

- SpEL
- Mvel
- Groovy
- JavaScript
- OGNL
- one of the supported Scripting Languages

The simple language uses \${body} placeholders for complex expressions where the expression contains constant literals. The ${} placeholders can be omitted if the expression is only the token itself.

TIP

Alternative syntax From Camel 2.5 onwards you can also use the alternative syntax which uses $simple{ } as placeholders. This can be used in situations to avoid clashes when using for example Spring property placeholder together with Camel.

282.1. SIMPLE LANGUAGE CHANGES IN CAMEL 2.9 ONWARDS

The Simple language have been improved from Camel 2.9 onwards to use a better syntax parser, which can do index precise error messages, so you know exactly what is wrong and where the problem is. For example if you have made a typo in one of the operators, then previously the parser would not be able to detect this, and cause the evaluation to be true. There are a few changes in the syntax which are no longer backwards compatible. When using Simple language as a Predicate then the literal text must be enclosed in either single or double quotes. For example: \"${body} == 'Camel'\". Notice how we have single quotes around the literal. The old style of using "body" and "header.foo" to refer to the message body and header is @deprecated, and it is encouraged to always use ${} tokens for the built-in functions. The range operator now requires the range to be in single quote as well as shown: "${header.zip} between '30000..39999'".

To get the body of the in message: "body", or "in.body" or \"${body}\".

A complex expression must use ${} placeholders, such as: "Hello ${in.header.name} how are you?".

You can have multiple functions in the same expression: "Hello ${in.header.name} this is ${in.header.me} speaking".

However you can not nest functions in Camel 2.8.x or older (i.e. having another ${} placeholder in an existing, is not allowed).

From Camel 2.9 onwards you can nest functions.
282.2. SIMPLE LANGUAGE OPTIONS

The Simple language supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>String</td>
<td><strong>Camel 2.17</strong>: As messageHistory but without the exchange details (only includes the route stack-trace). This can be used if you do not want to log sensitive data from the message itself.</td>
</tr>
</tbody>
</table>

### 282.4. OGNL EXPRESSION SUPPORT

**Available as of Camel 2.3**

INFO: Camel’s OGNL support is for invoking methods only. You cannot access fields. From **Camel 2.11.1** onwards we added special support for accessing the length field of Java arrays.

The Simple and Bean language now supports a Camel OGNL notation for invoking beans in a chain like fashion. Suppose the Message IN body contains a POJO which has a `getAddress()` method.

Then you can use Camel OGNL notation to access the address object:
Camel understands the shorthand names for getters, but you can invoke any method or use the real name such as:

```
simple($body.address)
simple($body.getAddress.getStreet())
simple($body.address.getZip())
simple($body.doSomething())
```

You can also use the null safe operator (?.) to avoid NPE if for example the body does NOT have an address

```
simple($body?.address?.street())
```

It is also possible to index in Map or List types, so you can do:

```
simple($body[foo].name)
```

To assume the body is Map based and lookup the value with foo as key, and invoke the getName method on that value.

If the key has space, then you must enclose the key with quotes, for example 'foo bar':

```
simple($body['foo bar'].name)
```

You can access the Map or List objects directly using their key name (with or without dots):

```
simple($body[foo])
simple($body[this.is.foo])
```

Suppose there was no value with the key foo then you can use the null safe operator to avoid the NPE as shown:

```
simple($body[foo]? .name)
```

You can also access List types, for example to get lines from the address you can do:

```
simple($body.address.lines[0])
simple($body.address.lines[1])
simple($body.address.lines[2])
```

There is a special last keyword which can be used to get the last value from a list.

```
simple($body.address.lines[last])
```

And to get the 2nd last you can subtract a number, so we can use last-1 to indicate this:

```
simple($body.address.lines[last-1])
```
And the 3rd last is of course:

```java
simple("\$\{body.address.lines[last-2]\}"")
```

And you can call the size method on the list with

```java
simple("\$\{body.address.lines.size\}"")
```

From Camel 2.11.1 onwards we added support for the length field for Java arrays as well, eg:

```java
String[] lines = new String[] {"foo", "bar", "cat"};
exchange.getIn().setBody(lines);
simple("There are \$\{body.length\} lines")
```

And yes you can combine this with the operator support as shown below:

```java
simple("\$\{body.address.zip\} > 1000")
```

### 282.5. OPERATOR SUPPORT

The parser is limited to only support a single operator.

To enable it the left value must be enclosed in `$\{ }`. The syntax is:

```java
$\{leftValue\} OP rightValue
```

Where the `rightValue` can be a String literal enclosed in `'`, `null`, a constant value or another expression enclosed in `$\{ }`.

**IMPORTANT**

There **must** be spaces around the operator.

Camel will automatically type convert the rightValue type to the leftValue type, so it is able to eg. convert a string into a numeric so you can use `>` comparison for numeric values.

The following operators are supported:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>equals</td>
</tr>
<tr>
<td>=~</td>
<td>Camel 2.16: equals ignore case (will ignore case when comparing String values)</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equals</td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>&lt;</code></td>
<td>less than</td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td>less than or equals</td>
</tr>
<tr>
<td><code>!=</code></td>
<td>not equals</td>
</tr>
<tr>
<td>contains</td>
<td>For testing if contains in a string based value</td>
</tr>
<tr>
<td>not contains</td>
<td>For testing if not contains in a string based value</td>
</tr>
<tr>
<td><code>~~</code></td>
<td>For testing if contains by ignoring case sensitivity in a string based value</td>
</tr>
<tr>
<td>regex</td>
<td>For matching against a given regular expression pattern defined as a String value</td>
</tr>
<tr>
<td>not regex</td>
<td>For not matching against a given regular expression pattern defined as a String value</td>
</tr>
<tr>
<td>in</td>
<td>For matching if in a set of values, each element must be separated by comma. If you want to include an empty value, then it must be defined using double comma, eg <code>,,bronze,silver,gold</code>, which is a set of four values with an empty value and then the three medals.</td>
</tr>
<tr>
<td>not in</td>
<td>For matching if not in a set of values, each element must be separated by comma. If you want to include an empty value, then it must be defined using double comma, eg <code>,,bronze,silver,gold</code>, which is a set of four values with an empty value and then the three medals.</td>
</tr>
<tr>
<td>is</td>
<td>For matching if the left hand side type is an instance of the value.</td>
</tr>
<tr>
<td>not is</td>
<td>For matching if the left hand side type is not an instance of the value.</td>
</tr>
<tr>
<td>range</td>
<td>For matching if the left hand side is within a range of values defined as numbers: <code>from..to</code>. From Camel 2.9 onwards the range values must be enclosed in single quotes.</td>
</tr>
<tr>
<td>not range</td>
<td>For matching if the left hand side is not within a range of values defined as numbers: <code>from..to</code>. From Camel 2.9 onwards the range values must be enclosed in single quotes.</td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>starts with</td>
<td>Camel 2.17.1, 2.18: For testing if the left hand side string starts with the right hand string.</td>
</tr>
<tr>
<td>ends with</td>
<td>Camel 2.17.1, 2.18: For testing if the left hand side string ends with the right hand string.</td>
</tr>
</tbody>
</table>

And the following unary operators can be used:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>++</td>
<td>Camel 2.9: To increment a number by one. The left hand side must be a function, otherwise parsed as literal.</td>
</tr>
<tr>
<td>–</td>
<td>Camel 2.9: To decrement a number by one. The left hand side must be a function, otherwise parsed as literal.</td>
</tr>
<tr>
<td>\</td>
<td>Camel 2.9.3 to 2.10.x: To escape a value, eg $, to indicate a $ sign. Special: Use \n for new line, \t for tab, and \r for carriage return. Notice: Escaping is not supported using the File Language. Notice: From Camel 2.11 onwards the escape character is no longer support, but replaced with the following three special escaping.</td>
</tr>
<tr>
<td>\n</td>
<td>Camel 2.11: To use newline character.</td>
</tr>
<tr>
<td>\t</td>
<td>Camel 2.11: To use tab character.</td>
</tr>
<tr>
<td>\r</td>
<td>Camel 2.11: To use carriage return character.</td>
</tr>
<tr>
<td>}</td>
<td>Camel 2.18: To use the } character as text</td>
</tr>
</tbody>
</table>

And the following logical operators can be used to group expressions:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>and</td>
<td>deprecated use &amp;&amp; instead. The logical and operator is used to group two expressions.</td>
</tr>
<tr>
<td>or</td>
<td>deprecated use</td>
</tr>
</tbody>
</table>
The logical and operator is used to group two expressions.

The logical or operator is used to group two expressions.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;&amp;</td>
<td>Camel 2.9: The logical and operator is used to group two expressions.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**IMPORTANT**

Using and, or operators In Camel 2.4 or older the and or or can only be used once in a simple language expression. From Camel 2.5 onwards you can use these operators multiple times.

The syntax for AND is:

```text
${leftValue} OP rightValue and ${leftValue} OP rightValue
```

And the syntax for OR is:

```text
${leftValue} OP rightValue or ${leftValue} OP rightValue
```

Some examples:

```java
// exact equals match
simple("${in.header.foo} == 'foo'")

// ignore case when comparing, so if the header has value FOO this will match
simple("${in.header.foo} =~ 'foo'")

// here Camel will type convert '100' into the type of in.header.bar and if it is an Integer '100' will also
// be converter to an Integer
simple("${in.header.bar} == '100'")

simple("${in.header.bar} == 100")

// 100 will be converter to the type of in.header.bar so we can do > comparison
simple("${in.header.bar} > 100")
```

**282.5.1. Comparing with different types**

When you compare with different types such as String and int, then you have to take a bit care. Camel will use the type from the left hand side as 1st priority. And fallback to the right hand side type if both values couldn’t be compared based on that type.

This means you can flip the values to enforce a specific type. Suppose the bar value above is a String. Then you can flip the equation:

```java
simple("100 < ${in.header.bar}")
```
which then ensures the int type is used as 1st priority.

This may change in the future if the Camel team improves the binary comparison operations to prefer numeric types over String based. It's most often the String type which causes problem when comparing with numbers.

```java
// testing for null
simple("${in.header.baz} == null")

// testing for not null
simple("${in.header.baz} != null")
```

And a bit more advanced example where the right value is another expression

```java
simple("${in.header.date} == ${date:now:yyyyMMdd")

simple("${in.header.type} == ${bean:orderService?method=getOrderType}"
```

And an example with contains, testing if the title contains the word Camel

```java
simple("${in.header.title} contains 'Camel'")
```

And an example with regex, testing if the number header is a 4 digit value:

```java
simple("${in.header.number} regex '[\d{4}']")
```

And finally an example if the header equals any of the values in the list. Each element must be separated by comma, and no space around.

This also works for numbers etc, as Camel will convert each element into the type of the left hand side.

```java
simple("${in.header.type} in 'gold,silver'")
```

And for all the last 3 we also support the negate test using not:

```java
simple("${in.header.type} not in 'gold,silver'")
```

And you can test if the type is a certain instance, eg for instance a String

```java
simple("${in.header.type} is 'java.lang.String'")
```

We have added a shorthand for all `java.lang` types so you can write it as:

```java
simple("${in.header.type} is 'String'")
```

Ranges are also supported. The range interval requires numbers and both from and end are inclusive.

For instance to test whether a value is between 100 and 199:

```java
simple("${in.header.number} range 100..199")
```

Notice we use .. in the range without spaces. It is based on the same syntax as Groovy.

From Camel 2.9 onwards the range value must be in single quotes
282.5.2. Using Spring XML

As the Spring XML does not have all the power as the Java DSL with all its various builder methods, you have to resort to use some other languages for testing with simple operators. Now you can do this with the simple language. In the sample below we want to test if the header is a widget order:

```
<from uri="seda:orders">
  <filter>
    <simple>${in.header.type} == 'widget'</simple>
    <to uri="bean:orderService?method=handleWidget"/>
  </filter>
</from>
```

282.6. USING AND / OR

If you have two expressions you can combine them with the **and** or **or** operator.

**TIP**

Camel 2.9 onwards Use && or || from Camel 2.9 onwards.

For instance:

```
simple("${in.header.title} contains 'Camel' and ${in.header.type} == 'gold'")
```

And of course the **or** is also supported. The sample would be:

```
simple("${in.header.title} contains 'Camel' or ${in.header.type} == 'gold'")
```

**Notice:** Currently **and** or **or** can only be used **once** in a simple language expression. This might change in the future.

So you **cannot** do:

```
simple("${in.header.title} contains 'Camel' and ${in.header.type} == 'gold' and ${in.header.number} range 100..200")
```

282.7. SAMPLES

In the Spring XML sample below we filter based on a header value:

```
<from uri="seda:orders">
  <filter>
    <simple>${in.header.foo}</simple>
    <to uri="mock:fooOrders"/>
  </filter>
</from>
```
The Simple language can be used for the predicate test above in the Message Filter pattern, where we test if the in message has a foo header (a header with the key foo exists). If the expression evaluates to true then the message is routed to the mock:fooOrders endpoint, otherwise the message is dropped.

The same example in Java DSL:

```java
from("seda:orders")
    .filter().simple("${in.header.foo}")
    .to("seda:fooOrders");
```

You can also use the simple language for simple text concatenations such as:

```java
from("direct:hello")
    .transform().simple("Hello ${in.header.user} how are you?"")
    .to("mock:reply");
```

Notice that we must use \{ \} placeholders in the expression now to allow Camel to parse it correctly.

And this sample uses the date command to output current date.

```java
from("direct:hello")
    .transform().simple("The today is ${date:now:yyyyMMdd} and it is a great day.")
    .to("mock:reply");
```

And in the sample below we invoke the bean language to invoke a method on a bean to be included in the returned string:

```java
from("direct:order")
    .transform().simple("OrderId: ${bean:orderIdGenerator}"
    .to("mock:reply");
```

Where orderIdGenerator is the id of the bean registered in the Registry. If using Spring then it is the Spring bean id.

If we want to declare which method to invoke on the order id generator bean we must prepend .method name such as below where we invoke the generateld method.

```java
from("direct:order")
    .transform().simple("OrderId: ${bean:orderIdGenerator.generateId}"
    .to("mock:reply");
```

We can use the ?method=methodname option that we are familiar with the Bean component itself:

```java
from("direct:order")
    .transform().simple("OrderId: ${bean:orderIdGenerator?method=generateId}"
    .to("mock:reply");
```

And from Camel 2.3 onwards you can also convert the body to a given type, for example to ensure that it is a String you can do:

```xml
<transform>
    <simple>Hello ${bodyAs(String)} how are you?</simple>
</transform>
```
There are a few types which have a shorthand notation, so we can use `String` instead of `java.lang.String`. These are: `byte[]`, `String`, `Integer`, `Long`. All other types must use their FQN name, e.g. `org.w3c.dom.Document`.

It is also possible to lookup a value from a header `Map` in Camel 2.3 onwards:

```xml
<transform>
  <simple>The gold value is ${header.type[gold]}
</simple>
</transform>
```

In the code above we lookup the header with name `type` and regard it as a `java.util.Map` and we then lookup with the key `gold` and return the value. If the header is not convertible to Map an exception is thrown. If the header with name `type` does not exist `null` is returned.

From Camel 2.9 onwards you can nest functions, such as shown below:

```xml
<setHeader headerName="myHeader">
  <simple>${properties:${header.someKey}}</simple>
</setHeader>
```

### 282.8. Referring to Constants or Enums

Available as of Camel 2.11

Suppose you have an enum for customers

And in a Content Based Router we can use the `Simple` language to refer to this enum, to check the message which enum it matches.

### 282.9. Using New Lines or Tabs in XML DSLs

Available as of Camel 2.9.3

From Camel 2.9.3 onwards it is easier to specify new lines or tabs in XML DSLs as you can escape the value now

```xml
<transform>
  <simple>The following text\nis on a new line</simple>
</transform>
```

### 282.10. Leading and Trailing Whitespace Handling

Available as of Camel 2.10.0

From Camel 2.10.0 onwards, the trim attribute of the expression can be used to control whether the leading and trailing whitespace characters are removed or preserved. The default value is true, which removes the whitespace characters.

```xml
<setBody>
  <simple trim="false">You get some trailing whitespace characters.
</simple>
</setBody>
```
282.11. SETTING RESULT TYPE

Available as of Camel 2.8

You can now provide a result type to the Simple expression, which means the result of the evaluation will be converted to the desired type. This is most useable to define types such as booleans, integers, etc.

For example to set a header as a boolean type you can do:

```java
.setHeader("cool", simple("true", Boolean.class))
```

And in XML DSL

```xml
<setHeader headerName="cool">
  <!-- use resultType to indicate that the type should be a java.lang.Boolean -->
  <simple resultType="java.lang.Boolean">true</simple>
</setHeader>
```

282.12. CHANGING FUNCTION START AND END TOKENS

Available as of Camel 2.9.1

You can configure the function start and end tokens - `{ }` using the setters `changeFunctionStartToken` and `changeFunctionEndToken` on `SimpleLanguage`, using Java code.

From Spring XML you can define a `<bean>` tag with the new changed tokens in the properties as shown below:

```xml
<bean id="simple" class="org.apache.camel.language.simple.SimpleLanguage">
  <property name="functionStartToken" value="["/>
  <property name="functionEndToken" value="]"/>
</bean>
```

In the example above we use `[ ]` as the changed tokens.

Notice by changing the start/end token you change those in all the Camel applications which share the same `camel-core` on their classpath.

For example in an OSGi server this may affect many applications, where as a Web Application as a WAR file it only affects the Web Application.

282.13. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as "classpath: ", "file: " or "http: ".

This is done using the following syntax: "resource:scheme:location", eg to refer to a file on the classpath you can do:

```java
.setHeader("myHeader").simple("resource:classpath:mysimple.txt")
```
282.14. SETTING SPRING BEANS TO EXCHANGE PROPERTIES

Available as of Camel 2.6

You can set a spring bean into an exchange property as shown below:

```xml
<bean id="myBeanId" class="my.package.MyCustomClass" />

<route>
...

<setProperty propertyName="monitoring.message">
  <simple>ref:myBeanId</simple>
</setProperty>
...

</route>
```

282.15. DEPENDENCIES

The Simple language is part of camel-core.
CHAPTER 283. SIP COMPONENT

Available as of Camel version 2.5

The sip component in Camel is a communication component, based on the Jain SIP implementation (available under the JCP license).

Session Initiation Protocol (SIP) is an IETF-defined signaling protocol, widely used for controlling multimedia communication sessions such as voice and video calls over Internet Protocol (IP). The SIP protocol is an Application Layer protocol designed to be independent of the underlying transport layer; it can run on Transmission Control Protocol (TCP), User Datagram Protocol (UDP) or Stream Control Transmission Protocol (SCTP).

The Jain SIP implementation supports TCP and UDP only.

The Camel SIP component only supports the SIP Publish and Subscribe capability as described in the RFC3903 - Session Initiation Protocol (SIP) Extension for Event

This camel component supports both producer and consumer endpoints.

Camel SIP Producers (Event Publishers) and SIP Consumers (Event Subscribers) communicate event & state information to each other using an intermediary entity called a SIP Presence Agent (a stateful brokering entity).

For SIP based communication, a SIP Stack with a listener must be instantiated on both the SIP Producer and Consumer (using separate ports if using localhost). This is necessary in order to support the handshakes & acknowledgements exchanged between the SIP Stacks during communication.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sip</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

283.1. URI FORMAT

The URI scheme for a sip endpoint is as follows:

```
sip://johndoe@localhost:99999[?options]
sips://johndoe@localhost:99999[?options]
```

This component supports producer and consumer endpoints for both TCP and UDP.

You can append query options to the URI in the following format, ?option=value&option=value&…

283.2. OPTIONS

The SIP Component offers an extensive set of configuration options & capability to create custom stateful headers needed to propagate state via the SIP protocol.

The SIP component has no options.
The SIP endpoint is configured using URI syntax:

```
sip:uri
```

with the following path and query parameters:

### 283.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>uri</td>
<td><strong>Required</strong> URI of the SIP server to connect to (the username and password can be included such as: john:secret@myserver:9999)</td>
<td></td>
<td>URI</td>
</tr>
</tbody>
</table>

### 283.2.2. Query Parameters (44 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>cacheConnections</td>
<td>Should connections be cached by the SipStack to reduce cost of connection creation. This is useful if the connection is used for long running conversations.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>contentSubType</td>
<td>Setting for contentSubType can be set to any valid MimeSubType.</td>
<td>plain</td>
<td>String</td>
</tr>
<tr>
<td>contentType</td>
<td>Setting for contentType can be set to any valid MimeType.</td>
<td>text</td>
<td>String</td>
</tr>
<tr>
<td>eventHeaderName</td>
<td>Setting for a String based event type.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>eventId</td>
<td>Setting for a String based event Id. Mandatory setting unless a registry based FromHeader is specified</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>fromHost</td>
<td>Hostname of the message originator. Mandatory setting unless a registry based FromHeader is specified</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>fromPort</td>
<td>Port of the message originator. Mandatory setting unless a registry based FromHeader is specified</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>fromUser</td>
<td>Username of the message originator. Mandatory setting unless a registry based custom FromHeader is specified</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>msgExpiration</strong></td>
<td>The amount of time a message received at an endpoint is considered valid</td>
<td>3600</td>
<td>int</td>
</tr>
<tr>
<td><strong>receiveTimeoutMillis</strong></td>
<td>Setting for specifying amount of time to wait for a Response and/or Acknowledgement can be received from another SIP stack</td>
<td>10000</td>
<td>long</td>
</tr>
<tr>
<td><strong>stackName</strong></td>
<td>Name of the SIP Stack instance associated with an SIP Endpoint.</td>
<td>NAME_NOT_SET</td>
<td>String</td>
</tr>
<tr>
<td><strong>toHost</strong></td>
<td>Hostname of the message receiver. Mandatory setting unless a registry based ToHeader is specified</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>toPort</strong></td>
<td>Portname of the message receiver. Mandatory setting unless a registry based ToHeader is specified</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td><strong>toUser</strong></td>
<td>Username of the message receiver. Mandatory setting unless a registry based custom ToHeader is specified.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>transport</strong></td>
<td>Setting for choice of transport protocol. Valid choices are tcp or udp.</td>
<td>tcp</td>
<td>String</td>
</tr>
<tr>
<td><strong>bridgeErrorHandler</strong></td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>consumer</strong></td>
<td>This setting is used to determine whether the kind of header (FromHeader,ToHeader etc) that needs to be created for this endpoint</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>presenceAgent</strong></td>
<td>This setting is used to distinguish between a Presence Agent &amp; a consumer. This is due to the fact that the SIP Camel component ships with a basic Presence Agent (for testing purposes only). Consumers have to set this flag to true.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------------------</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>addressFactory</td>
<td>To use a custom AddressFactory</td>
<td></td>
<td>AddressFactory</td>
</tr>
<tr>
<td>callIdHeader</td>
<td>A custom Header object containing call details. Must implement the type javax.sip.header.CallIdHeader</td>
<td></td>
<td>CallIdHeader</td>
</tr>
<tr>
<td>contactHeader</td>
<td>An optional custom Header object containing verbose contact details (email, phone number etc). Must implement the type javax.sip.header.ContactHeader</td>
<td></td>
<td>ContactHeader</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>A custom Header object containing message content details. Must implement the type javax.sip.header.ContentTypeHeader</td>
<td></td>
<td>ContentTypeHeader</td>
</tr>
<tr>
<td>eventHeader</td>
<td>A custom Header object containing event details. Must implement the type javax.sip.header.EventHeader</td>
<td></td>
<td>EventHeader</td>
</tr>
<tr>
<td>expiresHeader</td>
<td>A custom Header object containing message expiration details. Must implement the type javax.sip.header.ExpiresHeader</td>
<td></td>
<td>ExpiresHeader</td>
</tr>
<tr>
<td>extensionHeader</td>
<td>A custom Header object containing user/application specific details. Must implement the type javax.sip.header.ExtensionHeader</td>
<td></td>
<td>ExtensionHeader</td>
</tr>
<tr>
<td>fromHeader</td>
<td>A custom Header object containing message originator settings. Must implement the type javax.sip.header.FromHeader</td>
<td></td>
<td>FromHeader</td>
</tr>
<tr>
<td>headerFactory</td>
<td>To use a custom HeaderFactory</td>
<td></td>
<td>HeaderFactory</td>

<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>maxForwardsHeader</td>
<td>A custom Header object containing details on maximum proxy forwards. This header places a limit on the viaHeaders possible. Must implement the type javax.sip.header.MaxForwardsHeader</td>
<td></td>
<td>MaxForwardsHeader</td>
</tr>
<tr>
<td>maxMessageSize</td>
<td>Setting for maximum allowed Message size in bytes.</td>
<td>1048576</td>
<td>int</td>
</tr>
<tr>
<td>messageFactory</td>
<td>To use a custom MessageFactory</td>
<td></td>
<td>MessageFactory</td>
</tr>
<tr>
<td>sipFactory</td>
<td>To use a custom SipFactory to create the SipStack to be used</td>
<td></td>
<td>SipFactory</td>
</tr>
<tr>
<td>sipStack</td>
<td>To use a custom SipStack</td>
<td></td>
<td>SipStack</td>
</tr>
<tr>
<td>sipUri</td>
<td>To use a custom SipURI. If none configured, then the SipUri fallback to use the options toUser toHost:toPort</td>
<td></td>
<td>SipURI</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>toHeader</td>
<td>A custom Header object containing message receiver settings. Must implement the type javax.sip.header.ToHeader</td>
<td></td>
<td>ToHeader</td>
</tr>
<tr>
<td>viaHeaders</td>
<td>List of custom Header objects of the type javax.sip.header.ViaHeader. Each ViaHeader containing a proxy address for request forwarding. (Note this header is automatically updated by each proxy when the request arrives at its listener)</td>
<td></td>
<td>List</td>
</tr>
<tr>
<td>implementationDebugLogFile</td>
<td>Name of client debug log file to use for logging</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>implementationServerLogFile</td>
<td>Name of server log file to use for logging</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>implementationTraceLevel</td>
<td>Logging level for tracing</td>
<td>0</td>
<td>String</td>
</tr>
</tbody>
</table>
### 283.3. SENDING MESSAGES TO/FROM A SIP ENDPOINT

#### 283.3.1. Creating a Camel SIP Publisher

In the example below, a SIP Publisher is created to send SIP Event publications to a user "agent@localhost:5152". This is the address of the SIP Presence Agent which acts as a broker between the SIP Publisher and Subscriber

- using a SIP Stack named client
- using a registry based eventHeader called evtHdrName
- using a registry based eventId called evtid
- from a SIP Stack with Listener set up as user2@localhost:3534
- The Event being published is EVENT_A
- A Mandatory Header called REQUEST_METHOD is set to Request.Publish thereby setting up the endpoint as a Event publisher

```java
producerTemplate.sendBodyAndHeader(
    "sip://agent@localhost:5152?stackName=client&eventHeaderName=evtHdrName&eventId=evtid&fromUser=user2&fromHost=localhost&fromPort=3534","EVENT_A","REQUEST_METHOD", Request.PUBLISH);
```

#### 283.3.2. Creating a Camel SIP Subscriber

In the example below, a SIP Subscriber is created to receive SIP Event publications sent to a user "johndoe@localhost:5154"

- using a SIP Stack named Subscriber
- registering with a Presence Agent user called agent@localhost:5152
- using a registry based eventHeader called evtHdrName. The evtHdrName contains the Event which is set to "Event_A"
- using a registry based eventId called evtid

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxForwards (proxy)</td>
<td>Number of maximum proxy forwards</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>useRouterForAllUris</td>
<td>This setting is used when requests are sent to the Presence Agent via a proxy.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

CHAPTER 283. SIP COMPONENT
The Camel SIP component also ships with a Presence Agent that is meant to be used for Testing and Demo purposes only. An example of instantiating a Presence Agent is given above.

Note that the Presence Agent is set up as a user agent@localhost:5152 and is capable of communicating with both Publisher as well as Subscriber. It has a separate SIP stackName distinct from Publisher as well as Subscriber. While it is set up as a Camel Consumer, it does not actually send any messages along the route to the endpoint "mock:neverland".
SJMS Batch is a specialized component for highly performant, transactional batch consumption from a JMS queue. It can be thought of as a hybrid of a consumer-only component and an aggregator.

A common use case in Camel is to consume messages from a queue and aggregate them before sending the aggregated state to another endpoint. In order to ensure that data is not lost if the system performing the processing fails, it is typically consumed within a transaction from the queue, and once aggregated stored in a persistent AggregationRepository, such as the one found in the JDBC Component.

The behavior of the aggregator pattern involves fetching data from the AggregationRepository before an incoming message is aggregated, and writing back the result afterwards. By nature, the reads and writes take progressively longer as the number of aggregated artifacts increases. A rough example of this using arbitrary time units that demonstrates the impact of this is as follows:

<table>
<thead>
<tr>
<th>Item</th>
<th>Read Time</th>
<th>Write Time</th>
<th>Total Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>3</td>
<td>9</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>4</td>
<td>16</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>6</td>
<td>36</td>
</tr>
<tr>
<td>6</td>
<td>6</td>
<td>7</td>
<td>49</td>
</tr>
<tr>
<td>7</td>
<td>7</td>
<td>8</td>
<td>64</td>
</tr>
<tr>
<td>8</td>
<td>8</td>
<td>9</td>
<td>81</td>
</tr>
<tr>
<td>9</td>
<td>9</td>
<td>10</td>
<td>100</td>
</tr>
</tbody>
</table>

In contrast, consumption performance using the SJMS Batch component is linear. Each message is consumed and aggregated using an AggregationStrategy before the next one is fetched. As all of the consumption and aggregation is performed in a single JMS transaction no external storage is required to persist the intermediate state - this avoids the read and write costs described above. In practice, this yields multiple orders of magnitude higher throughput.

Once a completion condition is met, either by size or period since first message, the aggregated Exchange is passed into the route. During the processing of this Exchange, if an exception is thrown or the system shuts down, all of the original consumed messages end up back on the queue (or are placed on the dead-letter queue depending on the broker configuration).
Unlike using a regular aggregator, there is no facility for an aggregation condition, meaning that it is not possible to batch consume into multiple groups of messages. All consumed messages are aggregated together into a single batch.

Multiple JMS consumer support is available which allows you to consume in parallel using the one route, and at the same time use facilities like JMS message groups to group related messages.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sjms</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 284.1. URI FORMAT

<table>
<thead>
<tr>
<th>sjms:[queue:]destinationName[?options]</th>
</tr>
</thead>
</table>

Where `destinationName` is a JMS queue. By default, the `destinationName` is interpreted as a queue name.

- `sjms:FOO.BAR`

You can include the optional `queue:` prefix, if you prefer:

- `sjms:queue:FOO.BAR`

Topic consumption is not supported, as there is no advantage to using batch consumption within that context. Topic messages are usually non-persistent, and loss is acceptable. If consumed within a transaction that fails, a topic message will likely not be redelivered by the broker. A plain SJMS consumer endpoint can be used in conjunction with a regular non-persistence backed aggregator in this scenario.

### 284.2. COMPONENT OPTIONS AND CONFIGURATIONS

The Simple JMS Batch component supports 5 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>connectionFactor</code> (advanced)</td>
<td>A ConnectionFactory is required to enable the SjmsBatchComponent.</td>
<td></td>
<td>ConnectionFactory</td>
</tr>
</tbody>
</table>
The Simple JMS Batch endpoint is configured using URI syntax:

```
sjms-batch:destinationName
```

with the following path and query parameters:

### 284.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>destinationName</td>
<td><strong>Required</strong> The destination name. Only queues are supported, names may be prefixed by 'queue'.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 284.2.2. Query Parameters (23 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>asyncStartListener (advanced)</td>
<td>Whether to startup the consumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>recoveryInterval (advanced)</td>
<td>Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.</td>
<td>5000</td>
<td>int</td>
</tr>
<tr>
<td>headerFilterStrategy (filter)</td>
<td>To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------------</td>
</tr>
<tr>
<td>aggregationStrategy (consumer)</td>
<td><strong>Required</strong> The aggregation strategy to use, which merges all the batched messages into a single message</td>
<td></td>
<td>AggregationStrategy</td>
</tr>
<tr>
<td>allowNullBody (consumer)</td>
<td>Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSException is thrown.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>completionInterval (consumer)</td>
<td>The completion interval in millis, which causes batches to be completed in a scheduled fixed rate every interval. The batch may be empty if the timeout triggered and there was no messages in the batch. Notice you cannot use both completion timeout and completion interval at the same time, only one can be configured.</td>
<td>1000</td>
<td>int</td>
</tr>
<tr>
<td>completionPredicate (consumer)</td>
<td>The completion predicate, which causes batches to be completed when the predicate evaluates as true. The predicate can also be configured using the simple language using the string syntax. You may want to set the option eagerCheckCompletion to true to let the predicate match the incoming message, as otherwise it matches the aggregated message.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>completionSize (consumer)</td>
<td>The number of messages consumed at which the batch will be completed</td>
<td>200</td>
<td>int</td>
</tr>
<tr>
<td>completionTimeout (consumer)</td>
<td>The timeout in millis from receipt of the first first message when the batch will be completed. The batch may be empty if the timeout triggered and there was no messages in the batch. Notice you cannot use both completion timeout and completion interval at the same time, only one can be configured.</td>
<td>500</td>
<td>int</td>
</tr>
<tr>
<td>consumerCount (consumer)</td>
<td>The number of JMS sessions to consume from</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>eagerCheckCompletion</td>
<td>Use eager completion checking which means that the completionPredicate will use the incoming Exchange. As opposed to without eager completion checking the completionPredicate will use the aggregated Exchange.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>includeAllJMSXProperties</td>
<td>Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom headerFilterStrategy then this option does not apply.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>mapJmsMessage</td>
<td>Specifies whether Camel should auto map the received JMS message to a suited payload type, such as javax.jms.TextMessage to a String etc. See section about how mapping works below for more details.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>pollDuration</td>
<td>The duration in milliseconds of each poll for messages. completionTimeOut will be used if it is shorter and a batch has started.</td>
<td>1000</td>
<td>int</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle</td>
<td>If using completion timeout or interval, then the batch may be empty if the timeout triggered and there was no messages in the batch. If this option is true and the batch is empty then an empty message is added to the batch so an empty message is routed.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>asyncStartListener</td>
<td>Whether to startup the consumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><strong>headerFilterStrategy</strong> (advanced)</td>
<td>To use a custom HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td><strong>jmsKeyFormatStrategy</strong> (advanced)</td>
<td>Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and - ) . The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the notation.</td>
<td></td>
<td>JmsKeyFormatStrategy</td>
</tr>
<tr>
<td><strong>keepAliveDelay</strong> (advanced)</td>
<td>The delay in millis between attempts to re-establish a valid session. If this is a positive value the SjmsBatchConsumer will attempt to create a new session if it sees an IllegalStateException during message consumption. This delay value allows you to pause between attempts to prevent spamming the logs. If this is a negative value (default is -1) then the SjmsBatchConsumer will behave as it always has before - that is it will bail out and the route will shut down if it sees an IllegalStateException.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td><strong>messageCreatedStrategy</strong> (advanced)</td>
<td>To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.</td>
<td></td>
<td>MessageCreatedStrategy</td>
</tr>
<tr>
<td><strong>recoveryInterval</strong> (advanced)</td>
<td>Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.</td>
<td>5000</td>
<td>int</td>
</tr>
<tr>
<td><strong>synchronous</strong> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>timeoutCheckerExecutorService</strong> (advanced)</td>
<td>If using the completionInterval option a background thread is created to trigger the completion interval. Set this option to provide a custom thread pool to be used rather than creating a new thread for every consumer.</td>
<td></td>
<td>ScheduledExecutorService</td>
</tr>
</tbody>
</table>

The **completionSize** endpoint attribute is used in conjunction with **completionTimeout**, where the first condition to be met will cause the aggregated **Exchange** to be emitted down the route.
CHAPTER 285. SIMPLE JMS COMPONENT

Available as of Camel version 2.11

The Simple JMS Component, or SJMS, is a JMS client for use with Camel that uses well known best practices when it comes to JMS client creation and configuration. SJMS contains a brand new JMS client API written explicitly for Camel eliminating third party messaging implementations keeping it light and resilient. The following features is included:

- Standard Queue and Topic Support (Durable & Non-Durable)
- InOnly & InOut MEP Support
- Asynchronous Producer and Consumer Processing
- Internal JMS Transaction Support

Additional key features include:

- Plugable Connection Resource Management
- Session, Consumer, & Producer Pooling & Caching Management
- Batch Consumers and Producers
- Transacted Batch Consumers & Producers
- Support for Customizable Transaction Commit Strategies (Local JMS Transactions only)

NOTE

Why the S in SJMS

S stands for Simple and Standard and Springless. Also camel-jms was already taken.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sjms</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

285.1. URI FORMAT

sjms:[queue:]topic:destinationName[?options]

Where destinationName is a JMS queue or topic name. By default, the destinationName is interpreted as a queue name. For example, to connect to the queue, FOO.BAR use:

sjms:FOO.BAR

You can include the optional queue: prefix, if you prefer:
To connect to a topic, you must include the **topic:** prefix. For example, to connect to the topic, **Stocks.Prices**, use:

```
sjms:topic:Stocks.Prices
```

You append query options to the URI using the following format, `?option=value&option=value&...`

### 285.2. COMPONENT OPTIONS AND CONFIGURATIONS

The Simple JMS component supports 15 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>connectionFactory</code> (advanced)</td>
<td>A ConnectionFactory is required to enable the SjmsComponent. It can be set directly or set as part of a ConnectionResource.</td>
<td></td>
<td>ConnectionFactory</td>
</tr>
<tr>
<td><code>connectionResource</code> (advanced)</td>
<td>A ConnectionResource is an interface that allows for customization and container control of the ConnectionFactory. See Plugable Connection Resource Management for further details.</td>
<td></td>
<td>ConnectionResource</td>
</tr>
<tr>
<td><code>connectionCount</code> (common)</td>
<td>The maximum number of connections available to endpoints started under this component</td>
<td>1</td>
<td>Integer</td>
</tr>
<tr>
<td><code>jmsKeyFormatStrategy</code> (advanced)</td>
<td>Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides one implementation out of the box: default. The default strategy will safely marshal dots and hyphens ( . and - ). Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the notation.</td>
<td></td>
<td>JmsKeyFormatStrategy</td>
</tr>
<tr>
<td><code>transactionCommitStrategy</code> (transaction)</td>
<td>To configure which kind of commit strategy to use. Camel provides two implementations out of the box, default and batch.</td>
<td></td>
<td>TransactionCommitStrategy</td>
</tr>
<tr>
<td><code>destinationCreationStrategy</code> (advanced)</td>
<td>To use a custom DestinationCreationStrategy.</td>
<td></td>
<td>DestinationCreationStrategy</td>
</tr>
<tr>
<td><code>timedTaskManager</code> (advanced)</td>
<td>To use a custom TimedTaskManager</td>
<td></td>
<td>TimedTaskManager</td>
</tr>
</tbody>
</table>
messageCreatedStrategy (advanced)
To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.

connectionTestOnBorrow (advanced)
When using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource then should each javax.jms.Connection be tested (calling start) before returned from the pool. true boolean

connectionUsername (security)
The username to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource. String

connectionPassword (security)
The password to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource. String

connectionClientId (advanced)
The client ID to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource. String

connectionMaxWait (advanced)
The max wait time in millis to block and wait on free connection when the pool is exhausted when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource. 5000 long

headerFilterStrategy (filter)
To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. HeaderFilterStrategy

resolvePropertyPlaceholders (advanced)
Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders. true boolean

The Simple JMS endpoint is configured using URI syntax:
sjms:destinationType:destinationName

with the following path and query parameters:
### 285.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>destinationType</td>
<td>The kind of destination to use</td>
<td>queue</td>
<td>String</td>
</tr>
<tr>
<td>destinationName</td>
<td><strong>Required</strong> DestinationName is a JMS queue or topic name. By default, the destinationName is interpreted as a queue name.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 285.2.2. Query Parameters (34 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>acknowledgemen tMode (common)</td>
<td>The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE</td>
<td>AUTO_ACKNOWLEDGE</td>
<td>SessionAcknowledgment Type</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>consumerCount (consumer)</td>
<td>Sets the number of consumer listeners used for this endpoint.</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>durableSubscriptionId (consumer)</td>
<td>Sets the durable subscription Id required for durable topics.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous (consumer)</td>
<td>Sets whether synchronous processing should be strictly used or Camel is allowed to use asynchronous processing (if supported).</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>messageSelector (consumer)</td>
<td>Sets the JMS Message selector syntax.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>namedReplyTo (producer)</td>
<td>Sets the reply to destination name used for InOut producer endpoints.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>persistent (producer)</td>
<td>Flag used to enable/disable message persistence.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>producerCount (producer)</td>
<td>Sets the number of producers used for this endpoint.</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>ttl (producer)</td>
<td>Flag used to adjust the Time To Live value of produced messages.</td>
<td>-1</td>
<td>long</td>
</tr>
<tr>
<td>allowNullBody (producer)</td>
<td>Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSException is thrown.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>prefillPool (producer)</td>
<td>Whether to prefill the producer connection pool on startup, or create connections lazy when needed.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>responseTimeOut (producer)</td>
<td>Sets the amount of time we should wait before timing out a InOut response.</td>
<td>5000</td>
<td>long</td>
</tr>
<tr>
<td>asyncStartListener (advanced)</td>
<td>Whether to startup the consumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>asyncStopListener (advanced)</td>
<td>Whether to stop the consumer message listener asynchronously, when stopping a route.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>connectionCount (advanced)</td>
<td>The maximum number of connections available to this endpoint</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------------</td>
</tr>
<tr>
<td>connectionFactory (advanced)</td>
<td>Initializes the connectionFactory for the endpoint, which takes precedence over the component’s connectionFactory, if any</td>
<td></td>
<td>ConnectionFactory</td>
</tr>
<tr>
<td>connectionResource (advanced)</td>
<td>Initializes the connectionResource for the endpoint, which takes precedence over the component’s connectionResource, if any</td>
<td></td>
<td>ConnectionResource</td>
</tr>
<tr>
<td>destinationCreationStrategy (advanced)</td>
<td>To use a custom DestinationCreationStrategy.</td>
<td></td>
<td>DestinationCreationStrategy</td>
</tr>
<tr>
<td>exceptionListener (advanced)</td>
<td>Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.</td>
<td></td>
<td>ExceptionListener</td>
</tr>
<tr>
<td>headerFilterStrategy (advanced)</td>
<td>To use a custom HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>includeAllJMSXProperties (advanced)</td>
<td>Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom headerFilterStrategy then this option does not apply.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>jmsKeyFormatStrategy (advanced)</td>
<td>Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the notation.</td>
<td></td>
<td>JmsKeyFormatStrategy</td>
</tr>
<tr>
<td>mapJmsMessage (advanced)</td>
<td>Specifies whether Camel should auto map the received JMS message to a suited payload type, such as javax.jms.TextMessage to a String etc. See section about how mapping works below for more details.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>messageCreatedStrategy (advanced)</td>
<td>To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.</td>
<td></td>
<td>MessageCreatedStrategy</td>
</tr>
<tr>
<td>errorHandlerLoggingLevel (logging)</td>
<td>Allows to configure the default errorHandler logging level for logging uncaught exceptions.</td>
<td>WARN</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>errorHandlerLogStackTrace</td>
<td>Allows to control whether stacktraces should be logged or not, by the default errorHandler.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>transacted</td>
<td>Specifies whether to use transacted mode</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>transactionBatchCount</td>
<td>If transacted sets the number of messages to process before committing a transaction.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>transactionBatchTimeout</td>
<td>Sets timeout (in millis) for batch transactions, the value should be 1000 or higher.</td>
<td>5000</td>
<td>long</td>
</tr>
<tr>
<td>transactionCommitStrategy</td>
<td>Sets the commit strategy.</td>
<td></td>
<td>TransactionCommitStrategy</td>
</tr>
<tr>
<td>sharedJMSSession</td>
<td>Specifies whether to share JMS session with other SJMS endpoints. Turn this off if your route is accessing to multiple JMS providers. If you need transaction against multiple JMS providers, use jms component to leverage XA transaction.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

Below is an example of how to configure the **SjmsComponent** with its required **ConnectionFactory** provider. It will create a single connection by default and store it using the components internal pooling APIs to ensure that it is able to service Session creation requests in a thread safe manner.

```java
SjmsComponent component = new SjmsComponent();
component.setConnectionFactory(new ActiveMQConnectionFactory("tcp://localhost:61616"));
getContext().addComponent("sjms", component);
```

For a SJMS component that is required to support a durable subscription, you can override the default **ConnectionFactoryResource** instance and set the **clientId** property.

```java
ConnectionFactoryResource connectionResource = new ConnectionFactoryResource();
connectionResource.setConnectionFactory(new ActiveMQConnectionFactory("tcp://localhost:61616"));
connectionResource.setClientId("myclient-id");
SjmsComponent component = new SjmsComponent();
component.setConnectionResource(connectionResource);
component.setMaxConnections(1);
```

**285.3. PRODUCER USAGE**
285.3.1. InOnly Producer - (Default)

The InOnly producer is the default behavior of the SJMS Producer Endpoint.

```java
from("direct:start")
  .to("sjms:queue:bar");
```

285.3.2. InOut Producer

To enable InOut behavior append the exchangePattern attribute to the URI. By default it will use a dedicated TemporaryQueue for each consumer.

```java
from("direct:start")
  .to("sjms:queue:bar?exchangePattern=InOut");
```

You can specify a namedReplyTo though which can provide a better monitor point.

```java
from("direct:start")
  .to("sjms:queue:bar?exchangePattern=InOut&namedReplyTo=my.reply.to.queue");
```

285.4. CONSUMER USAGE

285.4.1. InOnly Consumer - (Default)

The InOnly consumer is the default Exchange behavior of the SJMS Consumer Endpoint.

```java
from("sjms:queue:bar")
  .to("mock:result");
```

285.4.2. InOut Consumer

To enable InOut behavior append the exchangePattern attribute to the URI.

```java
from("sjms:queue:in.out.test?exchangePattern=InOut")
  .transform(constant("Bye Camel"));
```

285.5. ADVANCED USAGE NOTES

285.5.1. Plugable Connection Resource Management

SJMS provides JMS Connection resource management through built-in connection pooling. This eliminates the need to depend on third party API pooling logic. However there may be times that you are required to use an external Connection resource manager such as those provided by J2EE or OSGi containers. For this SJMS provides an interface that can be used to override the internal SJMS Connection pooling capabilities. This is accomplished through the ConnectionResource interface.

The ConnectionResource provides methods for borrowing and returning Connections as needed is the contract used to provide Connection pools to the SJMS component. A user should use when it is necessary to integrate SJMS with an external connection pooling manager.
It is recommended though that for standard ConnectionFactory providers you use the ConnectionFactoryResource implementation that is provided with SJMS as-is or extend as it is optimized for this component.

Below is an example of using the plugable ConnectionResource with the ActiveMQ PooledConnectionFactory:

```java
public class AMQConnectionResource implements ConnectionResource {
    private PooledConnectionFactory pcf;

    public AMQConnectionResource(String connectString, int maxConnections) {
        super();
        pcf = new PooledConnectionFactory(connectString);
        pcf.setMaxConnections(maxConnections);
        pcf.start();
    }

    public void stop() {
        pcf.stop();
    }

    @Override
    public Connection borrowConnection() throws Exception {
        Connection answer = pcf.createConnection();
        answer.start();
        return answer;
    }

    @Override
    public Connection borrowConnection(long timeout) throws Exception {
        // SNIPPED...
    }

    @Override
    public void returnConnection(Connection connection) throws Exception {
        // Do nothing since there isn't a way to return a Connection
        // to the instance of PooledConnectionFactory
        log.info("Connection returned");
    }
}
```

Then pass in the ConnectionResource to the SjmsComponent:

```java
CamelContext camelContext = new DefaultCamelContext();
AMQConnectionResource pool = new AMQConnectionResource("tcp://localhost:33333", 1);
SjmsComponent component = new SjmsComponent();
component.setConnectionResource(pool);
camelContext.addComponent("sjms", component);
```

To see the full example of its usage please refer to the ConnectionResourceIT.

285.5.2. Batch Message Support
The SjmsProducer supports publishing a collection of messages by creating an Exchange that encapsulates a List. This SjmsProducer will take then iterate through the contents of the List and publish each message individually.

If when producing a batch of messages there is the need to set headers that are unique to each message you can use the SJMS BatchMessage class. When the SjmsProducer encounters a BatchMessage list it will iterate each BatchMessage and publish the included payload and headers.

Below is an example of using the BatchMessage class. First we create a list of BatchMessage:

```java
List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();
for (int i = 1; i <= messageCount; i++) {
    String body = "Hello World " + i;
    BatchMessage<String> message = new BatchMessage<String>(body, null);
    messages.add(message);
}
```

Then publish the list:

```java
template.sendBody("sjms:queue:batch.queue", messages);
```

285.5.3. Customizable Transaction Commit Strategies (Local JMS Transactions only)

SJMS provides a developer the means to create a custom and plugable transaction strategy through the use of the TransactionCommitStrategy interface. This allows a user to define a unique set of circumstances that the SessionTransactionSynchronization will use to determine when to commit the Session. An example of its use is the BatchTransactionCommitStrategy which is detailed further in the next section.

285.5.4. Transacted Batch Consumers & Producers

The SJMS component has been designed to support the batching of local JMS transactions on both the Producer and Consumer endpoints. How they are handled on each is very different though.

The SJMS consumer endpoint is a straightforward implementation that will process X messages before committing them with the associated Session. To enable batched transaction on the consumer first enable transactions by setting the transacted parameter to true and then adding the transactionBatchCount and setting it to any value that is greater than 0. For example the following configuration will commit the Session every 10 messages:

```java
sjms:queue:transacted.batch.consumer?transacted=true&transactionBatchCount=10
```

If an exception occurs during the processing of a batch on the consumer endpoint, the Session rollback is invoked causing the messages to be redelivered to the next available consumer. The counter is also reset to 0 for the BatchTransactionCommitStrategy for the associated Session as well. It is the responsibility of the user to ensure they put hooks in their processors of batch messages to watch for messages with the JMSRedelivered header set to true. This is the indicator that messages were rolled back at some point and that a verification of a successful processing should occur.

A transacted batch consumer also carries with it an instance of an internal timer that waits a default amount of time (5000ms) between messages before committing the open transactions on the Session. The default value of 5000ms (minimum of 1000ms) should be adequate for most use-cases but if further tuning is necessary simply set the transactionBatchTimeout parameter.
The minimal value that will be accepted is 1000ms as the amount of context switching may cause unnecessary performance impacts without gaining benefit.

The producer endpoint is handled much differently though. With the producer after each message is delivered to its destination the Exchange is closed and there is no longer a reference to that message. To make a available all the messages available for redelivery you simply enable transactions on a Producer Endpoint that is publishing BatchMessages. The transaction will commit at the conclusion of the exchange which includes all messages in the batch list. Nothing additional need be configured. For example:

```java
List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();
for (int i = 1; i <= messageCount; i++) {
    String body = "Hello World " + i;
    BatchMessage<String> message = new BatchMessage<String>(body, null);
    messages.add(message);
}
```

Now publish the List with transactions enabled:

```java
template.sendBody("sjms:queue:batch.queue?transacted=true", messages);
```

### 285.6. ADDITIONAL NOTES

#### 285.6.1. Message Header Format

The SJMS Component uses the same header format strategy that is used in the Camel JMS Component. This plugable strategy ensures that messages sent over the wire conform to the JMS Message spec.

For the `exchange.in.header` the following rules apply for the header keys:

- Keys starting with `JMS` or `JMSX` are reserved.
- `exchange.in.headers` keys must be literals and all be valid Java identifiers (do not use dots in the key name).
- Camel replaces dots & hyphens and the reverse when consuming JMS messages:
  - is replaced by `DOT` and the reverse replacement when Camel consumes the message.
  - is replaced by `HYPHEN` and the reverse replacement when Camel consumes the message. See also the option `jmsKeyFormatStrategy`, which allows use of your own custom strategy for formatting keys.

For the `exchange.in.header`, the following rules apply for the header values:

#### 285.6.2. Message Content

To deliver content over the wire we must ensure that the body of the message that is being delivered adheres to the JMS Message Specification. Therefore, all that are produced must either be primitives or their counter objects (such as `Integer`, `Long`, `Character`). The types, `String`, `CharSequence`, `Date`,

```java
List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();
for (int i = 1; i <= messageCount; i++) {
    String body = "Hello World " + i;
    BatchMessage<String> message = new BatchMessage<String>(body, null);
    messages.add(message);
}
```

```java
template.sendBody("sjms:queue:batch.queue?transacted=true", messages);
```
**BigDecimal** and **BigInteger** are all converted to their `toString()` representation. All other types are dropped.

### 285.6.3. Clustering

When using `InOut` with SJMS in a clustered environment you must either use TemporaryQueue destinations or use a unique named reply to destination per InOut producer endpoint. Message correlation is handled by the endpoint, not with message selectors at the broker. The InOut Producer Endpoint uses Java Concurrency Exchangers cached by the Message `JMSCorrelationID`. This provides a nice performance increase while reducing the overhead on the broker since all the messages are consumed from the destination in the order they are produced by the interested consumer.

Currently the only correlation strategy is to use the `JMSCorrelationId`. The `InOut` Consumer uses this strategy as well ensuring that all responses messages to the included `JMSReplyTo` destination also have the `JMSCorrelationId` copied from the request as well.

### 285.7. TRANSACTION SUPPORT

SJMS currently only supports the use of internal JMS Transactions. There is no support for the Camel Transaction Processor or the Java Transaction API (JTA).

#### 285.7.1. Does Springless Mean I Can’t Use Spring?

Not at all. Below is an example of the SJMS component using the Spring DSL:

```xml
<route id="inout.named.reply.to.producer.route">
  <from uri="direct:invoke.named.reply.to.queue" />
  <to uri="sjms:queue:named.reply.to.queue?namedReplyTo=my.response.queue&exchangePattern=InOut" />
</route>
```

Springless refers to moving away from the dependency on the Spring JMS API. A new JMS client API is being developed from the ground up to power SJMS.
The Simple JMS 2.0 Component, or SJMS2, is a JMS client for use with Camel that uses well known best practices when it comes to JMS client creation and configuration. SJMS2 contains a brand new JMS 2.0 client API written explicitly for Camel eliminating third party messaging implementations keeping it light and resilient. The following features is included:

- Standard Queue and Topic Support (Durable & Non-Durable)
- InOnly & InOut MEP Support
- Asynchronous Producer and Consumer Processing
- Internal JMS Transaction Support

Additional key features include:

- Plugable Connection Resource Management
- Session, Consumer, & Producer Pooling & Caching Management
- Batch Consumers and Producers
- Transacted Batch Consumers & Producers
- Support for Customizable Transaction Commit Strategies (Local JMS Transactions only)

**NOTE**

Why the S in SJMS

S stands for Simple and Standard and Springless. Also camel-jms was already taken.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sjms2</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 286.1. URI FORMAT

```
sjms2:[queue:|topic:]destinationName[?options]
```

Where `destinationName` is a JMS queue or topic name. By default, the `destinationName` is interpreted as a queue name. For example, to connect to the queue, `FOO.BAR` use:

```
sjms2:FOO.BAR
```

You can include the optional `queue:` prefix, if you prefer:
To connect to a topic, you must include the `topic:` prefix. For example, to connect to the topic, `Stocks.Prices`, use:

```
sjms2:topic:Stocks.Prices
```

You append query options to the URI using the following format, `?option=value&option=value&...`

### 286.2. COMPONENT OPTIONS AND CONFIGURATIONS

The Simple JMS2 component supports 15 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>connectionFactory</code></td>
<td>A ConnectionFactory is required to enable the SjmsComponent. It can be set directly or set as part of a ConnectionResource.</td>
<td></td>
<td>ConnectionFactory</td>
</tr>
<tr>
<td><code>connectionResource</code></td>
<td>A ConnectionResource is an interface that allows for customization and container control of the ConnectionFactory. See Plugable Connection Resource Management for further details.</td>
<td></td>
<td>ConnectionResource</td>
</tr>
<tr>
<td><code>connectionCount</code></td>
<td>The maximum number of connections available to endpoints started under this component</td>
<td>1</td>
<td>Integer</td>
</tr>
<tr>
<td><code>jmsKeyFormatStrategy</code></td>
<td>Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides one implementation out of the box: default. The default strategy will safely marshal dots and hyphens (. and -). Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the notation.</td>
<td></td>
<td>JmsKeyFormatStrategy</td>
</tr>
<tr>
<td><code>transactionCommitStrategy</code></td>
<td>To configure which kind of commit strategy to use. Camel provides two implementations out of the box, default and batch.</td>
<td></td>
<td>TransactionCommitStrategy</td>
</tr>
<tr>
<td><code>destinationCreationStrategy</code></td>
<td>To use a custom DestinationCreationStrategy.</td>
<td></td>
<td>DestinationCreationStrategy</td>
</tr>
<tr>
<td><code>timedTaskManager</code></td>
<td>To use a custom TimedTaskManager</td>
<td></td>
<td>TimedTaskManager</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td>messageCreatedStrategy (advanced)</td>
<td>To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.</td>
<td></td>
<td>MessageCreatedStrategy</td>
</tr>
<tr>
<td>connectionTestOnBorrow (advanced)</td>
<td>When using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource then should each javax.jms.Connection be tested (calling start) before returned from the pool.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>connectionUsername (security)</td>
<td>The username to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>connectionPassword (security)</td>
<td>The password to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>connectionClientId (advanced)</td>
<td>The client ID to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>connectionMaxWait (advanced)</td>
<td>The max wait time in millis to block and wait on free connection when the pool is exhausted when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.</td>
<td>5000</td>
<td>long</td>
</tr>
<tr>
<td>headerFilterStrategy (filter)</td>
<td>To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Simple JMS2 endpoint is configured using URI syntax:

```
sjms2:destinationType:destinationName
```

with the following path and query parameters:
286.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>destinationType</td>
<td>The kind of destination to use</td>
<td>queue</td>
<td>String</td>
</tr>
<tr>
<td>destinationName</td>
<td><strong>Required</strong> DestinationName is a JMS queue or topic name. By default, the destinationName is interpreted as a queue name.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

286.2.2. Query Parameters (37 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>acknowledgemen</td>
<td>The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE</td>
<td>AUTO_ACKNOWLEDGEMENT</td>
<td>SessionAcknowledgement Type</td>
</tr>
<tr>
<td>tMode (common)</td>
<td></td>
<td>AUTO_ACKNOWLEDGE</td>
<td>SessionAcknowledgement Type</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>

</tr>
<tr>
<td>destinationCreationStrategy (advanced)</td>
<td>To use a custom DestinationCreationStrategy.</td>
<td></td>
<td>DestinationCreationStrategy</td>
</tr>
<tr>
<td>exceptionListener (advanced)</td>
<td>Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.</td>
<td></td>
<td>ExceptionListener</td>
</tr>
<tr>
<td>headerFilterStrategy (advanced)</td>
<td>To use a custom HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
<tr>
<td>includeAllJMSXProperties (advanced)</td>
<td>Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom headerFilterStrategy then this option does not apply.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>jmsKeyFormatStrategy (advanced)</td>
<td>Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the notation.</td>
<td></td>
<td>JmsKeyFormatStrategy</td>
</tr>
<tr>
<td>mapJmsMessage (advanced)</td>
<td>Specifies whether Camel should auto map the received JMS message to a suited payload type, such as javax.jms.TextMessage to a String etc. See section about how mapping works below for more details.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
---|---|---|---
messageCreatedStrategy (advanced) | To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message. | | MessageCreatedStrategy
errorHandlerLoggingLevel (logging) | Allows to configure the default errorHandler logging level for logging uncaught exceptions. | WARN | LoggingLevel
errorHandlerLogStackTrace (logging) | Allows to control whether stacktraces should be logged or not, by the default errorHandler. | true | boolean
transacted (transaction) | Specifies whether to use transacted mode | false | boolean
transactionBatchCount (transaction) | If transacted sets the number of messages to process before committing a transaction. | -1 | int
transactionBatchTimeout (transaction) | Sets timeout (in millis) for batch transactions, the value should be 1000 or higher. | 5000 | long
transactionCommitStrategy (transaction) | Sets the commit strategy. | | TransactionCommitStrategy
sharedJMSSession (transaction) | Specifies whether to share JMS session with other SJMS endpoints. Turn this off if your route is accessing to multiple JMS providers. If you need transaction against multiple JMS providers, use jms component to leverage XA transaction. | true | boolean

Below is an example of how to configure the **S.jms2Component** with its required **ConnectionFactory** provider. It will create a single connection by default and store it using the component’s internal pooling APIs to ensure that it is able to service Session creation requests in a thread safe manner.

```java
S.jms2Component component = new S.jms2Component();
component.setConnectionFactory(new ActiveMQConnectionFactory("tcp://localhost:61616"));
getContext().addComponent("sjms2", component);
```

For a SJMS2 component that is required to support a durable subscription, you can override the default **ConnectionFactoryResource** instance and set the clientId property.

```java
ConnectionFactoryResource connectionResource = new ConnectionFactoryResource();
```
286.3. PRODUCER USAGE

286.3.1. InOnly Producer - (Default)

The *InOnly* producer is the default behavior of the SJMS2 Producer Endpoint.

```java
from("direct:start")
  .to("sjms2:queue:bar");
```

286.3.2. InOut Producer

To enable *InOut* behavior append the `exchangePattern` attribute to the URI. By default it will use a dedicated TemporaryQueue for each consumer.

```java
from("direct:start")
  .to("sjms2:queue:bar?exchangePattern=InOut");
```

You can specify a `namedReplyTo` though which can provide a better monitor point.

```java
from("direct:start")
  .to("sjms2:queue:bar?exchangePattern=InOut&namedReplyTo=my.reply.to.queue");
```

286.4. CONSUMER USAGE

286.4.1. Durable Shared Subscription

To create a durable subscription that can be shared between one or more consumers. Use a JMS 2.0 compliant connection factory and specify a common subscriptionId. Then set the subscription properties durable and shared to true.

```java
from("sjms2:topic:foo?consumerCount=3&subscriptionId=bar&durable=true&shared=true")
  .to("mock:result");
from("sjms2:topic:foo?consumerCount=2&subscriptionId=bar&durable=true&shared=true")
  .to("mock:result");
```

286.4.2. InOnly Consumer - (Default)

The *InOnly* consumer is the default Exchange behavior of the SJMS2 Consumer Endpoint.

```java
from("sjms2:queue:bar")
  .to("mock:result");
```
### 286.4.3. InOut Consumer

To enable InOut behavior append the `exchangePattern` attribute to the URI.

```java
from("sjms2:queue:in.out.test?exchangePattern=InOut")
  .transform(constant("Bye Camel"));
```

### 286.5. ADVANCED USAGE NOTES

#### 286.5.1. Plugable Connection Resource Management

SJMS2 provides JMS `Connection` resource management through built-in connection pooling. This eliminates the need to depend on third party API pooling logic. However there may be times that you are required to use an external Connection resource manager such as those provided by J2EE or OSGi containers. For this SJMS2 provides an interface that can be used to override the internal SJMS2 Connection pooling capabilities. This is accomplished through the `ConnectionResource` interface.

The `ConnectionResource` provides methods for borrowing and returning Connections as needed is the contract used to provide `Connection` pools to the SJMS2 component. A user should use when it is necessary to integrate SJMS2 with an external connection pooling manager.

It is recommended though that for standard `ConnectionFactory` providers you use the `ConnectionFactoryResource` implementation that is provided with SJMS2 as-is or extend as it is optimized for this component.

Below is an example of using the plugable ConnectionResource with the ActiveMQ `PooledConnectionFactory`:

```java
class AMQConnectionResource implements ConnectionResource {
  private PooledConnectionFactory pcf;

  public AMQConnectionResource(String connectString, int maxConnections) {
    super();
    pcf = new PooledConnectionFactory(connectString);
    pcf.setMaxConnections(maxConnections);
    pcf.start();
  }

  public void stop() {
    pcf.stop();
  }

  @Override
  public Connection borrowConnection() throws Exception {
    Connection answer = pcf.createConnection();
    answer.start();
    return answer;
  }

  @Override
  public Connection borrowConnection(long timeout) throws Exception {
    // SNIPPED...
  }
}
```
Then pass in the `ConnectionResource` to the `Sjms2Component`:

```java
@override
public void returnConnection(Connection connection) throws Exception {
    // Do nothing since there isn't a way to return a Connection
    // to the instance of PooledConnectionFactory
    log.info("Connection returned");
}
```

Then see the full example of its usage please refer to the `ConnectionResourceIT`.

### 286.5.2. Session, Consumer, & Producer Pooling & Caching Management

Coming soon …

### 286.5.3. Batch Message Support

The Sjms2Producer supports publishing a collection of messages by creating an Exchange that encapsulates a `List`. This Sjms2Producer will take then iterate through the contents of the List and publish each message individually.

If when producing a batch of messages there is the need to set headers that are unique to each message you can use the SJMS2 `BatchMessage` class. When the Sjms2Producer encounters a `BatchMessage` list it will iterate each `BatchMessage` and publish the included payload and headers.

Below is an example of using the `BatchMessage` class. First we create a list of `BatchMessage`:

```java
List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();
for (int i = 1; i <= messageCount; i++) {
    String body = "Hello World " + i;
    BatchMessage<String> message = new BatchMessage<String>(body, null);
    messages.add(message);
}
```

Then publish the list:

```java
template.sendBody("sjms2:queue:batch.queue", messages);
```

### 286.5.4. Customizable Transaction Commit Strategies (Local JMS Transactions only)

SJMS2 provides a developer the means to create a custom and plugable transaction strategy through the use of the `TransactionCommitStrategy` interface. This allows a user to define a unique set of circumstances that the `SessionTransactionSynchronization` will use to determine when to commit the Session. An example of its use is the `BatchTransactionCommitStrategy` which is detailed further in the next section.
286.5.5. Transacted Batch Consumers & Producers

The SJMS2 component has been designed to support the batching of local JMS transactions on both the Producer and Consumer endpoints. How they are handled on each is very different though.

The SJMS2 consumer endpoint is a straightforward implementation that will process X messages before committing them with the associated Session. To enable batched transaction on the consumer first enable transactions by setting the `transacted` parameter to true and then adding the `transactionBatchCount` and setting it to any value that is greater than 0. For example the following configuration will commit the Session every 10 messages:

```
sjms2:queue:transacted.batch.consumer?transacted=true&transactionBatchCount=10
```

If an exception occurs during the processing of a batch on the consumer endpoint, the Session rollback is invoked causing the messages to be redelivered to the next available consumer. The counter is also reset to 0 for the `BatchTransactionCommitStrategy` for the associated Session as well. It is the responsibility of the user to ensure they put hooks in their processors of batch messages to watch for messages with the JMSRedelivered header set to true. This is the indicator that messages were rolled back at some point and that a verification of a successful processing should occur.

A transacted batch consumer also carries with it an instance of an internal timer that waits a default amount of time (5000ms) between messages before committing the open transactions on the Session. The default value of 5000ms (minimum of 1000ms) should be adequate for most use-cases but if further tuning is necessary simply set the `transactionBatchTimeout` parameter.

```
```

The minimal value that will be accepted is 1000ms as the amount of context switching may cause unnecessary performance impacts without gaining benefit.

The producer endpoint is handled much differently though. With the producer after each message is delivered to its destination the Exchange is closed and there is no longer a reference to that message. To make a available all the messages available for redelivery you simply enable transactions on a Producer Endpoint that is publishing BatchMessages. The transaction will commit at the conclusion of the exchange which includes all messages in the batch list. Nothing additional need be configured. For example:

```
List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();
for (int i = 1; i <= messageCount; i++) {
    String body = "Hello World " + i;
    BatchMessage<String> message = new BatchMessage<String>(body, null);
    messages.add(message);
}
```

Now publish the List with transactions enabled:

```
template.sendBody("sjms2:queue:batch.queue?transacted=true", messages);
```

### 286.6. ADDITIONAL NOTES

#### 286.6.1. Message Header Format
The SJMS2 Component uses the same header format strategy that is used in the Camel JMS Component. This plugable strategy ensures that messages sent over the wire conform to the JMS Message spec.

For the `exchange.in.header` the following rules apply for the header keys:

- Keys starting with `JMS` or `JMSX` are reserved.
- `exchange.in.headers` keys must be literals and all be valid Java identifiers (do not use dots in the key name).
- Camel replaces dots & hyphens and the reverse when consuming JMS messages:
  - is replaced by `DOT` and the reverse replacement when Camel consumes the message.
  - is replaced by `HYPHEN` and the reverse replacement when Camel consumes the message.

See also the option `jmsKeyFormatStrategy`, which allows use of your own custom strategy for formatting keys.

For the `exchange.in.header`, the following rules apply for the header values:

**286.6.2. Message Content**

To deliver content over the wire we must ensure that the body of the message that is being delivered adheres to the JMS Message Specification. Therefore, all that are produced must either be primitives or their counter objects (such as `Integer`, `Long`, `Character`). The types, `String`, `CharSequence`, `Date`, `BigDecimal` and `BigInteger` are all converted to their `toString()` representation. All other types are dropped.

**286.6.3. Clustering**

When using `InOut` with SJMS2 in a clustered environment you must either use TemporaryQueue destinations or use a unique named reply to destination per InOut producer endpoint. Message correlation is handled by the endpoint, not with message selectors at the broker. The InOut Producer Endpoint uses Java Concurrency Exchangers cached by the Message `JMSCorrelationID`. This provides a nice performance increase while reducing the overhead on the broker since all the messages are consumed from the destination in the order they are produced by the interested consumer.

Currently the only correlation strategy is to use the `JMSCorrelationId`. The `InOut` Consumer uses this strategy as well ensuring that all responses messages to the included `JMSReplyTo` destination also have the `JMSCorrelationId` copied from the request as well.

**286.7. TRANSACTION SUPPORT**

SJMS2 currently only supports the use of internal JMS Transactions. There is no support for the Camel Transaction Processor or the Java Transaction API (JTA).

**286.7.1. Does Springless Mean I Can’t Use Spring?**

Not at all. Below is an example of the SJMS2 component using the Spring DSL:

```xml
<route
  id="inout.named.reply.to.producer.route">
  <from
    url="direct:invoke.named.reply.to.queue" />
</route>
```
Springless refers to moving away from the dependency on the Spring JMS API. A new JMS client API is being developed from the ground up to power SJMS2.
CHAPTER 287. SLACK COMPONENT

Available as of Camel version 2.16

The slack component allows you to connect to an instance of Slack and delivers a message contained in the message body via a pre established Slack incoming webhook.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-slack</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

287.1. URI FORMAT

To send a message to a channel.

```
slack:#channel[?options]
```

To send a direct message to a slackuser.

```
slack:@username[?options]
```

287.2. OPTIONS

The Slack component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>webhookUrl (producer)</td>
<td>The incoming webhook URL</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Slack endpoint is configured using URI syntax:

```
slack:channel
```

with the following path and query parameters:

287.2.1. Path Parameters (1 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>channel</td>
<td>Required The channel name (syntax name) or slackuser (syntax userName) to send a message directly to an user.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 287.2.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>iconEmoji</td>
<td>Use a Slack emoji as an avatar</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>iconUrl</td>
<td>The avatar that the component will use when sending message to a channel or user.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>username</td>
<td>This is the username that the bot will have when sending messages to a channel or user.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>webhookUrl</td>
<td>The incoming webhook URL</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 287.3. SLACKCOMPONENT

The SlackComponent with XML must be configured as a Spring or Blueprint bean that contains the incoming webhook url for the integration as a parameter.

```xml
<bean id="slack" class="org.apache.camel.component.slack.SlackComponent">
  <property name="webhookUrl" value="https://hooks.slack.com/services/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"/>
</bean>
```

For Java you can configure this using Java code.

### 287.4. EXAMPLE

A CamelContext with Blueprint could be as:

```xml
<bean id="slack" class="org.apache.camel.component.slack.SlackComponent">
  <property name="webhookUrl"/>
</bean>
```
value="https://hooks.slack.com/services/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"/
</bean>

<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <route>
    <from uri="direct:test"/>
    <to uri="slack:#channel?iconEmoji=:camel:&username=CamelTest"/>
  </route>
</camelContext>

</blueprint>

287.5. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 288. SMPP COMPONENT

Available as of Camel version 2.2

This component provides access to an SMSC (Short Message Service Center) over the SMPP protocol to send and receive SMS. The JSMPP library is used for the protocol implementation.

The Camel component currently operates as an ESME (External Short Messaging Entity) and not as an SMSC itself.

Starting with *Camel 2.9* you are also able to execute ReplaceSm, QuerySm, SubmitMulti, CancelSm and DataSm.

Maven users will need to add the following dependency to their *pom.xml* for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-smpp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

288.1. SMS LIMITATIONS

SMS is neither reliable or secure. Users who require reliable and secure delivery may want to consider using the XMPP or SIP components instead, combined with a smartphone app supporting the chosen protocol.

- **Reliability**: although the SMPP standard offers a range of feedback mechanisms to indicate errors, non-delivery and confirmation of delivery it is not uncommon for mobile networks to hide or simulate these responses. For example, some networks automatically send a delivery confirmation for every message even if the destination number is invalid or not switched on. Some networks silently drop messages if they think they are spam. Spam detection rules in the network may be very crude, sometimes more than 100 messages per day from a single sender may be considered spam.

- **Security**: there is basic encryption for the last hop from the radio tower down to the recipient handset. SMS messages are not encrypted or authenticated in any other part of the network. Some operators allow staff in retail outlets or call centres to browse through the SMS message histories of their customers. Message sender identity can be easily forged. Regulators and even the mobile telephone industry itself has cautioned against the use of SMS in two-factor authentication schemes and other purposes where security is important.

While the Camel component makes it as easy as possible to send messages to the SMS network, it cannot offer an easy solution to these problems.

288.2. DATA CODING, ALPHABET AND INTERNATIONAL CHARACTER SETS

Data coding and alphabet can be specified on a per-message basis. Default values can be specified for the endpoint. It is important to understand the relationship between these options and the way the component acts when more than one value is set.

Data coding is an 8 bit field in the SMPP wire format.
Alphabet corresponds to bits 0-3 of the data coding field. For some types of message, where a message class is used (by setting bit 5 of the data coding field), the lower two bits of the data coding field are not interpreted as alphabet and only bits 2 and 3 impact the alphabet.

Furthermore, current version of the JSMPP library only seems to support bits 2 and 3, assuming that bits 0 and 1 are used for message class. This is why the Alphabet class in JSMPP doesn’t support the value 3 (binary 0011) which indicates ISO-8859-1.

Although JSMPP provides a representation of the message class parameter, the Camel component doesn’t currently provide a way to set it other than manually setting the corresponding bits in the data coding field.

When setting the data coding field in the outgoing message, the Camel component considers the following values and uses the first one it can find:

- the data coding specified in a header
- the alphabet specified in a header
- the data coding specified in the endpoint configuration (URI parameter)

Older versions of Camel had bugs in support for international character sets. This feature only worked when a single encoding was used for all messages and was troublesome when users wanted to change it on a per-message basis. Users who require this to work should ensure their version of Camel includes the fix for

In addition to trying to send the data coding value to the SMSC, the Camel component also tries to analyze the message body, convert it to a Java String (Unicode) and convert that to a byte array in the corresponding alphabet. When deciding which alphabet to use in the byte array, the Camel SMPP component does not consider the data coding value (header or configuration), it only considers the specified alphabet (from either the header or endpoint parameter).

If some characters in the String can’t be represented in the chosen alphabet, they may be replaced by the question mark (?) symbol. Users of the API may want to consider checking if their message body can be converted to ISO-8859-1 before passing it to the component and if not, setting the alphabet header to request UCS-2 encoding. If the alphabet and data coding options are not specified at all then the component may try to detect the required encoding and set the data coding for you.

The list of alphabet codes are specified in the SMPP specification v3.4, section 5.2.19. One notable limitation of the SMPP specification is that there is no alphabet code for explicitly requesting use of the GSM 3.38 (7 bit) character set. Choosing the value 0 for the alphabet selects the SMSC default alphabet, this usually means GSM 3.38 but it is not guaranteed. The SMPP gateway Nexmo actually allows the default to be mapped to any other character set with a control panel option. It is suggested that users check with their SMSC operator to confirm exactly which character set is being used as the default.

288.3. MESSAGE SPLITTING AND THROTTLING

After transforming a message body from a String to a byte array, the Camel component is also responsible for splitting the message into parts (within the 140 byte SMS size limit) before passing it to JSMPP. This is completed automatically.
If the GSM 3.38 alphabet is used, the component will pack up to 160 characters into the 140 byte message body. If an 8 bit character set is used (e.g. ISO-8859-1 for western Europe) then 140 characters will be allowed within the 140 byte message body. If 16 bit UCS-2 encoding is used then just 70 characters fit into each 140 byte message.

Some SMSC providers implement throttling rules. Each part of a message that has been split may be counted separately by the provider’s throttling mechanism. The Camel Throttler component can be useful for throttling messages in the SMPP route before handing them to the SMSC.

288.4. URI FORMAT

```
smpp: //[username@]hostname[:port][?options]
smpp://[username@]hostname[:port][?options]
```

If no `username` is provided, then Camel will provide the default value `smppclient`. If no `port` number is provided, then Camel will provide the default value `2775`. **Camel 2.3:** If the protocol name is “smpps”, camel-smpp with try to use SSLSocket to init a connection to the server.

You can append query options to the URI in the following format, `?option=value&option=value&…`

288.5. URI OPTIONS

The SMPP component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>configuration</code> (advanced)</td>
<td>To use the shared SmppConfiguration as configuration.</td>
<td></td>
<td>SmppConfiguration</td>
</tr>
<tr>
<td><code>resolveProperty Placeholders</code> (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The SMPP endpoint is configured using URI syntax:

```
smpp:host:port
```

with the following path and query parameters:

288.5.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Hostname for the SMSC server to use.</td>
<td>localhost</td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>port</td>
<td>Port number for the SMSC server to use.</td>
<td>2775</td>
<td>Integer</td>
</tr>
</tbody>
</table>

288.5.2. Query Parameters (38 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>initialReconnectDelay (common)</td>
<td>Defines the initial delay in milliseconds after the consumer/producer tries to reconnect to the SMSC, after the connection was lost.</td>
<td>5000</td>
<td>long</td>
</tr>
<tr>
<td>maxReconnect (common)</td>
<td>Defines the maximum number of attempts to reconnect to the SMSC, if SMSC returns a negative bind response</td>
<td>214748 3647</td>
<td>int</td>
</tr>
<tr>
<td>reconnectDelay (common)</td>
<td>Defines the interval in milliseconds between the reconnect attempts, if the connection to the SMSC was lost and the previous was not succeed.</td>
<td>5000</td>
<td>long</td>
</tr>
<tr>
<td>splittingPolicy (common)</td>
<td>You can specify a policy for handling long messages: ALLOW - the default, long messages are split to 140 bytes per message TRUNCATE - long messages are split and only the first fragment will be sent to the SMSC. Some carriers drop subsequent fragments so this reduces load on the SMPP connection sending parts of a message that will never be delivered. REJECT - if a message would need to be split, it is rejected with an SMPP NegativeResponseException and the reason code signifying the message is too long.</td>
<td>ALLOW</td>
<td>SmppSplittingPolicy</td>
</tr>
<tr>
<td>systemType (common)</td>
<td>This parameter is used to categorize the type of ESME (External Short Message Entity) that is binding to the SMSC (max. 13 characters).</td>
<td>cp</td>
<td>String</td>
</tr>
<tr>
<td>addressRange (consumer)</td>
<td>You can specify the address range for the SmppConsumer as defined in section 5.2.7 of the SMPP 3.4 specification. The SmppConsumer will receive messages only from SMSC’s which target an address (MSISDN or IP address) within this range.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>destAddr (producer)</td>
<td>Defines the destination SME address. For mobile terminated messages, this is the directory number of the recipient MS. Only for SubmitSm, SubmitMulti, CancelSm and DataSm.</td>
<td>1717</td>
<td>String</td>
</tr>
<tr>
<td>destAddrNpi (producer)</td>
<td>Defines the type of number (TON) to be used in the SME destination address parameters. Only for SubmitSm, SubmitMulti, CancelSm and DataSm. The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>destAddrTon (producer)</td>
<td>Defines the type of number (TON) to be used in the SME destination address parameters. Only for SubmitSm, SubmitMulti, CancelSm and DataSm. The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>lazySessionCreation (producer)</td>
<td>Sessions can be lazily created to avoid exceptions, if the SMSC is not available when the Camel producer is started. Camel will check the in message headers 'CamelSmppSystemId' and 'CamelSmppPassword' of the first exchange. If they are present, Camel will use these data to connect to the SMSC.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>numberingPlanIndicator (producer)</td>
<td>Defines the numeric plan indicator (NPI) to be used in the SME. The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>priorityFlag (producer)</td>
<td>Allows the originating SME to assign a priority level to the short message. Only for SubmitSm and SubmitMulti. Four Priority Levels are supported: 0: Level 0 (lowest) priority 1: Level 1 priority 2: Level 2 priority 3: Level 3 (highest) priority</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>protocolId (producer)</td>
<td>The protocol id</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>registeredDelivery (producer)</td>
<td>Is used to request an SMSC delivery receipt and/or SME originated acknowledgements. The following values are defined: 0: No SMSC delivery receipt requested. 1: SMSC delivery receipt requested where final delivery outcome is success or failure. 2: SMSC delivery receipt requested where the final delivery outcome is delivery failure.</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>replaceIfPresentFlag (producer)</td>
<td>Used to request the SMSC to replace a previously submitted message, that is still pending delivery. The SMSC will replace an existing message provided that the source address, destination address and service type match the same fields in the new message. The following replace if present flag values are defined: 0: Don’t replace 1: Replace</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>serviceType (producer)</td>
<td>The service type parameter can be used to indicate the SMS Application service associated with the message. The following generic service_types are defined: CMT: Cellular Messaging CPT: Cellular Paging VMN: Voice Mail Notification VMA: Voice Mail Alerting WAP: Wireless Application Protocol USSD: Unstructured Supplementary Services Data</td>
<td>CMT</td>
<td>String</td>
</tr>
<tr>
<td>sourceAddr (producer)</td>
<td>Defines the address of SME (Short Message Entity) which originated this message.</td>
<td>1616</td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>sourceAddrNpi</td>
<td>Defines the numeric plan indicator (NPI) to be used in the SME originator address parameters. The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>sourceAddrTon</td>
<td>Defines the type of number (TON) to be used in the SME originator address parameters. The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>typeOfNumber</td>
<td>Defines the type of number (TON) to be used in the SME. The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>enquireLinkTimer</td>
<td>Defines the interval in milliseconds between the confidence checks. The confidence check is used to test the communication path between an ESME and an SMSC.</td>
<td>5000</td>
<td>Integer</td>
</tr>
<tr>
<td>sessionStateListe ner</td>
<td>You can refer to a org.jsmpp.session.SessionStateListener in the Registry to receive callbacks when the session state changed.</td>
<td></td>
<td>SessionStateListe ner</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>transactionTimer</td>
<td>Defines the maximum period of inactivity allowed after a transaction, after which an SMPP entity may assume that the session is no longer active. This timer may be active on either communicating SMPP entity (i.e. SMSC or ESME).</td>
<td>10000</td>
<td>Integer</td>
</tr>
<tr>
<td>alphabet</td>
<td>Defines encoding of data according the SMPP 3.4 specification, section 5.2.19. 0: SMSC Default Alphabet 4: 8 bit Alphabet 8: UCS2 Alphabet</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>dataCoding</strong></td>
<td>Defines the data coding according the SMPP 3.4 specification, section 5.2.19. Example data encodings are: 0: SMSC Default Alphabet 3: Latin 1 (ISO-8859-1) 4: Octet unspecified (8-bit binary) 8: UCS2 (ISO/IEC-10646) 13: Extended Kanji JIS(X 0212-1990)</td>
<td></td>
<td>byte</td>
</tr>
<tr>
<td><strong>encoding</strong></td>
<td>Defines the encoding scheme of the short message user data. Only for SubmitSm, ReplaceSm and SubmitMulti.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>httpProxyHost</strong></td>
<td>If you need to tunnel SMPP through a HTTP proxy, set this attribute to the hostname or ip address of your HTTP proxy.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>httpProxyPassword</strong></td>
<td>If your HTTP proxy requires basic authentication, set this attribute to the password required for your HTTP proxy.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>httpProxyPort</strong></td>
<td>If you need to tunnel SMPP through a HTTP proxy, set this attribute to the port of your HTTP proxy.</td>
<td>3128</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>httpProxyUsername</strong></td>
<td>If your HTTP proxy requires basic authentication, set this attribute to the username required for your HTTP proxy.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>proxyHeaders</strong></td>
<td>These headers will be passed to the proxy server while establishing the connection.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td><strong>password</strong></td>
<td>The password for connecting to SMSC server.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>systemId</strong></td>
<td>The system id (username) for connecting to SMSC server.</td>
<td>smppclient</td>
<td>String</td>
</tr>
<tr>
<td><strong>usingSSL</strong></td>
<td>Whether using SSL with the smpps protocol</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

You can have as many of these options as you like.

```
smpp://smppclient@localhost:2775?
pasword=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=consumer
```

## 288.6. PRODUCER MESSAGE HEADERS

The following message headers can be used to affect the behavior of the SMPP producer
<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel Smpp DestAddr</td>
<td>List/Str</td>
<td>Only for SubmitSm, SubmitMulti, CancelSm and DataSm Defines the destination SME address(es). For mobile terminated messages, this is the directory number of the recipient MS. Must be a List&lt;String&gt; for SubmitMulti and a String otherwise.</td>
</tr>
<tr>
<td>Byte</td>
<td></td>
<td>Only for SubmitSm, SubmitMulti, CancelSm and DataSm Defines the type of number (TON) to be used in the SME destination address parameters. Use the sourceAddrTon URI option values defined above.</td>
</tr>
<tr>
<td>String</td>
<td></td>
<td>Only for SubmitSm, SubmitMulti, CancelSm and DataSm Defines the numeric plan indicator (NPI) to be used in the SME destination address parameters. Use the sourceAddrNpi URI option values defined above.</td>
</tr>
<tr>
<td>String</td>
<td></td>
<td>Defines the address of SME (Short Message Entity) which originated this message.</td>
</tr>
<tr>
<td>Byte</td>
<td></td>
<td>Defines the type of number (TON) to be used in the SME originator address parameters. Use the sourceAddrTon URI option values defined above.</td>
</tr>
<tr>
<td>Byte</td>
<td></td>
<td>Defines the numeric plan indicator (NPI) to be used in the SME originator address parameters. Use the URI option sourceAddrNpi values defined above.</td>
</tr>
<tr>
<td>String</td>
<td></td>
<td>The service type parameter can be used to indicate the SMS Application service associated with the message. Use the URI option serviceType settings above.</td>
</tr>
<tr>
<td>Byte</td>
<td></td>
<td>Only for SubmitSm, ReplaceSm, SubmitMulti and DataSm Is used to request an SMSC delivery receipt and/or SME originated acknowledgements. Use the URI option registeredDelivery settings above.</td>
</tr>
<tr>
<td>Byte</td>
<td></td>
<td>Only for SubmitSm and SubmitMulti Allows the originating SME to assign a priority level to the short message. Use the URI option priorityFlag settings above.</td>
</tr>
<tr>
<td>Header</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Camel Smpp ScheduleDeliveryTime</strong></td>
<td>Date</td>
<td><em>only for SubmitSm, SubmitMulti and ReplaceSm</em> This parameter specifies the scheduled time at which the message delivery should be first attempted. It defines either the absolute date and time or relative time from the current SMSC time at which delivery of this message will be attempted by the SMSC. It can be specified in either absolute time format or relative time format. The encoding of a time format is specified in chapter 7.11 in the smpp specification v3.4.</td>
</tr>
<tr>
<td><strong>Camel Smpp ValidityPeriod</strong></td>
<td>String/Date</td>
<td><em>only for SubmitSm, SubmitMulti and ReplaceSm</em> The validity period parameter indicates the SMSC expiration time, after which the message should be discarded if not delivered to the destination. If it’s provided as <strong>Date</strong>, it’s interpreted as absolute time. <strong>Camel 2.9.1 onwards</strong>: It can be defined in absolute time format or relative time format if you provide it as <strong>String</strong> as specified in chapter 7.11 in the smpp specification v3.4.</td>
</tr>
<tr>
<td><strong>Camel Smpp ReplaceIfPresent Flag</strong></td>
<td>Byte</td>
<td><em>only for SubmitSm and SubmitMulti</em> The replace if present flag parameter is used to request the SMSC to replace a previously submitted message, that is still pending delivery. The SMSC will replace an existing message provided that the source address, destination address and service type match the same fields in the new message. The following values are defined: 0, Don’t replace and 1, Replace</td>
</tr>
<tr>
<td><strong>Camel Smpp Alphabet/Camel Smpp DataCoding</strong></td>
<td>Map&lt;String, String&gt;</td>
<td><strong>Camel 2.5 For SubmitSm, SubmitMulti and ReplaceSm</strong> <em>(Prior to Camel 2.9 use CamelSmppDataCoding instead of CamelSmppAlphabet.)</em> The data coding according to the SMPP 3.4 specification, section 5.2.19. Use the URI option <strong>alphabet</strong> settings above.</td>
</tr>
<tr>
<td><strong>Camel Smpp OptionalParameters</strong></td>
<td>Map&lt;String, String&gt;</td>
<td>Deprecated and will be removed in Camel 2.13.0/3.0.0 Camel 2.10.5 and 2.11.1 onwards and only for SubmitSm, SubmitMulti and DataSm The optional parameters send back by the SMSC.</td>
</tr>
<tr>
<td><strong>Camel Smpp OptionalParameter</strong></td>
<td>Map&lt;Short, Object&gt;</td>
<td>Camel 2.10.7 and 2.11.2 onwards and only for SubmitSm, SubmitMulti and DataSm The optional parameter which are send to the SMSC. The value is converted in the following way: <strong>String</strong> → org.jsmpp.bean.OptionalParameter.COctetString, <strong>byte[]</strong> → org.jsmpp.bean.OptionalParameter.OctetString, <strong>Byte</strong> → org.jsmpp.bean.OptionalParameter.Byte, <strong>Integer</strong> → org.jsmpp.bean.OptionalParameter.Int, <strong>Short</strong> → org.jsmpp.bean.OptionalParameter.Short, <strong>null</strong> → org.jsmpp.bean.OptionalParameter.Null</td>
</tr>
<tr>
<td>Header</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CamelSmppEncoding</td>
<td>String</td>
<td><strong>Camel 2.14.1 and Camel 2.15.0 onwards and only for SubmitSm, SubmitMulti and DataSm</strong>. Specifies the encoding (character set name) of the bytes in the message body. If the message body is a string then this is not relevant because Java Strings are always Unicode. If the body is a byte array then this header can be used to indicate that it is ISO-8859-1 or some other value. Default value is specified by the endpoint configuration parameter <code>encoding</code></td>
</tr>
<tr>
<td>CamelSmppSplittingPolicy</td>
<td>String</td>
<td><strong>Camel 2.14.1 and Camel 2.15.0 onwards and only for SubmitSm, SubmitMulti and DataSm</strong>. Specifies the policy for message splitting for this exchange. Possible values are described in the endpoint configuration parameter <code>splittingPolicy</code></td>
</tr>
</tbody>
</table>

The following message headers are used by the SMPP producer to set the response from the SMSC in the message header

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelSmppId</td>
<td>List&lt;String&gt; / String</td>
<td>The id to identify the submitted short message(s) for later use. <strong>From Camel 2.9.0</strong>: In case of a ReplaceSm, QuerySm, CancelSm and DataSm this header vaule is a <code>String</code>. In case of a SubmitSm or SubmitMultiSm this header vaule is a <code>List&lt;String&gt;</code></td>
</tr>
<tr>
<td>CamelSmppSentMessageCount</td>
<td>Integer</td>
<td>From Camel 2.9 onwards only for SubmitSm and SubmitMultiSm The total number of messages which has been sent.</td>
</tr>
<tr>
<td>CamelSmppError</td>
<td>Map&lt;String, List&lt;Map&lt;String, Object&gt;&gt;&gt;</td>
<td>From Camel 2.9 onwards only for SubmitMultiSm The errors which occurred by sending the short message(s) the form <code>Map&lt;String, List&lt;Map&lt;String, Object&gt;&gt;&gt;</code> (messageID : (destAddr : address, error : errorCode)).</td>
</tr>
<tr>
<td>CamelSmppOptionalParameters</td>
<td>Map&lt;String, String&gt;</td>
<td>Deprecated and will be removed in Camel 2.13.0/3.0.0 From Camel 2.11.1 onwards only for DataSm The optional parameters which are returned from the SMSC by sending the message.</td>
</tr>
</tbody>
</table>
The optional parameter which are returned from the SMSC by sending the message. The key is the *Short* code for the optional parameter. The value is converted in the following way:

- `org.jsmpp.bean.OptionalParameter.COctetString` → `String`
- `org.jsmpp.bean.OptionalParameter.OctetString` → `byte[]`
- `org.jsmpp.bean.OptionalParameter.Byte` → `Byte`
- `org.jsmpp.bean.OptionalParameter.Int` → `Integer`
- `org.jsmpp.bean.OptionalParameter.Short` → `Short`
- `org.jsmpp.bean.OptionalParameter.Null` → `null`

### 288.7. CONSUMER MESSAGE HEADERS

The following message headers are used by the SMPP consumer to set the request data from the SMSC in the message header.

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| CamelSmppOptioParame... | Map<Short, Object> | From Camel 2.10.7, 2.11.2 onwards only for DataSm The optional parameter which are returned from the SMSC by sending the message. The key is the *Short* code for the optional parameter. The value is converted in the following way:  
  - `org.jsmpp.bean.OptionalParameter.COctetString` → `String`
  - `org.jsmpp.bean.OptionalParameter.OctetString` → `byte[]`
  - `org.jsmpp.bean.OptionalParameter.Byte` → `Byte`
  - `org.jsmpp.bean.OptionalParameter.Int` → `Integer`
  - `org.jsmpp.bean.OptionalParameter.Short` → `Short`
  - `org.jsmpp.bean.OptionalParameter.Null` → `null` |

The sequence number allows a response PDU to be correlated with a request PDU. The associated SMPP response PDU must preserve this field.

- **CamelSmppSequenceNumber**: `Integer` only for AlertNotification, DeliverSm and DataSm. A sequence number allows a response PDU to be correlated with a request PDU. The associated SMPP response PDU must preserve this field.

- **CamelSmppCommandId**: `Integer` only for AlertNotification, DeliverSm and DataSm. The command id field identifies the particular SMPP PDU. For the complete list of defined values see chapter 5.1.2.1 in the smpp specification v3.4.

- **CamelSmppSourceAddr**: `String` only for AlertNotification, DeliverSm and DataSm. Defines the address of SME (Short Message Entity) which originated this message.

- **CamelSmppSourceAddrNpi**: `Byte` only for AlertNotification and DataSm. Defines the numeric plan indicator (NPI) to be used in the SME originator address parameters. Use the URI option `sourceAddrNpi` values defined above.

- **CamelSmppSourceAddrTon**: `Byte` only for AlertNotification and DataSm. Defines the type of number (TON) to be used in the SME originator address parameters. Use the `sourceAddrTon` URI option values defined above.
<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel Smpp Esme Addr</td>
<td>String</td>
<td><em>only for AlertNotification</em> Defines the destination ESME address. For mobile terminated messages, this is the directory number of the recipient MS.</td>
</tr>
<tr>
<td>Camel Smpp Esme AddrNpi</td>
<td>Byte</td>
<td><em>only for AlertNotification</em> Defines the numeric plan indicator (NPI) to be used in the ESME originator address parameters. Use the URI option sourceAddrNpi values defined above.</td>
</tr>
<tr>
<td>Camel Smpp Esme AddrTon</td>
<td>Byte</td>
<td><em>only for AlertNotification</em> Defines the type of number (TON) to be used in the ESME originator address parameters. Use the sourceAddrTon URI option values defined above.</td>

</tr>
</tbody>
</table>

**TIP**

**JSMPP library** See the documentation of the [JSMPP Library](#) for more details about the underlying library.

### 288.8. EXCEPTION HANDLING

This component supports the general Camel exception handling capabilities.

When an error occurs sending a message with SubmitSm (the default action), the org.apache.camel.component.smpp.SmppException is thrown with a nested exception, org.jsmpp.extra.NegativeResponseException. Call NegativeResponseException.getCommandStatus() to obtain the exact SMPP negative response code, the values are explained in the SMPP specification 3.4, section 5.1.3.

**Camel 2.8 onwards:** When the SMPP consumer receives a **DeliverSm** or **DataSm** short message and the processing of these messages fails, you can also throw a **ProcessRequestException** instead of handle the failure. In this case, this exception is forwarded to the underlying JSMPP library which will return the included error code to the SMSC. This feature is useful to e.g. instruct the SMSC to resend the short message at a later time. This could be done with the following lines of code:

```java
from("smpp://smppclient@localhost:2775?password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=consumer")
  .doTry()
  .to("bean:dao?method=updateSmsState")
  .doCatch(Exception.class)
  .throwException(new ProcessRequestException("update of sms state failed", 100))
  .end();
```
Please refer to the SMPP specification for the complete list of error codes and their meanings.

288.9. SAMPLES

A route which sends an SMS using the Java DSL:

```java
from("direct:start")
    .to("smpp://smppclient@localhost:2775?
        password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=producer");
```

A route which sends an SMS using the Spring XML DSL:

```xml
<route>
    <from uri="direct:start"/>
    <to uri="smpp://smppclient@localhost:2775?
        password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=producer"/>
</route>
```

A route which receives an SMS using the Java DSL:

```java
from("smpp://smppclient@localhost:2775?
    password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=consumer")
    .to("bean:foo");
```

A route which receives an SMS using the Spring XML DSL:

```xml
<route>
    <from uri="smpp://smppclient@localhost:2775?
        password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=consumer"/>
    <to uri="bean:foo"/>
</route>
```

TIP

**SMSC simulator** If you need an SMSC simulator for your test, you can use the simulator provided by Logica.

288.10. DEBUG LOGGING

This component has log level **DEBUG**, which can be helpful in debugging problems. If you use log4j, you can add the following line to your configuration:

```xml
log4j.logger.org.apache.camel.component.smpp=DEBUG
```

288.11. SEE ALSO

- Configuring Camel
• Component
• Endpoint
• Getting Started
CHAPTER 289. SNMP COMPONENT

Available as of Camel version 2.1

The `snmp:` component gives you the ability to poll SNMP capable devices or receiving traps.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-snmp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

289.1. URI FORMAT

`snmp://hostname[:port][?Options]`

The component supports polling OID values from an SNMP enabled device and receiving traps.

You can append query options to the URI in the following format, `?option=value&option=value&...`

289.2. SNMP PRODUCER

Available from 2.18 release

It can also be used to request information using GET method.

The response body type is `org.apache.camel.component.snmp.SnmpMessage`

289.3. OPTIONS

The SNMP component has no options.

The SNMP endpoint is configured using URI syntax:

`snmp:host:port`

with the following path and query parameters:

289.3.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required Hostname of the SNMP enabled device</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>Required Port number of the SNMP enabled device</td>
<td></td>
<td>Integer</td>
</tr>
</tbody>
</table>
### 289.3.2. Query Parameters (34 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>delay (consumer)</td>
<td>Sets update rate in seconds</td>
<td>60000</td>
<td>long</td>
</tr>
<tr>
<td>oids (consumer)</td>
<td>Defines which values you are interested in. Please have a look at the Wikipedia to get a better understanding. You may provide a single OID or a coma separated list of OIDs. Example: oids=1.3.6.1.2.1.1.3.0,1.3.6.1.2.1.25.3.2.1.5.1,1.3.6.1.2.1.25.3.5.1 .1,1.3.6.1.2.1.43.5.11.11.1</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>protocol (consumer)</td>
<td>Here you can select which protocol to use. You can use either udp or tcp.</td>
<td>udp</td>
<td>String</td>
</tr>
<tr>
<td>retries (consumer)</td>
<td>Defines how often a retry is made before canceling the request.</td>
<td>2</td>
<td>int</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>snmpCommunity (consumer)</td>
<td>Sets the community octet string for the snmp request.</td>
<td>public</td>
<td>String</td>
</tr>
<tr>
<td>snmpContextEngineId (consumer)</td>
<td>Sets the context engine ID field of the scoped PDU.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>snmpContextName (consumer)</td>
<td>Sets the context name field of this scoped PDU.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>snmpVersion (consumer)</td>
<td>Sets the snmp version for the request. The value 0 means SNMPv1, 1 means SNMPv2c, and the value 3 means SNMPv3</td>
<td>0</td>
<td>int</td>
</tr>
<tr>
<td>timeout (consumer)</td>
<td>Sets the timeout value for the request in millis.</td>
<td>1500</td>
<td>int</td>
</tr>
<tr>
<td>type (consumer)</td>
<td>Which operation to perform such as poll, trap, etc.</td>
<td></td>
<td>SnmpActionType</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------------</td>
</tr>
<tr>
<td><strong>exceptionHandler</strong> (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td><strong>exchangePattern</strong> (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td><strong>pollStrategy</strong> (consumer)</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td><strong>synchronous</strong> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>backoffErrorThreshold</strong> (scheduler)</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>backoffIdleThreshold</strong> (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>backoffMultiplier</strong> (scheduler)</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>greedy</strong> (scheduler)</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>initialDelay</strong> (scheduler)</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td><strong>runLoggingLevel</strong> (scheduler)</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
</tbody>
</table>

<tr>
<td>privacyPassphrase</td>
<td>The privacy passphrase. If not null, privacyProtocol must also be not null. RFC3414 11.2 requires passphrases to have a minimum length of 8 bytes. If the length of authenticationPassphrase is less than 8 bytes an IllegalArgumentException is thrown.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>privacyProtocol</td>
<td>The privacy protocol ID to be associated with this user. If set to null, this user only supports unencrypted messages.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### Security Level

Sets the security level for this target. The supplied security level must be supported by the security model dependent information associated with the security name set for this target. The value 1 means: No authentication and no encryption. Anyone can create and read messages with this security level. The value 2 means: Authentication and no encryption. Only the one with the right authentication key can create messages with this security level, but anyone can read the contents of the message. The value 3 means: Authentication and encryption. Only the one with the right authentication key can create messages with this security level, and only the one with the right encryption/decryption key can read the contents of the message.

<table>
<thead>
<tr>
<th>Name</th>

</tbody>
</table>

### 289.4. The Result of a Poll

Given the situation, that I poll for the following OIDs:

#### OIDs

- 1.3.6.1.2.1.1.3.0
- 1.3.6.1.2.1.25.3.2.1.5.1
- 1.3.6.1.2.1.25.3.5.1.1.1
- 1.3.6.1.2.1.43.5.1.11.1

The result will be the following:

#### Result of toString conversion

```xml
<?xml version="1.0" encoding="UTF-8"?>
<snmp>
  <entry>
    <oid>1.3.6.1.2.1.1.3.0</oid>
    <value>6 days, 21:14:28.00</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.25.3.2.1.5.1</oid>
    <value>2</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.25.3.5.1.1.1</oid>
    <value>3</value>
  </entry>
</snmp>
```
As you maybe recognized there is one more result than requested...\texttt{1.3.6.1.2.1.1.1.0}.
This one is filled in by the device automatically in this special case. So it may absolutely happen, that you receive more than you requested...be prepared.

\section*{289.5. EXAMPLES}

Polling a remote device:

\begin{verbatim}
snmp:192.168.178.23:161?protocol=udp&type=POLL&oids=1.3.6.1.2.1.1.5.0
\end{verbatim}

Setting up a trap receiver (\textbf{Note that no OID info is needed here}):

\begin{verbatim}
snmp:127.0.0.1:162?protocol=udp&type=TRAP
\end{verbatim}

From Camel 2.10.0, you can get the community of SNMP TRAP with message header \texttt{securityName}, peer address of the SNMP TRAP with message header \texttt{peerAddress}.

Routing example in Java: (converts the SNMP PDU to XML String)

\begin{verbatim}
from("snmp:192.168.178.23:161?protocol=udp&type=POLL&oids=1.3.6.1.2.1.1.5.0").
convertBodyTo(String.class).
to("activemq:snmp.states");
\end{verbatim}

\section*{289.6. SEE ALSO}

- Endpoint
- Getting Started
CHAPTER 290. SOAP DATAFORMAT

Available as of Camel version 2.3

SOAP is a Data Format which uses JAXB2 and JAX-WS annotations to marshal and unmarshal SOAP payloads. It provides the basic features of Apache CXF without need for the CXF Stack.

Supported SOAP versions

SOAP 1.1 is supported by default. SOAP 1.2 is supported from Camel 2.11 onwards.

Namespace prefix mapping

See JAXB for details how you can control namespace prefix mappings when marshalling using SOAP data format.

290.1. SOAP OPTIONS

The SOAP dataformat supports 7 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contextPath</td>
<td>String</td>
<td></td>
<td>Package name where your JAXB classes are located.</td>
</tr>
<tr>
<td>encoding</td>
<td>String</td>
<td></td>
<td>To overrule and use a specific encoding</td>
</tr>
<tr>
<td>elementNameStrategyRef</td>
<td>String</td>
<td></td>
<td>Refers to an element strategy to lookup from the registry. An element name strategy is used for two purposes. The first is to find a xml element name for a given object and soap action when marshaling the object into a SOAP message. The second is to find an Exception class for a given soap fault name. The following three element strategy class name is provided out of the box. QNameStrategy - Uses a fixed qName that is configured on instantiation. Exception lookup is not supported. TypeNameStrategy - Uses the name and namespace from the XMLType annotation of the given type. If no namespace is set then package-info is used. Exception lookup is not supported. ServiceInterfaceStrategy - Uses information from a webservice interface to determine the type name and to find the exception class for a SOAP fault All three classes is located in the package name org.apache.camel.dataformat.soap.name If you have generated the web service stub code with cxf-codegen or a similar tool then you probably will want to use the ServiceInterfaceStrategy. In the case you have no annotated service interface you should use QNameStrategy or TypeNameStrategy.</td>
</tr>
<tr>
<td>version</td>
<td>1.1</td>
<td>String</td>
<td>SOAP version should either be 1.1 or 1.2. Is by default 1.1</td>
</tr>
</tbody>
</table>
When marshalling using JAXB or SOAP then the JAXB implementation will automatically assign namespace prefixes, such as ns2, ns3, ns4 etc. To control this mapping, Camel allows you to refer to a map which contains the desired mapping.

To validate against an existing schema. Your can use the prefix classpath:, file: or http: to specify how the resource should be resolved. You can separate multiple schema files by using the ',' character.

Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

### 290.2. ELEMENTNAMESTRATEGY

An element name strategy is used for two purposes. The first is to find a xml element name for a given object and soap action when marshaling the object into a SOAP message. The second is to find an Exception class for a given soap fault name.

<table>
<thead>
<tr>
<th>Strategy</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>QNameStrategy</td>
<td>Uses a fixed QName that is configured on instantiation. Exception lookup is not supported</td>
</tr>
<tr>
<td>TypeNameStrategy</td>
<td>Uses the name and namespace from the @XMLType annotation of the given type. If no namespace is set then package-info is used. Exception lookup is not supported</td>
</tr>
<tr>
<td>ServiceInterfaceStrategy</td>
<td>Uses information from a webservice interface to determine the type name and to find the exception class for a SOAP fault</td>
</tr>
</tbody>
</table>

If you have generated the web service stub code with cxf-codegen or a similar tool then you probably will want to use the ServiceInterfaceStrategy. In the case you have no annotated service interface you should use QNameStrategy or TypeNameStrategy.

### 290.3. USING THE JAVA DSL

The following example uses a named DataFormat of soap which is configured with the package com.example.customerservice to initialize the JAXBContext. The second parameter is the ElementNameStrategy. The route is able to marshal normal objects as well as exceptions. (Note the
below just sends a SOAP Envelope to a queue. A web service provider would actually need to be
listening to the queue for a SOAP call to actually occur, in which case it would be a one way SOAP
request. If you need request reply then you should look at the next example.)

```
SoapJaxbDataFormat soap = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
from("direct:start")
 .marshal(soap)
 .to("jms:myQueue");
```

TIP

See also As the SOAP dataformat inherits from the JAXB dataformat most settings apply here as well

290.3.1. Using SOAP 1.2

Available as of Camel 2.11

```
SoapJaxbDataFormat soap = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
soap.setVersion("1.2");
from("direct:start")
 .marshal(soap)
 .to("jms:myQueue");
```

When using XML DSL there is a version attribute you can set on the <soapjaxb> element.

```
<!-- Defining a ServiceInterfaceStrategy for retrieving the element name when marshalling -->
<bean id="myNameStrategy"
 class="org.apache.camel.dataformat.soap.name.ServiceInterfaceStrategy">
  <constructor-arg value="com.example.customerservice.CustomerService"/>
  <constructor-arg value="true"/>
</bean>
```

And in the Camel route

```
<route>
  <from uri="direct:start"/>
  <marshal>
    <soapjaxb contentPath="com.example.customerservice" version="1.2"
      elementNameStrategyRef="myNameStrategy"/>
  </marshal>
  <to uri="jms:myQueue"/>
</route>
```

290.4. MULTI-PART MESSAGES

Available as of Camel 2.8.1

Multi-part SOAP messages are supported by the ServiceInterfaceStrategy. The
ServiceInterfaceStrategy must be initialized with a service interface definition that is annotated in
accordance with JAX-WS 2.2 and meets the requirements of the Document Bare style. The target
method must meet the following criteria, as per the JAX-WS specification: 1) it must have at most one in
or **in/out** non-header parameter, 2) if it has a return type other than **void** it must have no **in/out** or **out** non-header parameters, 3) if it has a return type of **void** it must have at most one **in/out** or **out** non-header parameter.

The ServiceInterfaceStrategy should be initialized with a boolean parameter that indicates whether the mapping strategy applies to the request parameters or response parameters.

```java
ServiceInterfaceStrategy strat = new ServiceInterfaceStrategy(com.example.customerservice.multipart.MultiPartCustomerService.class, true);
SoapJaxbDataFormat soapDataFormat = new SoapJaxbDataFormat("com.example.customerservice.multipart", strat);
```

### 290.4.1. Multi-part Request

The payload parameters for a multi-part request are initialized using a **BeanInvocation** object that reflects the signature of the target operation. The camel-soap DataFormat maps the content in the **BeanInvocation** to fields in the SOAP header and body in accordance with the JAX-WS mapping when the `marshal()` processor is invoked.

```java
BeanInvocation beanInvocation = new BeanInvocation();

// Identify the target method
beanInvocation.setMethod(MultiPartCustomerService.class.getMethod("getCustomersByName", GetCustomersByName.class, com.example.customerservice.multipart.Product.class));

// Populate the method arguments
GetCustomersByName getCustomersByName = new GetCustomersByName();
getCustomersByName.setName("Dr. Multipart");
Product product = new Product();
product.setName("Multiuse Product");
product.setDescription("Useful for lots of things.");

Object[] args = new Object[] {getCustomersByName, product};

// Add the arguments to the bean invocation
beanInvocation.setArgs(args);

// Set the bean invocation object as the message body
exchange.getIn().setBody(beanInvocation);
```

### 290.4.2. Multi-part Response

A multi-part soap response may include an element in the soap body and will have one or more elements in the soap header. The camel-soap DataFormat will unmarshall the element in the soap body (if it exists) and place it onto the body of the out message in the exchange. Header elements will **not** be marshaled into their JAXB mapped object types. Instead, these elements are placed into the camel out message header `org.apache.camel.dataformat.soap.UNMARSHALLED_HEADER_LIST`. The elements will appear either as element instance values, or as JAXBElement values, depending upon the setting for the `ignoreJAXBElement` property. This property is inherited from camel-jaxb.

You can also have the camel-soap DataFormat ignore header content all-together by setting the `ignoreUnmarshalledHeaders` value to `true`. 

2001
290.4.3. Holder Object mapping

JAX-WS specifies the use of a type-parameterized `javax.xml.ws.Holder` object for `In/Out` and `Out` parameters. A `Holder` object may be used when building the `BeanInvocation`, or you may use an instance of the parameterized-type directly. The camel-soap DataFormat marshals `Holder` values in accordance with the JAXB mapping for the class of the `Holder`'s value. **No mapping is provided for `Holder` objects in an unmarshalled response.**

290.5. EXAMPLES

290.5.1. Webservice client

The following route supports marshalling the request and unmarshalling a response or fault.

```
String WS_URI = "cxf://http://myserver/customerservice?
               serviceClass=com.example.customerservice&dataFormat=MESSAGE";
SoapJaxbDataFormat soapDF = new SoapJaxbDataFormat("com.example.customerservice", new ServiceInterfaceStrategy(CustomerService.class));
from("direct:customerServiceClient")
   .onException(Exception.class)
   .handled(true)
   .unmarshal(soapDF)
   .end()
   .marshal(soapDF)
   .to(WS_URI)
   .unmarshal(soapDF);
```

The below snippet creates a proxy for the service interface and makes a SOAP call to the above route.

```
import org.apache.camel.Endpoint;
import org.apache.camel.component.bean.ProxyHelper;
...
Endpoint startEndpoint = context.getEndpoint("direct:customerServiceClient");
ClassLoader classLoader = Thread.currentThread().getContextClassLoader();
// CustomerService below is the service endpoint interface, *not* the javax.xml.ws.Service subclass
CustomerService proxy = ProxyHelper.createProxy(startEndpoint, classLoader,
CustomerService.class);
GetCustomersByNameResponse response = proxy.getCustomersByName(new
GetCustomersByName());
```

290.5.2. Webservice Server

Using the following route sets up a webservice server that listens on jms queue customerServiceQueue and processes requests using the class CustomerServiceImpl. The customerServiceImpl of course should implement the interface CustomerService. Instead of directly instantiating the server class it could be defined in a spring context as a regular bean.

```
SoapJaxbDataFormat soapDF = new SoapJaxbDataFormat("com.example.customerservice", new ServiceInterfaceStrategy(CustomerService.class));
CustomerService serverBean = new CustomerServiceImpl();
from("jms://queue:customerServiceQueue")
   .onException(Exception.class)
```

2002
To use the SOAP dataformat in your camel routes you need to add the following dependency to your pom.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-soap</artifactId>
  <version>2.3.0</version>
</dependency>
```
CHAPTER 291. SOLR COMPONENT

Available as of Camel version 2.9

The Solr component allows you to interface with an Apache Lucene Solr server (based on SolrJ 3.5.0). Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-solr</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 291.1. URI FORMAT

**NOTE:** solrs and solrCloud are new added since Camel 2.14.

```
solr://host[:port]/solr?[options]
solrs://host[:port]/solr?[options]
solrCloud://host[:port]/solr?[options]
```

### 291.2. SOLR OPTIONS

The Solr component has no options.

The Solr endpoint is configured using URI syntax:

```
solr:url
```

with the following path and query parameters:

#### 291.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>Required Hostname and port for the solr server</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

#### 291.2.2. Query Parameters (13 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowCompression</td>
<td>Server side must support gzip or deflate for this to have any effect</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>connectionTimeout (producer)</td>
<td>connectionTimeout on the underlying HttpConnectionManager</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>defaultMaxConnectionsPerHost (producer)</td>
<td>maxConnectionsPerHost on the underlying HttpConnectionManager</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>followRedirects (producer)</td>
<td>indicates whether redirects are used to get to the Solr server</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>maxRetries (producer)</td>
<td>Maximum number of retries to attempt in the event of transient errors</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>maxTotalConnections (producer)</td>
<td>maxTotalConnection on the underlying HttpConnectionManager</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>requestHandler (producer)</td>
<td>Set the request handler to be used</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>soTimeout (producer)</td>
<td>Read timeout on the underlying HttpConnectionManager. This is desirable for queries, but probably not for indexing</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>streamingQueueSize (producer)</td>
<td>Set the queue size for the StreamingUpdateSolrServer</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>streamingThreadCount (producer)</td>
<td>Set the number of threads for the StreamingUpdateSolrServer</td>
<td>2</td>
<td>int</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>collection (solrCloud)</td>
<td>Set the collection name which the solrCloud server could use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>zkHost (solrCloud)</td>
<td>Set the ZooKeeper host information which the solrCloud could use, such as zkhost=localhost:8123.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 291.3. MESSAGE OPERATIONS

The following Solr operations are currently supported. Simply set an exchange header with a key of "SolrOperation" and a value set to one of the following. Some operations also require the message body to be set.

- the INSERT operations use the CommonsHttpSolrServer
the INSERT_STREAMING operations use the `StreamingUpdateSolrServer` (Camel 2.9.2)

<table>
<thead>
<tr>
<th>Operation</th>
<th>Message body</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSERT/INSERT_STREAMING</td>
<td>n/a</td>
<td>adds an index using message headers (must be prefixed with &quot;SolrField.&quot;)</td>
</tr>
<tr>
<td>INSERT/INSERT_STREAMING</td>
<td>File</td>
<td>adds an index using the given File (using ContentStreamUpdateRequest)</td>
</tr>
<tr>
<td>INSERT/INSERT_STREAMING</td>
<td>SolrInputDocument</td>
<td><strong>Camel 2.9.2</strong> updates index based on the given SolrInputDocument</td>
</tr>
<tr>
<td>INSERT/INSERT_STREAMING</td>
<td>String XML</td>
<td><strong>Camel 2.9.2</strong> updates index based on the given XML (must follow SolrInputDocument format)</td>
</tr>
<tr>
<td>ADD_B EAN</td>
<td>bean instance</td>
<td>adds an index based on values in an annotated bean</td>
</tr>
<tr>
<td>ADD_B EANS</td>
<td>collection&lt;bean&gt;</td>
<td><strong>Camel 2.15</strong> adds index based on a collection of annotated bean</td>
</tr>
<tr>
<td>DELETE_BY_ID</td>
<td>index id to delete</td>
<td>delete a record by ID</td>
</tr>
<tr>
<td>DELETE_BY_QUERY</td>
<td>query string</td>
<td>delete a record by a query</td>
</tr>
<tr>
<td>COMMIT</td>
<td>n/a</td>
<td>performs a commit on any pending index changes</td>
</tr>
<tr>
<td>ROLLBACK</td>
<td>n/a</td>
<td>performs a rollback on any pending index changes</td>
</tr>
</tbody>
</table>
OPTIMIZE performs a commit on any pending index changes and then runs the optimize command.

### 291.4. EXAMPLE

Below is a simple INSERT, DELETE and COMMIT example

```java
from("direct:insert")
    .setHeader(SolrConstants.OPERATION, constant(SolrConstants.OPERATION_INSERT))
    .setHeader(SolrConstants.FIELD + "id", body())
    .to("solr://localhost:8983/solr");

from("direct:delete")
    .setHeader(SolrConstants.OPERATION, constant(SolrConstants.OPERATION_DELETE_BY_ID))
    .to("solr://localhost:8983/solr");

from("direct:commit")
    .setHeader(SolrConstants.OPERATION, constant(SolrConstants.OPERATION_COMMIT))
    .to("solr://localhost:8983/solr");
```

```
<route>
    <from uri="direct:insert"/>
    <setHeader headerName="SolrOperation">INSERT</setHeader>
    <constant>${body}</constant>
    <setHeader headerName="SolrField.id">${body}</setHeader>
    <to uri="solr://localhost:8983/solr"/>
</route>

<route>
    <from uri="direct:delete"/>
    <setHeader headerName="SolrOperation">DELETE_BY_ID</setHeader>
    <to uri="solr://localhost:8983/solr"/>
</route>

<route>
    <from uri="direct:commit"/>
    <setHeader headerName="SolrOperation">COMMIT</setHeader>
    <to uri="solr://localhost:8983/solr"/>
</route>
```

A client would simply need to pass a body message to the insert or delete routes and then call the commit route.

```java
template.sendBody("direct:insert", "1234");
```
template.sendBody("direct:commit", null);
template.sendBody("direct:delete", "1234");
template.sendBody("direct:commit", null);

291.5. QUERYING SOLR

Currently, this component doesn’t support querying data natively (may be added later). For now, you can query Solr using HTTP as follows:

```java
//define the route to perform a basic query
from("direct:query")
  .recipientList(simple("http://localhost:8983/solr/select/?q=${body}"))
  .convertBodyTo(String.class);
...
//query for an id of '1234' (url encoded)
String responseXml = (String) template.requestBody("direct:query", "id%3A1234");
```

For more information, see these resources...

CHAPTER 292. APACHE SPARK COMPONENT

Available as of Camel version 2.17

This documentation page covers the Apache Spark component for the Apache Camel. The main purpose of the Spark integration with Camel is to provide a bridge between Camel connectors and Spark tasks. In particular, Camel connector provides a way to route messages from various transports, dynamically choose a task to execute, use incoming messages as input data for that task, and finally deliver the results of the execution back to the Camel pipeline.

292.1. SUPPORTED ARCHITECTURAL STYLES

Spark component can be used as a driver application deployed into an application server (or executed as a fat jar).

Spark component can also be submitted as a job directly into the Spark cluster.

While Spark component is primarily designed to work as a long running job serving as a bridge between Spark cluster and the other endpoints, you can also use it as a fire-once short job.
292.2. RUNNING SPARK IN OSGI SERVERS

Currently the Spark component doesn’t support execution in the OSGi container. Spark has been designed to be executed as a fat jar, usually submitted as a job to a cluster. For those reasons running Spark in an OSGi server is at least challenging and is not support by Camel as well.

292.3. URI FORMAT

Currently the Spark component supports only producers - it it intended to invoke a Spark job and return results. You can call RDD, data frame or Hive SQL job.

Spark URI format

```
spark:{rdd|dataframe|hive}
```

292.3.1. Spark options

The Apache Spark component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdd (producer)</td>
<td>RDD to compute against.</td>
<td></td>
<td>JavaRDDLike</td>
</tr>
<tr>
<td>rddCallback (producer)</td>
<td>Function performing action against an RDD.</td>
<td></td>
<td>RddCallback</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Apache Spark endpoint is configured using URI syntax:

```
spark:endpointType
```

with the following path and query parameters:

292.3.2. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>endpointType</td>
<td>Required Type of the endpoint (rdd, dataframe, hive).</td>
<td></td>
<td>EndpointType</td>
</tr>
</tbody>
</table>

292.3.3. Query Parameters (6 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>collect</code> (producer)</td>
<td>Indicates if results should be collected or counted.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><code>dataFrame</code> (producer)</td>
<td>DataFrame to compute against.</td>
<td></td>
<td>DataFrame</td>
</tr>
<tr>
<td><code>dataFrameCallback</code> (producer)</td>
<td>Function performing action against an DataFrame.</td>
<td></td>
<td>DataFrameCallback</td>
</tr>
<tr>
<td><code>rdd</code> (producer)</td>
<td>RDD to compute against.</td>
<td></td>
<td>JavaRDDLike</td>
</tr>
<tr>
<td><code>rddCallback</code> (producer)</td>
<td>Function performing action against an RDD.</td>
<td></td>
<td>RddCallback</td>
</tr>
<tr>
<td><code>synchronous</code> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

# RDD jobs

To invoke an RDD job, use the following URI:

**Spark RDD producer**

```
spark:rdd?rdd=#testFileRdd&rddCallback=#transformation
```

Where `rdd` option refers to the name of an RDD instance (subclass of `org.apache.spark.api.java.JavaRDDLike`) from a Camel registry, while `rddCallback` refers to the implementation of `org.apache.camel.component.spark.RddCallback` interface (also from a registry). RDD callback provides a single method used to apply incoming messages against the given RDD. Results of callback computations are saved as a body to an exchange.

**Spark RDD callback**

```
public interface RddCallback<T> {
    T onRdd(JavaRDDLike rdd, Object... payloads);
}
```

The following snippet demonstrates how to send message as an input to the job and return results:

**Calling spark job**

```
String pattern = "job input";
long linesCount = producerTemplate.requestBody("spark:rdd?
rdd=#myRdd&rddCallback=#countLinesContaining", pattern, long.class);
```

The RDD callback for the snippet above registered as Spring bean could look as follows:

**Spark RDD callback**

-
The RDD definition in Spring could look as follows:

Spark RDD definition

```java
@Bean
RddCallback<Long> countLinesContaining() {
    return new RddCallback<Long>() {
        Long onRdd(JavaRDDLike rdd, Object... payloads) {
            String pattern = (String) payloads[0];
            return rdd.filter(line -> line.contains(pattern)).count();
        }
    };
}
```

292.3.5. Converting RDD callbacks

If you know what type of the input data will be sent to the RDD callback, you can use `ConvertingRddCallback` and let Camel to automatically convert incoming messages before inserting those into the callback:

Spark RDD definition

```java
@Bean
RddCallback<Long> rddCallback(CamelContext context) {
    return new ConvertingRddCallback<Long>(context, int.class, int.class) {
        @Override
        public Long doOnRdd(JavaRDDLike rdd, Object... payloads) {
            return rdd.count() * (int) payloads[0] * (int) payloads[1];
        }
    };
}
```

292.3.4. Void RDD callbacks

If your RDD callback doesn't return any value back to a Camel pipeline, you can either return `null` value or use `VoidRddCallback` base class:

Spark RDD definition

```java
@Bean
JavaRDDLike myRdd(JavaSparkContext sparkContext) {
    return sparkContext.textFile("testrdd.txt");
}
```

```java
@Bean
RddCallback<Void> rddCallback() {
    return new VoidRddCallback() {
        @Override
        public void doOnRdd(JavaRDDLike rdd, Object... payloads) {
            rdd.saveAsTextFile(output.getAbsolutePath());
        }
    };
}
```
292.3.6. Annotated RDD callbacks

Probably the easiest way to work with the RDD callbacks is to provide class with method marked with `@RddCallback` annotation:

**Annotated RDD callback definition**

```java
import static org.apache.camel.component.spark.annotations.AnnotatedRddCallback.annotatedRddCallback;

@Bean
RddCallback<Long> rddCallback() {
    return annotatedRddCallback(new MyTransformation());
}
...

import org.apache.camel.component.spark.annotation.RddCallback;
public class MyTransformation {
    @RddCallback
    long countLines(JavaRDD<String> textFile, int first, int second) {
        return textFile.count() * first * second;
    }
}
```

If you will pass CamelContext to the annotated RDD callback factory method, the created callback will be able to convert incoming payloads to match the parameters of the annotated method:

**Body conversions for annotated RDD callbacks**

```java
import static org.apache.camel.component.spark.annotations.AnnotatedRddCallback.annotatedRddCallback;

@Bean
RddCallback<Long> rddCallback(CamelContext camelContext) {
    return annotatedRddCallback(new MyTransformation(), camelContext);
}
...

import org.apache.camel.component.spark.annotation.RddCallback;
public class MyTransformation {
    @RddCallback
    long countLines(JavaRDD<String> textFile, int first, int second) {
        return textFile.count() * first * second;
    }
}
```
292.4. DATAFRAME JOBS

Instead of working with RDDs Spark component can work with DataFrames as well.

To invoke a DataFrame job, use the following URI:

```
Spark RDD producer

spark:dataframe?dataFrame=#testDataFrame&dataFrameCallback=#transformation
```

Where `dataFrame` option refers to the name of an DataFrame instance (`instance of org.apache.spark.sql.DataFrame`) from a Camel registry, while `dataFrameCallback` refers to the implementation of `org.apache.camel.component.spark.DataFrameCallback` interface (also from a registry). DataFrame callback provides a single method used to apply incoming messages against the given DataFrame. Results of callback computations are saved as a body to an exchange.

```
Spark RDD callback

public interface DataFrameCallback<T> {
    T onDataFrame(DataFrame dataFrame, Object... payloads);
}
```

The following snippet demonstrates how to send message as an input to a job and return results:

```
Calling spark job

String model = "Micra";
long linesCount = producerTemplate.requestBody("spark:dataFrame?dataFrame=#cars&dataFrameCallback=#findCarWithModel", model, long.class);
```

The DataFrame callback for the snippet above registered as Spring bean could look as follows:

```
Spark RDD callback

@Bean
RddCallback<Long> findCarWithModel() {
    return new DataFrameCallback<Long>() {
        @Override
        public Long onDataFrame(DataFrame dataFrame, Object... payloads) {
            String model = (String) payloads[0];
            return dataFrame.where(dataFrame.col("model").eqNullSafe(model)).count();
        }
    };
}
```
The DataFrame definition in Spring could look as follows:

Spark RDD definition

```java
@Bean
DataFrame cars(HiveContext hiveContext) {
    DataFrame jsonCars = hiveContext.read().json("/var/data/cars.json");
    jsonCars.registerTempTable("cars");
    return jsonCars;
}
```

292.5. HIVE JOBS

Instead of working with RDDs or DataFrame Spark component can also receive Hive SQL queries as payloads. To send Hive query to Spark component, use the following URI:

Spark RDD producer

```java
spark:hive
```

The following snippet demonstrates how to send message as an input to a job and return results:

Calling spark job

```java
long carsCount = template.requestBody("spark:hive?collect=false", "SELECT * FROM cars", Long.class);
List<Row> cars = template.requestBody("spark:hive", "SELECT * FROM cars", List.class);
```

The table we want to execute query against should be registered in a HiveContext before we query it. For example in Spring such registration could look as follows:

Spark RDD definition

```java
@Bean
DataFrame cars(HiveContext hiveContext) {
    DataFrame jsonCars = hiveContext.read().json("/var/data/cars.json");
    jsonCars.registerTempTable("cars");
    return jsonCars;
}
```

CHAPTER 293. SPARK REST COMPONENT

Available as of Camel version 2.14

The Spark-rest component allows to define REST endpoints using the Spark REST Java library using the Rest DSL.

INFO: Spark Java requires Java 8 runtime.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spark-rest</artifactId>
  <version>${camel-version}</version>
</dependency>
```

293.1. URI FORMAT

`spark-rest://verb:path?[options]`

293.2. URI OPTIONS

The Spark Rest component supports 12 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>port (consumer)</td>
<td>Port number. Will by default use 4567</td>
<td>4567</td>
<td>int</td>
</tr>
<tr>
<td>ipAddress</td>
<td>Set the IP address that Spark should listen on. If not called the default address is '0.0.0.0'.</td>
<td>0.0.0.0</td>
<td>String</td>
</tr>
<tr>
<td>minThreads</td>
<td>Minimum number of threads in Spark thread-pool (shared globally)</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>maxThreads</td>
<td>Maximum number of threads in Spark thread-pool (shared globally)</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>timeOutMillis</td>
<td>Thread idle timeout in millis where threads that has been idle for a longer period will be terminated from the thread pool</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>keystoreFile</td>
<td>Configures connection to be secure to use the keystore file</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>keystorePassword</td>
<td>Configures connection to be secure to use the keystore password</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
---|---|---|---
**truststoreFile** (security) | Configures connection to be secure to use the truststore file | | String
**truststorePassword** (security) | Configures connection to be secure to use the truststore password | | String
**sparkConfiguration** (advanced) | To use the shared SparkConfiguration | | SparkConfiguration
**sparkBinding** (advanced) | To use a custom SparkBinding to map to/from Camel message. | | SparkBinding
**resolveProperty Placeholders** (advanced) | Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders. | true | boolean

The Spark Rest endpoint is configured using URI syntax:

```
spark-rest:verb:path
```

with the following path and query parameters:

### 293.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>verb</strong></td>
<td><strong>Required</strong> get, post, put, patch, delete, head, trace, connect, or options.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>path</strong></td>
<td><strong>Required</strong> The content path which support Spark syntax.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 293.2.2. Query Parameters (11 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>accept</strong> (consumer)</td>
<td>Accept type such as: ‘text/xml’, or ‘application/json’. By default we accept all kinds of types.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>disableStreamCache (consumer)</td>
<td>Determines whether or not the raw input stream from Spark HttpRequestgetContent() is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Spark raw stream.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>mapHeaders (consumer)</td>
<td>If this option is enabled, then during binding from Spark to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the org.apache.camel.component.sparkrest.SparkMessage message with the method getRequest() that returns the Spark HTTP request instance.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>transferException (consumer)</td>
<td>If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>urlDecodeHeaders (consumer)</td>
<td>If this option is enabled, then during binding from Spark to Camel Message then the header values will be URL decoded (eg %20 will be a space character.)</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
exceptionHandler (consumer) | To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored. | default | ExceptionHandler

exchangePattern (consumer) | Sets the exchange pattern when the consumer creates an exchange. |  | ExchangePattern

matchOnUriPrefix (advanced) | Whether or not the consumer should try to find a target consumer by matching the URI prefix if no exact match is found. | false | boolean

sparkBinding (advanced) | To use a custom SparkBinding to map to/from Camel message. |  | SparkBinding

synchronous (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

### 293.3. PATH USING SPARK SYNTAX

The path option is defined using a Spark REST syntax where you define the REST context path using support for parameters and splat. See more details at the Spark Java Route documentation.

The following is a Camel route using a fixed path

```
from("spark-rest:get:hello")
    .transform().constant("Bye World");
```

And the following route uses a parameter which is mapped to a Camel header with the key "me".

```
from("spark-rest:get:hello/:me")
    .transform().simple("Bye ${header.me}");
```

### 293.4. MAPPING TO CAMEL MESSAGE

The Spark Request object is mapped to a Camel Message as a `org.apache.camel.component.sparkrest.SparkMessage` which has access to the raw Spark request using the `get_request` method. By default the Spark body is mapped to Camel message body, and any HTTP headers / Spark parameters is mapped to Camel Message headers. There is special support for the Spark splat syntax, which is mapped to the Camel message header with key splat.

For example the given route below uses Spark splat (the asterisk sign) in the context path which we can access as a header form the Simple language to construct a response message.

```
from("spark-rest:get:/hello/*/to/*")
    .transform().simple("Bye big ${header.splat[1]} from ${header.splat[0]}");
```
293.5. REST DSL

Apache Camel provides a new Rest DSL that allow to define the REST services in a nice REST style. For example we can define a REST hello service as shown below:

```java
return new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        rest("/hello/{me}").get()
            .route().transform().simple("Bye ${header.me}");
    }
};
```

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
    <rest uri="/hello/{me}">
        <get>
            <route>
                <transform>
                    <simple>Bye ${header.me}</simple>
                </transform>
            </route>
        </get>
    </rest>
</camelContext>
```

See more details at the Rest DSL.

293.6. MORE EXAMPLES

There is a camel-example-spark-rest-tomcat example in the Apache Camel distribution, that demonstrates how to use camel-spark-rest in a web application that can be deployed on Apache Tomcat, or similar web containers.
CHAPTER 294. SPEL LANGUAGE

Available as of Camel version 2.7

Camel allows Spring Expression Language (SpEL) to be used as an Expression or Predicate in the DSL or XML Configuration.

**NOTE**

It is recommended to use SpEL in Spring runtimes. However from Camel 2.21 onwards you can use SpEL in other runtimes (there may be functionality SpEL cannot do when not running in a Spring runtime)

294.1. VARIABLES

The following variables are available in expressions and predicates written in SpEL:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>this</td>
<td>Exchange</td>
<td>the Exchange is the root object</td>
</tr>
<tr>
<td>exchange</td>
<td>Exchange</td>
<td>the Exchange object</td>
</tr>
<tr>
<td>exception</td>
<td>Throwable</td>
<td>the Exchange exception (if any)</td>
</tr>
<tr>
<td>exchangeId</td>
<td>String</td>
<td>the exchange id</td>
</tr>
<tr>
<td>fault</td>
<td>Message</td>
<td>the Fault message (if any)</td>
</tr>
<tr>
<td>body</td>
<td>Object</td>
<td>The IN message body.</td>
</tr>
<tr>
<td>request</td>
<td>Message</td>
<td>the exchange.in message</td>
</tr>
<tr>
<td>response</td>
<td>Message</td>
<td>the exchange.out message (if any)</td>
</tr>
<tr>
<td>properties</td>
<td>Map</td>
<td>the exchange properties</td>
</tr>
<tr>
<td>property(name)</td>
<td>Object</td>
<td>the property by the given name</td>
</tr>
</tbody>
</table>
294.2. OPTIONS

The SpEL language supports 1 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trim</td>
<td>true</td>
<td>Boolean</td>
<td>Whether to trim the value to remove leading and trailing whitespaces and line breaks</td>
</tr>
</tbody>
</table>

294.3. SAMPLES

294.3.1. Expression templating

SpEL expressions need to be surrounded by #{ } delimiters since expression templating is enabled. This allows you to combine SpEL expressions with regular text and use this as extremely lightweight template language.

For example if you construct the following route:

```java
from("direct:example")
    .setBody(spel("Hello #{request.body}! What a beautiful #{request.headers['dayOrNight']}"))
    .to("mock:result");
```

In the route above, notice spel is a static method which we need to import from org.apache.camel.language.spel.SpelExpression.spel, as we use spel as an Expression passed in as a parameter to the setBody method. Though if we use the fluent API we can do this instead:

```java
from("direct:example")
    .setBody().spel("Hello #{request.body}! What a beautiful #{request.headers['dayOrNight']}")
    .to("mock:result");
```

Notice we now use the spel method from the setBody() method. And this does not require us to static import the spel method from org.apache.camel.language.spel.SpelExpression.spel.

And sent a message with the string "World" in the body, and a header "dayOrNight" with value "day":

```java
template.sendBodyAndHeader("direct:example", "World", "dayOrNight", "day");
```

The output on mock:result will be "Hello World! What a beautiful day"
294.3.2. Bean integration

You can reference beans defined in the Registry (most likely an ApplicationContext) in your SpEL expressions. For example if you have a bean named "foo" in your ApplicationContext you can invoke the "bar" method on this bean like this:

```java
#{@foo.bar == 'xyz'}
```

294.3.3. SpEL in enterprise integration patterns

You can use SpEL as an expression for Recipient List or as a predicate inside a Message Filter:

```xml
<route>
  <from uri="direct:foo"/>
  <filter>
    <spel>#{request.headers['foo'] == 'bar'}</spel>
    <to uri="direct:bar"/>
  </filter>
</route>
```

And the equivalent in Java DSL:

```java
from("direct:foo")
  .filter().spel("#{request.headers['foo'] == 'bar'}")
  .to("direct:bar");
```

294.4. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as "classpath:" , "file:" , or "http:" .

This is done using the following syntax: "resource:scheme:location", eg to refer to a file on the classpath you can do:

```java
.setHeader("myHeader").spel("resource:classpath:myspel.txt")
```
CHAPTER 295. SPLUNK COMPONENT

Available as of Camel version 2.13

The Splunk component provides access to Splunk using the Splunk provided `client` api, and it enables you to publish and search for events in Splunk.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-splunk</artifactId>
    <version>${camel-version}</version>
</dependency>
```

295.1. URI FORMAT

`splunk://[endpoint]?[options]`

295.2. PRODUCER ENDPOINTS:

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stream</td>
<td>Streams data to a named index or the default if not specified. When using stream mode be aware of that Splunk has some internal buffer (about 1MB or so) before events gets to the index. If you need realtime, better use submit or tcp mode.</td>
</tr>
<tr>
<td>submit</td>
<td>submit mode. Uses Splunk rest api to publish events to a named index or the default if not specified.</td>
</tr>
<tr>
<td>tcp</td>
<td>tcp mode. Streams data to a tcp port, and requires a open receiver port in Splunk.</td>
</tr>
</tbody>
</table>

When publishing events the message body should contain a SplunkEvent. See comment under message body.

Example

```java
from("direct:start").convertBodyTo(SplunkEvent.class)
    .to("splunk://submit?username=user&password=123&index=myindex&sourceType=someSourceType&source=mySource")...
```

In this example a converter is required to convert to a SplunkEvent class.

295.3. CONSUMER ENDPOINTS:
### Endpoints

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>normal</td>
<td>Performs normal search and requires a search query in the search option.</td>
</tr>
<tr>
<td>savedSearch</td>
<td>Performs search based on a search query saved in splunk and requires the name of the query in the savedSearch option.</td>
</tr>
</tbody>
</table>

### Example
```
from("splunk://normal?delay=5s&username=user&password=123&initEarliestTime=-10s&search=search index=myindex sourcetype=someSourcetype")
.to("direct:search-result");
```

camel-splunk creates a route exchange per search result with a SplunkEvent in the body.

### 295.4. URI OPTIONS

The Splunk component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>splunkConfigurationFactory (advanced)</td>
<td>To use the SplunkConfigurationFactory</td>
<td></td>
<td>SplunkConfigurationFactory</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Splunk endpoint is configured using URI syntax:
```
splunk:name
```

with the following path and query parameters:

### 295.4.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required Name has no purpose</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 295.4.2. Query Parameters (42 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>app</strong> (common)</td>
<td>Splunk app</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>connectionTimeout</strong> (common)</td>
<td>Timeout in MS when connecting to Splunk server</td>
<td>5000</td>
<td>int</td>
</tr>
<tr>
<td><strong>host</strong> (common)</td>
<td>Splunk host.</td>
<td>localhost</td>
<td>String</td>
</tr>
<tr>
<td><strong>owner</strong> (common)</td>
<td>Splunk owner</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>port</strong> (common)</td>
<td>Splunk port</td>
<td>8089</td>
<td>int</td>
</tr>
<tr>
<td><strong>scheme</strong> (common)</td>
<td>Splunk scheme</td>
<td>https</td>
<td>String</td>
</tr>
<tr>
<td><strong>bridgeErrorHandler</strong> (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>count</strong> (consumer)</td>
<td>A number that indicates the maximum number of entities to return.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td><strong>earliestTime</strong> (consumer)</td>
<td>Earliest time of the search time window.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>initEarliestTime</strong> (consumer)</td>
<td>Initial start offset of the first search</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>latestTime</strong> (consumer)</td>
<td>Latest time of the search time window.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>savedSearch</strong> (consumer)</td>
<td>The name of the query saved in Splunk to run</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>search</strong> (consumer)</td>
<td>The Splunk query to run</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>sendEmptyMessageWhenIdle</strong> (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------------</td>
</tr>
<tr>
<td>streaming</td>
<td>Sets streaming mode. Streaming mode sends exchanges as they are received, rather than in a batch.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>pollStrategy</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td>eventHost</td>
<td>Override the default Splunk event host field</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>index</td>
<td>Splunk index to write to</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>raw</td>
<td>Should the payload be inserted raw</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>source</td>
<td>Splunk source argument</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>sourceType</td>
<td>Splunk sourcetype argument</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>tcpReceiverPort</td>
<td>Splunk tcp receiver port</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffIdleThreshold</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td>backoffMultiplier</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>delay</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>scheduledExecutorService</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td></td>
<td>ScheduledExecuto r Service</td>
</tr>
<tr>
<td>scheduler</td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollCon sumer Scheduler</td>
</tr>
<tr>
<td>schedulerProperties</td>
<td>To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>startScheduler</td>
<td>Whether the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>timeUnit</td>
<td>Time unit for initialDelay and delay options.</td>
<td>MILLIS ECONS</td>
<td>TimeUnit</td>
</tr>
<tr>
<td>useFixedDelay</td>
<td>Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
295.5. MESSAGE BODY

Splunk operates on data in key/value pairs. The SplunkEvent class is a placeholder for such data, and should be in the message body for the producer. Likewise it will be returned in the body per search result for the consumer.

As of Camel 2.16.0 you can send raw data to Splunk by setting the raw option on the producer endpoint. This is useful for eg. json/xml and other payloads where Splunk has build in support.

295.6. USE CASES

Search Twitter for tweets with music and publish events to Splunk

```java
from("twitter://search?type=polling&keywords=music&delay=10&consumerKey=abc&consumerSecret=def&accessToken=hij&accessTokenSecret=xxx")
    .convertBodyTo(SplunkEvent.class)
    .to("splunk://submit?username=foo&password=bar&index=camel-tweets&sourceType=twitter&source=music-tweets");
```

To convert a Tweet to a SplunkEvent you could use a converter like

```java
@Converter
public class Tweet2SplunkEvent {
    @Converter
    public static SplunkEvent convertTweet(Status status) {
        SplunkEvent data = new SplunkEvent("twitter-message", null);
        //data.addPair("source", status.getSource());
        data.addPair("from_user", status.getUser().getScreenName());
        data.addPair("in_reply_to", status.getInReplyToScreenName());
        data.addPair(SplunkEvent.COMMON_START_TIME, status.getCreatedAt());
        data.addPair(SplunkEvent.COMMON_EVENT_ID, status.getId());
        data.addPair("text", status.getText());
        data.addPair("retweet_count", status.getRetweetCount());
        if (status.getPlace() != null) {
            // Add place information here...
        }
    }
}
```
Splunk comes with a variety of options for leveraging machine generated data with prebuilt apps for analyzing and displaying this. For example, the jmx app could be used to publish jmx attributes, eg. route and jvm metrics to Splunk, and displaying this on a dashboard.

295.7. OTHER COMMENTS

Splunk comes with a variety of options for leveraging machine generated data with prebuilt apps for analyzing and displaying this.

- Getting Started
CHAPTER 296. SPRING SUPPORT

Apache Camel is designed to work nicely with the Spring Framework in a number of ways.

- Camel uses Spring Transactions as the default transaction handling in components like JMS and JPA.
- Camel works with Spring 2 XML processing with the Xml Configuration.
- Camel Spring XML Schema’s is defined at Xml Reference.
- Camel supports a powerful version of Spring Remoting which can use powerful routing between the client and server side along with using all of the available Components for the transport.
- Camel provides powerful Bean Integration with any bean defined in a Spring ApplicationContext.
- Camel integrates with various Spring helper classes; such as providing Type Converter support for Spring Resources etc.
- Allows Spring to dependency inject Component instances or the CamelContext instance itself and auto-expose Spring beans as components and endpoints.
- Allows you to reuse the Spring Testing framework to simplify your unit and integration testing using Enterprise Integration Patterns and Camel’s powerful Mock and Test endpoints.
- From Camel 2.15 onwards Camel supports Spring Boot using the camel-spring-boot component.

296.1. USING SPRING TO CONFIGURE THE CAMELCONTEXT

You can configure a CamelContext inside any spring.xml using the CamelContextFactoryBean. This will automatically start the CamelContext along with any referenced Routes along any referenced Component and Endpoint instances.

- Adding Camel schema
- Configure Routes in two ways:
  - Using Java Code
  - Using Spring XML

296.2. ADDING CAMEL SCHEMA

For Camel 1.x you need to use the following namespace:

http://activemq.apache.org/camel/schema/spring

with the following schema location:

http://activemq.apache.org/camel/schema/spring/camel-spring.xsd

You need to add Camel to the schemaLocation declaration.
So the XML file looks like this:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

   <camel:camelContext id="camel5">
      <camel:package>org.apache.camel.spring.example</camel:package>
   </camel:camelContext>

</beans>
```

### 296.2.1. Using camel: namespace

Or you can refer to camel XSD in the XML declaration:

```xml
<beans xmlns:camel="http://camel.apache.org/schema/spring"
       xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

   <camel:camelContext id="camel5">
      <camel:package>org.apache.camel.spring.example</camel:package>
   </camel:camelContext>

</beans>
```

### 296.2.2. Advanced configuration using Spring

See more details at [Advanced configuration of CamelContext using Spring](http://camel.apache.org/schema/spring).

### 296.2.3. Using `<package>`

Camel also provides a powerful feature that allows for the automatic discovery and initialization of routes in given packages. This is configured by adding tags to the camel context in your spring context definition, specifying the packages to be recursively searched for RouteBuilder implementations. To use this feature in 1.X, requires a `<package>` tag specifying a comma separated list of packages that should be searched e.g.
WARNING: Use caution when specifying the package name as org.apache.camel or a sub package of this. This causes Camel to search in its own packages for your routes which could cause problems.

INFO: *Will ignore already instantiated classes*. The <package> and <packageScan> will skip any classes which has already been created by Spring etc. So if you define a route builder as a spring bean tag then that class will be skipped. You can include those beans using <routeBuilder ref="theBeanId"/> or the <contextScan> feature.

### 296.2.4. Using <packageScan>

In Camel 2.0 this has been extended to allow selective inclusion and exclusion of discovered route classes using Ant like path matching. In spring this is specified by adding a <packageScan/> tag. The tag must contain one or more ‘package’ elements (similar to 1.x), and optionally one or more ‘includes’ or ‘excludes’ elements specifying patterns to be applied to the fully qualified names of the discovered classes. e.g.

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <packageScan>
    <package>org.example.routes</package>
    <excludes>**.*Excluded*</excludes>
    <includes>**.*</includes>
  </packageScan>
</camelContext>
```

Exclude patterns are applied before the include patterns. If no include or exclude patterns are defined then all the Route classes discovered in the packages will be returned.

In the above example, camel will scan all the ‘org.example.routes’ package and any subpackages for RouteBuilder classes. Say the scan finds two RouteBuilders, one in org.example.routes called ‘MyRoute” and another ‘MyExcludedRoute’ in a subpackage ‘excluded’. The fully qualified names of each of the classes are extracted (org.example.routes.MyRoute, org.example.routes.excluded.MyExcludedRoute) and the include and exclude patterns are applied.

The exclude pattern `*.Excluded` is going to match the fqcn ‘org.example.routes.excluded.MyExcludedRoute’ and veto camel from initializing it.

Under the covers, this is using Spring’s AntPatternMatcher implementation, which matches as follows

- `?` matches one character
- `*` matches zero or more characters
- `**` matches zero or more segments of a fully qualified name

For example:

- `*.Excluded` would match org.simple.Excluded, org.apache.camel.SomeExcludedRoute or org.example.RouteWhichIsExcluded

- `*.??cluded` would match org.simple.IncludedRoute, org.simple.Excluded but not match org.simple.PrecludedRoute
296.2.5. Using contextScan

Available as of Camel 2.4

You can allow Camel to scan the container context, e.g. the Spring ApplicationContext for route builder instances. This allow you to use the Spring `<component-scan>` feature and have Camel pickup any RouteBuilder instances which was created by Spring in its scan process.

This allows you to just annotate your routes using the Spring `@Component` and have those routes included by Camel

```java
@Component
public class MyRoute extends SpringRouteBuilder {
    @Override
    public void configure() throws Exception {
        from("direct:start").to("mock:result");
    }
}
```

You can also use the ANT style for inclusion and exclusion, as mentioned above in the `<packageScan>` documentation.

296.3. HOW DO I IMPORT ROUTES FROM OTHER XML FILES

Available as of Camel 2.3

When defining routes in Camel using Xml Configuration you may want to define some routes in other XML files. For example you may have many routes and it may help to maintain the application if some of the routes are in separate XML files. You may also want to store common and reusable routes in other XML files, which you can simply import when needed.

In Camel 2.3 it is now possible to define routes outside `<camelContext/>` which you do in a new `<routeContext/>` tag.

**Notice:** When you use `<routeContext/>` then they are separated, and cannot reuse existing `<onException>`, `<intercept>`, `<dataFormats>` and similar cross cutting functionality defined in the `<camelContext>`. In other words the `<routeContext>` is currently isolated. This may change in Camel 3.x.

For example we could have a file named `myCoolRoutes.xml` which contains a couple of routes as shown:

```
myCoolRoutes.xml
```

Then in your XML file which contains the CamelContext you can use Spring to import the `myCoolRoute.xml` file.

And then inside `<camelContext/>` you can refer to the `<routeContext/>` by its id as shown below:

```
Also notice that you can mix and match, having routes inside CamelContext and also externalized in RouteContext.

You can have as many `<routeContextRef/>` as you like.

Reusable routes
The routes defined in `<routeContext/>` can be reused by multiple `<camelContext/>`. However its only the definition which is reused. At runtime each CamelContext will create its own instance of the route based on the definition.

### 296.3.1. Test time exclusion.

At test time it is often desirable to be able to selectively exclude matching routes from being initialized that are not applicable or useful to the test scenario. For instance you might have a spring context file `routes-context.xml` and three Route builders RouteA, RouteB and RouteC in the `org.example.routes` package. The `packageScan` definition would discover all three of these routes and initialize them.

Say RouteC is not applicable to our test scenario and generates a lot of noise during test. It would be nice to be able to exclude this route from this specific test. The `SpringTestSupport` class has been modified to allow this. It provides two methods (excludedRoute and excludedRoutes) that may be overridden to exclude a single class or an array of classes.

```java
public class RouteAandRouteBOnlyTest extends SpringTestSupport {
    @Override
    protected Class excludeRoute() {
        return RouteC.class;
    }
}
```

In order to hook into the `camelContext` initialization by spring to exclude the `MyExcludedRouteBuilder.class` we need to intercept the spring context creation. When overriding `createApplicationContext` to create the spring context, we call the `getRouteExcludingApplicationContext()` method to provide a special parent spring context that takes care of the exclusion.

```java
@Override
protected AbstractXmlApplicationContext createApplicationContext() {
    return new ClassPathXmlApplicationContext(new String[] {"routes-context.xml"},
        getRouteExcludingApplicationContext());
}
```

RouteC will now be excluded from initialization. Similarly, in another test that is testing only RouteC, we could exclude RouteB and RouteA by overriding

```java
@Override
protected Class[] excludeRoutes() {
    return new Class[]{RouteA.class, RouteB.class};
}
```

### 296.4. USING SPRING XML

You can use Spring 2.0 XML configuration to specify your Xml Configuration for Routes such as in the following example.

### 296.5. CONFIGURING COMPONENTS AND ENDPOINTS

You can configure your Component or Endpoint instances in your Spring XML as follows in this example.

Which allows you to configure a component using some name (activemq in the above example), then
you can refer to the component using `activemq:[queue:|topic:]destinationName`. This works by the SpringCamelContext lazily fetching components from the spring context for the scheme name you use for Endpoint URIs.

For more detail see Configuring Endpoints and Components.

### 296.6. CAMELCONTEXTAWARE

If you want to be injected with the CamelContext in your POJO just implement the `CamelContextAware` interface; then when Spring creates your POJO the CamelContext will be injected into your POJO. Also see the Bean Integration for further injections.

### 296.7. INTEGRATION TESTING

To avoid a hung route when testing using Spring Transactions see the note about Spring Integration Testing under Transactional Client.

CHAPTER 297. SPRING BATCH COMPONENT

Available as of Camel version 2.10

The spring-batch: component and support classes provide integration bridge between Camel and Spring Batch infrastructure.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-batch</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

297.1. URI FORMAT

```
spring-batch:jobName[?options]
```

Where jobName represents the name of the Spring Batch job located in the Camel registry. Alternatively if a JobRegistry is provided it will be used to locate the job instead.

WARNING: This component can only be used to define producer endpoints, which means that you cannot use the Spring Batch component in a from() statement.

297.2. OPTIONS

The Spring Batch component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobLauncher (producer)</td>
<td>Explicitly specifies a JobLauncher to be used.</td>
<td></td>
<td>JobLauncher</td>
</tr>
<tr>
<td>jobRegistry (producer)</td>
<td>Explicitly specifies a JobRegistry to be used.</td>
<td></td>
<td>JobRegistry</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Spring Batch endpoint is configured using URI syntax:

```
spring-batch:jobName
```

with the following path and query parameters:
297.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobName</td>
<td><strong>Required</strong> The name of the Spring Batch job located in the registry.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

297.2.2. Query Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobFromHeader</td>
<td>Explicitly defines if the jobName should be taken from the headers instead of the URI.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>jobLauncher</td>
<td>Explicitly specifies a JobLauncher to be used.</td>
<td></td>
<td>JobLauncher</td>
</tr>
<tr>
<td>jobRegistry</td>
<td>Explicitly specifies a JobRegistry to be used.</td>
<td></td>
<td>JobRegistry</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

297.3. USAGE

When Spring Batch component receives the message, it triggers the job execution. The job will be executed using the `org.springframework.batch.core.launch.JobLaucher` instance resolved according to the following algorithm:

- if `JobLauncher` is manually set on the component, then use it.
- if `jobLauncherRef` option is set on the component, then search Camel Registry for the `JobLauncher` with the given name. **Deprecated and will be removed in Camel 3.0**!
- if there is `JobLauncher` registered in the Camel Registry under `jobLauncher` name, then use it.
- if none of the steps above allow to resolve the `JobLauncher` and there is exactly one `JobLauncher` instance in the Camel Registry, then use it.

All headers found in the message are passed to the `JobLauncher` as job parameters. `String`, `Long`, `Double` and `java.util.Date` values are copied to the `org.springframework.batch.core.JobParametersBuilder` - other data types are converted to Strings.

297.4. EXAMPLES

Triggering the Spring Batch job execution:
Triggering the Spring Batch job execution with the **JobLauncher** set explicitly.

Starting from the Camel 2.11.1 **JobExecution** instance returned by the **JobLauncher** is forwarded by the **SpringBatchProducer** as the output message. You can use the **JobExecution** instance to perform some operations using the Spring Batch API directly.

Apart from the Component, Camel Spring Batch provides also support classes, which can be used to hook into Spring Batch infrastructure.

### 297.5.1. CamelItemReader

**CamelItemReader** can be used to read batch data directly from the Camel infrastructure. For example the snippet below configures Spring Batch to read data from JMS queue.

```
<bean id="camelReader" class="org.apache.camel.component.spring.batch.support.CamelItemReader">
    <constructor-arg ref="consumerTemplate"/>
    <constructor-arg value="jms:dataQueue"/>
</bean>

<batch:job id="myJob">
    <batch:step id="step">
        <batch:tasklet>
            <batch:chunk reader="camelReader" writer="someWriter" commit-interval="100"/>
        </batch:tasklet>
    </batch:step>
</batch:job>
```

### 297.5.2. CamelItemWriter

**CamelItemWriter** has similar purpose as **CamelItemReader**, but it is dedicated to write chunk of the processed data. For example the snippet below configures Spring Batch to read data from JMS queue.

```
<bean id="camelwriter" class="org.apache.camel.component.spring.batch.support.CamelItemWriter">
    <constructor-arg ref="producerTemplate"/>
    <constructor-arg value="jms:dataQueue"/>
</bean>
```
297.5.3. CamelItemProcessor

CamelItemProcessor is the implementation of Spring Batch org.springframework.batch.item.ItemProcessor interface. The latter implementation relays on Request Reply pattern to delegate the processing of the batch item to the Camel infrastructure. The item to process is sent to the Camel endpoint as the body of the message.

For example the snippet below performs simple processing of the batch item using the Direct endpoint and the Simple expression language.

```xml
<camel:camelContext>
  <camel:route>
    <camel:from uri="direct:processor"/>
    <camel:setExchangePattern pattern="InOut"/>
    <camel:setBody>
      <camel:simple>
        Processed ${body}
      </camel:simple>
    </camel:setBody>
  </camel:route>
</camel:camelContext>

<bean id="camelProcessor"
  class="org.apache.camel.component.spring.batch.support.CamelItemProcessor">
  <constructor-arg ref="producerTemplate"/>
  <constructor-arg value="direct:processor"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="someReader" writer="camelwriter" commit-interval="100"/>
    </batch:tasklet>
  </batch:step>
</batch:job>
```

297.5.4. CamelJobExecutionListener

CamelJobExecutionListener is the implementation of the org.springframework.batch.core.JobExecutionListener interface sending job execution events to the Camel endpoint.

The org.springframework.batch.core.JobExecution instance produced by the Spring Batch is sent as a body of the message. To distinguish between before- and after-callbacks SPRING_BATCH_JOB_EVENT_TYPE header is set to the BEFORE or AFTER value.

The example snippet below sends Spring Batch job execution events to the JMS queue.

```xml
<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="someReader" writer="someWriter" processor="camelProcessor" commit-interval="100"/>
    </batch:tasklet>
  </batch:step>
</batch:job>
```
297.6. SPRING CLOUD

Available as of Camel 2.19

Spring Cloud component

Maven users will need to add the following dependency to their `pom.xml` in order to use this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId.camel-spring-cloud</artifactId>
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->
</dependency>
```

camel-spring-cloud jar comes with the `spring.factories` file, so as soon as you add that dependency into your classpath, Spring Boot will automatically auto-configure Camel for you.

297.6.1. Camel Spring Cloud Starter

Available as of Camel 2.19

To use the starter, add the following to your spring boot `pom.xml` file:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId.camel-spring-cloud-starter</artifactId>
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->
</dependency>
```

297.7. SPRING CLOUD NETFLIX

Available as of Camel 2.19

The Spring Cloud Netflix component bridges Camel Cloud and Spring Cloud Netflix so you can leverage Spring Cloud Netflix service discovery and load balance features in Camel and/or you can use Camel...
Service Discovery implementations as ServerList source for Spring Cloud Netflix’s Ribbon load balancer.

Maven users will need to add the following dependency to their `pom.xml` in order to use this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-cloud-netflix</artifactId>
  <version>${camel.version}</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

camel-spring-cloud-netflix jar comes with the `spring.factories` file, so as soon as you add that dependency into your classpath, Spring Boot will automatically auto-configure Camel for you.

You can disable Camel Spring Cloud Netflix with the following properties:

```
# Enable/Disable the whole integration, default true
camel.cloud.netflix = true

# Enable/Disable the integration with Ribbon, default true
camel.cloud.netflix.ribbon = true
```

### 297.8. SPRING CLOUD NETFLIX STARTER

Available as of Camel 2.19

To use the starter, add the following to your spring boot pom.xml file:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-cloud-netflix-starter</artifactId>
  <version>${camel.version}</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 298. SPRING EVENT COMPONENT

Available as of Camel version 1.4

The spring-event: component provides access to the Spring ApplicationEvent objects. This allows you to publish ApplicationEvent objects to a Spring ApplicationContext or to consume them. You can then use Enterprise Integration Patterns to process them such as Message Filter.

298.1. URI FORMAT

| spring-event://default[?options] |

Note, at the moment there are no options for this component. That can easily change in future releases, so please check back.

298.2. SPRING EVENT OPTIONS

The Spring Event component has no options.

The Spring Event endpoint is configured using URI syntax:

| spring-event:name |

with the following path and query parameters:

298.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of endpoint</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

298.2.2. Query Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

- Getting Started
CHAPTER 299. SPRING INTEGRATION COMPONENT

Available as of Camel version 1.4

The spring-integration: component provides a bridge for Camel components to talk to spring integration endpoints.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-integration</artifactId>
  <version>1.4.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

299.1. URI FORMAT

```
spring-integration:defaultChannelName[?options]
```

Where defaultChannelName represents the default channel name which is used by the Spring Integration Spring context. It will equal to the inputChannel name for the Spring Integration consumer and the outputChannel name for the Spring Integration provider.

You can append query options to the URI in the following format, `?option=value&option=value&...`

299.2. OPTIONS

The Spring Integration component has no options.

The Spring Integration endpoint is configured using URI syntax:

```
spring-integration:defaultChannel
```

with the following path and query parameters:

299.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultChannel</td>
<td>Required The default channel name which is used by the Spring Integration Spring context. It will equal to the inputChannel name for the Spring Integration consumer and the outputChannel name for the Spring Integration provider.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

299.2.2. Query Parameters (7 parameters):
299.3. USAGE

The Spring integration component is a bridge that connects Camel endpoints with Spring integration endpoints through the Spring integration’s input channels and output channels. Using this component, we can send Camel messages to Spring Integration endpoints or receive messages from Spring integration endpoints in a Camel routing context.

299.4. EXAMPLES

299.4.1. Using the Spring integration endpoint

You can set up a Spring integration endpoint using a URI, as follows:
Or directly using a Spring integration channel name:

### 299.4.2. The Source and Target adapter

Spring integration also provides the Spring integration’s source and target adapters, which can route messages from a Spring integration channel to a Camel endpoint or from a Camel endpoint to a Spring integration channel.

This example uses the following namespaces:

You can bind your source or target to a Camel endpoint as follows:

### 299.5. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started

### 299.6. SPRING JAVA CONFIG

Spring started life using XML Config to wire beans together. However some folks don’t like using XML and would rather use Java code which led to the creation of Guice along with the Spring JavaConfig project.

You can use either the XML or Java config approaches with Camel; its your choice really on which you prefer.

#### 299.6.1. Using Spring Java Config

To use Spring Java Config in your Camel project the easiest thing to do is add the following to your pom.xml

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId.camel-spring-javaconfig</artifactId>
    <version>${camel-version}</version>
</dependency>
```

This will then add the dependencies on the Spring JavaConfig library along with some helper classes for configuring Camel inside Spring.

Note that this library is totally optional; you could just wire Camel together yourself with Java Config.

#### 299.6.2. Configuration

The most common case of using JavaConfig with Camel would be to create configuration with defined list of routes to be used by router.

```java
@Configuration
public class MyRouteConfiguration extends CamelConfiguration {
```
Starting from Camel 2.13.0 you can skip the `routes()` definition, and fall back to the `RouteBuilder` instances located in the Spring context.

```java
@Configuration
@ComponentScan("com.example.routes")
public class MyRouteConfiguration extends CamelConfiguration {

    @Autowire
    private MyRouteBuilder myRouteBuilder;

    @Autowire
    private MyAnotherRouteBuilder myAnotherRouteBuilder;

    @Override
    public List<RouteBuilder> routes() {
        return Arrays.asList(myRouteBuilder, myAnotherRouteBuilder);
    }
}
```

299.6.3. Testing

Since Camel 2.11.0 you can use the `CamelSpringJUnit4ClassRunner` with `CamelSpringDelegatingTestContextLoader`. This is the recommended way to test Java Config and Camel integration.

If you wish to create a collection of `RouteBuilder` instances then derive from the `CamelConfiguration` helper class and implement the `routes()` method. Keep in mind that (starting from the Camel 2.13.0) if you don’t override `routes()` method, then `CamelConfiguration` will use all `RouteBuilder` instances available in the Spring context.

The following example using Java Config demonstrates how to test Java Config integration with Camel 2.10 and lower. Keep in mind that `JavaConfigContextLoader` is deprecated and could be removed in the future versions of Camel on the behalf of the `CamelSpringDelegatingTestContextLoader`.

The `@ContextConfiguration` annotation tells the Spring Testing framework to load the `ContextConfig` class as the configuration to use. This class derives from `SingleRouteCamelConfiguration` which is a helper Spring Java Config class which will configure the CamelContext for us and then register the RouteBuilder we create.
CHAPTER 300. SPRING LDAP COMPONENT

Available as of Camel version 2.11

The `spring-ldap:` component provides a Camel wrapper for Spring LDAP.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-ldap</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

300.1. URI FORMAT

```
spring-ldap:springLdapTemplate[?options]
```

Where `springLdapTemplate` is the name of the Spring LDAP Template bean. In this bean, you configure the URL and the credentials for your LDAP access.

300.2. OPTIONS

The Spring LDAP component has no options.

The Spring LDAP endpoint is configured using URI syntax:

```
spring-ldap:templateName
```

with the following path and query parameters:

300.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>templateName</td>
<td>Required Name of the Spring LDAP Template bean</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

300.2.2. Query Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>Required The LDAP operation to be performed.</td>
<td></td>
<td>LdapOperation</td>
</tr>
<tr>
<td>scope</td>
<td>The scope of the search operation.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(producer)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(producer)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
300.3. USAGE

The component supports producer endpoint only. An attempt to create a consumer endpoint will result in an `UnsupportedOperationException`. The body of the message must be a map (an instance of `java.util.Map`). Unless a base DN is specified by in the configuration of your ContextSource, this map must contain at least an entry with the key `dn` (not needed for function_driven operation) that specifies the root node for the LDAP operation to be performed. Other entries of the map are operation-specific (see below).

The body of the message remains unchanged for the `bind` and `unbind` operations. For the `search` and function_driven operations, the body is set to the result of the search, see http://static.springsource.org/spring-ldap/site/apidocs/org/springframework/ldap/core/LdapTemplate.html#search%28java.lang.String,%20java.lang.String,%20int,%20org.springframework.ldap.core.AttributesMapper%29

300.3.1. Search

The message body must have an entry with the key `filter`. The value must be a `String` representing a valid LDAP filter, see http://en.wikipedia.org/wiki/Lightweight_Directory_Access_Protocol#Search_and_Compare.

300.3.2. Bind

The message body must have an entry with the key `attributes`. The value must be an instance of `javax.naming.directory.Attributes` This entry specifies the LDAP node to be created.

300.3.3. Unbind

No further entries necessary, the node with the specified `dn` is deleted.

300.3.4. Authenticate

The message body must have entries with the keys `filter` and `password`. The values must be an instance of `String` representing a valid LDAP filter and a user password, respectively.

300.3.5. Modify Attributes

The message body must have an entry with the key `modificationItems`. The value must be an instance of any array of type `javax.naming.directory.ModificationItem`

300.3.6. Function-Driven

The message body must have entries with the keys `function` and `request`. The `function` value must be of type `java.util.function.BiFunction<L, Q, S>`. The `L` type parameter must be of type `org.springframework.ldap.core.LdapOperations`. The `request` value must be the same type as the `Q` type parameter in the `function` and it must encapsulate the parameters expected by the LdapTemplate
method being invoked within the **function**. The **S** type parameter represents the response type as returned by the LdapTemplate method being invoked. This operation allows dynamic invocation of LdapTemplate methods that are not covered by the operations mentioned above.

**Key definitions**

In order to avoid spelling errors, the following constants are defined in `org.apache.camel.springldap.SpringLdapProducer`:

- public static final String DN = "dn"
- public static final String FILTER = "filter"
- public static final String ATTRIBUTES = "attributes"
- public static final String PASSWORD = "password"
- public static final String MODIFICATION_ITEMS = "modificationItems"
- public static final String FUNCTION = "function"
- public static final String REQUEST = "request"
CHAPTER 301. SPRING REDIS COMPONENT

Available as of Camel version 2.11

This component allows sending and receiving messages from Redis. Redis is an advanced key-value store where keys can contain strings, hashes, lists, sets and sorted sets. In addition, it provides pub/sub functionality for inter-app communications. Camel provides a producer for executing commands, a consumer for subscribing to pub/sub messages, and an idempotent repository for filtering out duplicate messages.

INFO:*Prerequisites* In order to use this component, you must have a Redis server running.

### 301.1. URI FORMAT

```
spring-redis://host:port[?options]
```

You can append query options to the URI in the following format, `?options=value&option2=value&...`

### 301.2. URI OPTIONS

The Spring Redis component has no options.

The Spring Redis endpoint is configured using URI syntax:

```
spring-redis:host:port
```

with the following path and query parameters:

#### 301.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required The host where Redis server is running.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>Required Redis server port number</td>
<td></td>
<td>Integer</td>
</tr>
</tbody>
</table>

#### 301.2.2. Query Parameters (10 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>channels (common)</td>
<td>List of topic names or name patterns to subscribe to. Multiple names can be separated by comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>command (common)</td>
<td>Default command, which can be overridden by message header. Notice the consumer only supports the following commands: PSUBSCRIBE and SUBSCRIBE</td>
<td>SET</td>
<td>Command</td>
</tr>
</tbody>
</table>
### Name

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectionFactory (common)</td>
<td>Reference to a pre-configured RedisConnectionFactory instance to use.</td>
<td></td>
<td>RedisConnectionFactory</td>
</tr>
<tr>
<td>redisTemplate (common)</td>
<td>Reference to a pre-configured RedisTemplate instance to use.</td>
<td></td>
<td>RedisTemplate</td>
</tr>
<tr>
<td>serializer (common)</td>
<td>Reference to a pre-configured RedisSerializer instance to use.</td>
<td></td>
<td>RedisSerializer</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>listenerContainer (consumer)</td>
<td>Reference to a pre-configured RedisMessageListenerContainer instance to use.</td>
<td></td>
<td>RedisMessageListenerContainer</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 301.3. USAGE

### 301.3.1. Message headers evaluated by the Redis producer

The producer issues commands to the server and each command has different set of parameters with specific types. The result from the command execution is returned in the message body.
<table>
<thead>
<tr>
<th>Hash Commands</th>
<th>Description</th>
<th>Parameters</th>
<th>Result</th>

### 301.4. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId.camel-spring-redis</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel (2.11 or higher).

CHAPTER 302. SPRING SECURITY

Available as of Camel 2.3

The camel-spring-security component provides role-based authorization for Camel routes. It leverages the authentication and user services provided by Spring Security (formerly Acegi Security) and adds a declarative, role-based policy system to control whether a route can be executed by a given principal.

If you are not familiar with the Spring Security authentication and authorization system, please review the current reference documentation on the SpringSource web site linked above.

302.1. CREATING AUTHORIZATION POLICIES

Access to a route is controlled by an instance of a SpringSecurityAuthorizationPolicy object. A policy object contains the name of the Spring Security authority (role) required to run a set of endpoints and references to Spring Security AuthenticationManager and AccessDecisionManager objects used to determine whether the current principal has been assigned that role. Policy objects may be configured as Spring beans or by using an <authorizationPolicy> element in Spring XML.

The <authorizationPolicy> element may contain the following attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>null</td>
<td>The unique Spring bean identifier which is used to reference the policy in routes (required)</td>
</tr>
<tr>
<td>access</td>
<td>null</td>
<td>The Spring Security authority name that is passed to the access decision manager (required)</td>
</tr>
<tr>
<td>authenticationManager</td>
<td>authenticationManager</td>
<td>The name of the Spring Security AuthenticationManager object in the context</td>
</tr>
<tr>
<td>accessDecisionManager</td>
<td>accessDecisionManager</td>
<td>The name of the Spring Security AccessDecisionManager object in the context</td>
</tr>
<tr>
<td>authenticationAdapter</td>
<td>Default Authentication Adapter</td>
<td>Camel 2.4 The name of a camel-spring-securityAuthenticationAdapter object in the context that is used to convert a javax.security.auth.Subject into a Spring Security Authentication instance.</td>
</tr>
</tbody>
</table>
### 302.2. CONTROLLING ACCESS TO CAMEL ROUTES

A Spring Security `AuthenticationManager` and `AccessDecisionManager` are required to use this component. Here is an example of how to configure these objects in Spring XML using the Spring Security namespace:

Now that the underlying security objects are set up, we can use them to configure an authorization policy and use that policy to control access to a route:

In this example, the endpoint `mock:end` will not be executed unless a Spring Security `Authentication` object that has been or can be authenticated and contains the `ROLE_ADMIN` authority can be located by the `admin SpringSecurityAuthorizationPolicy`.

### 302.3. AUTHENTICATION

The process of obtaining security credentials that are used for authorization is not specified by this component. You can write your own processors or components which get authentication information from the exchange depending on your needs. For example, you might create a processor that gets credentials from an HTTP request header originating in the Jetty component. No matter how the credentials are collected, they need to be placed in the In message or the `SecurityContextHolder` so the Camel `Spring Security` component can access them:

```java
import javax.security.auth.Subject;
import org.apache.camel.*;
import org.apache.commons.codec.binary.Base64;
import org.springframework.security.authentication.*;

public class MyAuthService implements Processor {
    public void process(Exchange exchange) throws Exception {
        // get the username and password from the HTTP header
        // http://en.wikipedia.org/wiki/Basic_access_authentication
        String userpass = new String(Base64.decodeBase64(exchange.getIn().getHeader("Authorization", String.class)));
        String[] tokens = userpass.split(":");

        // create an Authentication object
        UsernamePasswordAuthenticationToken authToken = new UsernamePasswordAuthenticationToken(tokens[0], tokens[1]);
    }
}
```
The SpringSecurityAuthorizationPolicy will automatically authenticate the Authentication object if necessary.

There are two issues to be aware of when using the SecurityContextHolder instead of or in addition to the Exchange.AUTHENTICATION header. First, the context holder uses a thread-local variable to hold the Authentication object. Any routes that cross thread boundaries, like seda or jms, will lose the Authentication object. Second, the Spring Security system appears to expect that an Authentication object in the context is already authenticated and has roles (see the Technical Overview section 5.3.1 for more details).

The default behavior of camel-spring-security is to look for a Subject in the Exchange.AUTHENTICATION header. This Subject must contain at least one principal, which must be a subclass of org.springframework.security.core.Authentication. You can customize the mapping of Subject to Authentication object by providing an implementation of the org.apache.camel.component.spring.security.AuthenticationAdapter to your <authorizationPolicy> bean. This can be useful if you are working with components that do not use Spring Security but do provide a Subject. At this time, only the CXF component populates the Exchange.AUTHENTICATION header.

302.4. HANDLING AUTHENTICATION AND AUTHORIZATION ERRORS

If authentication or authorization fails in the SpringSecurityAuthorizationPolicy, a CamelAuthorizationException will be thrown. This can be handled using Camel's standard exception handling methods, like the Exception Clause. The CamelAuthorizationException will have a reference to the ID of the policy which threw the exception so you can handle errors based on the policy as well as the type of exception:

```xml
<onException>
  <exception>org.springframework.security.authentication.AccessDeniedException</exception>
  <choice>
    <when>
      <simple>${exception.policyId} == 'user'</simple>
      <transform>
        <constant>You do not have ROLE_USER access!</constant>
      </transform>
    </when>
    <when>
      <simple>${exception.policyId} == 'admin'</simple>
      <transform>
        <constant>You do not have ROLE_ADMIN access!</constant>
      </transform>
    </when>
  </choice>
</onException>
```
302.5. DEPENDENCIES

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-security</artifactId>
  <version>2.4.0</version>
</dependency>
```

This dependency will also pull in `org.springframework.security:spring-security-core:3.0.3.RELEASE` and `org.springframework.security:spring-security-config:3.0.3.RELEASE`.

 CHAPTER 303. SPRING WEBSERVICE COMPONENT

Available as of Camel version 2.6

The spring-ws: component allows you to integrate with Spring Web Services. It offers both client-side support, for accessing web services, and server-side support for creating your own contract-first web services.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-spring-ws</artifactId>
    <version>x.x.x</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

INFO:*Dependencies* As of Camel 2.8 this component ships with Spring-WS 2.0.x which (like the rest of Camel) requires Spring 3.0.x. Earlier Camel versions shipped Spring-WS 1.5.9 which is compatible with Spring 2.5.x and 3.0.x. In order to run earlier versions of camel-spring-ws on Spring 2.5.x you need to add the spring-webmvc module from Spring 2.5.x. In order to run Spring-WS 1.5.9 on Spring 3.0.x you need to exclude the OXM module from Spring 3.0.x as this module is also included in Spring-WS 1.5.9 (see this post)

303.1. URI FORMAT

The URI scheme for this component is as follows

`spring-ws:[mapping-type:]address[?options]`

To expose a web service mapping-type needs to be set to any of the following:

<table>
<thead>
<tr>
<th>Mapping type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rootqname</td>
<td>Offers the option to map web service requests based on the qualified name of the root element contained in the message.</td>
</tr>
<tr>
<td>soapaction</td>
<td>Used to map web service requests based on the SOAP action specified in the header of the message.</td>
</tr>
<tr>
<td>uri</td>
<td>In order to map web service requests that target a specific URI.</td>
</tr>
<tr>
<td>xpathresult</td>
<td>Used to map web service requests based on the evaluation of an XPath expression against the incoming message. The result of the evaluation should match the XPath result specified in the endpoint URI.</td>
</tr>
</tbody>
</table>
**Mapping type**

**beanname:** Allows you to reference an `org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher` object in order to integrate with existing (legacy) endpoint mappings like `PayloadRootQNameEndpointMapping`, `SoapActionEndpointMapping`, etc.

As a consumer the **address** should contain a value relevant to the specified mapping-type (e.g. a SOAP action, XPath expression). As a producer the address should be set to the URI of the web service your calling upon.

You can append query **options** to the URI in the following format, `?option=value&option=value&...`

### 303.2. OPTIONS

The Spring WebService component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>useGlobalSslContext Parameters (security)</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Spring WebService endpoint is configured using URI syntax:

```
spring-ws:type:lookupKey:webServiceEndpointUri
```

with the following path and query parameters:

### 303.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
</table>
### Endpoint Mapping Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Endpoint mapping type if endpoint mapping is used.</td>
</tr>
<tr>
<td>rootqname</td>
<td>Offers the option to map web service requests based on the qualified name of the root element contained in the message.</td>
</tr>
<tr>
<td>soapaction</td>
<td>Used to map web service requests based on the SOAP action specified in the header of the message.</td>
</tr>
<tr>
<td>uri</td>
<td>In order to map web service requests that target a specific URI.</td>
</tr>
<tr>
<td>xpathresult</td>
<td>Used to map web service requests based on the evaluation of an XPath expression against the incoming message. The result of the evaluation should match the XPath result specified in the endpoint URI.</td>
</tr>
<tr>
<td>beannme</td>
<td>Allows you to reference an org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher object in order to integrate with existing (legacy) endpoint mappings like PayloadRootQNameEndpointMapping, SoapActionEndpointMapping, etc.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>lookupKey</td>
<td>Endpoint mapping key if endpoint mapping is used</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>webServiceEndpoint</td>
<td>The default Web Service endpoint uri to use for the producer.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 303.2.2. Query Parameters (22 parameters)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageFilter</td>
<td>Option to provide a custom MessageFilter. For example when you want to process your headers or attachments by your own.</td>
<td></td>
<td>MessageFilter</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>endpointDispatcher (consumer)</td>
<td>Spring org.springframework.ws.server.endpoint.MessageEndpoint for dispatching messages received by Spring-WS to a Camel endpoint, to integrate with existing (legacy) endpoint mappings like PayloadRootQNameEndpointMapping, SoapActionEndpointMapping, etc.</td>
<td></td>
<td>CamelEndpointDispatcher</td>
</tr>
<tr>
<td>endpointMapping (consumer)</td>
<td>Reference to an instance of org.apache.camel.component.spring.ws.bean.CamelEndpointMapping in the Registry/ApplicationContext. Only one bean is required in the registry to serve all Camel/Spring-WS endpoints. This bean is auto-discovered by the MessageDispatcher and used to map requests to Camel endpoints based on characteristics specified on the endpoint (like root QName, SOAP action, etc)</td>
<td></td>
<td>CamelSpringWSEndpointMapping</td>
</tr>
<tr>
<td>expression (consumer)</td>
<td>The XPath expression to use when option type=xpathresult. Then this option is required to be configured.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>allowResponseAttachmentOverride (producer)</td>
<td>Option to override soap response attachments in in/out exchange with attachments from the actual service layer. If the invoked service appends or rewrites the soap attachments this option when set to true, allows the modified soap attachments to be overwritten in in/out message attachments</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>allowResponseHeaderOverride (producer)</td>
<td>Option to override soap response header in in/out exchange with header info from the actual service layer. If the invoked service appends or rewrites the soap header this option when set to true, allows the modified soap header to be overwritten in in/out message headers</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------------</td>
</tr>
<tr>
<td>faultAction</td>
<td>Signifies the value for the faultAction response WS-Addressing Fault Action header that is provided by the method.</td>
<td></td>
<td>URI</td>
</tr>
<tr>
<td>faultTo</td>
<td>Signifies the value for the faultAction response WS-Addressing FaultTo header that is provided by the method.</td>
<td></td>
<td>URI</td>
</tr>
<tr>
<td>messageFactory</td>
<td>Option to provide a custom WebServiceMessageFactory. For example when you want Apache Axiom to handle web service messages instead of SAAJ.</td>
<td></td>
<td>WebServiceMessageFactory</td>
</tr>
<tr>
<td>messageIdStrategy</td>
<td>Option to provide a custom MessageIdStrategy to control generation of unique message ids.</td>
<td></td>
<td>MessageIdStrategy</td>
</tr>
<tr>
<td>messageSender</td>
<td>Option to provide a custom WebServiceMessageSender. For example to perform authentication or use alternative transports</td>
<td></td>
<td>WebServiceMessageSender</td>
</tr>
<tr>
<td>outputAction</td>
<td>Signifies the value for the response WS-Addressing Action header that is provided by the method.</td>
<td></td>
<td>URI</td>
</tr>
<tr>
<td>replyTo</td>
<td>Signifies the value for the replyTo response WS-Addressing ReplyTo header that is provided by the method.</td>
<td></td>
<td>URI</td>
</tr>
<tr>
<td>soapAction</td>
<td>SOAP action to include inside a SOAP request when accessing remote web services</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### 303.2.3. Message headers

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelSpringWebServiceEndpointUri</td>
<td>String</td>
<td>URI of the web service your accessing as a client, overrides address part of the endpoint URI</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>CamelSpringWebServiceSoapAction</code></td>
<td>String</td>
<td>Header to specify the SOAP action of the message, overrides <code>soapAction</code> option if present</td>

<td>Use this header to specify the WS-Addressing FaultTo, overrides <code>faultTo</code> option if present</td>
</tr>
<tr>
<td><code>CamelSpringWebServiceAddressingReplyTo</code></td>
<td>URI</td>
<td>Use this header to specify the WS-Addressing ReplyTo, overrides <code>replyTo</code> option if present</td>
</tr>
<tr>
<td><code>CamelSpringWebServiceAddressingOutputAction</code></td>
<td>URI</td>
<td>Use this header to specify the WS-Addressing Action, overrides <code>outputAction</code> option if present</td>
</tr>
</tbody>
</table>
### 303.3. ACCESSING WEB SERVICES

To call a web service at `http://foo.com/bar` simply define a route:

```java
from("direct:example").to("spring-ws:http://foo.com/bar")
```

And sent a message:

```java
template.requestBody("direct:example", "<foobar xmlns="http://foo.com"><msg>test message</msg></foobar>");
```

Remember if it’s a SOAP service you’re calling you don’t have to include SOAP tags. Spring-WS will perform the XML-to-SOAP marshaling.

### 303.4. SENDING SOAP AND WS-ADDRESSING ACTION HEADERS

When a remote web service requires a SOAP action or use of the WS-Addressing standard you define your route as:

```java
from("direct:example")
```

Optionally you can override the endpoint options with header values:

```java
template.requestBodyAndHeader("direct:example", "<foobar xmlns="http://foo.com"><msg>test message</msg></foobar>",
SpringWebserviceConstants.SPRING_WS_SOAP_ACTION, "http://baz.com");
```

### 303.5. USING SOAP HEADERS

**Available as of Camel 2.11.1**

You can provide the SOAP header(s) as a Camel Message header when sending a message to a spring-ws endpoint, for example given the following SOAP header in a String

```java
String body = ...
String soapHeader = "<h:Header xmlns:h="http://www.webserviceX.NET/">
  <h:MessageID>1234567890</h:MessageID>
  <h:Nested><h:NestedID>1111</h:NestedID></h:Nested>
</h:Header>";
```
We can set the body and header on the Camel Message as follows:

```java
exchange.getIn().setBody(body);
exchange.getIn().setHeader(SpringWebserviceConstants.SPRING_WS_SOAP_HEADER, soapHeader);
```

And then send the Exchange to a `spring-ws` endpoint to call the Web Service.

Likewise the spring-ws consumer will also enrich the Camel Message with the SOAP header.

For an example see this [unit test](#).

### 303.6. THE HEADER AND ATTACHMENT PROPAGATION

Spring WS Camel supports propagation of the headers and attachments into Spring-WS WebServiceMessage response since version 2.10.3. The endpoint will use so called "hook" the MessageFilter (default implementation is provided by BasicMessageFilter) to propagate the exchange headers and attachments into WebServiceMessage response. Now you can use

```java
exchange.getOut().getHeaders().put("myCustom", "myHeaderValue")
exchange.getIn().addAttachment("myAttachment", new DataHandler(...))
```

Note: If the exchange header in the pipeline contains text, it generates QName(key)=value attribute in the soap header. Recommended is to create a QName class directly and put into any key into header.

### 303.7. HOW TO TRANSFORM THE SOAP HEADER USING A STYLESHEET

The header transformation filter (HeaderTransformationMessageFilter.java) can be used to transform the soap header for a soap request. If you want to use the header transformation filter, see the below example:

```xml
<bean id="headerTransformationFilter" class="org.apache.camel.component.spring.ws.filter.impl.HeaderTransformationMessageFilter">
  <constructor-arg index="0" value="org/apache/camel/component/spring/ws/soap-header-transform.xslt"/>
</bean>
```

Use the bead defined above in the camel endpoint

```xml
<route>
  <from uri="direct:stockQuoteWebserviceHeaderTransformation"/>
</route>
```

### 303.8. HOW TO USE MTOM ATTACHMENTS

The BasicMessageFilter provides all required information for Apache Axiom in order to produce MTOM message. If you want to use Apache Camel Spring WS within Apache Axiom, here is an example: - Simply define the messageFactory as is bellow and Spring-WS will use MTOM strategy to populate your SOAP
message with optimized attachments.

```xml
<bean id="axiomMessageFactory"
     class="org.springframework.ws.soap.axiom.AxiomSoapMessageFactory">
  <property name="payloadCaching" value="false" />
  <property name="attachmentCaching" value="true" />
  <property name="attachmentCacheThreshold" value="1024" />
</bean>
```

- Add into your pom.xml the following dependencies

```xml
<dependency>
  <groupId>org.apache.ws.commons.axiom</groupId>
  <artifactId>axiom-api</artifactId>
  <version>1.2.13</version>
</dependency>
<dependency>
  <groupId>org.apache.ws.commons.axiom</groupId>
  <artifactId>axiom-impl</artifactId>
  <version>1.2.13</version>
  <scope>runtime</scope>
</dependency>
```

- Add your attachment into the pipeline, for example using a Processor implementation.

```java
private class Attachement implements Processor {
  public void process(Exchange exchange) throws Exception {
      exchange.getOut().copyFrom(exchange.getIn());
      File file = new File("testAttachment.txt");
      exchange.getOut().addAttachment("test", new DataHandler(new FileDataSource(file)));
  }
}
```

- Define endpoint (producer) as usual, for example like this:

```xml
from("direct:send")
 .process(new Attachement())
 .to("spring-ws:http://localhost:8089/mySoapService?
 soapAction=mySoap&messageFactory=axiomMessageFactory");
```

- Now, your producer will generate MTOM message with optimized attachments.

### 303.9. THE CUSTOM HEADER AND ATTACHMENT FILTERING

If you need to provide your custom processing of either headers or attachments, extend existing BasicMessageFilter and override the appropriate methods or write a brand new implementation of the MessageFilter interface.

To use your custom filter, add this into your spring context:

You can specify either a global a or a local message filter as follows: a) the global custom filter that provides the global configuration for all Spring-WS endpoints

```xml
<bean id="messageFilter" class="your.domain.myMessageFiler" scope="singleton" />
```

or b) the local messageFilter directly on the endpoint as follows:
For more information see CAMEL-5724

If you want to create your own MessageFilter, consider overriding the following methods in the default implementation of MessageFilter in class BasicMessageFilter:

```java
protected void doProcessSoapHeader(Message inOrOut, SoapMessage soapMessage) {
    your code /*no need to call super*/
}

protected void doProcessSoapAttachments(Message inOrOut, SoapMessage response) {
    your code /*no need to call super*/
}
```

### 303.10. USING A CUSTOM MESSAGESENDER AND MESSAGEFACTORY

A custom message sender or factory in the registry can be referenced like this:

```xml
from("direct:example")
.to("spring-ws:http://foo.com/bar?messageFactory=#messageFactory&messageSender=#messageSender")
```

**Spring configuration:**

```xml
<bean id="messageSender" class="org.springframework.ws.transport.http.HttpComponentsMessageSender">
    <property name="credentials">
        <bean class="org.apache.commons.httpclient.UsernamePasswordCredentials">
            <constructor-arg index="0" value="admin"/>
            <constructor-arg index="1" value="secret"/>
        </bean>
    </property>
</bean>

<bean id="messageFactory" class="org.springframework.ws.soap.saaj.SaajSoapMessageFactory">
    <property name="messageFactory">
        <bean class="com.sun.xml.messaging.saaj.soap.ver1_1.SOAPMessageFactory1_1Impl"></bean>
    </property>
</bean>
```

### 303.11. EXPOSING WEB SERVICES

In order to expose a web service using this component you first need to set-up a MessageDispatcher to look for endpoint mappings in a Spring XML file. If you plan on running inside a servlet container you probably want to use a MessageDispatcherServlet configured in web.xml.

By default the MessageDispatcherServlet will look for a Spring XML named WEB-INF/spring-ws-servlet.xml. To use Camel with Spring-WS the only mandatory bean in that XML file is CamelEndpointMapping. This bean allows the MessageDispatcher to dispatch web service requests.
to your routes.

**web.xml**

```xml
<web-app>
    <servlet>
        <servlet-name>spring-ws</servlet-name>
        <servlet-class>org.springframework.ws.transport.http.MessageDispatcherServlet</servlet-class>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <servlet-mapping>
        <servlet-name>spring-ws</servlet-name>
        <url-pattern/>/</url-pattern>
    </servlet-mapping>
</web-app>
```

**spring-ws-servlet.xml**

```xml
<bean id="endpointMapping" class="org.apache.camel.component.spring.ws.bean.CamelEndpointMapping" />
<bean id="wsdl" class="org.springframework.ws.wsdl.wsdl11.DefaultWsdl11Definition">
    <property name="schema">
        <bean class="org.springframework.xml.xsd.SimpleXsdSchema">
            <property name="xsd" value="/WEB-INF/foobar.xsd"/>
        </bean>
    </property>
    <property name="portTypeName" value="FooBar"/>
    <property name="locationUri" value=""/>
    <property name="targetNamespace" value="http://example.com/"/>
</bean>
```

More information on setting up Spring-WS can be found in [Writing Contract-First Web Services](#). Basically paragraph 3.6 "Implementing the Endpoint" is handled by this component (specifically paragraph 3.6.2 "Routing the Message to the Endpoint" is where `CamelEndpointMapping` comes in). Also don’t forget to check out the Spring Web Services Example included in the Camel distribution.

### 303.12. ENDPOINT MAPPING IN ROUTES

With the XML configuration in-place you can now use Camel’s DSL to define what web service requests are handled by your endpoint:

The following route will receive all web service requests that have a root element named "GetFoo" within the `http://example.com/` namespace.

```java
from("spring-ws:rootqname:{http://example.com/}GetFoo?endpointMapping=#endpointMapping")
    .convertBodyTo(String.class).to(mock:example)
```

The following route will receive web service requests containing the `http://example.com/GetFoo` SOAP action.

```java
from("spring-ws:soapaction:http://example.com/GetFoo?endpointMapping=#endpointMapping")
    .convertBodyTo(String.class).to(mock:example)
```
The following route will receive all requests sent to http://example.com/foobar.

```java
from("spring-ws:uri:http://example.com/foobar?endpointMapping=#endpointMapping")
    .convertBodyTo(String.class).to("mock:example")
```

The route below will receive requests that contain the element `<foobar>abc</foobar>` anywhere inside the message (and the default namespace).

```java
from("spring-ws:xpathresult:abc?expression=//foobar&endpointMapping=#endpointMapping")
    .convertBodyTo(String.class).to("mock:example")
```

### 303.13. ALTERNATIVE CONFIGURATION, USING EXISTING ENDPOINT MAPPINGS

For every endpoint with mapping-type `beanname` one bean of type `CamelEndpointDispatcher` with a corresponding name is required in the Registry/ApplicationContext. This bean acts as a bridge between the Camel endpoint and an existing endpoint mapping like `PayloadRootQNameEndpointMapping`.

**NOTE:** The use of the `beanname` mapping-type is primarily meant for (legacy) situations where you’re already using Spring-WS and have endpoint mappings defined in a Spring XML file. The `beanname` mapping-type allows you to wire your Camel route into an existing endpoint mapping. When you’re starting from scratch it’s recommended to define your endpoint mappings as Camel URI’s (as illustrated above with `endpointMapping`) since it requires less configuration and is more expressive. Alternatively you could use vanilla Spring-WS with the help of annotations.

An example of a route using `beanname`:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="spring-ws:beanname:QuoteEndpointDispatcher"/>
        <to uri="mock:example"/>
    </route>
</camelContext>
```

```xml
<bean id="legacyEndpointMapping"
    class="org.springframework.ws.server.endpoint.mapping.PayloadRootQNameEndpointMapping">
    <property name="mappings">
        <props>
            <prop key="{http://example.com/}GetFuture">FutureEndpointDispatcher</prop>
            <prop key="{http://example.com/}GetQuote">QuoteEndpointDispatcher</prop>
        </props>
    </property>
</bean>
```

```xml
<bean id="QuoteEndpointDispatcher"
    class="org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher" />
<bean id="FutureEndpointDispatcher"
    class="org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher" />
```

### 303.14. POJO (UN)MARSHALLING

Camel’s pluggable data formats offer support for pojo/xml marshalling using libraries such as JAXB, from `http://example.com/foobar?endpointMapping=#endpointMapping`. convertBodyTo(String.class).to("mock:example") from `http://example.com/foobar?endpointMapping=#endpointMapping`. convertBodyTo(String.class).to("mock:example")
Camel’s pluggable data formats offer support for pojo/xml marshalling using libraries such as JAXB, XStream, JibX, Castor and XMLBeans. You can use these data formats in your route to sent and receive pojo’s, to and from web services.

When accessing web services you can marshal the request and unmarshal the response message:

```java
JAXBDataFormat jxb = new JAXBDataFormat(false);
jxb.setContextPath("com.example.model");

from("direct:example").marshal(jxb).to("spring-ws:http://foo.com/bar").unmarshal(jxb);
```

Similarly when providing web services, you can unmarshal XML requests to POJO’s and marshal the response message back to XML:

```java
to("mock:example").marshal(jxb);
```

### 303.15. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 304. SQL COMPONENT

Available as of Camel version 1.4

The sql: component allows you to work with databases using JDBC queries. The difference between this component and JDBC component is that in case of SQL the query is a property of the endpoint and it uses message payload as parameters passed to the query.

This component uses spring-jdbc behind the scenes for the actual SQL handling.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sql</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The SQL component also supports:

- a JDBC based repository for the Idempotent Consumer EIP pattern. See further below.
- a JDBC based repository for the Aggregator EIP pattern. See further below.

304.1. URI FORMAT

WARNING: From Camel 2.11 onwards this component can create both consumer (e.g. from()) and producer endpoints (e.g. to()). In previous versions, it could only act as a producer.

INFO: This component can be used as a Transactional Client.

The SQL component uses the following endpoint URI notation:

```sql
SELECT * FROM table WHERE id=##order by name[?options]  
```

From Camel 2.11 onwards you can use named parameters by using :`#name_of_the_parameter` style as shown:

```sql
SELECT * FROM table WHERE id=:myId order by name[?options]  
```

When using named parameters, Camel will lookup the names from, in the given precedence:
1. from message body if its a java.util.Map
2. from message headers

If a named parameter cannot be resolved, then an exception is thrown.

From Camel 2.14 onward you can use Simple expressions as parameters as shown:

```sql
SELECT * FROM table WHERE id=:${property.myId} order by name[?options]  
```

Notice that the standard ? symbol that denotes the parameters to an SQL query is substituted with the # symbol, because the ? symbol is used to specify options for the endpoint. The ? symbol replacement can be configured on endpoint basis.
From Camel 2.17 onwards you can externalize your SQL queries to files in the classpath or file system as shown:

```
sql:classpath:sql/myquery.sql[?options]
```

And the myquery.sql file is in the classpath and is just a plain text

```
-- this is a comment
select * from table
where
  id = :${property.myId}
order by
  name
```

In the file you can use multilines and format the SQL as you wish. And also use comments such as the – dash line.

You can append query options to the URI in the following format, `?option=value&option=value&…`

### 304.2. OPTIONS

The SQL component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataSource</td>
<td>Sets the DataSource to use to communicate with the database.</td>
<td></td>
<td>DataSource</td>
</tr>
<tr>
<td>usePlaceholder</td>
<td>Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries. This option is default true</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The SQL endpoint is configured using URI syntax:

```
sql:query
```

with the following path and query parameters:

### 304.2.1. Path Parameters (1 parameters):
### 304.2.2. Query Parameters (45 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowNamedParameters</td>
<td>Whether to allow using named parameters in the queries.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>dataSource</td>
<td>Sets the DataSource to use to communicate with the database.</td>
<td></td>
<td>DataSource</td>
</tr>
<tr>
<td>dataSourceRef</td>
<td>Deprecated Sets the reference to a DataSource to lookup from the registry, to use for communicating with the database.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>outputClass</td>
<td>Specify the full package and class name to use as conversion when outputType=SelectOne.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>outputHeader</td>
<td>Store the query result in a header instead of the message body. By default, outputHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>outputType</td>
<td>Make the output of consumer or producer to SelectList as List of Map, or SelectOne as single Java object in the following way: a) If the query has only single column, then that JDBC Column object is returned. (such as SELECT COUNT( ) FROM PROJECT will return a Long object. b) If the query has more than one column, then it will return a Map of that result. c) If the outputClass is set, then it will convert the query result into an Java bean object by calling all the setters that match the column names. It will assume your class has a default constructor to create instance with. d) If the query resulted in more than one rows, it throws an non-unique result exception.</td>
<td>Select List</td>
<td>SqlOutputType</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>separator</strong> (common)</td>
<td>The separator to use when parameter values is taken from message body (if the body is a String type), to be inserted at placeholders. Notice if you use named parameters, then a Map type is used instead. The default value is comma.</td>
<td>,</td>
<td>char</td>
</tr>
<tr>
<td><strong>breakBatchOnConsumeFail</strong> (consumer)</td>
<td>Sets whether to break batch if onConsume failed.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>bridgeErrorHandler</strong> (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>expectedUpdateCount</strong> (consumer)</td>
<td>Sets an expected update count to validate when using onConsume.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td><strong>maxMessagesPerPoll</strong> (consumer)</td>
<td>Sets the maximum number of messages to poll</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td><strong>onConsume</strong> (consumer)</td>
<td>After processing each row then this query can be executed, if the Exchange was processed successfully, for example to mark the row as processed. The query can have parameter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>onConsumeBatchComplete</strong> (consumer)</td>
<td>After processing the entire batch, this query can be executed to bulk update rows etc. The query cannot have parameters.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>onConsumeFailed</strong> (consumer)</td>
<td>After processing each row then this query can be executed, if the Exchange failed, for example to mark the row as failed. The query can have parameter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>routeEmptyResultSet</strong> (consumer)</td>
<td>Sets whether empty resultset should be allowed to be sent to the next hop. Defaults to false. So the empty resultset will be filtered out.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>sendEmptyMessageWhenIdle</strong> (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>transacted (consumer)</td>
<td>Enables or disables transaction. If enabled then if processing an exchange failed then the consumer break out processing any further exchanges to cause a rollback eager</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>useIterator (consumer)</td>
<td>Sets how resultset should be delivered to route. Indicates delivery as either a list or individual object. defaults to true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>pollStrategy (consumer)</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td>PollingConsumerPollingStrategy</td>
<td></td>
</tr>
<tr>
<td>processingStrategy (consumer)</td>
<td>Allows to plugin to use a custom org.apache.camel.component.sql.SqlProcessingStrategy to execute queries when the consumer has processed the rows/batch.</td>
<td>SqlProcessingStrategy</td>
<td></td>
</tr>
<tr>
<td>batch (producer)</td>
<td>Enables or disables batch mode</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>noop (producer)</td>
<td>If set, will ignore the results of the SQL query and use the existing IN message as the OUT message for the continuation of processing</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>useMessageBody ForSql (producer)</td>
<td>Whether to use the message body as the SQL and then headers for parameters. If this option is enabled then the SQL in the uri is not used.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td><strong>alwaysPopulateStatement</strong></td>
<td>If enabled then the populateStatement method from org.apache.camel.component.sql.SqlPrepareStatementStrategy is always invoked, also if there is no expected parameters to be prepared. When this is false then the populateStatement is only invoked if there is 1 or more expected parameters to be set; for example this avoids reading the message body/headers for SQL queries with no parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>parametersCount</strong></td>
<td>If set greater than zero, then Camel will use this count value of parameters to replace instead of querying via JDBC metadata API. This is useful if the JDBC vendor could not return correct parameters count, then user may override instead.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>placeholder</strong></td>
<td>Specifies a character that will be replaced to in SQL query. Notice, that it is simple String.replaceAll() operation and no SQL parsing is involved (quoted strings will also change).</td>
<td>#</td>
<td>String</td>
</tr>
<tr>
<td><strong>prepareStatementStrategy</strong></td>
<td>Allows to plugin to use a custom org.apache.camel.component.sql.SqlPrepareStatementStrategy to control preparation of the query and prepared statement.</td>
<td></td>
<td>SqlPrepareStatementStrategy</td>
</tr>
<tr>
<td><strong>synchronous</strong></td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>templateOptions</strong></td>
<td>Configures the Spring JdbcTemplate with the key/values from the Map</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td><strong>usePlaceholder</strong></td>
<td>Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries. This option is default true</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>backoffErrorThreshold</strong></td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>backoffIdleThreshold</strong></td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>backoffMultiplier</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>delay</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>scheduledExecutorService</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td></td>
<td>ScheduledExecutorService</td>
</tr>
<tr>
<td>scheduler</td>

<td>boolean</td>
</tr>
</tbody>
</table>
304.3. TREATMENT OF THE MESSAGE BODY

The SQL component tries to convert the message body to an object of `java.util.Iterator` type and then uses this iterator to fill the query parameters (where each query parameter is represented by a `#` symbol (or configured placeholder) in the endpoint URI). If the message body is not an array or collection, the conversion results in an iterator that iterates over only one object, which is the body itself.

For example, if the message body is an instance of `java.util.List`, the first item in the list is substituted into the first occurrence of `#` in the SQL query, the second item in the list is substituted into the second occurrence of `#`, and so on.

If `batch` is set to `true`, then the interpretation of the inbound message body changes slightly – instead of an iterator of parameters, the component expects an iterator that contains the parameter iterators; the size of the outer iterator determines the batch size.

From Camel 2.16 onwards you can use the option `useMessageBodyForSql` that allows to use the message body as the SQL statement, and then the SQL parameters must be provided in a header with the key `SqlConstants.SQL_PARAMETERS`. This allows the SQL component to work more dynamic as the SQL query is from the message body.

304.4. RESULT OF THE QUERY

For `select` operations, the result is an instance of `List<Map<String, Object>>` type, as returned by the `JdbcTemplate.queryForList()` method. For `update` operations, the result is the number of updated rows, returned as an `Integer`.

By default, the result is placed in the message body. If the `outputHeader` parameter is set, the result is placed in the header. This is an alternative to using a full message enrichment pattern to add headers, it provides a concise syntax for querying a sequence or some other small value into a header. It is convenient to use `outputHeader` and `outputType` together:

```camel
from("jms:order.inbox")
    .to("sql:select order_seq.nextval from dual?outputHeader=OrderId&outputType=SelectOne")
    .to("jms:order.booking");
```

304.5. USING STREAMLIST

From Camel 2.18 onwards the producer supports `outputType=StreamList` that uses an iterator to stream the output of the query. This allows to process the data in a streaming fashion which for example can be used by the Splitter EIP to process each row one at a time, and load data from the database as needed.

```camel
from("direct:withSplitModel")
    .to("sql:select * from projects order by id?outputType=StreamList&outputClass=org.apache.camel.component.sql.ProjectModel")
    .to("log:stream")
    .split(body()).streaming()
    .to("log:row")
    .to("mock:result")
    .end();
```
304.6. HEADER VALUES

When performing update operations, the SQL Component stores the update count in the following message headers:

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelSqlUpdateCount</td>
<td>The number of rows updated for update operations, returned as an Integer object. This header is not provided when using outputType=StreamList.</td>
</tr>
<tr>
<td>CamelSqlRowCount</td>
<td>The number of rows returned for select operations, returned as an Integer object. This header is not provided when using outputType=StreamList.</td>
</tr>
</tbody>
</table>

Camel 2.8: Query to execute. This query takes precedence over the query specified in the endpoint URI. Note that query parameters in the header are represented by a ? instead of a # symbol.

When performing insert operations, the SQL Component stores the rows with the generated keys and number of these rows in the following message headers (Available as of Camel 2.12.4, 2.13.1):

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelSqlGeneratedKeysRowCount</td>
<td>The number of rows in the header that contains generated keys.</td>
</tr>
<tr>
<td>CamelSqlGeneratedKeyRows</td>
<td>Rows that contains the generated keys (a list of maps of keys).</td>
</tr>
</tbody>
</table>

304.7. GENERATED KEYS

*Available as of Camel 2.12.4, 2.13.1 and 2.14 *

If you insert data using SQL INSERT, then the RDBMS may support auto generated keys. You can instruct the SQL producer to return the generated keys in headers.

To do that set the header CamelSqlRetrieveGeneratedKeys=true. Then the generated keys will be provided as headers with the keys listed in the table above.

You can see more details in this unit test.

304.8. CONFIGURATION
You can now set a reference to a **DataSource** in the URI directly:

```java
sql:select * from table where id=# order by name?dataSource=myDS
```

### 304.9. SAMPLE

In the sample below we execute a query and retrieve the result as a **List** of rows, where each row is a **Map<String, Object>** and the key is the column name.

First, we set up a table to use for our sample. As this is based on an unit test, we do it in java:

The SQL script **createAndPopulateDatabase.sql** we execute looks like as described below:

Then we configure our route and our **sql** component. Notice that we use a **direct** endpoint in front of the **sql** endpoint. This allows us to send an exchange to the **direct** endpoint with the URI, **direct:simple**, which is much easier for the client to use than the long **sql**: URI. Note that the **DataSource** is looked up up in the registry, so we can use standard Spring XML to configure our **DataSource**.

And then we fire the message into the **direct** endpoint that will route it to our **sql** component that queries the database.

We could configure the **DataSource** in Spring XML as follows:

```java
<jee:jndi-lookup id="myDS" jndi-name="jdbc/myDataSource"/>
```

### 304.9.1. Using named parameters

**Available as of Camel 2.11**

In the given route below, we want to get all the projects from the projects table. Notice the SQL query has 2 named parameters, :#lic and :#min. Camel will then lookup for these parameters from the message body or message headers. Notice in the example above we set two headers with constant value for the named parameters:

```java
from("direct:projects")
  .setHeader("lic", constant("ASF"))
  .setHeader("min", constant(123))
  .to("sql:select * from projects where license = :#lic and id > :#min order by id")
```

Though if the message body is a **java.util.Map** then the named parameters will be taken from the body.

```java
from("direct:projects")
  .to("sql:select * from projects where license = :#lic and id > :#min order by id")
```

### 304.9.2. Using expression parameters

**Available as of Camel 2.14**

In the given route below, we want to get all the project from the database. It uses the body of the exchange for defining the license and uses the value of a property as the second parameter.

```java
from("direct:projects")
  .to("sql:select * from projects where license = :#lic and id > :#min order by id")
```
304.9.3. Using IN queries with dynamic values

Available as of Camel 2.17

From Camel 2.17 onwards the SQL producer allows to use SQL queries with IN statements where the IN values is dynamic computed. For example from the message body or a header etc.

To use IN you need to:

- prefix the parameter name with **in:**
- add ( ) around the parameter

An example explains this better. The following query is used:

```sql
-- this is a comment
select *
from projects
where project in ( :#{body} )
order by id
```

In the following route:

```java
from("direct:query")
  .to("sql:classpath:sq!selectProjectsIn.sql")
  .to("log:query")
  .to("mock:query”);
```

Then the IN query can use a header with the key names with the dynamic values such as:

```java
// use an array
template.requestBodyAndHeader("direct:query", "Hi there!", "names", new String[] {"Camel", "AMQ"});

// use a list
List<String> names = new ArrayList<String>();
names.add("Camel");
names.add("AMQ");

template.requestBodyAndHeader("direct:query", "Hi there!", "names", names);

// use a string separated values with comma
template.requestBodyAndHeader("direct:query", "Hi there!", "names", "Camel,AMQ");
```

The query can also be specified in the endpoint instead of being externalized (notice that externalizing makes maintaining the SQL queries easier)

```java
from("direct:query")
  .to("sql:select * from projects where project in (:#{in:names} order by id")
```

```

CHAPTER 304. SQL COMPONENT

2095
```
304.10. USING THE JDBC BASED IDEMPOTENT REPOSITORY

Available as of Camel 2.7 In this section we will use the JDBC based idempotent repository.

TIP:*Abstract class* From Camel 2.9 onwards there is an abstract class
org.apache.camel.processor.idempotent.jdbc.AbstractJdbcMessageIdRepository you can extend
to build custom JDBC idempotent repository.

First we have to create the database table which will be used by the idempotent repository. For Camel
2.7, we use the following schema:

```
CREATE TABLE CAMEL_MESSAGEPROCESSED ( processorName VARCHAR(255),
messageId VARCHAR(100) )
```

In Camel 2.8, we added the createdAt column:

```
CREATE TABLE CAMEL_MESSAGEPROCESSED ( processorName VARCHAR(255),
messageId VARCHAR(100), createdAt TIMESTAMP )
```

WARNING: The SQL Server TIMESTAMP type is a fixed-length binary-string type. It does not map to
any of the JDBC time types: DATE, TIME, or TIMESTAMP.

Customize the JdbcMessageIdRepository

Starting with Camel 2.9.1 you have a few options to tune the
org.apache.camel.processor.idempotent.jdbc.JdbcMessageIdRepository for your needs:

<table>
<thead>
<tr>
<th>Paramater</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>createTableIfNotExists</td>
<td>true</td>
<td>Defines whether or not Camel should try to create the table if it doesn’t exist.</td>
</tr>
</tbody>
</table>
This query is used to figure out whether the table already exists or not. It must throw an exception to indicate the table doesn’t exist.

The statement which is used to create the table.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queryString</td>
<td>SELECT COUNT(*) FROM CAMEL_MESSAGES_PROCESSED WHERE processorName = ? AND messageId = ?</td>
<td>The query which is used to figure out whether the message already exists in the repository (the result is not equal to '0'). It takes two parameters. This first one is the processor name (String) and the second one is the message id (String).</td>
</tr>
<tr>
<td>insertString</td>
<td>INSERT INTO CAMEL_MESSAGES_PROCESSED (processorName, messageId, createDAt) VALUES (?, ?, ?)</td>
<td>The statement which is used to add the entry into the table. It takes three parameters. The first one is the processor name (String), the second one is the message id (String) and the third one is the timestamp (java.sql.Timestamp) when this entry was added to the repository.</td>
</tr>
</tbody>
</table>
The statement which is used to delete the entry from the database. It takes two parameter. This first one is the processor name (String) and the second one is the message id (String).

Using the JDBC based aggregation repository

**Available as of Camel 2.6**

**INFO:** Using JdbcAggregationRepository in Camel 2.6

In Camel 2.6, the JdbcAggregationRepository is provided in the camel-jdbc-aggregator component. From Camel 2.7 onwards, the JdbcAggregationRepository is provided in the camel-sql component.

**JdbcAggregationRepository** is an AggregationRepository which on the fly persists the aggregated messages. This ensures that you will not loose messages, as the default aggregator will use an in memory only AggregationRepository. The JdbcAggregationRepository allows together with Camel to provide persistent support for the Aggregator.

Only when an Exchange has been successfully processed it will be marked as complete which happens when the **confirm** method is invoked on the AggregationRepository. This means if the same Exchange fails again it will be kept retried until it success.

You can use option **maximumRedeliveries** to limit the maximum number of redelivery attempts for a given recovered Exchange. You must also set the **deadLetterUri** option so Camel knows where to send the Exchange when the **maximumRedeliveries** was hit.

You can see some examples in the unit tests of camel-sql, for example this **test**.

**Database**

To be operational, each aggregator uses two table: the aggregation and completed one. By convention the completed has the same name as the aggregation one suffixed with "_COMPLETED". The name must be configured in the Spring bean with the RepositoryName property. In the following example aggregation will be used.

The table structure definition of both table are identical: in both case a String value is used as key (id) whereas a Blob contains the exchange serialized in byte array.

However one difference should be remembered: the id field does not have the same content depending
on the table. In the aggregation table id holds the correlation Id used by the component to aggregate the messages. In the completed table, id holds the id of the exchange stored in corresponding the blob field.

Here is the SQL query used to create the tables, just replace "aggregation" with your aggregator repository name.

```sql
CREATE TABLE aggregation ( id varchar(255) NOT NULL, exchange blob NOT NULL, constraint aggregation_pk PRIMARY KEY (id) );
CREATE TABLE aggregation_completed ( id varchar(255) NOT NULL, exchange blob NOT NULL, constraint aggregation_completed_pk PRIMARY KEY (id) );
```

Storing body and headers as text

Available as of Camel 2.11

You can configure the `JdbcAggregationRepository` to store message body and select(ed) headers as String in separate columns. For example to store the body, and the following two headers `companyName` and `accountName` use the following SQL:

```sql
CREATE TABLE aggregationRepo3 ( id varchar(255) NOT NULL, exchange blob NOT NULL, body varchar(1000), companyName varchar(1000), accountName varchar(1000), constraint aggregationRepo3_pk PRIMARY KEY (id) );
CREATE TABLE aggregationRepo3_completed ( id varchar(255) NOT NULL, exchange blob NOT NULL, body varchar(1000), companyName varchar(1000), accountName varchar(1000), constraint aggregationRepo3_completed_pk PRIMARY KEY (id) );
```

And then configure the repository to enable this behavior as shown below:

```xml
<bean id="repo3"
     class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="repositoryName" value="aggregationRepo3"/>
  <property name="transactionManager" ref="txManager3"/>
  <property name="dataSource" ref="dataSource3"/>
  <!-- configure to store the message body and following headers as text in the repo -->
  <property name="storeBodyAsText" value="true"/>
  <property name="headersToStoreAsText">
    <list>
      <value>companyName</value>
      <value>accountName</value>
    </list>
  </property>
</bean>
```

Codec (Serialization)

Since they can contain any type of payload, Exchanges are not serializable by design. It is converted into a byte array to be stored in a database BLOB field. All those conversions are handled by the `JdbcCodec` class. One detail of the code requires your attention: the `ClassLoaderAwareObjectInputStream`. The `ClassLoaderAwareObjectInputStream` has been reused from the Apache ActiveMQ project. It wraps an `ObjectInputStream` and use it with the `ClassLoader` rather than the `currentThread` one. The benefit is to be able to load classes exposed by other bundles. This allows the exchange body and headers to have custom types object references.

Transaction
A Spring PlatformTransactionManager is required to orchestrate transaction.

Service (Start/Stop)

The start method verify the connection of the database and the presence of the required tables. If anything is wrong it will fail during starting.

Aggregator configuration

Depending on the targeted environment, the aggregator might need some configuration. As you already know, each aggregator should have its own repository (with the corresponding pair of table created in the database) and a data source. If the default lobHandler is not adapted to your database system, it can be injected with the lobHandler property.

Here is the declaration for Oracle:

```xml
<bean id="lobHandler"
  class="org.springframework.jdbc.support.lob.OracleLobHandler"> <property
  name="nativeJdbcExtractor" ref="nativeJdbcExtractor"/> </bean> <bean
  id="nativeJdbcExtractor"
  class="org.springframework.jdbc.support.nativejdbc.CommonsDbcpNativeJdbcExtractor"/>

<bean id="repo" class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="transactionManager" ref="transactionManager"/>
  <property name="repositoryName" value="aggregation"/>
  <property name="dataSource" ref="dataSource"/>
<!-- Only with Oracle, else use default --> <property
  name="lobHandler" ref="lobHandler"/>
</bean>
```

Optimistic locking

From Camel 2.12 onwards you can turn on optimisticLocking and use this JDBC based aggregation repository in a clustered environment where multiple Camel applications shared the same database for the aggregation repository. If there is a race condition there JDBC driver will throw a vendor specific exception which the JdbcAggregationRepository can react upon. To know which caused exceptions from the JDBC driver is regarded as an optimistic locking error we need a mapper to do this. Therefore there is a org.apache.camel.processor.aggregate.jdbc.JdbcOptimisticLockingExceptionMapper allows you to implement your custom logic if needed. There is a default implementation org.apache.camel.processor.aggregate.jdbc.DefaultJdbcOptimisticLockingExceptionMapper which works as follows:

The following check is done:

If the caused exception is an SQLException then the SQLState is checked if starts with 23.

If the caused exception is a DataIntegrityViolationException

If the caused exception class name has "ConstraintViolation" in its name.

optional checking for FQN class name matches if any class names has been configured

You can in addition add FQN classnames, and if any of the caused exception (or any nested) equals any of the FQN class names, then its an optimistic locking error.

Here is an example, where we define 2 extra FQN class names from the JDBC vendor.

```xml
<bean id="repo"
  class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="lobHandler" ref="lobHandler"/>
```
A starter module is available to spring-boot users. When using the starter, the `DataSource` can be directly configured using spring-boot properties.

```xml
<bean id="myExceptionMapper" class="org.apache.camel.processor.aggregate.jdbc.DefaultJdbcOptimisticLockingExceptionMapper">
    <property name="classNames">
        <util:set>
            <value>com.foo.sql.MyViolationExceptoion</value>
            <value>com.foo.sql.MyOtherViolationExceptoion</value>
        </util:set>
    </property>
</bean>
```

### 304.11. CAMEL SQL STARTER

A starter module is available to spring-boot users. When using the starter, the `DataSource` can be directly configured using spring-boot properties.

`# Example for a mysql datasource`

```xml
spring.datasource.url=jdbc:mysql://localhost/test
spring.datasource.username=dbuser
spring.datasource.password=dbpass
spring.datasource.driver-class-name=com.mysql.jdbc.Driver
```

To use this feature, add the following dependencies to your spring boot pom.xml file:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-sql-starter</artifactId>
    <version>${camel.version}</version> <!-- use the same version as your Camel core version -->
</dependency>

<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-jdbc</artifactId>
    <version>${spring-boot-version}</version>
</dependency>
```

You should also include the specific database driver, if needed.

### 304.12. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
- SQL Stored Procedure
- JDBC
CHAPTER 305. SQL STORED PROCEDURE COMPONENT

Available as of Camel version 2.17

The `sql-stored:` component allows you to work with databases using JDBC Stored Procedure queries. This component is an extension to the SQL Component but specialized for calling stored procedures. This component uses `spring-jdbc` behind the scenes for the actual SQL handling.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sql</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

305.1. URI FORMAT

The SQL component uses the following endpoint URI notation:

```
sql-stored:template[?options]
```

Where `template` is the stored procedure template, where you declare the name of the stored procedure and the IN, INOUT, and OUT arguments.

You can also refer to the template in a external file on the file system or classpath such as:

```
sql-stored:classpath:sql/myprocedure.sql[?options]
```

Where `sql/myprocedure.sql` is a plain text file in the classpath with the template, as show:

```sql
SUBNUMBERS(
  INTEGER ${headers.num1},
  INTEGER ${headers.num2},
  INOUT INTEGER ${headers.num3} out1,
  OUT INTEGER out2
)
```

You can append query options to the URI in the following format, `?option=value&option=value&...`

305.2. OPTIONS

The SQL Stored Procedure component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataSource (producer)</td>
<td>Sets the DataSource to use to communicate with the database.</td>
<td></td>
<td>DataSource</td>
</tr>
</tbody>
</table>
Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

The SQL Stored Procedure endpoint is configured using URI syntax:

```
sql-stored:template
```

with the following path and query parameters:

### 305.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>template</td>
<td>Required Sets the StoredProcedure template to perform</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 305.2.2. Query Parameters (7 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>batch (producer)</td>
<td>Enables or disables batch mode</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>dataSource (producer)</td>
<td>Sets the DataSource to use to communicate with the database.</td>
<td></td>
<td>DataSource</td>
</tr>
<tr>
<td>function (producer)</td>
<td>Whether this call is for a function.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>noop (producer)</td>
<td>If set, will ignore the results of the template and use the existing IN message as the OUT message for the continuation of processing</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>outputHeader (producer)</td>
<td>Store the template result in a header instead of the message body. By default, outputHeader == null and the template result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the template result and the original message body is preserved.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### 305.3. Declaring the Stored Procedure Template

The template is declared using a syntax that would be similar to a Java method signature. The name of the stored procedure, and then the arguments enclosed in parenthesis. An example explains this well:

```xml
<to uri="sql-stored:STOREDSAMPLE(INTEGER ${headers.num1},INTEGER ${headers.num2},INOUT INTEGER ${headers.num3} result1,OUT INTEGER result2)"/>
```

The arguments are declared by a type and then a mapping to the Camel message using simple expression. So, in this example the first two parameters are IN values of INTEGER type, mapped to the message headers. The third parameter is INOUT, meaning it accepts an INTEGER and then returns a different INTEGER result. The last parameter is the OUT value, also an INTEGER type.

In SQL term the stored procedure could be declared as:

```
CREATE PROCEDURE STOREDSAMPLE(VALUE1 INTEGER, VALUE2 INTEGER, INOUT RESULT1 INTEGER, OUT RESULT2 INTEGER)
```

### 305.3.1. IN Parameters

IN parameters take four parts separated by a space: parameter name, SQL type (with scale), type name and value source.

Parameter name is optional and will be auto generated if not provided. It must be given between quotes(').

SQL type is required and can be an integer (positive or negative) or reference to integer field in some class. If SQL type contains a dot then component tries resolve that class and read the given field. For example SQL type com.Foo.INTEGER is read from the field INTEGER of class com.Foo. If the type doesn’t contain comma then class to resolve the integer value will be java.sql.Types. Type can be postfixed by scale for example DECIMAL(10) would mean java.sql.Types.DECIMAL with scale 10.

Type name is optional and must be given between quotes(').

Value source is required. Value source populates the parameter value from the Exchange. It can be either a Simple expression or header location i.e. :#<header name>. For example Simple expression ${header.val} would mean that parameter value will be read from the header "val". Header location expression :#val would have identical effect.

```xml
<to uri="sql-stored:MYFUNC(param1 org.example.Types.INTEGER(10) ${header.srcValue})"/>
```
URI means that the stored procedure will be called with parameter name "param1", its SQL type is read from field INTEGER of class org.example.Types and scale will be set to 10. Input value for the parameter is passed from the header "srcValue".

```
<to uri="sql-stored:MYFUNC('param1' 100 'mytypename' ${header.srcValue})"/>
```

URI is identical to previous on except SQL-type is 100 and type name is "mytypename".

Actual call will be done using org.springframework.jdbc.core.SqlParameter.

305.3.2. OUT Parameters

OUT parameters work similarly IN parameters and contain three parts: SQL type(with scale), type name and output parameter name.

SQL type works the same as IN parameters.

Type name is optional and also works the same as IN parameters.

Output parameter name is used for the OUT parameter name, as well as the header name where the result will be stored.

```
<to uri="sql-stored:MYFUNC(OUT org.example.Types.DECIMAL(10) outheader1)"/>
```

URI means that OUT parameter’s name is "outheader1" and result will be but into header "outheader1".

```
<to uri="sql-stored:MYFUNC(OUT org.example.Types.NUMERIC(10) 'mytype' outheader1)"/>
```

This is identical to previous one but type name will be "mytype".

Actual call will be done using org.springframework.jdbc.core.SqlOutParameter.

305.3.3. INOUT Parameters

INOUT parameters are a combination of all of the above. They receive a value from the exchange, as well as store a result as a message header. The only caveat is that the IN parameter’s "name" is skipped. Instead, the OUT parameter’s "name" defines both the SQL parameter name, as well as the result header name.

```
<to uri="sql-stored:MYFUNC(INOUT DECIMAL(10) ${headers.inheader} outheader)"/>
```

Actual call will be done using org.springframework.jdbc.core.SqlInOutParameter.

305.4. CAMEL SQL STARTER

A starter module is available to spring-boot users. When using the starter, the DataSource can be directly configured using spring-boot properties.

```
# Example for a mysql datasource
spring.datasource.url=jdbc:mysql://localhost/test
spring.datasource.username=dbuser
```
spring.datasource.password=dbpass
spring.datasource.driver-class-name=com.mysql.jdbc.Driver

To use this feature, add the following dependencies to your spring boot pom.xml file:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sql-starter</artifactId>
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->
</dependency>

<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-jdbc</artifactId>
  <version>${spring-boot-version}</version>
</dependency>
```

You should also include the specific database driver, if needed.

### 305.5. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
- SQL Component
CHAPTER 306. SSH COMPONENT

Available as of Camel version 2.10

The SSH component enables access to SSH servers such that you can send an SSH command, and process the response.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ssh</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

306.1. URI FORMAT

```
ssh:[username[:password]@]host[:port][?options]
```

306.2. OPTIONS

The SSH component supports 12 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>To use the shared SSH configuration</td>
<td>SshConfiguration</td>
<td></td>
</tr>
<tr>
<td>host</td>
<td>Sets the hostname of the remote SSH server.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>port</td>
<td>Sets the port number for the remote SSH server.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>username</td>
<td>Sets the username to use in logging into the remote SSH server.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>password</td>
<td>Sets the password to use in connecting to remote SSH server. Requires keyPairProvider to be set to null.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>pollCommand</td>
<td>Sets the command string to send to the remote SSH server during every poll cycle. Only works with camel-ssh component being used as a consumer, i.e. from(ssh://...). You may need to end your command with a newline, and that must be URL encoded %0A</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>keyPairProvider</td>
<td>Sets the KeyPairProvider reference to use when connecting using Certificates to the remote SSH Server.</td>
<td>KeyPairProvider</td>
<td></td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
--- | --- | --- | ---
**keyType** (security) | Sets the key type to pass to the KeyPairProvider as part of authentication. KeyPairProvider.loadKey(...) will be passed this value. Defaults to ssh-rsa. |  | String
**timeout** (common) | Sets the timeout in milliseconds to wait in establishing the remote SSH server connection. Defaults to 30000 milliseconds. |  | long
**certFilename** (security) | Deprecated | Sets the resource path of the certificate to use for Authentication. | String
**certResource** (security) | Sets the resource path of the certificate to use for Authentication. Will use ResourceHelperKeyPairProvider to resolve file based certificate, and depends on keyType setting. |  | String
**resolvePropertyPlaceholders** (advanced) | Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders. | true | boolean

The SSH endpoint is configured using URI syntax:

```
ssh:host:port
```

with the following path and query parameters:

#### 306.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>host</strong></td>
<td>Required</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>port</strong></td>
<td></td>
<td>22</td>
<td>int</td>
</tr>
</tbody>
</table>

#### 306.2.2. Query Parameters (28 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>failOnUnknownHost</strong> (common)</td>
<td>Specifies whether a connection to an unknown host should fail or not. This value is only checked when the property knownHosts is set.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>

<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffIdleThreshold (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffMultiplier (scheduler)</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>delay (scheduler)</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy (scheduler)</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>initialDelay (scheduler)</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>runLoggingLevel (scheduler)</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td>scheduledExecutorService (scheduler)</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td></td>
<td>ScheduledExecutorService</td>
</tr>
<tr>
<td>scheduler (scheduler)</td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollConsumerScheduler</td>
</tr>
<tr>
<td>schedulerProperties (scheduler)</td>
<td>To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>startScheduler (scheduler)</td>
<td>Whether the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### 306.3. Usage as a Producer Endpoint

When the SSH Component is used as a Producer \((.to("ssh://\ldots\"))\), it will send the message body as the command to execute on the remote SSH server.

Here is an example of this within the XML DSL. Note that the command has an XML encoded newline \((\&#10;\)):

```xml
<route id="camel-example-ssh-producer">
  <from uri="direct:exampleSshProducer"/>
  <setBody>
    <constant>features:list</constant>
  </setBody>
  <to uri="ssh://karaf/karaf@localhost:8101"/>
  <log message="${body}"/>
</route>
```

### 306.4. Authentication

The SSH Component can authenticate against the remote SSH server using one of two mechanisms:
The SSH Component can authenticate against the remote SSH server using one of two mechanisms: Public Key certificate or username/password. Configuring how the SSH Component does authentication is based on how and which options are set.

1. First, it will look to see if the `certResource` option has been set, and if so, use it to locate the referenced Public Key certificate and use that for authentication.

2. If `certResource` is not set, it will look to see if a `keyPairProvider` has been set, and if so, it will use that to for certificate based authentication.

3. If neither `certResource` nor `keyPairProvider` are set, it will use the `username` and `password` options for authentication. Even though the `username` and `password` are provided in the endpoint configuration and headers set with `SshConstants.USERNAME_HEADER (CamelSshUsername)` and `SshConstants.PASSWORD_HEADER (CamelSshPassword)`, the endpoint configuration is surpassed and credentials set in the headers are used.

The following route fragment shows an SSH polling consumer using a certificate from the classpath.

In the XML DSL,

```xml
<route>
  <from uri="ssh://scott@localhost:8101?certResource=classpath:test_rsa&useFixedDelay=true&delay=5000&pollCommand=features:list%0A"/>
  <log message="${body}"/>
</route>
```

In the Java DSL,

```java
from("ssh://scott@localhost:8101?certResource=classpath:test_rsa&useFixedDelay=true&delay=5000&pollCommand=features:list%0A")
  .log("${body}");
```

An example of using Public Key authentication is provided in `examples/camel-example-ssh-security`.

Certificate Dependencies

You will need to add some additional runtime dependencies if you use certificate based authentication. The dependency versions shown are as of Camel 2.11, you may need to use later versions depending what version of Camel you are using.

```xml
<dependency>
  <groupId>org.apache.sshd</groupId>
  <artifactId>sshd-core</artifactId>
  <version>0.8.0</version>
</dependency>
<dependency>
  <groupId>org.bouncycastle</groupId>
  <artifactId>bcpg-jdk15on</artifactId>
  <version>1.47</version>
</dependency>
<dependency>
  <groupId>org.bouncycastle</groupId>
</dependency>
```
306.5. EXAMPLE

See the `examples/camel-example-ssh` and `examples/camel-example-ssh-security` in the Camel distribution.

306.6. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 307. STAX COMPONENT

Available as of Camel version 2.9

The StAX component allows messages to be processed through a SAX `ContentHandler`. Another feature of this component is to allow to iterate over JAXB records using StAX, for example using the Splitter EIP.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-stax</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

307.1. URI FORMAT

- `stax:content-handler-class`

example:

- `stax:org.superbiz.FooContentHandler`

From Camel 2.11.1 onwards you can lookup a `org.xml.sax.ContentHandler` bean from the Registry using the `#` syntax as shown:

- `stax:#myHandler`

307.2. OPTIONS

The StAX component has no options.

The StAX endpoint is configured using URI syntax:

- `stax:contentHandlerClass`

with the following path and query parameters:

307.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentHandlerClass</td>
<td>Required The FQN class name for the ContentHandler implementation to use.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

307.2.2. Query Parameters (1 parameters):
### Name | Description | Default | Type
--- | --- | --- | ---
**synchronous** *(advanced)* | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

## 307.3. USAGE OF A CONTENT HANDLER AS STAX PARSER

The message body after the handling is the handler itself.

Here an example:

```java
from("file:target/in")
    .to("stax:org.superbiz.handler.CountingHandler")
    // CountingHandler implements org.xml.sax.ContentHandler or extends org.xml.sax.helpers.DefaultHandler
    .process(new Processor() {
        @Override
        public void process(Exchange exchange) throws Exception {
            CountingHandler handler = exchange.getIn().getBody(CountingHandler.class);
            // do some great work with the handler
            handler.doSomething();
        }
    });
```

## 307.4. ITERATE OVER A COLLECTION USING JAXB AND STAX

First we suppose you have JAXB objects.

For instance a list of records in a wrapper object:

```java
import java.util.ArrayList;
import java.util.List;
import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
import javax.xml.bind.annotation.XmlElement;
import javax.xml.bind.annotation.XmlRootElement;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlRootElement(name = "records")
public class Records {
    @XmlElement(required = true)
    protected List<Record> record;

    public List<Record> getRecord() {
        if (record == null) {
            record = new ArrayList<Record>();
        }
        return record;
    }
}
```
and

```java
import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
import javax.xml.bind.annotation.XmlAttribute;
import javax.xml.bind.annotation.XmlType;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlType(name = "record", propOrder = { "key", "value" })
public class Record {
    @XmlAttribute(required = true)
    protected String key;

    @XmlAttribute(required = true)
    protected String value;

    public String getKey() {
        return key;
    }

    public void setKey(String key) {
        this.key = key;
    }

    public String getValue() {
        return value;
    }

    public void setValue(String value) {
        this.value = value;
    }
}
```

Then you get a XML file to process:

```xml
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<records>
    <record value="v0" key="0"/>
    <record value="v1" key="1"/>
    <record value="v2" key="2"/>
    <record value="v3" key="3"/>
    <record value="v4" key="4"/>
    <record value="v5" key="5"/>
</records>
```

The StAX component provides an **StAXBuilder** which can be used when iterating XML elements with the Camel Splitter

```java
from("file:target/in")
    .split(stax(Record.class)).streaming()
    .to("mock:records");
```

Where **stax** is a static method on **org.apache.camel.component.stax.StAXBuilder** which you can static import in the Java code. The stax builder is by default namespace aware on the XMLReader it uses. From **Camel 2.11.1** onwards you can turn this off by setting the boolean parameter to false, as
shown below:

```java
from("file:target/in")
    .split(stax(Record.class, false)).streaming()
    .to("mock:records");
```

### 307.4.1. The previous example with XML DSL

The example above could be implemented as follows in XML DSL

### 307.5. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 308. STOMP COMPONENT

Available as of Camel version 2.12

The stomp: component is used for communicating with Stomp compliant message brokers, like Apache ActiveMQ or ActiveMQ Apollo

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-stomp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

308.1. URI FORMAT

```
stomp:queue:destination[?options]
```

Where destination is the name of the queue.

308.2. OPTIONS

The Stomp component supports 8 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>To use the shared stomp configuration</td>
<td></td>
<td>StompConfiguration</td>
</tr>
<tr>
<td>brokerURL</td>
<td>The URI of the Stomp broker to connect to</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>login</td>
<td>The username</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>passcode</td>
<td>The password</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td>The virtual host</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>useGlobalSslContextParameters</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>headerFilterStrategy</td>
<td>To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.</td>
<td></td>
<td>HeaderFilterStrategy</td>
</tr>
</tbody>
</table>

configuration (advanced)

brokerURL (common)

login (security)

passcode (security)

host (common)

useGlobalSslContextParameters (security)

headerFilterStrategy (filter)
### Stomp Component

The Stomp endpoint is configured using URI syntax:

```
stomp:destination
```

with the following path and query parameters:

#### 308.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination</td>
<td>Required Name of the queue</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

#### 308.2.2. Query Parameters (10 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>brokerURL</td>
<td>Required The URI of the Stomp broker to connect to</td>
<td>tcp://localhost:61613</td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td>The virtual host name</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

---

**resolveProperty Placeholders**

Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
--- | --- | --- | ---
**ExceptionHandler** (consumer) | To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored. | | ExceptionHandler
**exchangePattern** (consumer) | Sets the exchange pattern when the consumer creates an exchange. | | ExchangePattern
**headerFilterStrategy** (advanced) | To use a custom HeaderFilterStrategy to filter header to and from Camel message. | | HeaderFilterStrategy
**synchronous** (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean
**login** (security) | The username | | String
**passcode** (security) | The password | | String
**sslContextParameters** (security) | To configure security using SSLContextParameters | | SSLContextParameters

You can append query options to the URI in the following format, `?option=value&option=value&…`

### 308.3. SAMPLES

#### Sending messages:
```
from("direct:foo").to("stomp:queue:test");
```

#### Consuming messages:
```
from("stomp:queue:test").transform(body().convertToString()).to("mock:result")
```

### 308.4. ENDPOINTS

Camel supports the Message Endpoint pattern using the Endpoint interface. Endpoints are usually created by a Component and Endpoints are usually referred to in the DSL via their URIs.

From an Endpoint you can use the following methods

* `createProducer()` will create a Producer for sending message exchanges to the endpoint *
* `createConsumer()` implements the Event Driven Consumer pattern for consuming message exchanges from the endpoint via a Processor when creating a Consumer * `createPollingConsumer()` implements
the Polling Consumer pattern for consuming message exchanges from the endpoint via a
PollingConsumer

308.5. SEE ALSO

- Configuring Camel
- Message Endpoint pattern
- URIs
- Writing Components
The *stream:* component provides access to the *System.in*, *System.out* and *System.err* streams as well as allowing streaming of file and URL.

Maven users will need to add the following dependency to their *pom.xml* for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-stream</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

### 309.1. URI FORMAT

- `stream:in[?options]`
- `stream:out[?options]`
- `stream:err[?options]`
- `stream:header[?options]`
- `stream:file?fileName=/foo/bar.txt`
- `stream:url[?options]`

In addition, the *file* and *url* endpoint URIs are supported:

- `stream:file?fileName=/foo/bar.txt`
- `stream:url[?options]`

If the `stream:header` URI is specified, the `stream` header is used to find the stream to write to. This option is available only for stream producers (that is, it cannot appear in `from()`).

You can append query options to the URI in the following format, `?option=value&option=value&...`

### 309.2. OPTIONS

The Stream component has no options.

The Stream endpoint is configured using URI syntax:

- `stream:kind`

with the following path and query parameters:

### 309.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>Required Kind of stream to use such as System.in or System.out.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
309.2.2. Query Parameters (18 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoding</td>
<td>You can configure the encoding (is a charset name) to use text-based streams (for example, message body is a String object). If not provided, Camel uses the JVM default Charset.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>fileName</td>
<td>When using the stream:file URI format, this option specifies the filename to stream to/from.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>url</td>
<td>When using the stream:url URI format, this option specifies the URL to stream to/from. The input/output stream will be opened using the JDK URLConnection facility.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>groupLines</td>
<td>To group X number of lines in the consumer. For example to group 10 lines and therefore only spit out an Exchange with 10 lines, instead of 1 Exchange per line.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>groupStrategy</td>
<td>Allows to use a custom GroupStrategy to control how to group lines.</td>
<td></td>
<td>GroupStrategy</td>
</tr>
<tr>
<td>initialPromptDelay</td>
<td>Initial delay in milliseconds before showing the message prompt. This delay occurs only once. Can be used during system startup to avoid message prompts being written while other logging is done to the system out.</td>
<td>2000</td>
<td>long</td>
</tr>
<tr>
<td>promptDelay</td>
<td>Optional delay in milliseconds before showing the message prompt.</td>
<td></td>
<td>long</td>
</tr>
<tr>
<td>promptMessage</td>
<td>Message prompt to use when reading from stream:in; for example, you could set this to Enter a command:</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>retry</td>
<td>Will retry opening the file if it’s overwritten, somewhat like tail --retry</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### 309.3. MESSAGE CONTENT

The **stream** component supports either **String** or **byte[]** for writing to streams. Just add either **String** or **byte[]** content to the **message.in.body**. Messages sent to the **stream** producer in binary mode are not followed by the newline character (as opposed to the **String** messages). Message with **null** body will not be appended to the output stream.

The special **stream:header** URI is used for custom output streams. Just add a **java.io.OutputStream** object to **message.in.header** in the key **header**.

See samples for an example.

### 309.4. SAMPLES

In the following sample we route messages from the **direct:in** endpoint to the **System.out** stream:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>scanStream (consumer)</td>
<td>To be used for continuously reading a stream such as the unix tail command.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>scanStreamDelay (consumer)</td>
<td>Delay in milliseconds between read attempts when using scanStream.</td>
<td></td>
<td>long</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>autoCloseCount (producer)</td>
<td>Number of messages to process before closing stream on Producer side. Never close stream by default (only when Producer is stopped). If more messages are sent, the stream is reopened for another autoCloseCount batch.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>closeOnDone (producer)</td>
<td>This option is used in combination with Splitter and streaming to the same file. The idea is to keep the stream open and only close when the Splitter is done, to improve performance. Mind this requires that you only stream to the same file, and not 2 or more files.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>delay (producer)</td>
<td>Initial delay in milliseconds before producing the stream.</td>
<td></td>
<td>long</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
The following sample demonstrates how the header type can be used to determine which stream to use. In the sample we use our own output stream, `MyOutputStream`.

The following sample demonstrates how to continuously read a file stream (analogous to the UNIX `tail` command):

```java
from("stream:file?
    fileName=/server/logs/server.log&scanStream=true&scanStreamDelay=1000").to("bean:logService?
    method=parseLogLine");
```

One gotcha with `scanStream` (pre Camel 2.7) or `scanStream + retry` is the file will be re-opened and scanned with each iteration of `scanStreamDelay`. Until NIO2 is available we cannot reliably detect when a file is deleted/recreated.

- Endpoint
- Getting Started
CHAPTER 310. STRING ENCODING DATAFORMAT

Available as of Camel version 2.12

The String Data Format is a textual based format that supports encoding.

310.1. OPTIONS

The String Encoding dataformat supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>charset</td>
<td></td>
<td>String</td>
<td>Sets an encoding to use. Will by default use the JVM platform default charset.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example, application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

310.2. MARSHAL

In this example we marshal the file content to String object in UTF-8 encoding.

```java
from("file://data.csv").marshal().string("UTF-8").to("jms://myqueue");
```

310.3. UNMARSHAL

In this example we unmarshal the payload from the JMS queue to a String object using UTF-8 encoding, before it's processed by the newOrder processor.

```java
from("jms://queue/order").unmarshal().string("UTF-8").processRef("newOrder");
```

310.4. DEPENDENCIES

This data format is provided in camel-core so no additional dependencies is needed.
CHAPTER 311. STRING TEMPLATE COMPONENT

Available as of Camel version 1.2

The string-template: component allows you to process a message using a String Template. This can be ideal when using Templating to generate responses for requests.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-stringtemplate</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

311.1. URI FORMAT

```
string-template:templateName[?options]
```

Where `TemplateName` is the classpath-local URI of the template to invoke; or the complete URL of the remote template.

You can append query options to the URI in the following format, `?option=value&option=value&...`

311.2. OPTIONS

The String Template component has no options.

The String Template endpoint is configured using URI syntax:

```
string-template:resourceUri
```

with the following path and query parameters:

311.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td><strong>Required</strong> Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

311.2.2. Query Parameters (4 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentCache (producer)</td>
<td>Sets whether to use resource content cache or not</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>delimiterStart (producer)</td>
<td>The variable start delimiter</td>
<td>&lt;</td>
<td>char</td>
</tr>
<tr>
<td>delimiterStop (producer)</td>
<td>The variable end delimiter</td>
<td>&gt;</td>
<td>char</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

311.3. HEADERS

Camel will store a reference to the resource in the message header with key, `org.apache.camel.stringtemplate.resource`. The Resource is an `org.springframework.core.io.Resource` object.

311.4. HOT RELOADING

The string template resource is by default hot-reloadable for both file and classpath resources (expanded jar). If you set `contentCache=true`, Camel loads the resource only once and hot-reloading is not possible. This scenario can be used in production when the resource never changes.

311.5. STRINGTEMPLATE ATTRIBUTES

Since Camel 2.14, you can define the custom context map by setting the message header "CamelStringTemplateVariableMap" just like the below code.

```java
Map<String, Object> variableMap = new HashMap<String, Object>();
Map<String, Object> headersMap = new HashMap<String, Object>();
headersMap.put("name", "Willem");
variableMap.put("headers", headersMap);
variableMap.put("body", "Monday");
variableMap.put("exchange", exchange);
exchange.getIn().setHeader("CamelStringTemplateVariableMap", variableMap);
```

311.6. SAMPLES

For example you could use a string template as follows in order to formulate a response to a message:

```java
from("activemq:My.Queue").
to("string-template:com/acme/MyResponse.tm");
```

311.7. THE EMAIL SAMPLE
In this sample we want to use a string template to send an order confirmation email. The email template is laid out in StringTemplate as: This example works for camel 2.11.0. If your camel version is less than 2.11.0, the variables should be started and ended with $.

Dear <headers.lastName>, <headers.firstName>

Thanks for the order of <headers.item>.

Regards Camel Riders Bookstore

And the java code is as follows:

311.8. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 312. STUB COMPONENT

Available as of Camel version 2.10

The stub: component provides a simple way to stub out any physical endpoints while in development or testing, allowing you for example to run a route without needing to actually connect to a specific SMTP or Http endpoint. Just add stub: in front of any endpoint URI to stub out the endpoint.

Internally the Stub component creates VM endpoints. The main difference between Stub and VM is that VM will validate the URI and parameters you give it, so putting vm: in front of a typical URI with query arguments will usually fail. Stub won’t though, as it basically ignores all query parameters to let you quickly stub out one or more endpoints in your route temporarily.

312.1. URI FORMAT

stub:someUri

Where someUri can be any URI with any query parameters.

312.2. OPTIONS

The Stub component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>queueSize (advanced)</td>
<td>Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>concurrentConsumers (consumer)</td>
<td>Sets the default number of concurrent threads processing exchanges.</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>defaultQueueFactory (advanced)</td>
<td>Sets the default queue factory.</td>
<td></td>
<td>Exchange&gt;</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Stub endpoint is configured using URI syntax:

stub:name

with the following path and query parameters:

312.2.1. Path Parameters (1 parameters):
### 312.2.2. Query Parameters (16 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td><strong>Required</strong> Name of queue</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>size</strong> (common)</td>
<td>The maximum capacity of the SEDA queue (i.e., the number of messages it can hold).</td>
<td>214748</td>
<td>int</td>
</tr>
<tr>
<td><strong>bridgeErrorHandler</strong> (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>concurrentConsumers</strong> (consumer)</td>
<td>Number of concurrent threads processing exchanges.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td><strong>exceptionHandler</strong> (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td><strong>exchangePattern</strong> (consumer)</td>
<td>Sets the default exchange pattern when creating an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td><strong>limitConcurrentConsumers</strong> (consumer)</td>
<td>Whether to limit the number of concurrentConsumers to the maximum of 500. By default, an exception will be thrown if an endpoint is configured with a greater number. You can disable that check by turning this option off.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>multipleConsumers</strong> (consumer)</td>
<td>Specifies whether multiple consumers are allowed. If enabled, you can use SEDA for Publish-Subscribe messaging. That is, you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>pollTimeout</td>
<td>The timeout used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.</td>
<td>1000</td>
<td>int</td>
</tr>
<tr>
<td>purgeWhenStopping</td>
<td>Whether to purge the task queue when stopping the consumer/route. This allows to stop faster, as any pending messages on the queue is discarded.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>blockWhenFull</td>
<td>Whether a thread that sends messages to a full SEDA queue will block until the queue’s capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>discardIfNoConsumers</td>
<td>Whether the producer should discard the message (do not add the message to the queue), when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>failIfNoConsumers</td>
<td>Whether the producer should fail by throwing an exception, when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>timeout</td>
<td>Timeout (in milliseconds) before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable timeout by using 0 or a negative value.</td>
<td>30000</td>
<td>long</td>
</tr>
<tr>
<td>waitForTaskToComplete</td>
<td>Option to specify whether the caller should wait for the async task to complete or not before continuing. The following three options are supported: Always, Never or IfReplyExpected. The first two values are self-explanatory. The last value, IfReplyExpected, will only wait if the message is Request Reply based. The default option is IfReplyExpected.</td>
<td>IfReplyExpected</td>
<td>WaitForTaskToComplete</td>
</tr>
<tr>
<td>queue (advanced)</td>
<td>Define the queue instance which will be used by the endpoint. This option is only for rare use-cases where you want to use a custom queue instance.</td>
<td></td>
<td>BlockingQueue</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
312.3. EXAMPLES

Here are a few samples of stubbing endpoint uris

```
stub:smtp://somehost.foo.com?user=whatnot&something=else
stub:http://somehost.bar.com/something
```
CHAPTER 313. SWAGGER JAVA COMPONENT

Available as of Camel 2.16

The Rest DSL can be integrated with the camel-swagger-java module which is used for exposing the REST services and their APIs using Swagger.

Maven users will need to add the following dependency to their pom.xml for this component:

From Camel 2.16 onwards the swagger component is purely Java based, and its

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-swagger-java</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The camel-swagger-java module can be used from the REST components (without the need for servlet)

For an example see the camel-example-swagger-cdi in the examples directory of the Apache Camel distribution.

### 313.1. USING SWAGGER IN REST-DSL

You can enable the swagger api from the rest-dsl by configuring the apiContextPath dsl as shown below:

```java
public class UserRouteBuilder extends RouteBuilder {
  @Override
  public void configure() throws Exception {
    // configure we want to use servlet as the component for the rest DSL
    // and we enable json binding mode
    restConfiguration().component("netty4-http").bindingMode(RestBindingMode.json)
      // and output using pretty print
      .dataFormatProperty("prettyPrint", "true")
    // setup context path and port number that netty will use
    .contextPath("/").port(8080)
    // add swagger api-doc out of the box
    .apiContextPath("/api-doc")
      .apiProperty("api.title", "User API").apiProperty("api.version", "1.2.3")
      // and enable CORS
      .apiProperty("cors", "true");

    // this user REST service is json only
    rest("/user").description("User rest service")
      .consumes("application/json").produces("application/json")
      .get("/{id}").description("Find user by id").outType(User.class)
        .param().name("id").type(path).description("The id of the user to get")
        .dataType("int")
      .endParam()
      .to("bean:userService?method=getUser(${header.id})")
    .put().description("Updates or create a user").type(User.class)
      .param().name("body").type(body).description("The user to update or create")
      .to("bean:userService?method=updateUser")
    .get("/findAll").description("Find all users").outTypeList(User.class)
  }
}
```
313.2. OPTIONS

The swagger module can be configured using the following options. To configure using a servlet you use the init-param as shown above. When configuring directly in the rest-dsl, you use the appropriate method, such as `enableCORS`, `host`, `contextPath`, `dsl`. The options with `api.xxx` is configured using `apiProperty` `dsl`.

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cors</td>
<td>Boolean</td>
<td>Whether to enable CORS. Notice this only enables CORS for the api browser, and not the actual access to the REST services. Is default false. Instead of using this option is recommended to use the CorsFilter, see further below.</td>
</tr>
<tr>
<td>swagger.version</td>
<td>String</td>
<td>Swagger spec version. Is default 2.0.</td>
</tr>
<tr>
<td>host</td>
<td>String</td>
<td>To setup the hostname. If not configured camel-swagger-java will calculate the name as localhost based.</td>
</tr>
<tr>
<td>schemas</td>
<td>String</td>
<td>The protocol schemes to use. Multiple values can be separated by comma such as &quot;http,https&quot;. The default value is &quot;http&quot;. This option is deprecated from Camel 2.17 onwards due it should have been named schemes.</td>
</tr>
<tr>
<td>schemes</td>
<td>String</td>
<td>Camel 2.17: The protocol schemes to use. Multiple values can be separated by comma such as &quot;http,https&quot;. The default value is &quot;http&quot;.</td>
</tr>
<tr>
<td>base.path</td>
<td>String</td>
<td>Required: To setup the base path where the REST services is available. The path is relative (eg do not start with http/https) and camel-swagger-java will calculate the absolute base path at runtime, which will be <code>protocol://host:port/context-path/base.path</code>.</td>
</tr>
<tr>
<td>api.path</td>
<td>String</td>
<td>To setup the path where the API is available (eg /api-docs). The path is relative (eg do not start with http/https) and camel-swagger-java will calculate the absolute base path at runtime, which will be <code>protocol://host:port/context-path/api.path</code>. So using relative paths is much easier. See above for an example.</td>
</tr>
<tr>
<td>api.version</td>
<td>String</td>
<td>The version of the api. Is default 0.0.0.</td>
</tr>
<tr>
<td>api.title</td>
<td>String</td>
<td>The title of the application.</td>
</tr>
<tr>
<td>api.description</td>
<td>String</td>
<td>A short description of the application.</td>
</tr>
<tr>
<td>Option</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>api.termsOfService</td>
<td>String</td>
<td>A URL to the Terms of Service of the API.</td>
</tr>
<tr>
<td>api.contact.name</td>
<td>String</td>
<td>Name of person or organization to contact</td>
</tr>
<tr>
<td>api.contact.email</td>
<td>String</td>
<td>An email to be used for API-related correspondence.</td>
</tr>
<tr>
<td>api.contact.url</td>
<td>String</td>
<td>A URL to a website for more contact information.</td>
</tr>
<tr>
<td>api.license.name</td>
<td>String</td>
<td>The license name used for the API.</td>
</tr>
<tr>
<td>api.license.url</td>
<td>String</td>
<td>A URL to the license used for the API.</td>
</tr>
<tr>
<td>apiContextIdListing</td>
<td>boolean</td>
<td>Whether to allow listing all the CamelContext names in the JVM that has REST services. When enabled then the root path of the api-doc will list all the contexts. When disabled then no context ids is listed and the root path of the api-doc lists the current CamelContext. Is default false.</td>
</tr>
<tr>
<td>apiContextIdPattern</td>
<td>String</td>
<td>A pattern that allows to filter which CamelContext names is shown in the context listing. The pattern is using regular expression and * as wildcard. Its the same pattern matching as used by Intercept.</td>
</tr>
</tbody>
</table>

### 313.3. CONTEXTIDLISTING ENABLED

When contextIdListing is enabled then its detecting all the running CamelContexts in the same JVM. These contexts are listed in the root path, eg `/api-docs` as a simple list of names in json format. To access the swagger documentation then the context-path must be appended with the Camel context id, such as `api-docs/myCamel`. The option apiContextIdPattern can be used to filter the names in this list.

### 313.4. JSON OR YAML

Available as of Camel 2.17

The camel-swagger-java module supports both JSON and Yaml out of the box. You can specify in the request url what you want returned by using `/swagger.json` or `/swagger.yaml` for either one. If none is specified then the HTTP Accept header is used to detect if json or yaml can be accepted. If either both is accepted or none was set as accepted then json is returned as the default format.
313.5. EXAMPLES

In the Apache Camel distribution we ship the `camel-example-swagger-cdi` and `camel-example-swagger-java` which demonstrates using this Swagger component.
CHAPTER 314. SYSLOG DATAFORMAT

Available as of Camel version 2.6

The syslog dataformat is used for working with RFC3164 and RFC5424 messages.

This component supports the following:

- UDP consumption of syslog messages
- Agnostic data format using either plain String objects or SyslogMessage model objects.
- Type Converter from/to SyslogMessage and String
- Integration with the camel-mina component.
- Integration with the camel-netty component.
- Camel 2.14: Encoder and decoder for the camel-netty component.
- Camel 2.14: Support for RFC5424 also.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-syslog</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

314.1. RFC3164 SYSLOG PROTOCOL

Syslog uses the user datagram protocol (UDP) as its underlying transport layer mechanism. The UDP port that has been assigned to syslog is 514.

To expose a Syslog listener service we reuse the existing camel-mina component or camel-netty where we just use the Rfc3164SyslogDataFormat to marshal and unmarshal messages. Notice that from Camel 2.14 onwards the syslog dataformat is renamed to SyslogDataFormat.

314.2. OPTIONS

The Syslog dataformat supports 1 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>
314.3. RFC5424 SYSLOG PROTOCOL

Available as of Camel 2.14

To expose a Syslog listener service we reuse the existing camel-mina component or camel-netty where we just use the SyslogDataFormat to marshal and unmarshal messages.

314.3.1. Exposing a Syslog listener

In our Spring XML file, we configure an endpoint to listen for udp messages on port 10514, note that in netty we disable the defaultCodec, this will allow a fallback to a NettyTypeConverter and delivers the message as an InputStream:

```xml
<camelContext id="myCamel" xmlns="http://camel.apache.org/schema/spring">
  <dataFormats>
    <syslog id="mySyslog"/>
  </dataFormats>
  <route>
    <from uri="netty:udp://localhost:10514?sync=false&allowDefaultCodec=false"/>
    <unmarshal ref="mySyslog"/>
    <to uri="mock:stop1"/>
  </route>
</camelContext>
```

The same route using camel-mina

```xml
<camelContext id="myCamel" xmlns="http://camel.apache.org/schema/spring">
  <dataFormats>
    <syslog id="mySyslog"/>
  </dataFormats>
  <route>
    <from uri="mina:udp://localhost:10514"/>
    <unmarshal ref="mySyslog"/>
    <to uri="mock:stop1"/>
  </route>
</camelContext>
```

314.3.2. Sending syslog messages to a remote destination

```xml
<camelContext id="myCamel" xmlns="http://camel.apache.org/schema/spring">
  <dataFormats>
    <syslog id="mySyslog"/>
  </dataFormats>
  <route>
    <from uri="direct:syslogMessages"/>
    <marshal ref="mySyslog"/>
  </route>
</camelContext>
```
314. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started

```xml
<to uri="mina:udp://remotehost:10514"/>
</route>
</camelContext>
```
CHAPTER 315. TAR FILE DATAFORMAT

Available as of Camel version 2.16

The Tar File Data Format is a message compression and de-compression format. Messages can be marshalled (compressed) to Tar Files containing a single entry, and Tar Files containing a single entry can be unmarshalled (decompressed) to the original file contents.

There is also a aggregation strategy that can aggregate multiple messages into a single Tar File.

315.1. TARFILE OPTIONS

The Tar File dataformat supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usingIterator</td>
<td>false</td>
<td>Boolean</td>
<td>If the tar file has more than one entry, the setting this option to true, allows to work with the splitter EIP, to split the data using an iterator in a streaming mode.</td>
</tr>
<tr>
<td>allowEmptyDirectory</td>
<td>false</td>
<td>Boolean</td>
<td>If the tar file has more than one entry, setting this option to true, allows to get the iterator even if the directory is empty</td>
</tr>
<tr>
<td>preservePathElements</td>
<td>false</td>
<td>Boolean</td>
<td>If the file name contains path elements, setting this option to true, allows the path to be maintained in the tar file.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

315.2. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload using Tar File compression, and send it to an ActiveMQ queue called MY_QUEUE.

```
from("direct:start").marshal().tarFile().to("activemq:queue:MY_QUEUE");
```

The name of the Tar entry inside the created Tar File is based on the incoming CamelFileName message header, which is the standard message header used by the file component. Additionally, the outgoing CamelFileName message header is automatically set to the value of the incoming CamelFileName message header, with the ".tar" suffix. So for example, if the following route finds a file named "test.txt" in the input directory, the output will be a Tar File named "test.txt.tar" containing a single Tar entry named "test.txt".

```
from("file:input/directory?antInclude=*/.txt").marshal().tarFile().to("file:output/directory");
```

If there is no incoming CamelFileName message header (for example, if the file component is not the consumer), then the message ID is used by default, and since the message ID is normally a unique
generated ID, you will end up with filenames like \texttt{ID-MACHINENAME-2443-1211718892437-1-0.tar}. If you want to override this behavior, then you can set the value of the \texttt{CamelFileName} header explicitly in your route:

\begin{verbatim}
from("direct:start").setHeader(Exchange.FILE_NAME,
    constant("report.txt"))
    .marshal().tarFile().to(\texttt{\"file:output/directory\"});
\end{verbatim}

This route would result in a Tar File named "report.txt.tar" in the output directory, containing a single Tar entry named "report.txt".

### 315.3. UNMARSHAL

In this example we unmarshal a Tar File payload from an ActiveMQ queue called \texttt{MY_QUEUE} to its original format, and forward it for processing to the \texttt{UnTarpedMessageProcessor}.

\begin{verbatim}
from("activemq:queue:MY_QUEUE")
    .unmarshal().tarFile().process(new UnTarpedMessageProcessor());
\end{verbatim}

If the Tar File has more then one entry, the usingIterator option of \texttt{TarFileDataFormat} to be true, and you can use splitter to do the further work.

\begin{verbatim}
TarFileDataFormat tarFile = new TarFileDataFormat();
    tarFile.setUsingIterator(true);
    from("file:src/test/resources/org/apache/camel/dataformat/tarfile/?consumer.delay=1000&noop=true")
        .unmarshal(tarFile)
        .split(body(Iterator.class))
        .streaming()
        .process(new UnTarpedMessageProcessor())
        .end();
\end{verbatim}

Or you can use the TarSplitter as an expression for splitter directly like this

\begin{verbatim}
from("file:src/test/resources/org/apache/camel/dataformat/tarfile/?consumer.delay=1000&noop=true")
    .split(new TarSplitter())
    .streaming()
    .process(new UnTarpedMessageProcessor())
    .end();
\end{verbatim}

### 315.4. AGGREGATE

\textbf{INFO:} Please note that this aggregation strategy requires eager completion check to work properly.

In this example we aggregate all text files found in the input directory into a single Tar File that is stored in the output directory.

\begin{verbatim}
from("file:input/directory?antInclude=*/.txt")
    .aggregate(new TarAggregationStrategy())
        .constant(true)
        .completionFromBatchConsumer()
        .eagerCheckCompletion()
    .to("file:output/directory");
\end{verbatim}
The outgoing **CamelFileName** message header is created using java.io.File.createTempFile, with the ".tar" suffix. If you want to override this behavior, then you can set the value of the **CamelFileName** header explicitly in your route:

```java
from("file:input/directory?antInclude=*/.txt")
  .aggregate(new TarAggregationStrategy())
  .constant(true)
  .completionFromBatchConsumer()
  .eagerCheckCompletion()
  .setHeader(Exchange.FILE_NAME, constant("reports.tar"))
  .to("file:output/directory");
```

### 315.5. DEPENDENCIES

To use Tar Files in your camel routes you need to add a dependency on **camel-tarfile** which implements this data format.

If you use Maven you can just add the following to your **pom.xml**, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-tarfile</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 316. TELEGRAM COMPONENT

Available as of Camel version 2.18

The Telegram component provides access to the Telegram Bot API. It allows a Camel-based application to send and receive messages by acting as a Bot, participating in direct conversations with normal users, private and public groups or channels.

A Telegram Bot must be created before using this component, following the instructions at the Telegram Bot developers home. When a new Bot is created, the BotFather provides an authorization token corresponding to the Bot. The authorization token is a mandatory parameter for the camel-telegram endpoint.

NOTE

In order to allow the Bot to receive all messages exchanged within a group or channel (not just the ones starting with a '/ ' character), ask the BotFather to disable the privacy mode, using the /setprivacy command.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-telegram</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

316.1. URI FORMAT

```
telegram:type/authorizationToken[?options]
```

You can append query options to the URI in the following format, `?option=value&option=value&...`

316.2. OPTIONS

The Telegram component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorizationToken</td>
<td>The default Telegram authorization token to be used when the information is not provided in the endpoints.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>resolveProperty</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Placeholder</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Telegram endpoint is configured using URI syntax:
teleGram.getType/authorizationToken

with the following path and query parameters:

### 316.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Required The endpoint type. Currently, only the 'bots' type is supported.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>authorizationToken</td>
<td>Required The authorization token for using the bot (ask the BotFather), eg. 654321531:HGF_dTra456323dHuOedsE34321fqr3t-H.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 316.2.2. Query Parameters (22 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>limit (consumer)</td>
<td>Limit on the number of updates that can be received in a single polling request.</td>
<td>100</td>
<td>Integer</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>timeout (consumer)</td>
<td>Timeout in seconds for long polling. Put 0 for short polling or a bigger number for long polling. Long polling produces shorter response time.</td>
<td>30</td>
<td>Integer</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------------</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>pollStrategy (consumer)</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td>chatId (producer)</td>
<td>The identifier of the chat that will receive the produced messages. Chat ids can be first obtained from incoming messages (eg. when a telegram user starts a conversation with a bot, its client sends automatically a '/start' message containing the chat id). It is an optional parameter, as the chat id can be set dynamically for each outgoing message (using body or headers).</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold (scheduler)</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffIdleThreshold (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>backoffMultiplier (scheduler)</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>delay (scheduler)</td>
<td>Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>500</td>
<td>long</td>
</tr>
<tr>
<td>greedy (scheduler)</td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td><strong>initialDelay</strong>&lt;br&gt;(scheduler)</td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td><strong>runLoggingLevel</strong>&lt;br&gt;(scheduler)</td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td><strong>scheduledExecutorService</strong>&lt;br&gt;(scheduler)</td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td></td>
<td>ScheduledExecutorService</td>
</tr>
<tr>
<td><strong>scheduler</strong>&lt;br&gt;(scheduler)</td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollConsumerScheduler</td>
</tr>
<tr>
<td><strong>schedulerProperties</strong>&lt;br&gt;(scheduler)</td>
<td>To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td><strong>startScheduler</strong>&lt;br&gt;(scheduler)</td>
<td>Whether the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>timeUnit</strong>&lt;br&gt;(scheduler)</td>
<td>Time unit for initialDelay and delay options.</td>
<td>MILLISECONDS</td>
<td>TimeUnit</td>
</tr>
<tr>
<td><strong>useFixedDelay</strong>&lt;br&gt;(scheduler)</td>
<td>Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 316.3. MESSAGE HEADERS

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CamelTelegram ChatId</strong></td>
<td>This header is used by the producer endpoint in order to resolve the chat id that will receive the message. The recipient chat id can be placed (in order of priority) in message body, in the CamelTelegramChatId header or in the endpoint configuration (chatId option). This header is also present in all incoming messages.</td>
</tr>
<tr>
<td><strong>CamelTelegram MediaType</strong></td>
<td>This header is used to identify the media type when the outgoing message is composed of pure binary data. Possible values are strings or enum values belonging to the org.apache.camel.component.telegram.TelegramMediaType enumeration.</td>
</tr>
<tr>
<td><strong>CamelTelegram MediaTitleCaption</strong></td>
<td>This header is used to provide a caption or title for outgoing binary messages.</td>
</tr>
</tbody>
</table>

2148
316.4. USAGE

The Telegram component supports both consumer and producer endpoints. It can also be used in **reactive chat-bot mode** (to consume, then produce messages).

316.5. PRODUCER EXAMPLE

The following is a basic example of how to send a message to a Telegram chat through the Telegram Bot API.

**in Java DSL**

```java
from("direct:start").to("telegram:bots/123456789:insertAuthorizationTokenHere");
```

**or in Spring XML**

```xml
<route>
  <from uri="direct:start"/>
  <to uri="telegram:bots/123456789:insertAuthorizationTokenHere"/>
</route>
```

The code `123456789:insertAuthorizationTokenHere` is the *authorization token* corresponding to the Bot.

When using the producer endpoint without specifying the `chat id` option, the target chat will be identified using information contained in the body or headers of the message. The following message bodies are allowed for a producer endpoint (messages of type *OutgoingXXXMessage* belong to the package `org.apache.camel.component.telegram.model`)

<table>
<thead>
<tr>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>OutgoingTextMessage</strong></td>
<td>To send a text message to a chat</td>
</tr>
<tr>
<td><strong>OutgoingPhotoMessage</strong></td>
<td>To send a photo (JPG, PNG) to a chat</td>
</tr>
<tr>
<td><strong>OutgoingAudioMessage</strong></td>
<td>To send a mp3 audio to a chat</td>
</tr>
<tr>
<td><strong>OutgoingVideoMessage</strong></td>
<td>To send a mp4 video to a chat</td>
</tr>
<tr>
<td><strong>OutgoingDocumentMessage</strong></td>
<td>To send a file to a chat (any media type)</td>
</tr>
<tr>
<td><code>byte[]</code></td>
<td>To send any media type supported. It requires the <code>CamelTelegramMediaType</code> header to be set to the appropriate media type</td>
</tr>
</tbody>
</table>
To send a text message to a chat. It gets converted automatically into a `OutgoingTextMessage`.

### 316.6. CONSUMER EXAMPLE

The following is a basic example of how to receive all messages that telegram users are sending to the configured Bot. In Java DSL

```java
from("telegram:bots/123456789:insertAuthorizationTokenHere")
.bean(ProcessorBean.class)
```

or in Spring XML

```xml
<route>
    <from uri="telegram:bots/123456789:insertAuthorizationTokenHere"/>
    <bean ref="myBean"/>
</route>

<bean id="myBean" class="com.example.MyBean"/>
```

The `MyBean` is a simple bean that will receive the messages.

```java
public class MyBean {
    public void process(String message) {
        // or Exchange, or org.apache.camel.component.telegram.model.IncomingMessage (or both)
        // do process
    }
}
```

Supported types for incoming messages are

<table>
<thead>
<tr>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>IncomingMessage</code></td>
<td>The full object representation of an incoming message</td>
</tr>
<tr>
<td><code>String</code></td>
<td>The content of the message, for text messages only</td>
</tr>
</tbody>
</table>

### 316.7. REACTIVE CHAT-BOT EXAMPLE

The reactive chat-bot mode is a simple way of using the Camel component to build a simple chat bot that replies directly to chat messages received from the Telegram users.

The following is a basic configuration of the chat-bot in Java DSL:

```java
public class MyBean {
    public void process(String message) {
        // or Exchange, or org.apache.camel.component.telegram.model.IncomingMessage (or both)
        // do process
    }
}
```
The ChatBotLogic is a simple bean that implements a generic String-to-String method.

```java
import com.example.ChatBotLogic;

public class ChatBotLogic {
    public String chatBotProcess(String message) {
        if ("do-not-reply".equals(message)) {
            return null; // no response in the chat
        }
        return "echo from the bot: " + message; // echoes the message
    }
}
```

Every non-null string returned by the chatBotProcess method is automatically routed to the chat that originated the request (as the CamelTelegramChatId header is used to route the message).

### 316.8. GETTING THE CHAT ID

If you want to push messages to a specific Telegram chat when an event occurs, you need to retrieve the corresponding chat ID. The chat ID is not currently shown in the telegram client, but you can obtain it using a simple route.

First, add the bot to the chat where you want to push messages, then run a route like the following one.

```java
from("telegram:bots/123456789:insertAuthorizationTokenHere")
    .to("telegram:bots/123456789:insertAuthorizationTokenHere");
```

Any message received by the bot will be dumped to your log together with information about the chat (CamelTelegramChatId header).

Once you get the chat ID, you can use the following sample route to push message to it.

```java
from("timer:tick")
    .setBody().constant("Hello")
    .to("telegram:bots/123456789:insertAuthorizationTokenHere?chatId=123456");
```

Note that the corresponding URI parameter is simply `chatId`.
CHAPTER 317. TEST COMPONENT

Available as of Camel version 1.3

Testing of distributed and asynchronous processing is notoriously difficult. The Mock, Test and DataSet endpoints work great with the Camel Testing Framework to simplify your unit and integration testing using Enterprise Integration Patterns and Camel's large range of Components together with the powerful Bean Integration.

The test component extends the Mock component to support pulling messages from another endpoint on startup to set the expected message bodies on the underlying Mock endpoint. That is, you use the test endpoint in a route and messages arriving on it will be implicitly compared to some expected messages extracted from some other location.

So you can use, for example, an expected set of message bodies as files. This will then set up a properly configured Mock endpoint, which is only valid if the received messages match the number of expected messages and their message payloads are equal.

Maven users will need to add the following dependency to their pom.xml for this component when using Camel 2.8 or older:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

From Camel 2.9 onwards the Test component is provided directly in the camel-core.

317.1. URI FORMAT

test:expectedMessagesEndpointUri

Where expectedMessagesEndpointUri refers to some other Component URI that the expected message bodies are pulled from before starting the test.

317.2. URI OPTIONS

The Test component has no options.

The Test endpoint is configured using URI syntax:

test:name

with the following path and query parameters:

317.2.1. Path Parameters (1 parameters):
### 317.2.2. Query Parameters (14 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>anyOrder (producer)</td>
<td>Whether the expected messages should arrive in the same order or can be in any order.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>assertPeriod (producer)</td>
<td>Sets a grace period after which the mock endpoint will re-assert to ensure the preliminary assertion is still valid. This is used for example to assert that exactly a number of messages arrives. For example if link expectedMessageCount(int) was set to 5, then the assertion is satisfied when 5 or more message arrives. To ensure that exactly 5 messages arrives, then you would need to wait a little period to ensure no further message arrives. This is what you can use this link setAssertPeriod(long) method for. By default this period is disabled.</td>
<td>0</td>
<td>long</td>
</tr>
<tr>
<td>delimiter (producer)</td>
<td>The split delimiter to use when split is enabled. By default the delimiter is new line based. The delimiter can be a regular expression.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>expectedCount (producer)</td>
<td>Specifies the expected number of message exchanges that should be received by this endpoint. Beware: If you want to expect that 0 messages, then take extra care, as 0 matches when the tests starts, so you need to set a assert period time to let the test run for a while to make sure there are still no messages arrived; for that use link setAssertPeriod(long). An alternative is to use NotifyBuilder, and use the notifier to know when Camel is done routing some messages, before you call the link assertIsSatisfied() method on the mocks. This allows you to not use a fixed assert period, to speedup testing times. If you want to assert that exactly n'th message arrives to this mock endpoint, then see also the link setAssertPeriod(long) method for further details.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>reportGroup (producer)</td>
<td>A number that is used to turn on throughput logging based on groups of the size.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>resultMinimumWaitTime</td>
<td>Sets the minimum expected amount of time (in millis) the link assertIsSatisfied() will wait on a latch until it is satisfied</td>
<td>0</td>
<td>long</td>
</tr>
<tr>
<td>resultWaitTime</td>
<td>Sets the maximum amount of time (in millis) the link assertIsSatisfied() will wait on a latch until it is satisfied</td>
<td>0</td>
<td>long</td>
</tr>
<tr>
<td>retainFirst</td>
<td>Specifies to only retain the first n’th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the link getReceivedCounter() will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the first 10 Exchanges, then the link getReceivedCounter() will still return 5000 but there is only the first 10 Exchanges in the link getExchanges() and link getReceivedExchanges() methods. When using this method, then some of the other expectation methods is not supported, for example the link expectedBodiesReceived(Object…) sets a expectation on the first number of bodies received. You can configure both link setRetainFirst(int) and link setRetainLast(int) methods, to limit both the first and last received.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>retainLast</td>
<td>Specifies to only retain the last n’th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the link getReceivedCounter() will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the last 20 Exchanges, then the link getReceivedCounter() will still return 5000 but there is only the last 20 Exchanges in the link getExchanges() and link getReceivedExchanges() methods. When using this method, then some of the other expectation methods is not supported, for example the link expectedBodiesReceived(Object…) sets a expectation on the first number of bodies received. You can configure both link setRetainFirst(int) and link setRetainLast(int) methods, to limit both the first and last received.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>sleepForEmptyTest (producer)</td>
<td>Allows a sleep to be specified to wait to check that this endpoint really is empty when link expectedMessageCount(int) is called with zero</td>
<td>0</td>
<td>long</td>
</tr>
<tr>
<td>split (producer)</td>
<td>If enabled the messages loaded from the test endpoint will be split using new line delimiters so each line is an expected message. For example to use a file endpoint to load a file where each line is an expected message.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>timeout (producer)</td>
<td>The timeout to use when polling for message bodies from the URI</td>
<td>2000</td>
<td>long</td>
</tr>
<tr>
<td>copyOnExchange (producer)</td>
<td>Sets whether to make a deep copy of the incoming Exchange when received at this mock endpoint. Is by default true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 317.3. EXAMPLE

For example, you could write a test case as follows:

```java
from("seda:someEndpoint").
to("test:file://data/expectedOutput?noop=true");
```

If your test then invokes the `MockEndpoint.assertIsSatisfied(camelContext)` method, your test case will perform the necessary assertions.

To see how you can set other expectations on the test endpoint, see the Mock component.

### 317.4. SEE ALSO

- Spring Testing
CHAPTER 318. THRIFT COMPONENT

Available as of Camel version 2.20

The Thrift component allows you to call or expose Remote Procedure Call (RPC) services using Apache Thrift binary communication protocol and serialization mechanism.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-thrift</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

318.1. URI FORMAT

```
thrift://service[?options]
```

318.2. ENDPOINT OPTIONS

The Thrift component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>useGlobalSslContext Parameters (security)</td>
<td>Determine if the thrift component is using global SSL context parameters</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Thrift endpoint is configured using URI syntax:

```
thrift:host:port/service
```

with the following path and query parameters:

318.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
</table>
### CHAPTER 318. THRIFT COMPONENT

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>The Thrift server host name. This is localhost or 0.0.0.0 (if not defined) when being a consumer or remote server host name when using producer.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td><strong>Required</strong> The Thrift server port</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>service</td>
<td><strong>Required</strong> Fully qualified service name from the thrift descriptor file (package dot service definition name)</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

#### 318.2.2. Query Parameters (12 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>compressionType (common)</td>
<td>Protocol compression mechanism type</td>
<td>NONE</td>
<td>ThriftCompressionType</td>
</tr>
<tr>
<td>exchangeProtocol (common)</td>
<td>Exchange protocol serialization type</td>
<td>BINAR Y</td>
<td>ThriftExchangeProtocol</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>clientTimeout (consumer)</td>
<td>Client timeout for consumers</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>maxPoolSize (consumer)</td>
<td>The Thrift server consumer max thread pool size</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>poolSize (consumer)</td>
<td>The Thrift server consumer initial thread pool size</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
</tbody>
</table>
### 318.3. THRIFT METHOD PARAMETERS MAPPING

Parameters in the called procedure must be passed as a list of objects inside the message body. The primitives are converted from the objects on the fly. In order to correctly find the corresponding method, all types must be transmitted regardless of the values. Please see an example below, how to pass different parameters to the method with the Camel body.

```
List requestBody = new ArrayList();
requestBody.add((boolean)true);
requestBody.add((byte)THRIFT_TEST_NUM1);
requestBody.add((short)THRIFT_TEST_NUM1);
requestBody.add((int)THRIFT_TEST_NUM1);
requestBody.add((long)THRIFT_TEST_NUM1);
requestBody.add((double)THRIFT_TEST_NUM1);
requestBody.add("empty"); // String parameter
requestBody.add(ByteBuffer.allocate(10)); // binary parameter
requestBody.add(new Work(THRIFT_TEST_NUM1, THRIFT_TEST_NUM2, Operation.MULTIPLY)); // Struct parameter
requestBody.add(new ArrayList<Integer>()); // list parameter
requestBody.add(new HashSet<String>()); // set parameter
requestBody.add(new HashMap<String, Long>()); // map parameter

Object responseBody = template.requestBody("direct:thrift-alltypes", requestBody);
```

Incoming parameters in the service consumer will also be passed to the message body as a list of objects.

### 318.4. THRIFT CONSUMER HEADERS (WILL BE INSTALLED AFTER THE CONSUMER INVOCATION)
<table>
<thead>
<tr>
<th>Header name</th>
<th>Description</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelThriftMethodName</td>
<td>Method name handled by the consumer service</td>
<td></td>
</tr>
</tbody>
</table>

### 318.5. EXAMPLES

Below is a simple synchronous method invoke with host and port parameters

```
from("direct:thrift-calculate")
    method=calculate&synchronous=true");
```

Below is a simple synchronous method invoke for the XML DSL configuration

```
<route>
  <from uri="direct:thrift-add"/>
  <to uri="thrift://localhost:1101/org.apache.camel.component.thrift.generated.Calculator?
    method=add&synchronous=true"/>
</route>
```

Thrift service consumer with asynchronous communication

```
from("thrift://localhost:1101/org.apache.camel.component.thrift.generated.Calculator")
  .to("direct:thrift-service");
```

It’s possible to automate Java code generation for .thrift files using `thrift-maven-plugin`, but before start the thrift compiler binary distribution for your operating system must be present on the running host.

CHAPTER 319. THRIFT DATAFORMAT

Available as of Camel version 2.20

Camel provides a Data Format to serialize between Java and the Apache Thrift. The project's site details why you may wish to visit https://thrift.apache.org/. Apache Thrift is language-neutral and platform-neutral, so messages produced by your Camel routes may be consumed by other language implementations.

Apache Thrift Implementation

319.1. THRIFT OPTIONS

The Thrift dataformat supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instanceClass</td>
<td></td>
<td>String</td>
<td>Name of class to use when unmarshalling</td>
</tr>
<tr>
<td>contentTypeFormat</td>
<td>binary</td>
<td>String</td>
<td>Defines a content type format in which thrift message will be serialized/deserialized from/to the Java been. The format can either be native or json for either native binary thrift, json or simple json fields representation. The default value is binary.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

319.2. CONTENT TYPE FORMAT

It's possible to parse JSON message to convert it to the Thrift format and unparse it back using native util converter. To use this option, set contentTypeFormat value to 'json' or call thrift with second parameter. If default instance is not specified, always use native binary Thrift format. The simple JSON format is write-only (marshal) and produces a simple output format suitable for parsing by scripting languages. The sample code shows below:

```java
from("direct:marshal")
  .unmarshal()
  .thrift("org.apache.camel.dataformat.thrift.generated.Work", "json")
  .to("mock:reverse");
```

319.3. THRIFT OVERVIEW

This quick overview of how to use Thrift. For more detail see the complete tutorial

319.4. DEFINING THE THRIFT FORMAT

The first step is to define the format for the body of your exchange. This is defined in a .thrift file as so:
319.5. GENERATING JAVA CLASSES

The Apache Thrift provides a compiler which will generate the Java classes for the format we defined in our .thrift file.

You can also run the compiler for any additional supported languages you require manually.

```
thrift -r --gen java -out ../java/ ./tutorial-dataformat.thrift
```

This will generate separate Java class for each type defined in .thrift file, i.e. struct or enum. The generated classes implement org.apache.thrift.TBase which is required by the serialization mechanism. For this reason it important that only these classes are used in the body of your exchanges. Camel will throw an exception on route creation if you attempt to tell the Data Format to use a class that does not implement org.apache.thrift.TBase.

319.6. JAVA DSL

You can use create the ThriftDataFormat instance and pass it to Camel DataFormat marshal and unmarshal API like this.

```
ThriftDataFormat format = new ThriftDataFormat(new Work());
from("direct:in").marshal(format);
from("direct:back").unmarshal(format).to("mock:reverse");
```

Or use the DSL thrift() passing the unmarshal default instance or default instance class name like this.

```
// You don't need to specify the default instance for the thrift marshaling
from("direct:marshal").marshal().thrift();
from("direct:unmarshalA").unmarshal().thrift("org.apache.camel.dataformat.thrift.generated.Work")
    .to("mock:reverse");
from("direct:unmarshalB").unmarshal().thrift(new Work()).to("mock:reverse");
```
319.7. SPRING DSL

The following example shows how to use Thrift to unmarshal using Spring configuring the thrift data type

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <unmarshal>
      <thrift instanceClass="org.apache.camel.dataformat.thrift.generated.Work"/>
    </unmarshal>
    <to uri="mock:result"/>
  </route>
</camelContext>
```

319.8. DEPENDENCIES

To use Thrift in your camel routes you need to add the a dependency on camel-thrift which implements this data format.

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-thrift</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 320. TIDYMARKUP DATAFORMAT

Available as of Camel version 2.0

TidyMarkup is a Data Format that uses the TagSoup to tidy up HTML. It can be used to parse ugly HTML and return it as pretty wellformed HTML.

Camel eats our own -dog food- soap

We had some issues in our pdf Manual where we had some strange symbols. So Jonathan used this data format to tidy up the wiki html pages that are used as base for rendering the pdf manuals. And then the mysterious symbols vanished.

TidyMarkup only supports the unmarshal operation as we really don’t want to turn well formed HTML into ugly HTML.

320.1. TIDYMARKUP OPTIONS

The TidyMarkup dataformat supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataObjectType</td>
<td>org.w3c.dom.Node</td>
<td>String</td>
<td>What data type to unmarshal as, can either be org.w3c.dom.Node or java.lang.String. Is by default org.w3c.dom.Node</td>
</tr>
<tr>
<td>omitXmlDeclaration</td>
<td>false</td>
<td>Boolean</td>
<td>When returning a String, do we omit the XML declaration in the top.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

320.2. JAVA DSL EXAMPLE

An example where the consumer provides some HTML

```java
from("file://site/inbox").unmarshal().tidyMarkup().to("file://site/blogs");
```

320.3. SPRING XML EXAMPLE

The following example shows how to use TidyMarkup to unmarshal using Spring

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="file://site/inbox"/>
    <unmarshal>
```

"2163"
To use TidyMarkup in your camel routes you need to add the a dependency on camel-tagsoup which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-tagsoup</artifactId>
  <version>x.x.x</version>
</dependency>
```
CHAPTER 321. TIKA COMPONENT

Available as of Camel version 2.19

The Tika component provides the ability to detect and parse documents with Apache Tika. This component uses Apache Tika as underlying library to work with documents.

In order to use the Tika component, Maven users will need to add the following dependency to their pom.xml:

```
pom.xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-tika</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The TIKA component only supports producer endpoints.

321.1. OPTIONS

The Tika component has no options.

The Tika endpoint is configured using URI syntax:

```
tika:operation
```

with the following path and query parameters:

321.1.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>Required Tika Operation. parse or detect</td>
<td></td>
<td>TikaOperation</td>
</tr>
</tbody>
</table>

321.1.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>tikaConfig (producer)</td>
<td>Tika Config</td>
<td></td>
<td>TikaConfig</td>
</tr>
<tr>
<td>tikaConfigUri (producer)</td>
<td>Tika Config Uri: The URI of tika-config.xml</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### 321.2. TO DETECT A FILE’S MIME TYPE

The file should be placed in the Body.

```camel
from("direct:start")
  .to("tika:detect");
```

### 321.3. TO PARSE A FILE

The file should be placed in the Body.

```camel
from("direct:start")
  .to("tika:parse");
```
CHAPTER 322. TIMER COMPONENT

Available as of Camel version 1.0

The timer component is used to generate message exchanges when a timer fires. You can only consume events from this endpoint.

322.1. URI FORMAT

```
timer:name[?options]
```

Where `name` is the name of the Timer object, which is created and shared across endpoints. So if you use the same name for all your timer endpoints, only one Timer object and thread will be used.

You can append query options to the URI in the following format, `?option=value&option=value&…`

**Note:** The IN body of the generated exchange is `null`. So `exchange.getIn().getBody()` returns `null`.

**Tip:** *Advanced Scheduler* See also the Quartz component that supports much more advanced scheduling.

**Tip:** *Specify time in human friendly format* In Camel 2.3 onwards you can specify the time in human friendly syntax.

322.2. OPTIONS

The Timer component has no options.

The Timer endpoint is configured using URI syntax:

```
timer:timerName
```

with the following path and query parameters:

322.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>timerName</td>
<td>Required The name of the timer</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

322.2.2. Query Parameters (12 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------------</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>delay</td>
<td>The number of milliseconds to wait before the first event is generated. Should not be used in conjunction with the time option. The default value is 1000. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>fixedRate</td>
<td>Events take place at approximately regular intervals, separated by the specified period.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>period</td>
<td>If greater than 0, generate periodic events every period milliseconds. The default value is 1000. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td>repeatCount</td>
<td>Specifies a maximum limit of number of fires. So if you set it to 1, the timer will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.</td>
<td>0</td>
<td>long</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the default exchange pattern when creating an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>daemon</td>
<td>Specifies whether or not the thread associated with the timer endpoint runs as a daemon. The default value is true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>pattern</td>
<td>Allows you to specify a custom Date pattern to use for setting the time option using URI syntax.</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>
322.3. EXCHANGE PROPERTIES

When the timer is fired, it adds the following information as properties to the Exchange:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exchange.TIMER_NAME</td>
<td>String</td>
<td>The value of the name option.</td>
</tr>
<tr>
<td>Exchange.TIMER_TIME</td>
<td>Date</td>
<td>The value of the time option.</td>
</tr>
<tr>
<td>Exchange.TIMER_PERIOD</td>
<td>long</td>
<td>The value of the period option.</td>
</tr>
<tr>
<td>Exchange.TIMER_FIRED_TIME</td>
<td>Date</td>
<td>The time when the consumer fired.</td>
</tr>
<tr>
<td>Exchange.TIMER_COUNTER</td>
<td>Long</td>
<td>Camel 2.8: The current fire counter. Starts from 1.</td>
</tr>
</tbody>
</table>
To set up a route that generates an event every 60 seconds:

```java
from("timer://foo?fixedRate=true&period=60000").to("bean:myBean?method=someMethodName");
```

**TIP**

Instead of 60000 you can use period=60s which is more friendly to read.

The above route will generate an event and then invoke the `someMethodName` method on the bean called `myBean` in the Registry such as JNDI or Spring.

And the route in Spring DSL:

```xml
<route>
  <from uri="timer://foo?fixedRate=true&period=60000"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

### 322.5. FIRING AS SOON AS POSSIBLE

**Available as of Camel 2.17**

You may want to fire messages in a Camel route as soon as possible you can use a negative delay:

```xml
<route>
  <from uri="timer://foo?delay=-1"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

In this way the timer will fire messages immediately.

You can also specify a repeatCount parameter in conjunction with a negative delay to stop firing messages after a fixed number has been reached.

If you don’t specify a repeatCount then the timer will continue firing messages until the route will be stopped.

### 322.6. FIRING ONLY ONCE

**Available as of Camel 2.8**

You may want to fire a message in a Camel route only once, such as when starting the route. To do that you use the repeatCount option as shown:

```xml
<route>
  <from uri="timer://foo?repeatCount=1"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

### 322.7. SEE ALSO

- [Scheduler](#)
- Quartz
CHAPTER 323. TWILIO COMPONENT

Available as of Camel version 2.20

The Twilio component provides access to Version 2010-04-01 of Twilio REST APIs accessible using Twilio Java SDK.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-twilio</artifactId>
  <version>${camel-version}</version>
</dependency>
```

### 323.1. TWILIO OPTIONS

The Twilio component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>To use the shared configuration</td>
<td></td>
<td>TwilioConfiguration</td>
</tr>
<tr>
<td></td>
<td>(advanced)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>RestClient</td>
<td>To use the shared REST client</td>
<td></td>
<td>TwilioRestClient</td>
</tr>
<tr>
<td></td>
<td>(advanced)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>resolveProperty</td>
<td>Whether the component should resolve property placeholders on itself when</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Placeholders</td>
<td>starting. Only properties which are of String type can use property</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>placeholders.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(advanced)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Twilio endpoint is configured using URI syntax:

```
twilio:apiName/methodName
```

with the following path and query parameters:

### 323.1.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiName</td>
<td>Required What kind of</td>
<td></td>
<td>TwilioApiName</td>
</tr>
<tr>
<td></td>
<td>operation to perform</td>
<td></td>
<td></td>
</tr>
<tr>
<td>methodName</td>
<td>Required What sub operation</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td></td>
<td>to use for the selected</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>operation</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
323.1.2. Query Parameters (8 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>inBody (common)</td>
<td>Sets the name of a parameter to be passed in the exchange In Body</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>accountSid (security)</td>
<td>The account SID to use.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>password (security)</td>
<td>Auth token for the account.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>username (security)</td>
<td>The account to use.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

323.2. URI FORMAT

```
twilio://endpoint-prefix/endpoint?[options]
```

Endpoint prefix can be one of:
- account
- address
- address-dependent-phone-number
- application
- available-phone-number-country
- available-phone-number-country-local
- available-phone-number-country-mobile
- available-phone-number-country-toll-free
- call
- call-feedback
- call-feedback-summary
- call-notification
- call-recording
- conference
- conference-participant
- connect-app
- incoming-phone-number
- incoming-phone-number-local
- incoming-phone-number-mobile
- incoming-phone-number-toll-free
- key
- message
- message-feedback
- message-media
- new-key
- new-signing-key
- notification
- outgoing-caller-id
- queue
- queue-member
- recording
- recording-add-on-result
323.3. PRODUCER ENDPOINTS:

Producer endpoints can use endpoint prefixes followed by endpoint names and associated options described next. A shorthand alias can be used for all of the endpoints. The endpoint URI MUST contain a prefix.

Any of the endpoint options can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format CamelTwilio.<option>. Note that the inBody option overrides message header, i.e. the endpoint option inBody=option would override
a **CamelTwilio.option** header.

Endpoint can be one of:

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Shorthand Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>creator</td>
<td>create</td>
<td>Make the request to the Twilio API to perform the create</td>
</tr>
<tr>
<td>deleter</td>
<td>delete</td>
<td>Make the request to the Twilio API to perform the delete</td>
</tr>
<tr>
<td>fetcher</td>
<td>fetch</td>
<td>Make the request to the Twilio API to perform the fetch</td>
</tr>
<tr>
<td>reader</td>
<td>read</td>
<td>Make the request to the Twilio API to perform the read</td>
</tr>
<tr>
<td>updater</td>
<td>update</td>
<td>Make the request to the Twilio API to perform the update</td>
</tr>
</tbody>
</table>

Available endpoints differ depending on the endpoint prefixes.

For more information on the endpoints and options see API documentation at: [https://www.twilio.com/docs/libraries/reference/twilio-java/index.html](https://www.twilio.com/docs/libraries/reference/twilio-java/index.html)

### 323.4. CONSUMER ENDPOINTS:

Any of the producer endpoints can be used as a consumer endpoint. Consumer endpoints can use **Scheduled Poll Consumer Options** with a **consumer** prefix to schedule endpoint invocation. Consumer endpoints that return an array or collection will generate one exchange per element, and their routes will be executed once for each exchange.

If you want to receive calls or messages from Twilio and respond to them using a Camel consumer endpoint, you can use other HTTP-based components such as **camel-servlet**, **camel-undertow**, **camel-jetty**, and **camel-netty-http** to respond with TwiML.

### 323.5. MESSAGE HEADER

Any of the options can be provided in a message header for producer endpoints with **CamelTwilio** prefix.

### 323.6. MESSAGE BODY

All result message bodies utilize objects provided by the Twilio Java SDK. Producer endpoints can specify the option name for incoming message body in the **inBody** endpoint parameter.
CHAPTER 324. TWITTER COMPONENTS

Available as of Camel version 2.10

The camel-twitter consists of 4 components:

- Twitter Direct Message
- Twitter Search
- Twitter Streaming
- Twitter Timeline

The Twitter components enable the most useful features of the Twitter API by encapsulating Twitter4J. It allows direct, polling, or event-driven consumption of timelines, users, trends, and direct messages. Also, it supports producing messages as status updates or direct messages.

Twitter now requires the use of OAuth for all client application authentication. In order to use camel-twitter with your account, you'll need to create a new application within Twitter at https://dev.twitter.com/apps/new and grant the application access to your account. Finally, generate your access token and secret.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-twitter</artifactId>
  <version>${camel-version}</version>
</dependency>
```

### 324.1. CONSUMER ENDPOINTS

Rather than the endpoints returning a List through one single route exchange, camel-twitter creates one route exchange per returned object. As an example, if "timeline/home" results in five statuses, the route will be executed five times (one for each Status).

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Context</th>
<th>Body Type</th>
<th>Notice</th>
</tr>
</thead>
<tbody>
<tr>
<td>twitter-directmessage</td>
<td>direct, polling</td>
<td>twitter4j.DirectMessage</td>
<td></td>
</tr>
<tr>
<td>twitter-search</td>
<td>direct, polling</td>
<td>twitter4j.Status</td>
<td></td>
</tr>
<tr>
<td>twitter-streaming</td>
<td>event, polling</td>
<td>twitter4j.Status</td>
<td></td>
</tr>
</tbody>
</table>
### 324.2. PRODUCER ENDPOINTS

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Context</th>
<th>Body Type</th>
<th>Notice</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>twitter-timeline</code></td>
<td>direct, polling</td>
<td><code>twitter4j.Status</code></td>
<td></td>
</tr>
<tr>
<td><code>twitter-directmessage</code></td>
<td></td>
<td><code>String</code></td>
<td></td>
</tr>
<tr>
<td><code>twitter-search</code></td>
<td></td>
<td><code>List&lt;twitter4j.Status&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>twitter-timeline</code></td>
<td></td>
<td><code>String</code></td>
<td>Only ‘user’ timelineType is supported for producer</td>
</tr>
</tbody>
</table>

### 324.3. MESSAGE HEADERS

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CamelTwitterKeywords</code></td>
<td>This header is used by the search producer to change the search key words dynamically.</td>
</tr>
<tr>
<td><code>CamelTwitterSearchLanguage</code></td>
<td><strong>Camel 2.11.0:</strong> This header can override the option of <code>lang</code> which set the search language for the search endpoint dynamically.</td>
</tr>
<tr>
<td><code>CamelTwitterCount</code></td>
<td><strong>Camel 2.11.0</strong> This header can override the option of <code>count</code> which sets the max twitters that will be returned.</td>
</tr>
<tr>
<td><code>CamelTwitterNumberOfPages</code></td>
<td><strong>Camel 2.11.0</strong> This header can override the option of <code>numberOfPages</code> which sets how many pages we want to twitter returns.</td>
</tr>
</tbody>
</table>

### 324.4. MESSAGE BODY

All message bodies utilize objects provided by the Twitter4J API.

### 324.5. USE CASES
NOTE

API Rate Limits: Twitter REST APIs encapsulated by Twitter4J are subjected to API Rate Limiting. You can find the per method limits in the API Rate Limits documentation. Note that endpoints/resources not listed in that page are default to 15 requests per allotted user per window.

324.5.1. To create a status update within your Twitter profile, send this producer a String body:

```java
from("direct:foo")
  .to("twitter-timeline://user?consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]");
```

324.5.2. To poll, every 60 sec., all statuses on your home timeline:

```java
from("twitter-timeline://home?type=polling&delay=60&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]"
  .to("bean:blah");
```

324.5.3. To search for all statuses with the keyword 'camel' only once:

```java
from("twitter-search://foo?type=polling&keywords=camel&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]"
  .to("bean:blah");
```

324.5.4. Searching using a producer with static keywords:

```java
from("direct:foo")
  .to("twitter-search://foo?keywords=camel&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]");
```

324.5.5. Searching using a producer with dynamic keywords from header:

In the `bar` header we have the keywords we want to search, so we can assign this value to the `CamelTwitterKeywords` header:

```java
from("direct:foo")
  .setHeader("CamelTwitterKeywords", header("bar"))
  .to("twitter-search://foo?consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]");
```

CHAPTER 325. TWITTER DIRECT MESSAGE COMPONENT

Available as of Camel version 2.10

The Twitter Direct Message Component consumes/produces a user’s direct messages.

325.1. COMPONENT OPTIONS

The Twitter Direct Message component supports 9 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessToken</td>
<td>The access token</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>accessTokenSecret</td>
<td>The access token secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerKey</td>
<td>The consumer key</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerSecret</td>
<td>The consumer secret</td>
<td></td>
<td>String</td>
</tr>
<tr>

325.2. ENDPOINT OPTIONS

The Twitter Direct Message endpoint is configured using URI syntax:

```
twitter-directmessage:user
```

with the following path and query parameters:
### 325.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>Required The user name to send a direct message. This will be ignored for consumer.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 325.2.2. Query Parameters (42 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>type (consumer)</td>
<td>Endpoint type to use. Only streaming supports event type.</td>
<td>polling</td>
<td>EndpointType</td>
</tr>
<tr>
<td>distanceMetric (consumer)</td>
<td>Used by the non-stream geography search, to search by radius using the configured metrics. The unit can either be mi for miles, or km for kilometers. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.</td>
<td>km</td>
<td>String</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>

CHAPTER 326. TWITTER SEARCH COMPONENT

Available as of Camel version 2.10

The Twitter Search component consumes search results.

326.1. COMPONENT OPTIONS

The Twitter Search component supports 9 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessToken</td>
<td>The access token</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>accessTokenSecret</td>
<td>The access token secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerKey</td>
<td>The consumer key</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerSecret</td>
<td>The consumer secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyHost</td>
<td>The http proxy host which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyUser</td>
<td>The http proxy user which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyPassword</td>
<td>The http proxy password which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyPort</td>
<td>The http proxy port which can be used for the camel-twitter.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

326.2. ENDPOINT OPTIONS

The Twitter Search endpoint is configured using URI syntax:

```
twitter-search:keywords
```

with the following path and query parameters:
326.2.1. Path Parameters (1 parameters):

<table>

CHAPTER 328. TWITTER TIMELINE COMPONENT

Available as of Camel version 2.10

The Twitter Timeline component consumes twitter timeline or update the status of specific user.

328.1. COMPONENT OPTIONS

The Twitter Timeline component supports 9 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessToken</td>
<td>The access token</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>accessTokenSecret</td>
<td>The access token secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerKey</td>
<td>The consumer key</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerSecret</td>
<td>The consumer secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyHost</td>
<td>The http proxy host which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyUser</td>
<td>The http proxy user which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyPassword</td>
<td>The http proxy password which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyPort</td>
<td>The http proxy port which can be used for the camel-twitter.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

328.2. ENDPOINT OPTIONS

The Twitter Timeline endpoint is configured using URI syntax:

```
twitter-timeline:timelineType
```

with the following path and query parameters:
### 328.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>timelineType</td>
<td>Required The timeline type to produce/consume.</td>
<td></td>
<td>TimelineType</td>
</tr>
</tbody>
</table>

### 328.2.2. Query Parameters (43 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>The username when using timelineType=user</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>type</td>
<td>Endpoint type to use. Only streaming supports event type.</td>
<td>polling</td>
<td>EndpointType</td>
</tr>
<tr>
<td>distanceMetric</td>
<td>Used by the non-stream geography search, to search by radius using the configured metrics. The unit can either be mi for miles, or km for kilometers. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.</td>
<td>km</td>
<td>String</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>extendedMode</td>
<td>Used for enabling full text from twitter (eg receive tweets that contains more than 140 characters).</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>latitude</td>
<td>Used by the non-stream geography search to search by latitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.</td>
<td>Double</td>
<td></td>
</tr>
<tr>
<td>locations</td>
<td>Bounding boxes, created by pairs of lat/lons. Can be used for streaming/filter. A pair is defined as lat,lon. And multiple paris can be separated by semi colon.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>longitude</td>
<td>Used by the non-stream geography search to search by longitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.</td>
<td>Double</td>
<td></td>
</tr>
<tr>
<td>pollStrategy</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td>PollingConsumerPollingStrategy</td>
<td></td>
</tr>
<tr>
<td>radius</td>
<td>Used by the non-stream geography search to search by radius. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.</td>
<td>Double</td>
<td></td>
</tr>
<tr>
<td>twitterStream</td>
<td>To use a custom instance of TwitterStream</td>
<td>TwitterStream</td>
<td></td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>count</td>
<td>Limiting number of results per page.</td>
<td>Integer</td>
<td></td>
</tr>
<tr>
<td>filterOld</td>
<td>Filter out old tweets, that has previously been polled. This state is stored in memory only, and based on last tweet id.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>lang</td>
<td>The lang string ISO_639-1 which will be used for searching</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>numberOfPages</td>
<td>The number of pages result which you want camel-twitter to consume.</td>
<td>1</td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>------------</td>
</tr>
<tr>
<td><strong>sinceId</strong> (filter)</td>
<td>The last tweet id which will be used for pulling the tweets. It is useful when the camel route is restarted after a long running.</td>
<td>1</td>
<td>long</td>
</tr>
<tr>
<td><strong>userIds</strong> (filter)</td>
<td>To filter by user ids for streaming/filter. Multiple values can be separated by comma.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td><strong>backoffErrorThreshold</strong> (scheduler)</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>backoffIdleThreshold</strong> (scheduler)</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>backoffMultiplier</strong> (scheduler)</td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>delay</strong> (scheduler)</td>
<td>Milliseconds before the next poll.</td>
<td>30000</td>
<td>long</td>
</tr>
<tr>

<td>The consumer key. Can also be configured on the TwitterComponent level instead.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerSecret (security)</td>
<td>The consumer secret. Can also be configured on the TwitterComponent level instead.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
IMPORTANT

The composite twitter component has been deprecated. Use individual component for directmessage, search, streaming and timeline.

- Twitter Components
  - Twitter Direct Message
  - Twitter Search
  - Twitter Streaming
  - Twitter Timeline

The Twitter component enables the most useful features of the Twitter API by encapsulating Twitter4J. It allows direct, polling, or event-driven consumption of timelines, users, trends, and direct messages. Also, it supports producing messages as status updates or direct messages.

Twitter now requires the use of OAuth for all client application authentication. In order to use camel-twitter with your account, you'll need to create a new application within Twitter at https://dev.twitter.com/apps/new and grant the application access to your account. Finally, generate your access token and secret.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-twitter</artifactId>
  <version>${camel-version}</version>
</dependency>
```

329.1. URI FORMAT

```
twitter://endpoint[?options]
```

329.2. TWITTER COMPONENT

The twitter component can be configured with the Twitter account settings which is mandatory to configure before using.

The Twitter component supports 9 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessToken</td>
<td>The access token</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>accessTokenSecret</td>
<td>The access token secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerKey</td>
<td>The consumer key</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerSecret</td>
<td>The consumer secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyHost</td>
<td>The http proxy host which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyUser</td>
<td>The http proxy user which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyPassword</td>
<td>The http proxy password which can be used for the camel-twitter.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>httpProxyPort</td>
<td>The http proxy port which can be used for the camel-twitter.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

You can also configure these options directly in the endpoint.

### 329.3. CONSUMER ENDPOINTS

Rather than the endpoints returning a List through one single route exchange, camel-twitter creates one route exchange per returned object. As an example, if "timeline/home" results in five statuses, the route will be executed five times (one for each Status).
<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Context</th>
<th>Body Type</th>
<th>Notice</th>
</tr>
</thead>
<tbody>
<tr>
<td>streaming/filters</td>
<td>event, polling</td>
<td>twitter 4j.Status</td>
<td></td>
</tr>
<tr>
<td>streaming/sample</td>
<td>event, polling</td>
<td>twitter 4j.Status</td>
<td></td>
</tr>
<tr>
<td>streaming/user</td>
<td>event, polling</td>
<td>twitter 4j.Status</td>
<td><em>Camel 2.16: To receive tweets from protected users and accounts.</em></td>
</tr>
<tr>
<td>timeline/home</td>
<td>direct, polling</td>
<td>twitter 4j.Status</td>
<td></td>
</tr>
<tr>
<td>timeline/mentions</td>
<td>direct, polling</td>
<td>twitter 4j.Status</td>
<td></td>
</tr>
<tr>
<td>timeline/public</td>
<td>direct, polling</td>
<td>twitter 4j.Status</td>
<td>*@deprecated. Use timeline/home or direct/home instead. Removed from <em>Camel 2.11 onwards.</em></td>
</tr>
<tr>
<td>timeline/reweets/ame</td>
<td>direct, polling</td>
<td>twitter 4j.Status</td>
<td></td>
</tr>
<tr>
<td>timeline/user</td>
<td>direct, polling</td>
<td>twitter 4j.Status</td>
<td></td>
</tr>
<tr>
<td>trends/daily</td>
<td>*Camel 2.10.1:</td>
<td>twitter 4j.Status</td>

<td>Camel 2.11.0 This header can override the option of <code>numberOfPages</code> which sets how many pages we want to twitter returns.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### 329.7. MESSAGE BODY

All message bodies utilize objects provided by the Twitter4J API.

### 329.8. USE CASES

**NOTE**

*API Rate Limits:* Twitter REST APIs encapsulated by Twitter4J are subjected to API Rate Limiting. You can find the per method limits in the API Rate Limits documentation. Note that endpoints/resources not listed in that page are default to 15 requests per allotted user per window.
329.8.1. To create a status update within your Twitter profile, send this producer a String body:

```java
from("direct:foo")
  .to("twitter://timeline/user?consumerKey=[s]&consumerSecret=[s]&accessToken=[s] &accessTokenSecret=[s])
```

329.8.2. To poll, every 60 sec., all statuses on your home timeline:

```java
from("twitter://timeline/home?type=polling&delay=60&consumerKey=[s] &consumerSecret=[s] &accessToken=[s] &accessTokenSecret=[s]")
  .to("bean:blah")
```

329.8.3. To search for all statuses with the keyword 'camel' only once:

```java
from("twitter://search?type=polling&keywords=camel&consumerKey=[s] &consumerSecret=[s] &accessToken=[s] &accessTokenSecret=[s]")
  .to("bean:blah")
```

329.8.4. Searching using a producer with static keywords:

```java
from("direct:foo")
  .to("twitter://search?keywords=camel&consumerKey=[s] &consumerSecret=[s] &accessToken=[s] &accessTokenSecret=[s])
```

329.8.5. Searching using a producer with dynamic keywords from header:

In the `bar` header we have the keywords we want to search, so we can assign this value to the `CamelTwitterKeywords` header:

```java
from("direct:foo")
  .setHeader("CamelTwitterKeywords", header("bar"))
  .to("twitter://search?consumerKey=[s] &consumerSecret=[s] &accessToken=[s] &accessTokenSecret=[s]")
```

329.9. EXAMPLE

See also the Twitter Websocket Example.

- Getting Started
- Twitter Websocket Example
CHAPTER 330. UNDERTOW COMPONENT

Available as of Camel version 2.16

The undertow component provides HTTP and WebSocket based endpoints for consuming and producing HTTP/WebSocket requests.

That is, the Undertow component behaves as a simple Web server. Undertow can also be used as a http client which mean you can also use it with Camel as a producer.

TIP

Since Camel version 2.21, the undertow component also supports WebSocket connections and can thus serve as a drop-in replacement for Camel websocket component or atmosphere-websocket component.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-undertow</artifactId>
    <version>x.x.x</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

330.1. URI FORMAT

undertow:http://hostname[:port][/resourceUri][?options]
undertow:https://hostname[:port][/resourceUri][?options]
undertow:ws://hostname[:port][/resourceUri][?options]
undertow:wss://hostname[:port][/resourceUri][?options]

You can append query options to the URI in the following format, ?option=value&option=value&...

330.2. OPTIONS

The Undertow component supports 5 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>undertowHttpBinding (advanced)</td>
<td>To use a custom HttpBinding to control the mapping between Camel message and HttpClient.</td>
<td></td>
<td>UndertowHttpBinding</td>
</tr>
<tr>
<td>sslContextParameters (security)</td>
<td>To configure security using SSLContextParameters</td>
<td></td>
<td>SSLContextParameters</td>
</tr>
<tr>
<td>useGlobalSslContext Parameters (security)</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### hostOptions (advanced)

To configure common options, such as thread pools.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostOptions</td>
<td>To configure common options, such as thread pools</td>
<td></td>
<td>UndertowHostOptions</td>
</tr>
</tbody>
</table>

### resolveProperty Placeholders (advanced)

Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Undertow endpoint is configured using URI syntax:

```
undertow:httpURI
```

with the following path and query parameters:

#### 330.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>httpURI</td>
<td>Required The url of the HTTP endpoint to use.</td>
<td></td>
<td>URI</td>
</tr>
</tbody>
</table>

#### 330.2.2. Query Parameters (21 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>httpMethodRestrict (consumer)</td>
<td>Used to only allow consuming if the HttpMethod matches, such as GET/POST/PUT etc. Multiple methods can be specified separated by comma.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>matchOnUriPrefix (consumer)</td>
<td>Whether or not the consumer should try to find a target consumer by matching the URI prefix if no exact match is found.</td>
<td>false</td>
<td>Boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td><strong>optionsEnabled</strong></td>
<td>Specifies whether to enable HTTP OPTIONS for this Servlet consumer. By default OPTIONS is turned off.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>exceptionHandler</strong></td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td><strong>exchangePattern</strong></td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td><strong>cookieHandler</strong></td>
<td>Configure a cookie handler to maintain a HTTP session</td>
<td></td>
<td>CookieHandler</td>
</tr>
<tr>
<td><strong>keepAlive</strong></td>
<td>Setting to ensure socket is not closed due to inactivity</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>options</strong></td>
<td>Sets additional channel options. The options that can be used are defined in org.xnio.Options. To configure from endpoint uri, then prefix each option with option., such as option.close-abort=true&amp;option.send-buffer=8192</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td><strong>reuseAddresses</strong></td>
<td>Setting to facilitate socket multiplexing</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>tcpNoDelay</strong></td>
<td>Setting to improve TCP protocol performance</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>throwExceptionOnFailure</strong></td>
<td>Option to disable throwing the HttpOperationFailedException in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td><strong>transferException</strong></td>
<td>If enabled and an Exchange failed processing on the consumer side and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is instead of the HttpOperationFailedException. The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.</td>
<td>false</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
### 330.3. MESSAGE HEADERS

Camel uses the same message headers as the HTTP component. From Camel 2.2, it also uses `Exchange.HTTP_CHUNKED, CamelHttpChunked` header to turn on or turn off the chunked encoding on the camel-undertow consumer.

Camel also populates all request parameter and request headers. For example, given a client request with the URL, `http://myserver/myserver?orderid=123`, the exchange will contain a header named `orderid` with the value 123.

### 330.4. HTTP PRODUCER EXAMPLE

The following is a basic example of how to send an HTTP request to an existing HTTP endpoint.

```java
in Java DSL
```
from("direct:start")
    .to("undertow:http://www.google.com");

or in XML

```xml
    <route>
        <from uri="direct:start"/>
        <to uri="undertow:http://www.google.com"/>
    </route>
```

**330.5. HTTP CONSUMER EXAMPLE**

In this sample we define a route that exposes a HTTP service at
http://localhost:8080/myapp/myservice:

```xml
    <route>
        <from uri="undertow:http://localhost:8080/myapp/myservice"/>
        <to uri="bean:myBean"/>
    </route>
```

**330.6. WEBSOCKET EXAMPLE**

In this sample we define a route that exposes a WebSocket service at
http://localhost:8080/myapp/mysocket and returns back a response to the same channel:

```xml
    <route>
        <from uri="undertow:ws://localhost:8080/myapp/mysocket"/>
        <transform><simple>Echo ${body}</simple></transform>
        <to uri="undertow:ws://localhost:8080/myapp/mysocket"/>
    </route>
```

**330.7. USING LOCALHOST AS HOST**

When you specify localhost in a URL, Camel exposes the endpoint only on the local TCP/IP network interface, so it cannot be accessed from outside the machine it operates on.

If you need to expose a Jetty endpoint on a specific network interface, the numerical IP address of this interface should be used as the host. If you need to expose a Jetty endpoint on all network interfaces, the 0.0.0.0 address should be used.

To listen across an entire URI prefix, see How do I let Jetty match wildcards.

If you actually want to expose routes by HTTP and already have a Servlet, you should instead refer to the Servlet Transport.

**330.8. UNDERTOW CONSUMERS ON {WILDFLY}**

The configuration of camel-undertow consumers on {wildfly} is different to that of standalone Camel. Producer endpoints work as per normal.
On {wildfly}, camel-undertow consumers leverage the default Undertow HTTP server provided by the container. The server is defined within the undertow subsystem configuration. Here’s an excerpt of the default configuration from standalone.xml:

```xml
<subsystem xmlns="urn:jboss:domain:undertow:4.0">
  <buffer-cache name="default" />
  <server name="default-server">
    <http-listener name="default" socket-binding="http" redirect-socket="https" enable-http2="true" />
    <https-listener name="https" socket-binding="https" security-realm="ApplicationRealm" enable-http2="true" />
      <host name="default-host" alias="localhost">
        <location name="/" handler="welcome-content" />
        <filter-ref name="server-header" />
        <filter-ref name="x-powered-by-header" />
        <http-invoker security-realm="ApplicationRealm" />
      </host>
  </server>
</subsystem>
```

In this instance, Undertow is configured to listen on interfaces / ports specified by the http and https socket-binding. By default this is port 8080 for http and 8443 for https.

This has the following implications:

- camel-undertow consumers will only bind to localhost:8080 or localhost:8443
- Some endpoint consumer configuration options have no effect (see below), since these settings are managed by the {wildfly} container

For example, if you configure an endpoint consumer using different host or port combinations, a warning will appear within the server log file. For example the following host & port configurations would be ignored:

```
from("undertow:http://somehost:1234/path/to/resource")
```

```text
[org.wildfly.extension.camel] (pool-2-thread-1) Ignoring configured host:
http://somehost:1234/path/to/resource
```

However, the consumer is still available on the default host & port localhost:8080 or localhost:8443.

**330.8.1. Configuring alternative ports**

If alternative ports are to be accepted, then these must be configured via the {wildfly} subsystem configuration. This is explained in the server documentation:

https://access.redhat.com/documentation/en-us/red_hat_jboss_enterprise_application_platform/7.1/html/configuration_guide/configuring_the_web_server

**330.8.2. Ignored camel-undertow consumer configuration options on {wildfly}**

`hostOptions`

Refer to the {wildfly} undertow configuration guide for how to configure server host options:
sslContextParameters

To configure SSL, refer to the {wildfly} SSL configuration guide:

CHAPTER 331. UNIVOCITY CSV DATAFORMAT

Available as of Camel version 2.15

This Data Format uses uniVocity-parsers for reading and writing 3 kinds of tabular data text files:

- CSV (Comma Separated Values), where the values are separated by a symbol (usually a comma)
- fixed-width, where the values have known sizes
- TSV (Tabular Separated Values), where the fields are separated by a tabulation

Thus there are 3 data formats based on uniVocity-parsers.

If you use Maven you can just add the following to your pom.xml, substituting the version number for the latest and greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-univocity-parsers</artifactId>
  <version>x.x.x</version>
</dependency>
```

331.1. OPTIONS

Most configuration options of the uniVocity-parsers are available in the data formats. If you want more information about a particular option, please refer to their documentation page.

The 3 data formats share common options and have dedicated ones, this section presents them all.

331.2. OPTIONS

The uniVocity CSV dataformat supports 18 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quoteAllFields</td>
<td>false</td>
<td>Boolean</td>
<td>Whether or not all values must be quoted when writing them.</td>
</tr>
<tr>
<td>quote</td>
<td>&quot;</td>
<td>String</td>
<td>The quote symbol.</td>
</tr>
<tr>
<td>quoteEscape</td>
<td>&quot;</td>
<td>String</td>
<td>The quote escape symbol</td>
</tr>
<tr>
<td>delimiter</td>
<td>,</td>
<td>String</td>
<td>The delimiter of values</td>
</tr>
<tr>
<td>nullValue</td>
<td>String</td>
<td>String</td>
<td>The string representation of a null value. The default value is null</td>
</tr>
<tr>
<td>skipEmptyLines</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the empty lines must be ignored. The default value is true</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ignoreTrailingSpaces</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the trailing white spaces must ignored. The default value is true</td>
</tr>
<tr>
<td>ignoreLeadingSpaces</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the leading white spaces must be ignored. The default value is true</td>
</tr>
<tr>
<td>headersDisabled</td>
<td>false</td>
<td>Boolean</td>
<td>Whether or not the headers are disabled. When defined, this option explicitly sets the headers as null which indicates that there is no header. The default value is false</td>
</tr>
<tr>
<td>headerExtractionEnabled</td>
<td>false</td>
<td>Boolean</td>
<td>Whether or not the header must be read in the first line of the test document The default value is false</td>
</tr>
<tr>
<td>numberOfRecordsToRead</td>
<td></td>
<td>Integer</td>
<td>The maximum number of record to read.</td>
</tr>
<tr>
<td>emptyValue</td>
<td></td>
<td>String</td>
<td>The String representation of an empty value</td>
</tr>
<tr>
<td>lineSeparator</td>
<td></td>
<td>String</td>
<td>The line separator of the files The default value is to use the JVM platform line separator</td>
</tr>
<tr>
<td>normalizedLineSeparator</td>
<td></td>
<td>String</td>
<td>The normalized line separator of the files The default value is a new line character.</td>
</tr>
<tr>
<td>comment</td>
<td>#</td>
<td>String</td>
<td>The comment symbol. The default value is</td>
</tr>
<tr>
<td>lazyLoad</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the unmarshalling should produce an iterator that reads the lines on the fly or if all the lines must be read at one. The default value is false</td>
</tr>
<tr>
<td>asMap</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the unmarshalling should produce maps for the lines values instead of lists. It requires to have header (either defined or collected). The default value is false</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

### 331.3. MARSHALLING USAGES

The marshalling accepts either:

- A list of maps (`List<Map<String, ?>>`), one for each line
• A single map \(\text{Map<}\text{String, ?>\text{)}\), for a single line

Any other body will throw an exception.

### 331.3.1. Usage example: marshalling a Map into CSV format

```xml
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-csv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

### 331.3.2. Usage example: marshalling a Map into fixed-width format

```xml
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-fixed padding="_">
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </marshal>
  <to uri="mock:result"/>
</route>
```

### 331.3.3. Usage example: marshalling a Map into TSV format

```xml
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-tsv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

### 331.4. UNMARSHALLING USAGES

The unmarshalling uses an \texttt{Input}Stream in order to read the data.

Each row produces either:

• a list with all the values in it (\texttt{asMap} option with \texttt{false});

• A map with all the values indexed by the headers (\texttt{asMap} option with \texttt{true}).

All the rows can either:

• be collected at once into a list (\texttt{lazyLoad} option with \texttt{false});

• be read on the fly using an iterator (\texttt{lazyLoad} option with \texttt{true}).
331.4.1. Usage example: unmarshalling a CSV format into maps with automatic headers

```xml
<route>
    <from uri="direct:input"/>
    <unmarshal>
        <univocity-csv headerExtractionEnabled="true" asMap="true"/>
    </unmarshal>
    <to uri="mock:result"/>
</route>
```

331.4.2. Usage example: unmarshalling a fixed-width format into lists

```xml
<route>
    <from uri="direct:input"/>
    <unmarshal>
        <univocity-fixed>
            <univocity-header length="5"/>
            <univocity-header length="5"/>
            <univocity-header length="5"/>
        </univocity-fixed>
    </unmarshal>
    <to uri="mock:result"/>
</route>
```
CHAPTER 332. UNIVOCITY FIXED LENGTH DATAFORMAT

Available as of Camel version 2.15

This Data Format uses uniVocity-parsers for reading and writing 3 kinds of tabular data text files:

- CSV (Comma Separated Values), where the values are separated by a symbol (usually a comma)
- fixed-width, where the values have known sizes
- TSV (Tabular Separated Values), where the fields are separated by a tabulation

Thus there are 3 data formats based on uniVocity-parsers.

If you use Maven you can just add the following to your pom.xml, substituting the version number for the latest and greatest release (see the download page for the latest versions).

```xml
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-univocity-parsers</artifactId>
    <version>x.x.x</version>
</dependency>
```

332.1. OPTIONS

Most configuration options of the uniVocity-parsers are available in the data formats. If you want more information about a particular option, please refer to their documentation page.

The 3 data formats share common options and have dedicated ones, this section presents them all.

332.2. OPTIONS

The uniVocity Fixed Length dataformat supports 17 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>skipTrailingChars UntilNewline</td>
<td>false</td>
<td>Boolean</td>
<td>Whether or not the trailing characters until new line must be ignored. The default value is false</td>
</tr>
<tr>
<td>recordEndsOnNewline</td>
<td>false</td>
<td>Boolean</td>
<td>Whether or not the record ends on new line. The default value is false</td>
</tr>
<tr>
<td>padding</td>
<td></td>
<td>String</td>
<td>The padding character. The default value is a space</td>
</tr>
<tr>
<td>nullValue</td>
<td></td>
<td>String</td>
<td>The string representation of a null value. The default value is null</td>
</tr>
<tr>
<td>skipEmptyLines</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the empty lines must be ignored. The default value is true</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>---------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ignoreTrailingWhiteSpaces</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the trailing white spaces must be ignored. The default value is true</td>
</tr>
<tr>
<td>ignoreLeadingWhiteSpaces</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the leading white spaces must be ignored. The default value is true</td>
</tr>
<tr>
<td>headersDisabled</td>
<td>false</td>
<td>Boolean</td>
<td>Whether or not the headers are disabled. When defined, this option explicitly sets the headers as null which indicates that there is no header. The default value is false</td>
</tr>
<tr>
<td>headerExtractionEnabled</td>
<td>false</td>
<td>Boolean</td>
<td>Whether or not the header must be read in the first line of the test document The default value is false</td>
</tr>
<tr>
<td>numberOfRecordsToRead</td>
<td></td>
<td>Integer</td>
<td>The maximum number of record to read.</td>
</tr>
<tr>
<td>emptyValue</td>
<td></td>
<td>String</td>
<td>The String representation of an empty value</td>
</tr>
<tr>
<td>lineSeparator</td>
<td></td>
<td>String</td>
<td>The line separator of the files The default value is to use the JVM platform line separator</td>
</tr>
<tr>
<td>normalizedLineSeparator</td>
<td></td>
<td>String</td>
<td>The normalized line separator of the files The default value is a new line character.</td>
</tr>
<tr>
<td>comment</td>
<td>#</td>
<td>String</td>
<td>The comment symbol. The default value is</td>
</tr>
<tr>
<td>lazyLoad</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the unmarshalling should produce an iterator that reads the lines on the fly or if all the lines must be read at one. The default value is false</td>
</tr>
<tr>
<td>asMap</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the unmarshalling should produce maps for the lines values instead of lists. It requires to have header (either defined or collected). The default value is false</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.</td>
</tr>
</tbody>
</table>

### 332.3. MARSHALLING USAGES

The marshalling accepts either:

- A list of maps (L`<Map<String, ?>>`)，one for each line
- A single map (Map<String, ?>)，for a single line
Any other body will throws an exception.

### 332.3.1. Usage example: marshalling a Map into CSV format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-csv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

### 332.3.2. Usage example: marshalling a Map into fixed-width format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-fixed padding="_">
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </marshal>
  <to uri="mock:result"/>
</route>
```

### 332.3.3. Usage example: marshalling a Map into TSV format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-tsv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

### 332.4. UNMARSHALLING USAGES

The unmarshalling uses an `InputStream` in order to read the data.

Each row produces either:

- a list with all the values in it (`asMap` option with `false`);
- A map with all the values indexed by the headers (`asMap` option with `true`).

All the rows can either:

- be collected at once into a list (`lazyLoad` option with `false`);
- be read on the fly using an iterator (`lazyLoad` option with `true`).
332.4.1. Usage example: unmarshalling a CSV format into maps with automatic headers

```xml
<route>
  <from uri="direct:input"/>
  <unmarshal>
    <univocity-csv headerExtractionEnabled="true" asMap="true"/>
  </unmarshal>
  <to uri="mock:result"/>
</route>
```

332.4.2. Usage example: unmarshalling a fixed-width format into lists

```xml
<route>
  <from uri="direct:input"/>
  <unmarshal>
    <univocity-fixed>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </unmarshal>
  <to uri="mock:result"/>
</route>
```
CHAPTER 333. UNIVOCITY TSV DATAFORMAT

Available as of Camel version 2.15

This Data Format uses uniVocity-parsers for reading and writing 3 kinds of tabular data text files:

- CSV (Comma Separated Values), where the values are separated by a symbol (usually a comma)
- fixed-width, where the values have known sizes
- TSV (Tabular Separated Values), where the fields are separated by a tabulation

Thus there are 3 data formats based on uniVocity-parsers.

If you use Maven you can just add the following to your pom.xml, substituting the version number for the latest and greatest release (see the download page for the latest versions ).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-univocity-parsers</artifactId>
  <version>x.x.x</version>
</dependency>
```

333.1. OPTIONS

Most configuration options of the uniVocity-parsers are available in the data formats. If you want more information about a particular option, please refer to their documentation page.

The 3 data formats share common options and have dedicated ones, this section presents them all.

333.2. OPTIONS

The uniVocity TSV dataformat supports 15 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>escapeChar</td>
<td>\</td>
<td>String</td>
<td>The escape character.</td>
</tr>
<tr>
<td>nullValue</td>
<td></td>
<td>String</td>
<td>The string representation of a null value. The default value is null</td>
</tr>
<tr>
<td>skipEmptyLines</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the empty lines must be ignored. The default value is true</td>
</tr>
<tr>
<td>ignoreTrailingWhitespaces</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the trailing white spaces must be ignored. The default value is true</td>
</tr>
<tr>
<td>ignoreLeadingWhitespaces</td>
<td>true</td>
<td>Boolean</td>
<td>Whether or not the leading white spaces must be ignored. The default value is true</td>
</tr>
</tbody>
</table>
### 333.3. MARSHALLING USAGES

The marshalling accepts either:

- A list of maps (`List<Map<String, ?>>`), one for each line
- A single map (`Map<String, ?>`), for a single line

Any other body will throws an exception.

#### 333.3.1. Usage example: marshalling a Map into CSV format
333.3.2. Usage example: marshalling a Map into fixed-width format

```xml
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-fixed padding="_">
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </marshal>
  <to uri="mock:result"/>
</route>
```

333.3.3. Usage example: marshalling a Map into TSV format

```xml
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-tsv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

333.4. UNMARSHALLING USAGES

The unmarshalling uses an `InputStream` in order to read the data.

Each row produces either:

- a list with all the values in it (`asMap` option with `false`);
- A map with all the values indexed by the headers (`asMap` option with `true`).

All the rows can either:

- be collected at once into a list (`lazyLoad` option with `false`);
- be read on the fly using an iterator (`lazyLoad` option with `true`).

333.4.1. Usage example: unmarshalling a CSV format into maps with automatic headers

```xml
<route>
</route>
```
333.4.2. Usage example: unmarshalling a fixed-width format into lists

```xml
<from uri="direct:input"/>
<unmarshal>
    <univocity-fixed>
        <univocity-header length="5"/>
        <univocity-header length="5"/>
        <univocity-header length="5"/>
    </univocity-fixed>
</unmarshal>
<to uri="mock:result"/>
</route>
```
CHAPTER 334. VALIDATOR COMPONENT

Available as of Camel version 1.1

The Validation component performs XML validation of the message body using the JAXP Validation API and based on any of the supported XML schema languages, which defaults to XML Schema

Note that the Jing component also supports the following useful schema languages:

- RelaxNG Compact Syntax
- RelaxNG XML Syntax

The MSV component also supports RelaxNG XML Syntax.

334.1. URI FORMAT

validator:someLocalOrRemoteResource

Where someLocalOrRemoteResource is some URL to a local resource on the classpath or a full URL to a remote resource or resource on the file system which contains the XSD to validate against. For example:

- msv:org/foo/bar.xsd
- msv:file:../foo/bar.xsd
- msv:http://acme.com/cheese.xsd
- validator:com/mypackage/myschema.xsd

Maven users will need to add the following dependency to their pom.xml for this component when using Camel 2.8 or older:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

From Camel 2.9 onwards the Validation component is provided directly in the camel-core.

334.2. OPTIONS

The Validator component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceResolver</td>
<td>To use a custom LSResourceResolver which depends on a dynamic endpoint resource URI</td>
<td></td>
<td>ValidatorResourceResolverFactory</td>
</tr>
</tbody>
</table>
### Resolve Property Placeholders (advanced)

Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resolveProperty</td>
<td>Whether the component should resolve property placeholders on itself when</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Placeholders</td>
<td>starting. Only properties which are of String type can use property</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(advanced)</td>
<td>placeholders.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Validator endpoint is configured using URI syntax:

```text
validator:resourceUri
```

with the following path and query parameters:

#### 334.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td>Required URL to a local resource on the classpath, or a reference to lookup a bean in the Registry, or a full URL to a remote resource or resource on the file system which contains the XSD to validate against.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

#### 334.2.2. Query Parameters (11 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>failOnNullBody</td>
<td>Whether to fail if no body exists.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(producer)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>failOnNullHeader</td>
<td>Whether to fail if no header exists when validating against a header.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(producer)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>headerName</td>
<td>To validate against a header instead of the message body.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>(producer)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>errorHandler</td>
<td>To use a custom org.apache.camel.processor.validation.ValidatorErrorHandler. The default error handler captures the errors and throws an exception.</td>
<td></td>
<td>ValidatorErrorHandler</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>resourceResolver</td>
<td>To use a custom LSResourceResolver. See also link setResourceResolverFactory(ValidatorResourceResolverFactory)</td>
<td></td>
<td>LSResourceResolver</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>resourceResolverFactory (advanced)</td>
<td>For creating a resource resolver which depends on the endpoint resource URI. Must not be used in combination with method link setResourceResolver(LSResourceResolver). If not set then DefaultValidatorResourceResolverFactory is used</td>
<td></td>
<td>ValidatorResourceResolverFactory</td>
</tr>
<tr>
<td>schemaFactory (advanced)</td>
<td>To use a custom javax.xml.validation.SchemaFactory</td>
<td></td>
<td>SchemaFactory</td>
</tr>
<tr>
<td>schemaLanguage (advanced)</td>
<td>Configures the W3C XML Schema Namespace URI.</td>
<td><a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a></td>
<td>String</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>useDom (advanced)</td>
<td>Whether DOMSource/DOMResult or SaxSource/SaxResult should be used by the validator.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>useSharedSchema (advanced)</td>
<td>Whether the Schema instance should be shared or not. This option is introduced to work around a JDK 1.6.x bug. Xerces should not have this issue.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 334.3. EXAMPLE

The following example shows how to configure a route from endpoint `direct:start` which then goes to one of two endpoints, either `mock:valid` or `mock:invalid` based on whether or not the XML matches the given schema (which is supplied on the classpath).

### 334.4. ADVANCED: JMX METHOD CLEARCACHEDSCHEMA

Since Camel 2.17, you can force that the cached schema in the validator endpoint is cleared and reread with the next process call with the JMX operation `clearCachedSchema`. `You can also use this method to programmatically clear the cache. This method is available on the `ValidatorEndpoint` class.`
CHAPTER 335. VELOCITY COMPONENT

Available as of Camel version 1.2

The velocity: component allows you to process a message using an Apache Velocity template. This can be ideal when using Templating to generate responses for requests.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-velocity</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

335.1. URI FORMAT

velocity:templateName[?options]

Where templateName is the classpath-local URI of the template to invoke; or the complete URL of the remote template (eg: file://folder/myfile.vm).

You can append query options to the URI in the following format, ?option=value&option=value&...

335.2. OPTIONS

The Velocity component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>velocityEngine (advanced)</td>
<td>To use the VelocityEngine otherwise a new engine is created</td>
<td></td>
<td>VelocityEngine</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Velocity endpoint is configured using URI syntax:

velocity:resourceUri

with the following path and query parameters:

335.2.1. Path Parameters (1 parameters):
### 335.2.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td><strong>Required</strong> Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>contentCache</td>
<td>Sets whether to use resource content cache or not</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>encoding</td>
<td>Character encoding of the resource content.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>loaderCache</td>
<td>Enables / disables the velocity resource loader cache which is enabled by default</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>propertiesFile</td>
<td>The URI of the properties file which is used for VelocityEngine initialization.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 335.3. MESSAGE HEADERS

The velocity component sets a couple headers on the message (you can’t set these yourself and from Camel 2.1 velocity component will not set these headers which will cause some side effect on the dynamic template support):

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelVelocityResourceUri</td>
<td>The <code>templateName</code> as a <code>String</code> object.</td>
</tr>
</tbody>
</table>
### Camel 2.16: VelocitySupplementalContext

To add additional information to the used VelocityContext. The value of this header should be a `Map` with key/values that will be added (override any existing key with the same name). This can be used to pre setup some common key/values you want to reuse in your velocity endpoints.

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel VelocitySupplementalContext</td>
<td>To add additional information to the used VelocityContext. The value of this header should be a <code>Map</code> with key/values that will be added (override any existing key with the same name). This can be used to pre setup some common key/values you want to reuse in your velocity endpoints.</td>
</tr>
</tbody>
</table>

Headers set during the Velocity evaluation are returned to the message and added as headers. Then it's kinda possible to return values from Velocity to the Message.

For example, to set the header value of `fruit` in the Velocity template `.tm`:

```java
$sin.setHeader("fruit", "Apple")
```

The `fruit` header is now accessible from the `message.out.headers`.

### 335.4. VELOCITY CONTEXT

Camel will provide exchange information in the Velocity context (just a `Map`). The `Exchange` is transferred as:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>exchange</code></td>
<td>The <code>Exchange</code> itself.</td>
</tr>
<tr>
<td><code>exchange.properties</code></td>
<td>The <code>Exchange</code> properties.</td>
</tr>
<tr>
<td><code>headers</code></td>
<td>The headers of the In message.</td>
</tr>
<tr>
<td><code>camelContext</code></td>
<td>The Camel Context instance.</td>
</tr>
<tr>
<td><code>request</code></td>
<td>The In message.</td>
</tr>
<tr>
<td><code>in</code></td>
<td>The In message.</td>
</tr>
<tr>
<td><code>body</code></td>
<td>The In message body.</td>
</tr>
<tr>
<td><code>out</code></td>
<td>The Out message (only for InOut message exchange pattern).</td>
</tr>
</tbody>
</table>
Since Camel-2.14, you can setup a custom Velocity Context yourself by setting the message header *CamelVelocityContext* just like this

```java
VelocityContext velocityContext = new VelocityContext(variableMap);
exchange.getIn().setHeader("CamelVelocityContext", velocityContext);
```

### 335.5. HOT RELOADING

The Velocity template resource is, by default, hot reloadable for both file and classpath resources (expanded jar). If you set `contentCache=true`, Camel will only load the resource once, and thus hot reloading is not possible. This scenario can be used in production, when the resource never changes.

### 335.6. DYNAMIC TEMPLATES

**Available as of Camel 2.1**

Camel provides two headers by which you can define a different resource location for a template or the template content itself. If any of these headers is set then Camel uses this over the endpoint configured resource. This allows you to provide a dynamic template at runtime.

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelVelocityResourceUri</td>
<td>String</td>
<td><strong>Camel 2.1</strong>: A URI for the template resource to use instead of the endpoint configured.</td>
</tr>
<tr>
<td>CamelVelocityTemplate</td>
<td>String</td>
<td><strong>Camel 2.1</strong>: The template to use instead of the endpoint configured.</td>
</tr>
</tbody>
</table>

### 335.7. SAMPLES

For example you could use something like

```java
from("activemq:My.Queue").
to("velocity:com/acme/MyResponse.vm");
```

To use a Velocity template to formulate a response to a message for InOut message exchanges (where there is a `JMSReplyTo` header).
If you want to use InOnly and consume the message and send it to another destination, you could use the following route:

```java
from("activemq:My.Queue").
  to("velocity:com/acme/MyResponse.vm").
  to("activemq:Another.Queue");
```

And to use the content cache, e.g. for use in production, where the .vm template never changes:

```java
from("activemq:My.Queue").
  to("velocity:com/acme/MyResponse.vm?contentCache=true").
  to("activemq:Another.Queue");
```

And a file based resource:

```java
from("activemq:My.Queue").
  to("velocity:file://myfolder/MyResponse.vm?contentCache=true").
  to("activemq:Another.Queue");
```

In **Camel 2.1** it’s possible to specify what template the component should use dynamically via a header, so for example:

```java
from("direct:in").
  setHeader("CamelVelocityResourceUri").constant("path/to/my/template.vm").
  to("velocity:dummy");
```

In **Camel 2.1** it’s possible to specify a template directly as a header the component should use dynamically via a header, so for example:

```java
from("direct:in").
  setHeader("CamelVelocityTemplate").constant("Hi this is a velocity template that can do templating ${body}").
  to("velocity:dummy");
```

### 335.8. THE EMAIL SAMPLE

In this sample we want to use Velocity templating for an order confirmation email. The email template is laid out in Velocity as:

```html
Dear ${headers.lastName}, ${headers.firstName}

Thanks for the order of ${headers.item}.

Regards Camel Riders Bookstore
${body}
```

And the java code:

### 335.9. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 336. VERT.X COMPONENT

Available as of Camel version 2.12

The `vertx` component is for working with the `VertxEventBus`.

The `vertx` `EventBus` sends and receives JSON events.

INFO: From Camel 2.16 onwards `vertx` 3 is in use which requires Java 1.8 at runtime.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-vertx</artifactId>
    <version>x.x.x</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

336.1. URI FORMAT

```
vertx:channelName[?options]
```

336.2. OPTIONS

The Vert.x component supports 7 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>vertxFactory</code></td>
<td>To use a custom <code>VertxFactory</code> implementation</td>
<td></td>
<td><code>VertxFactory</code></td>
</tr>
<tr>
<td><code>host</code></td>
<td>Hostname for creating an embedded clustered EventBus</td>
<td></td>
<td><code>String</code></td>
</tr>
<tr>
<td><code>port</code></td>
<td>Port for creating an embedded clustered EventBus</td>
<td></td>
<td><code>int</code></td>
</tr>
<tr>
<td><code>vertxOptions</code></td>
<td>Options to use for creating <code>vertx</code></td>
<td></td>
<td><code>VertxOptions</code></td>
</tr>
<tr>
<td><code>vertx</code></td>
<td>To use the given <code>vertx</code> <code>EventBus</code> instead of creating a new embedded <code>EventBus</code></td>
<td></td>
<td><code>Vertx</code></td>
</tr>
<tr>
<td><code>timeout</code></td>
<td>Timeout in seconds to wait for clustered <code>Vertx EventBus</code> to be ready. The default value is 60.</td>
<td>60</td>
<td><code>int</code></td>
</tr>
</tbody>
</table>
### 336.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>Required Sets the event bus address used to communicate</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 336.2.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pubSub (common)</td>
<td>Whether to use publish/subscribe instead of point to point when sending to a vertx endpoint.</td>
<td></td>
<td>Boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

**Camel 2.12.3**: Whether to use publish/subscribe instead of point to point when sending to a vertx endpoint.

You can append query options to the URI in the following format, `?option=value&option=value&...`

### 336.3. CONNECTING TO THE EXISTING VERT.X INSTANCE

If you would like to connect to the Vert.x instance already existing in your JVM, you can set the instance on the component level:

```java
Vertx vertx = ...;
VertxComponent vertxComponent = new VertxComponent();
vertxComponent.setVertx(vertx);
camelContext.addComponent("vertx", vertxComponent);
```

### 336.4. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
The \texttt{vm} component provides asynchronous SEDA behavior, exchanging messages on a \texttt{BlockingQueue} and invoking consumers in a separate thread pool.

This component differs from the \texttt{Seda} component in that VM supports communication across CamelContext instances – so you can use this mechanism to communicate across web applications (provided that \texttt{camel-core.jar} is on the system/\texttt{boot} classpath).

VM is an extension to the \texttt{Seda} component.

### 337.1. URI FORMAT

\texttt{vm:queueName[?options]}

Where \texttt{queueName} can be any string to uniquely identify the endpoint within the JVM (or at least within the classloader that loaded camel-core.jar)

You can append query options to the URI in the following format: \texttt{?option=value&option=value&…}

An exactly identical VM endpoint URI must be used for both the producer and the consumer endpoint. Otherwise, Camel will create a second VM endpoint despite that the \texttt{queueName} portion of the URI is identical. For example:

```java
from("direct:foo").to("vm:bar?concurrentConsumers=5");
from("vm:bar?concurrentConsumers=5").to("file://output");
```

Notice that we have to use the full URI, including options in both the producer and consumer.

In Camel 2.4 this has been fixed so that only the queue name must match. Using the queue name \texttt{bar}, we could rewrite the previous example as follows:

```java
from("direct:foo").to("vm:bar");
from("vm:bar?concurrentConsumers=5").to("file://output");
```

### 337.2. OPTIONS

The VM component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{queueSize} (advanced)</td>
<td>Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>\texttt{concurrentConsumers} (consumer)</td>
<td>Sets the default number of concurrent threads processing exchanges.</td>
<td>1</td>
<td>int</td>
</tr>
</tbody>
</table>
## defaultQueueFactory (advanced)

Sets the default queue factory.

<table>
<thead>
<tr>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Exchange</td>
</tr>
</tbody>
</table>

## resolveProperty Placeholders (advanced)

Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

<table>
<thead>
<tr>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The VM endpoint is configured using URI syntax:

```
vm:name
```

with the following path and query parameters:

### 337.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required Name of queue</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 337.2.2. Query Parameters (16 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>size (common)</td>
<td>The maximum capacity of the SEDA queue (i.e., the number of messages it can hold).</td>
<td>2147483647</td>
<td>int</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>concurrentConsumers (consumer)</td>
<td>Number of concurrent threads processing exchanges.</td>
<td>1</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the default exchange pattern when creating an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td>limitConcurrentConsumers (consumer)</td>
<td>Whether to limit the number of concurrentConsumers to the maximum of 500. By default, an exception will be thrown if an endpoint is configured with a greater number. You can disable that check by turning this option off.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>multipleConsumers (consumer)</td>
<td>Specifies whether multiple consumers are allowed. If enabled, you can use SEDA for Publish-Subscribe messaging. That is, you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>pollTimeout (consumer)</td>
<td>The timeout used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.</td>
<td>1000</td>
<td>int</td>
</tr>
<tr>
<td>purgeWhenStopping (consumer)</td>
<td>Whether to purge the task queue when stopping the consumer/route. This allows to stop faster, as any pending messages on the queue is discarded.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>blockWhenFull (producer)</td>
<td>Whether a thread that sends messages to a full SEDA queue will block until the queue’s capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>discardIfNoConsumers (producer)</td>
<td>Whether the producer should discard the message (do not add the message to the queue), when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
--- | --- | --- | ---
**failIfNoConsumers** (producer) | Whether the producer should fail by throwing an exception, when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time. | false | boolean

**timeout** (producer) | Timeout (in milliseconds) before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable timeout by using 0 or a negative value. | 30000 | long

**waitForTaskToComplete** (producer) | Option to specify whether the caller should wait for the async task to complete or not before continuing. The following three options are supported: Always, Never or IfReplyExpected. The first two values are self-explanatory. The last value, IfReplyExpected, will only wait if the message is Request Reply based. The default option is IfReplyExpected. | IfReplyExpected | WaitForTaskToComplete

**queue** (advanced) | Define the queue instance which will be used by the endpoint. This option is only for rare use-cases where you want to use a custom queue instance. | BlockingQueue

**synchronous** (advanced) | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

See the [Seda component](#) for options and other important usage details as the same rules apply to the Vm component.

#### 337.3. SAMPLES

In the route below we send exchanges across CamelContext instances to a VM queue named `order.email`:

```java
from("direct:in").bean(MyOrderBean.class).to("vm:order.email");
```

And then we receive exchanges in some other Camel context (such as deployed in another .war application):

```java
from("vm:order.email").bean(MyOrderEmailSender.class);
```

#### 337.4. SEE ALSO

- [Seda](#)
CHAPTER 338. WEATHER COMPONENT

Available as of Camel version 2.12

The **weather** component is used for polling weather information from [Open Weather Map](https://openweathermap.org) - a site that provides free global weather and forecast information. The information is returned as a json String object.

Camel will poll for updates to the current weather and forecasts once per hour by default. It can also be used to query the weather api based on the parameters defined on the endpoint which is used as producer.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-weather</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

338.1. URI FORMAT

`weather://<unused name>/?options`

338.2. REMARK

Since the 9th of October, an Api Key is required to access the openweather service. This key is passed as parameter to the URI definition of the weather endpoint using the appid param!

338.3. GEOLOCATION PROVIDER

Since July 2018 FreegeoIP is no longer available. The camel-weather component was using this API. We switch to [IPstack](https://ipstack.com) so you’ll need to specify and Access Key and the IP from where you’re using the API now on.

338.4. OPTIONS

The Weather component supports 3 options, which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>geolocationAccessKey</td>
<td>The geolocation service now needs an accessKey to be used</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>geolocationRequestIP</td>
<td>The geolocation service now needs to specify the IP associated to the accessKey you’re using</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.

The Weather endpoint is configured using URI syntax:

```
weather:name
```

with the following path and query parameters:

### 338.4.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required The name value is not used.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 338.4.2. Query Parameters (45 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>appid (common)</td>
<td>Required APPID ID used to authenticate the user connected to the API Server</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>headerName (common)</td>
<td>To store the weather result in this header instead of the message body. This is useable if you want to keep current message body as-is.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>language (common)</td>
<td>Language of the response.</td>
<td>en</td>
<td>WeatherLanguage</td>
</tr>
<tr>
<td>mode (common)</td>
<td>The output format of the weather data.</td>
<td>JSON</td>
<td>WeatherMode</td>
</tr>
<tr>
<td>period (common)</td>
<td>If null, the current weather will be returned, else use values of 5, 7, 14 days. Only the numeric value for the forecast period is actually parsed, so spelling, capitalisation of the time period is up to you (its ignored)</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>units (common)</td>
<td>The units for temperature measurement.</td>
<td></td>
<td>WeatherUnits</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------</td>
</tr>
<tr>
<td><strong>weatherApi (common)</strong></td>
<td>The API to be use (current, forecast/3 hour, forecast daily, station)</td>
<td></td>
<td>WeatherApi</td>
</tr>
<tr>
<td><strong>bridgeErrorHandler (consumer)</strong></td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>boolean</td>
</tr>
<tr>
<td><strong>sendEmptyMessageWhenIdle (consumer)</strong></td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>exceptionHandler (consumer)</strong></td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td><strong>exchangePattern (consumer)</strong></td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td><strong>pollStrategy (consumer)</strong></td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td></td>
<td>PollingConsumerPollingStrategy</td>
</tr>
<tr>
<td><strong>httpConnectionManager (advanced)</strong></td>
<td>To use a custom HttpConnectionManager to manage connections</td>
<td></td>
<td>HttpConnectionManager</td>
</tr>
<tr>
<td><strong>synchronous (advanced)</strong></td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>backoffErrorThreshold (scheduler)</strong></td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td><strong>backoffIdleThreshold (scheduler)</strong></td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td></td>
<td>int</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type  
--- | --- | --- | ---  
**backoffMultiplier** (scheduler) | To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured. |  | int  
**delay** (scheduler) | Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour). | 500 | long  
**greedy** (scheduler) | If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages. | false | boolean  
**initialDelay** (scheduler) | Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour). | 1000 | long  
**runLoggingLevel** (scheduler) | The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. | TRACE | LoggingLevel  
**scheduledExecutorService** (scheduler) | Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool. |  | ScheduledExecutorService  
**scheduler** (scheduler) | To use a cron scheduler from either camel-spring or camel-quartz2 component | none | ScheduledPollConsumer Scheduler  
**schedulerProperties** (scheduler) | To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler. |  | Map  
**startScheduler** (scheduler) | Whether the scheduler should be auto started. | true | boolean  
**timeUnit** (scheduler) | Time unit for initialDelay and delay options. | MILLIS ECON DS | TimeUnit  
**useFixedDelay** (scheduler) | Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details. | true | boolean
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cnt</code> (filter)</td>
<td>Number of results to be found</td>

<td>String</td>
</tr>
<tr>
<td><code>proxyAuthMethod</code> (proxy)</td>
<td>Authentication method for proxy, either as Basic, Digest or NTLM.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><code>proxyAuthPassword</code> (proxy)</td>
<td>Password for proxy authentication</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>
### 338.5. EXCHANGE DATA FORMAT

Camel will deliver the body as a `java.lang.String` (see the `mode` option above).

### 338.6. MESSAGE HEADERS

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelWeatherQuery</td>
<td>The original query URL sent to the Open Weather Map site</td>
</tr>
<tr>
<td>CamelWeatherLocation</td>
<td>Used by the producer to override the endpoint location and use the location from this header instead.</td>
</tr>
</tbody>
</table>

### 338.7. SAMPLES

In this sample we find the 7 day weather forecast for Madrid, Spain:

```java
from("weather:foo?location=Madrid,Spain&period=7
days&appid=APIKEY&geolocationAccessKey=IPSTACK_ACCESS_KEY&geolocationRequestHostIP=LOCAL_IP").to("jms:queue:weather");
```

To just find the current weather for your current location you can use this:
And to find the weather using the producer we do:

```java
from("weather:foo?
appid=APIKEY&geolocationAccessKey=IPSTACK_ACCESS_KEY&geolocationRequestHostIP=LOCAL_IP").to("jms:queue:weather");
```

And we can send in a message with a header to get the weather for any location as shown:

```java
from("direct:start")
.to("weather:foo?
location=Madrid,Spain&appid=APIKEY&geolocationAccessKey=IPSTACK_ACCESS_KEY&geolocationRequestHostIP=LOCAL_IP");
```

And to get the weather at the current location, then:

```java
String json = template.requestBodyAndHeader("direct:start", "", "CamelWeatherLocation", "Paris,France&appid=APIKEY", String.class);
```

And to get the weather at the current location, then:

```java
String json = template.requestBodyAndHeader("direct:start", "", "CamelWeatherLocation", "current&appid=APIKEY", String.class);
```
CHAPTER 339. JETTY WEBSOCKET COMPONENT

Available as of Camel version 2.10

The `websocket` component provides websocket endpoints for communicating with clients using websocket. The component uses Eclipse Jetty Server which implements the IETF specification (drafts and RFC 6455). It supports the protocols `ws://` and `wss://`. To use `wss://` protocol, the SSLContextParameters must be defined.

Version currently supported

Camel 2.18 uses Jetty 9

339.1. URI FORMAT

```
websocket://hostname[:port]/[resourceUri][?options]
```

You can append query options to the URI in the following format, `?option=value&option=value&…`

339.2. WEBSOCKET OPTIONS

The Jetty Websocket component supports 14 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>staticResources</td>
<td>Set a resource path for static resources (such as .html files etc). The resources can be loaded from classpath, if you prefix with classpath:, otherwise the resources is loaded from file system or from JAR files. For example to load from root classpath use classpath:, or classpath:WEB-INF/static If not configured (eg null) then no static resource is in use.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>host</td>
<td>The hostname. The default value is 0.0.0.0</td>
<td>0.0.0.0</td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>The port number. The default value is 9292</td>
<td>9292</td>
<td>Integer</td>
</tr>
<tr>
<td>sslKeyPassword</td>
<td>The password for the keystore when using SSL.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>sslPassword</td>
<td>The password when using SSL.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>sslKeystore</td>
<td>The path to the keystore.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>enableJmx</td>
<td>If this option is true, Jetty JMX support will be enabled for this endpoint. See Jetty JMX support for more details.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>minThreads (advanced)</td>
<td>To set a value for minimum number of threads in server thread pool. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9. The default values for minThreads is 1.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>maxThreads (advanced)</td>
<td>To set a value for maximum number of threads in server thread pool. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9. The default values for maxThreads is 12 noCores.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>threadPool (advanced)</td>
<td>To use a custom thread pool for the server. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9.</td>
<td></td>
<td>ThreadPool</td>
</tr>
<tr>
<td>sslContextParameters (security)</td>
<td>To configure security using SSLContextParameters</td>
<td></td>
<td>SSLContextParameters</td>
</tr>
<tr>
<td>useGlobalSslContextParameters (security)</td>
<td>Enable usage of global SSL context parameters.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>socketFactory (common)</td>
<td>To configure a map which contains custom WebSocketFactory for sub protocols. The key in the map is the sub protocol. The default key is reserved for the default implementation.</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Jetty Websocket endpoint is configured using URI syntax:

```
websocket:host:port/resourceUri
```

with the following path and query parameters:

### 339.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>The hostname. The default value is 0.0.0.0. Setting this option on the component will use the component configured value as default.</td>
<td>0.0.0.0</td>
<td>String</td>
</tr>
</tbody>
</table>
### port

The port number. The default value is 9292. Setting this option on the component will use the component configured value as default.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>port</td>
<td>The port number. The default value is 9292. Setting this option on the component will use the component configured value as default.</td>
<td>9292</td>
<td>Integer</td>
</tr>
</tbody>
</table>

### resourceUri

**Required** Name of the websocket channel to use.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td>Required Name of the websocket channel to use</td>
<td>String</td>
</tr>
</tbody>
</table>

### 339.2.2. Query Parameters (18 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxBinaryMessageSize (common)</td>
<td>Can be used to set the size in bytes that the websocket created by the websocketServlet may be accept before closing. (Default is -1 - or unlimited)</td>
<td>-1</td>
<td>Integer</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sessionSupport (consumer)</td>
<td>Whether to enable session support which enables HttpSession for each http request.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>staticResources (consumer)</td>
<td>Set a resource path for static resources (such as .html files etc). The resources can be loaded from classpath, if you prefix with classpath:, otherwise the resources is loaded from file system or from JAR files. For example to load from root classpath use classpath:., or classpath:WEB-INF/static If not configured (eg null) then no static resource is in use.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>sendTimeout (producer)</td>
<td>Timeout in millis when sending to a websocket channel. The default timeout is 30000 (30 seconds).</td>
<td>30000</td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>sendToAll (producer)</td>
<td>To send to all websocket subscribers. Can be used to configure on endpoint level, instead of having to use the WebsocketConstants.SEND_TO_ALL header on the message.</td>
<td>True</td>
<td>Boolean</td>
</tr>
<tr>
<td>bufferSize (advanced)</td>
<td>Set the buffer size of the websocketServlet, which is also the max frame byte size (default 8192)</td>
<td>8192</td>
<td>Integer</td>
</tr>
<tr>
<td>maxIdleTime (advanced)</td>
<td>Set the time in ms that the websocket created by the websocketServlet may be idle before closing. (default is 300000)</td>
<td>300000</td>
<td>Integer</td>
</tr>
<tr>
<td>maxTextMessage Size (advanced)</td>
<td>Can be used to set the size in characters that the websocket created by the websocketServlet may be accept before closing.</td>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>minVersion (advanced)</td>
<td>Can be used to set the minimum protocol version accepted for the websocketServlet. (Default 13 - the RFC6455 version)</td>
<td>13</td>
<td>Integer</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>allowedOrigins (cors)</td>
<td>The CORS allowed origins. Use to allow all.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>crossOriginFilter On (cors)</td>
<td>Whether to enable CORS</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>filterPath (cors)</td>
<td>Context path for filtering CORS</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>enableJmx (monitoring)</td>
<td>If this option is true, Jetty JMX support will be enabled for this endpoint. See Jetty JMX support for more details.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sslContextParameters (security)</td>
<td>To configure security using SSLContextParameters</td>
<td></td>
<td>SSLContextParameters</td>
</tr>
</tbody>
</table>

### 339.3. MESSAGE HEADERS

The websocket component uses 2 headers to indicate to either send messages back to a single/current client, or to all clients.
Webs oket Const ants.S END TO A LL

Sends the message to all clients which are currently connected. You can use the `sendToAll` option on the endpoint instead of using this header.

Webs oket Const ants.CO NNE CTION _KEY

Sends the message to the client with the given connection key.

339.4. USAGE

In this example we let Camel exposes a websocket server which clients can communicate with. The websocket server uses the default host and port, which would be `0.0.0.0:9292`. The example will send back an echo of the input. To send back a message, we need to send the transformed message to the same endpoint "websocket://echo". This is needed because by default the messaging is InOnly.

This example is part of an unit test, which you can find here. As a client we use the AHC library which offers support for web socket as well.

Here is another example where webapp resources location have been defined to allow the Jetty Application Server to not only register the WebSocket servlet but also to expose web resources for the browser. Resources should be defined under the webapp directory.

```java
from("activemq:topic:newsTopic")
    .routeId("fromJMStoWebSocket")
    .to("websocket://localhost:8443/newsTopic?sendToAll=true&staticResources=classpath:webapp");
```

339.5. SETTING UP SSL FOR WEBSOCKET COMPONENT

339.5.1. Using the JSSE Configuration Utility

As of Camel 2.10, the WebSocket component supports SSL/TLS configuration through the Camel JSSE Configuration Utility. This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the Cometd component.

Programmatic configuration of the component

```java
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
```
kmp.setKeyPassword("keyPassword");

TrustManagersParameters tmp = new TrustManagersParameters();
tmp.setKeyStore(ksp);

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);
scp.setTrustManagers(tmp);

CometdComponent cometdComponent = getContext().getComponent("cometds", CometdComponent.class);
cometdComponent.setSslContextParameters(scp);

Spring DSL based configuration of endpoint

```xml
<kmp.setKeyPassword("keyPassword")>
<tmp.setKeyStore(ksp)>
<scp.setKeyManagers(kmp)>
<scp.setTrustManagers(tmp)>
<cometdComponent.setSslContextParameters(scp)>
```

Java DSL based configuration of endpoint

```java
protected RouteBuilder createRouteBuilder() throws Exception {
    return new RouteBuilder() {
        public void configure() {
            String uri = "websocket://127.0.0.1:8443/test?sslContextParameters=#sslContextParameters";

            from(uri)
                .log(">>> Message received from WebSocket Client : ${body}\n")
                .to("mock:client")
                .loop(10)
                .setBody().constant(">>> Welcome on board!")
                .to(uri);
```

- Twitter Websocket Example demonstrates how to poll a constant feed of twitter searches and publish results in real time using web socket to a web page.
CHAPTER 340. WORDPRESS COMPONENT

Available as of Camel version 2.21

Camel component for Wordpress API.

Currently only the Posts and Users operations are supported.

340.1. OPTIONS

The Wordpress component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>Wordpress component configuration</td>
<td></td>
<td>WordpressComponent Configuration</td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Wordpress endpoint is configured using URI syntax:

```
wordpress:operationDetail
```

with the following path and query parameters:

340.1.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>Required The endpoint operation.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>operationDetail</td>
<td>The second part of an endpoint operation. Needed only when endpoint semantic is not enough, like wordpress:post:delete</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

340.1.2. Query Parameters (11 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The Wordpress REST API version</td>
<td>2</td>
<td>String</td>
</tr>
</tbody>
</table>
Most of parameters needed when performing a read operation mirrors from the official API. When performing searches operations, the criteria suffix is needed. Take the following Consumer as example:

```plaintext
wordpress:post?criteria.perPage=10&criteria.orderBy=author&criteria.categories=camel,dozer,json
```

### 340.1.3. Configuring Wordpress component
The `WordpressConfiguration` class can be used to set initial properties configuration to the component instead of passing it as query parameter. The following listing shows how to set the component to be used in your routes.

```java
public void configure() {
    final WordpressConfiguration configuration = new WordpressConfiguration();
    final WordpressComponentConfiguration component = new WordpressComponentConfiguration();
    configuration.setApiVersion("2");
    configuration.setUrl("http://yoursite.com/wp-json/");
    component.setConfiguration(configuration);
    getComponent().addComponent("wordpress", component);

    from("wordpress:post?id=1")
        .to("mock:result");
}
```

### 340.1.4. Consumer Example

Consumer polls from the API from time to time domain objects from Wordpress. Following, an example using the `Post` operation:

- `wordpress:post` retrieves posts (defaults to 10 posts)
- `wordpress:post?id=1` search for a specific post

### 340.1.5. Producer Example

Producer performs write operations on Wordpress like adding a new user or update a post. To be able to write, you must have an authorized user credentials (see Authentication).

- `wordpress:post` creates a new post from the `org.apache.camel.component.wordpress.api.model.Post` class in the message body.
- `wordpress:post?id=1` updates a post based on data `org.apache.camel.component.wordpress.api.model.Post` from the message body.
- `wordpress:post:delete?id=1` deletes a specific post

### 340.2. AUTHENTICATION

Producers that perform write operations (e.g. create a new post) must have an authenticated user to do so. The standard authentication mechanism used by Wordpress is cookie. Unfortunately this method is not supported outside Wordpress environment because it’s rely on nonce internal function.

There’s some alternatives to use the Wordpress API without nonces, but requires specific plugin installations.

At this time, `camel-wordpress` only supports Basic Authentication (more to come). To configure it, you must install the `Basic-Auth Wordpress plugin` and pass the credentials to the endpoint:

```java
from("direct:deletePost").to("wordpress:post:delete?id=9&user=ben&password=password123").to("mock:resultDelete");
```

It’s not recommend to use Basic Authentication in production without TLS!!
CHAPTER 341. XCHANGE COMPONENT

Available as of Camel version 2.21

The xchange: component uses the XChange Java library to provide access to 60+ Bitcoin and Altcoin exchanges. It comes with a consistent interface for trading and accessing market data.

Camel can get crypto currency market data, query historical data, place market orders and much more.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xchange</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

341.1. URI FORMAT

`xchange://exchange?options`

341.2. OPTIONS

The XChange component has no options.

The XChange endpoint is configured using URI syntax:

```
xchange:name
```

with the following path and query parameters:

341.2.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required The exchange to connect to</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

341.2.2. Query Parameters (5 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>currency (producer)</td>
<td>The currency</td>
<td></td>
<td>Currency</td>
</tr>
<tr>
<td>currencyPair (producer)</td>
<td>The currency pair</td>
<td></td>
<td>CurrencyPair</td>
</tr>
</tbody>
</table>

### 341.3. AUTHENTICATION

This component communicates with supported crypto currency exchanges via REST API. Some API requests use simple unauthenticated GET request. For most of the interesting stuff however, you’d need an account with the exchange and have API access keys enabled.

These API access keys need to be guarded tightly, especially so when they also allow for the withdraw functionality. In which case, anyone who can get hold of your API keys can easily transfer funds from your account to some other address i.e. steal your money.

Your API access keys can be stored in an exchange specific properties file in your SSH directory. For Binance for example this would be: ~/.ssh/binance-secret.keys

```
##
# This file MUST NEVER be committed to source control.
# It is therefore added to .gitignore.
#
apiKey = GuRW0*********
secretKey = nKLki************
```

### 341.4. MESSAGE HEADERS

<TODO><title>Samples</title>
In this sample we find the current Bitcoin market price in USDT:

```
from("direct:ticker").to("xchange:binance?service=market&method=ticker&currencyPair=BTC/USDT")
```

</TODO>
CHAPTER 342. XML BEANS DATAFORMAT (DEPRECATED)

Available as of Camel version 1.2

XmlBeans is a Data Format which uses the XmlBeans library to unmarshal an XML payload into Java objects or to marshal Java objects into an XML payload.

from("activemq:My.Queue").unmarshal().xmlBeans().to("mqseries:Another.Queue");

342.1. OPTIONS

The XML Beans dataformat supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>prettyPrint</td>
<td>false</td>
<td>Boolean</td>
<td>To enable pretty printing output nicely formatted. Is by default false.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

342.2. DEPENDENCIES

To use XmlBeans in your camel routes you need to add the dependency on camel-xmlbeans which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xmlbeans</artifactId>
  <version>x.x.x</version>
<!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 343. XML JSON DATAFORMAT (DEPRECATED)

Available as of Camel version 2.10

Camel already supports a number of data formats to perform XML and JSON-related conversions, but all of them require a POJO either as an input (for marshalling) or produce a POJO as output (for unmarshalling). This data format provides the capability to convert from XML to JSON and vice-versa directly, without stepping through intermediate POJOs.

This data format leverages the Json-lib library to achieve direct conversion. In this context, XML is considered the high-level format, while JSON is the low-level format. Hence, the marshal/unmarshal semantics are assigned as follows:

- marshalling ⇒ converting from XML to JSON
- unmarshalling ⇒ converting from JSON to XML.

343.1. OPTIONS

The XML JSon dataformat supports 13 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoding</td>
<td></td>
<td>String</td>
<td>Sets the encoding. Used for unmarshalling (JSON to XML conversion).</td>
</tr>
<tr>
<td>elementName</td>
<td></td>
<td>String</td>
<td>Specifies the name of the XML elements representing each array element. Used for unmarshalling (JSON to XML conversion).</td>
</tr>
<tr>
<td>arrayName</td>
<td></td>
<td>String</td>
<td>Specifies the name of the top-level XML element. Used for unmarshalling (JSON to XML conversion). For example, when converting 1, 2, 3, it will be output by default as 123. By setting this option or rootName, you can alter the name of element 'a'.</td>
</tr>
<tr>
<td>forceTopLevelObject</td>
<td>false</td>
<td>Boolean</td>
<td>Determines whether the resulting JSON will start off with a top-most element whose name matches the XML root element. Used for marshalling (XML to JSON conversion). If disabled, XML string 12 turns into 'x: '1', 'y': '2'. Otherwise, it turns into 'a': 'x: '1', 'y': '2'.</td>
</tr>
<tr>
<td>namespaceLenient</td>
<td>false</td>
<td>Boolean</td>
<td>Flag to be tolerant to incomplete namespace prefixes. Used for unmarshalling (JSON to XML conversion). In most cases, json-lib automatically changes this flag at runtime to match the processing.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Java Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>rootName</td>
<td>String</td>
<td></td>
<td>Specifies the name of the top-level element. Used for unmarshalling (JSON to XML conversion). If not set, json-lib will use arrayName or objectName (default value: 'o', at the current time it is not configurable in this data format). If set to 'root', the JSON string 'x': 'value1', 'y': 'value2' would turn into value1value2, otherwise the 'root' element would be named 'o'.</td>
</tr>
<tr>
<td>skipWhitespace</td>
<td>false</td>
<td>Boolean</td>
<td>Determines whether white spaces between XML elements will be regarded as text values or disregarded. Used for marshalling (XML to JSON conversion).</td>
</tr>
<tr>
<td>trimSpaces</td>
<td>false</td>
<td>Boolean</td>
<td>Determines whether leading and trailing white spaces will be omitted from String values. Used for marshalling (XML to JSON conversion).</td>
</tr>
<tr>
<td>skipNamespaces</td>
<td>false</td>
<td>Boolean</td>
<td>Signals whether namespaces should be ignored. By default they will be added to the JSON output using xmlns elements. Used for marshalling (XML to JSON conversion).</td>
</tr>
<tr>
<td>removeNamespacePrefixes</td>
<td>false</td>
<td>Boolean</td>
<td>Removes the namespace prefixes from XML qualified elements, so that the resulting JSON string does not contain them. Used for marshalling (XML to JSON conversion).</td>
</tr>
<tr>
<td>expandableProperties</td>
<td>List</td>
<td></td>
<td>With expandable properties, JSON array elements are converted to XML as a sequence of repetitive XML elements with the local name equal to the JSON key, for example: number: 1,2,3, normally converted to: 123 (where e can be modified by setting elementName), would instead translate to 123, if number is set as an expandable property Used for unmarshalling (JSON to XML conversion).</td>
</tr>
<tr>
<td>typeHints</td>
<td>String</td>
<td></td>
<td>Adds type hints to the resulting XML to aid conversion back to JSON. Used for unmarshalling (JSON to XML conversion).</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

### 343.2. BASIC USAGE WITH JAVA DSL

#### 343.2.1. Explicitly instantiating the data format

Just instantiate the `XmlJsonDataFormat` from package `org.apache.camel.dataformat.xmljson`. Make sure you have installed the `camel-xmljson` feature (if running on OSGi) or that you’ve included `camel-xmljson-7.2.jar` and its transitive dependencies in your classpath. Example initialization with a default configuration:

```java
XmlJsonDataFormat formatter = new XmlJsonDataFormat();
```
To tune the behaviour of the data format as per the options above, use the appropriate setters:

```java
XmlJsonDataFormat xmlJsonFormat = new XmlJsonDataFormat();
xmlJsonFormat.setEncoding("UTF-8");
xmlJsonFormat.setForceTopLevelObject(true);
xmlJsonFormat.setTrimSpaces(true);
xmlJsonFormat.setRootName("newRoot");
xmlJsonFormat.setSkipNamespaces(true);
xmlJsonFormat.setRemoveNamespacePrefixes(true);
xmlJsonFormat.setExpandableProperties(Arrays.asList("d", "e");
```

Once you’ve instantiated the data format, the next step is to actually use the it from within the `marshal()` and `unmarshal()` DSL elements:

```java
// from XML to JSON
from("direct:marshal").marshal(xmlJsonFormat).to("mock:json");
// from JSON to XML
from("direct:unmarshal").unmarshal(xmlJsonFormat).to("mock:xml");
```

343.2.2. Defining the data format in-line

Alternatively, you can define the data format inline by using the `xmljson()` DSL element:

```java
// from XML to JSON - inline dataformat
from("direct:marshalInline").marshal().xmljson().to("mock:jsonInline");
// from JSON to XML - inline dataformat
from("direct:unmarshalInline").unmarshal().xmljson().to("mock:xmlInline");
```

If you wish, you can even pass in a `Map<String, String>` to the inline methods to provide custom options:

```java
Map<String, String> xmlJsonOptions = new HashMap<String, String>();
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.ENCODING, "UTF-8");
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.ROOT_NAME, "newRoot");
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.SKIP_NAMESPACES, "true");
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.REMOVE_NAMESPACE_PREFIXES, "true");
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.EXPANDABLE_PROPERTIES, "d e");
// from XML to JSON - inline dataformat w/ options
from("direct:marshalInlineOptions").marshal().xmljson(xmlJsonOptions).to("mock:jsonInlineOptions");
// form JSON to XML - inline dataformat w/ options
from("direct:unmarshalInlineOptions").unmarshal().xmljson(xmlJsonOptions).to("mock:xmlInlineOptions");
```

343.3. BASIC USAGE WITH SPRING OR BLUEPRINT DSL

Within the `<dataFormats>` block, simply configure an `xmljson` element with unique IDs:
Then you simply refer to the data format object within your `<marshal />` and `<unmarshal />` DSLs:

```xml
<route>
  <from uri="direct:marshal"/>
  <marshal ref="xmljson"/>
  <to uri="mock:json"/>
</route>

<route>
  <from uri="direct:unmarshalWithOptions"/>
  <unmarshal ref="xmljsonWithOptions"/>
  <to uri="mock:xmlWithOptions"/>
</route>
```

Enabling XML DSL autocompletion for this component is easy: just refer to the appropriate `Schema locations`, depending on whether you’re using Spring or Blueprint DSL. Remember that this data format is available from Camel 2.10 onwards, so only schemas from that version onwards will include these new XML elements and attributes.

The syntax with Blueprint is identical to that of the Spring DSL. Just ensure the correct namespaces and schemaLocations are in use.

### 343.4. NAMESPACE MAPPINGS

XML has namespaces to fully qualify elements and attributes; JSON doesn’t. You need to take this into account when performing XML-JS0N conversions.

To bridge the gap, Json-lib has an option to bind namespace declarations in the form of prefixes and namespace URIs to XML output elements while unmarshalling (i.e. converting from JSON to XML). For example, provided the following JSON string:

```json
{ "pref1:a": "value1", "pref2:b": "value2" }
```

you can ask Json-lib to output namespace declarations on elements `pref1:a` and `pref2:b` to bind the prefixes `pref1` and `pref2` to specific namespace URIs.

To use this feature, simply create `XmlJsonDataFormat.NamespacesPerElementMapping` objects and add them to the `namespaceMappings` option (which is a List).

The `XmlJsonDataFormat.NamespacesPerElementMapping` holds an element name and a Map of [prefix => namespace URI]. To facilitate mapping multiple prefixes and namespace URIs, the `NamespacesPerElementMapping(String element, String pipeSeparatedMappings)` constructor takes a String-based pipe-separated sequence of [prefix, namespaceURI] pairs in the following way:

```text
|ns2|http://camel.apache.org/personalData|ns3|http://camel.apache.org/personalData2|
```

In order to define a default namespace, just leave the corresponding key field empty:

```text
|ns1|http://camel.apache.org/test1||http://camel.apache.org/default|
```
Binding namespace declarations to an element name = empty string will attach those namespaces to the root element.

The full code would look like that:

```java
XmlJsonDataFormat namespacesFormat = new XmlJsonDataFormat();
List<XmlJsonDataFormat.NamespacesPerElementMapping> namespaces = new
ArrayList<XmlJsonDataFormat.NamespacesPerElementMapping>();
namespaces.add(new XmlJsonDataFormat.
NamespacesPerElementMapping("",
"|ns1|http://camel.apache.org/test1||http://camel.apache.org/default|"));
namespaces.add(new XmlJsonDataFormat.
NamespacesPerElementMapping("surname",
"|ns2|http://camel.apache.org/personalData| +
"ns3|http://camel.apache.org/personalData2|"));
namespacesFormat.setNamespaceMappings(namespaces);
namespacesFormat.setRootElement("person");
```

And you can achieve the same in Spring DSL.

### 343.4.1. Example

Using the namespace bindings in the Java snippet above on the following JSON string:

```json
{
  "name": "Raul",
  "surname": "Kripalani",
  "f": true,
  "g": null
}
```

Would yield the following XML:

```
<person xmlns="http://camel.apache.org/default" xmlns:ns1="http://camel.apache.org/test1">
  <f>true</f>
  <g null="true"/>
  <name>Raul</name>
  <surname xmlns:ns2="http://camel.apache.org/personalData"
           xmlns:ns3="http://camel.apache.org/personalData2">Kripalani</surname>
</person>
```

Remember that the JSON spec defines a JSON object as follows:

An object is an unordered set of name/value pairs. [...].

That's why the elements are in a different order in the output XML.

### 343.5. DEPENDENCIES

To use the XmlJson dataformat in your camel routes you need to add the following dependency to your pom:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId.camel-xmljson</artifactId>
  <version>x.x.x</version>
</dependency>
```

<!-- Use the same version as camel-core, but remember that this component is only available from... -->
343.6. SEE ALSO

- Data Format
- json-lib
CHAPTER 344. XML SECURITY COMPONENT

Available as of Camel version 2.12

With this Apache Camel component, you can generate and validate XML signatures as described in the W3C standard XML Signature Syntax and Processing or as described in the successor version 1.1. For XML Encryption support, please refer to the XML Security Data Format.

You can find an introduction to XML signature here. The implementation of the component is based on JSR 105, the Java API corresponding to the W3C standard and supports the Apache Santuario and the JDK provider for JSR 105. The implementation will first try to use the Apache Santuario provider; if it does not find the Santuario provider, it will use the JDK provider. Further, the implementation is DOM based.

Since Camel 2.15.0 we also provide support for XAdES-BES/EPES for the signer endpoint; see subsection "XAdES-BES/EPES for the Signer Endpoint".

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xmlsecurity</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

344.1. XML SIGNATURE WRAPPING MODES

XML Signature differs between enveloped, enveloping, and detached XML signature. In the enveloped XML signature case, the XML Signature is wrapped by the signed XML Document; which means that the XML signature element is a child element of a parent element, which belongs to the signed XML Document. In the enveloping XML signature case, the XML Signature contains the signed content. All other cases are called detached XML signatures. A certain form of detached XML signature is supported since 2.14.0.

In the enveloped XML signature case, the supported generated XML signature has the following structure (Variables are surrounded by []):

```xml
<parent element>
  ...
</parent element>
<Signature Id="generated_unique_signature_id">
  <SignedInfo>
    <Reference URI=""/>
    <Transform Algorithm="http://www.w3.org/2000/09/xmldsig#enveloped-signature"/>
    (<Transform>)  <!-- By default "http://www.w3.org/2006/12/xml-c14n11" is added to the transforms -->
    <DigestMethod>
    <DigestValue>
    </Reference>
    (<Reference URI="#[keyinfo_Id]">)
    <Transform Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315"/>
    <DigestMethod>
    <DigestValue>
    </Reference>)?
  </SignedInfo>
</Signature>
```

Further references possible, see option 'properties' below -->
In the enveloping XML signature case, the supported generated XML signature has the structure:

```xml
<Signature Id="generated_unique_signature_id">
  <SignedInfo>
    <Reference URI="#generated_unique_object_id" type=[optional_type_value]>
      (<Transform>)* <!-- By default "http://www.w3.org/2006/12/xml-c14n11" is added to the transforms -->
    </Reference>
    <DigestMethod>
      <DigestValue>
    </DigestMethod>
    <Reference URI="#[keyinfo_id]">
      <Digest Method="http://www.w3.org/TR/2001/REC-xml-c14n-20010315"/>
      <DigestValue>
    </DigestMethod>
    <Reference>
    </Reference>)?
    <!-- further references possible, see option 'properties' below -->
  </SignedInfo>
  <SignatureValue>
    (<KeyInfo Id="[keyinfo_id]">)?
    <Object Id="generated_unique_object_id"/>
    <!-- The Object element contains the in-message body; the object ID can either be generated or set by the option parameter "contentObjectId" -->
    <!-- Further Object elements possible, see option 'properties' below -->
  </SignatureValue>
</Signature>
```

As of 2.14.0 detached XML signatures with the following structure are supported (see also sub-chapter XML Signatures as Siblings of Signed Elements):

```xml
<signed element Id="[id_value]">
  <!-- signed element must have an attribute of type ID -->
  ...
</signed element>

<other sibling>/*
  <!-- between the signed element and the corresponding signature element, there can be other siblings. Signature element is added as last sibling. -->
  <Signature Id="generated_unique_ID">
    <SignedInfo>
      <CanonicalizationMethod>
        <SignatureMethod>
          <Reference URI="#[id_value]" type=[optional_type_value]">
            <!-- reference URI contains the ID attribute value of the signed element -->
            (<Transform>)* <!-- By default "http://www.w3.org/2006/12/xml-c14n11" is added to the transforms -->
          </Reference>
          <DigestMethod>
            <DigestValue>
          </DigestMethod>
          <Reference>
          </Reference>
        </SignatureMethod>
      </CanonicalizationMethod>
    </SignedInfo>
    <SignatureValue>
      (<KeyInfo Id="[keyinfo_id]">)?
    </SignatureValue>
  </Signature>
```

Red Hat Fuse 7.2 Apache Camel Component Reference
344.2. URI FORMAT

The camel component consists of two endpoints which have the following URI format:

- xmlsecurity:sign:name[?options]
- xmlsecurity:verify:name[?options]

- With the signer endpoint, you can generate a XML signature for the body of the in-message which can be either a XML document or a plain text. The enveloped, enveloping, or detached (as of 12.14) XML signature(s) will be set to the body of the out-message.

- With the verifier endpoint, you can validate an enveloped or enveloping XML signature or even several detached (as of 2.14.0) XML signatures contained in the body of the in-message; if the validation is successful, then the original content is extracted from the XML signature and set to the body of the out-message.

- The name part in the URI can be chosen by the user to distinguish between different signer/verifier endpoints within the camel context.

344.3. BASIC EXAMPLE

The following example shows the basic usage of the component.

```xml
<from("direct:enveloping").to("xmlsecurity:sign://enveloping?keyAccessor=#accessor",
    "xmlsecurity:verify://enveloping?keySelector=#selector",
    "mock:result")
```

In Spring XML:

```xml
<from uri="direct:enveloping" />
<to uri="xmlsecurity:sign://enveloping?keyAccessor=#accessor" />
<to uri="xmlsecurity:verify://enveloping?keySelector=#selector" />
<to uri="mock:result" />
```

For the signing process, a private key is necessary. You specify a key accessor bean which provides this private key. For the validation, the corresponding public key is necessary; you specify a key selector bean which provides this public key.

The key accessor bean must implement the `KeyAccessor` interface. The package `org.apache.camel.component.xmlsecurity.api` contains the default implementation class `DefaultKeyAccessor` which reads the private key from a Java keystore.
The key selector bean must implement the `javax.xml.crypto.KeySelector` interface. The package `org.apache.camel.component.xmlsecurity.api` contains the default implementation class `DefaultKeySelector` which reads the public key from a keystore.

In the example, the default signature algorithm `http://www.w3.org/2000/09/xmldsig#rsa-sha1` is used. You can set the signature algorithm of your choice by the option `signatureAlgorithm` (see below). The signer endpoint creates an `enveloping` XML signature. If you want to create an `enveloped` XML signature then you must specify the parent element of the Signature element; see option `parentLocalName` for more details.

For creating `detached` XML signatures, see sub-chapter "Detached XML Signatures as Siblings of the Signed Elements".

### 344.4. COMPONENT OPTIONS

The XML Security component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>signerConfiguration</td>
<td>To use a shared XmlSignerConfiguration configuration to use as base for configuring endpoints.</td>
<td></td>
<td>XmlSignerConfiguration</td>
</tr>
<tr>
<td>verifierConfiguration</td>
<td>To use a shared XmlVerifierConfiguration configuration to use as base for configuring endpoints.</td>
<td></td>
<td>XmlVerifierConfiguration</td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 344.5. ENDPOINT OPTIONS

The XML Security endpoint is configured using URI syntax:

```
xmlsecurity:command:name
```

with the following path and query parameters:

#### 344.5.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>command</td>
<td>Required Whether to sign or verify.</td>
<td></td>
<td>XmlCommand</td>
</tr>
</tbody>
</table>
### 344.5.2. Query Parameters (35 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseUri (common)</td>
<td>You can set a base URI which is used in the URI dereferencing. Relative URIs are then concatenated with the base URI.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>clearHeaders (common)</td>
<td>Determines if the XML signature specific headers be cleared after signing and verification. Defaults to true.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td>cryptoContextProperties (common)</td>
<td>Sets the crypto context properties. See link XMLCryptoContextsetProperty(String, Object). Possible properties are defined in XMLSignContext or XMLValidateContext (see Supported Properties). The following properties are set by default to the value link BooleanTRUE for the XML validation. If you want to switch these features off you must set the property value to link BooleanFALSE. org.jcp.xml.dsig.validateManifests javax.xml.crypto.dsig.cacheReference</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>disallowDoctypeDecl (common)</td>
<td>Disallows that the incoming XML document contains DTD DOCTYPE declaration. The default value is link BooleanTRUE.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td>omitXmlDeclaration (common)</td>
<td>Indicator whether the XML declaration in the outgoing message body should be omitted. Default value is false. Can be overwritten by the header link XmlSignatureConstantsHEADER_OMIT_XML_DECLARATION.</td>
<td>false</td>
<td>Boolean</td>
</tr>
<tr>
<td>outputXmlEncoding (common)</td>
<td>The character encoding of the resulting signed XML document. If null then the encoding of the original XML document is used.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>schemaResource Uri (common)</td>
<td>Classpath to the XML Schema. Must be specified in the detached XML Signature case for determining the ID attributes, might be set in the enveloped and enveloping case. If set, then the XML document is validated with the specified XML schema. The schema resource URI can be overwritten by the header link XmlSignatureConstantsHEADER_SCHEMARESOURCE_URI.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>uriDereferencer (advanced)</td>
<td>If you want to restrict the remote access via reference URIs, you can set an own dereferencer. Optional parameter. If not set the provider default dereferencer is used which can resolve URI fragments, HTTP, file and XPpointer URIs. Attention: The implementation is provider dependent!</td>
<td></td>
<td>URIDereferencer</td>
</tr>
<tr>
<td>addKeyInfoReference (sign)</td>
<td>In order to protect the KeyInfo element from tampering you can add a reference to the signed info element so that it is protected via the signature value. The default value is true. Only relevant when a KeyInfo is returned by KeyAccessor. and link KeyInfogetId() is not null.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td>canonicalizationMethod (sign)</td>
<td>Canonicalization method used to canonicalize the SignedInfo element before the digest is calculated. You can use the helper methods XmlSignatureHelper.getCanonicalizationMethod(String algorithm) or getCanonicalizationMethod(String algorithm, List inclusiveNamespacePrefixes) to create a canonicalization method.</td>
<td><a href="http://www.w3.org/TR/2001REC-xml-c14n-20010315">http://www.w3.org/TR/2001REC-xml-c14n-20010315</a></td>
<td>AlgorithmMethod</td>

<td>removeSignature Elements</td>
<td>(verify) Indicator whether the XML signature elements (elements with local name Signature and namespace <a href="http://www.w3.org/2000/09/xmldsig">http://www.w3.org/2000/09/xmldsig</a>) shall be removed from the document set to the output message. Normally, this is only necessary, if the XML signature is enveloped. The default value is link BooleanFALSE. This parameter is forwarded to XmlSignature2Message. This indicator has no effect if the output node search is of type link DefaultXmlSignature2MessageOUTPUT_NODE_SEARCH_TYPE_DEFAULT.F</td>
<td>false</td>
<td>Boolean</td>
</tr>
<tr>
<td>secureValidation</td>
<td>(verify) Enables secure validation. If true then secure validation is enabled.</td>
<td>true</td>
<td>Boolean</td>
</tr>
<tr>
<td>validationFailedHandler</td>
<td>(verify) Handles the different validation failed situations. The default implementation throws specific exceptions for the different situations (All exceptions have the package name org.apache.camel.component.xmlsecurity.api and are a sub-class of XmlSignatureInvalidException. If the signature value validation fails, a XmlSignatureInvalidValueException is thrown. If a reference validation fails, a XmlSignatureInvalidContentHashException is thrown. For more detailed information, see the JavaDoc.</td>
<td>ValidationFailedHandler</td>
<td></td>
</tr>
</tbody>
</table>
xmlSignature2Message (verify)

Bean which maps the XML signature to the output-message after the validation. How this mapping should be done can be configured by the options outputNodeSearchType, outputNodeSearch, and removeSignatureElements. The default implementation offers three possibilities which are related to the three output node search types Default, ElementName, and XPath. The default implementation determines a node which is then serialized and set to the body of the output message. If the search type is ElementName then the output node (which must be in this case an element) is determined by the local name and namespace defined in the search value (see option outputNodeSearch). If the search type is XPath then the output node is determined by the XPath specified in the search value (in this case the output node can be of type Element, TextNode or Document). If the output node search type is Default then the following rules apply: In the enveloped XML signature case (there is a reference with URI= and transform http://www.w3.org/2000/09/xmldsig-enveloped-signature), the incoming XML document without the Signature element is set to the output message body. In the non-enveloped XML signature case, the message body is determined from a referenced Object; this is explained in more detail in chapter Output Node Determination in Enveloping XML Signature Case.

xmlSignatureChecker (verify)

This interface allows the application to check the XML signature before the validation is executed. This step is recommended in http://www.w3.org/TR/xmldsig-bestpractices/check-what-is-signed

344.5.3. Output Node Determination in Enveloping XML Signature Case

After the validation the node is extracted from the XML signature document which is finally returned to the output-message body. In the enveloping XML signature case, the default implementation DefaultXmlSignature2Message of XmlSignature2Message does this for the node search type Default in the following way (see option xmlSignature2Message):

- First an object reference is determined:
  - Only same document references are taken into account (URI must start with #)
  - Also indirect same document references to an object via manifest are taken into account.
  - The resulting number of object references must be 1.
Then, the object is dereferenced and the object must only contain one XML element. This element is returned as output node.

This does mean that the enveloping XML signature must have either the structure:

```xml
<Signature>
  <SignedInfo>
    <Reference URI="#object"/>
    <!-- further references possible but they must not point to an Object or Manifest containing an object reference -->
    ...
  </SignedInfo>
  <Object Id="object">
    <!-- contains one XML element which is extracted to the message body -->
    <Object>
      <!-- further object elements possible which are not referenced-->
      ...
      (<KeyInfo>)?
    </Object>
  </Object>
</Signature>
```

or the structure:

```xml
<Signature>
  <SignedInfo>
    <Reference URI="#manifest"/>
    <!-- further references are possible but they must not point to an Object or other manifest containing an object reference -->
    ...
  </SignedInfo>
  <Object>
    <Manifest Id="manifest">
      <Reference URI="#object"/>
    </Manifest>
    <Object Id="object">
      <!-- contains the DOM node which is extracted to the message body -->
      <Object>
        <!-- further object elements possible which are not referenced-->
        ...
        (<KeyInfo>)?
      </Object>
    </Object>
  </Object>
</Signature>
```

344.6. DETACHED XML SIGNATURES AS SIBLINGS OF THE SIGNED ELEMENTS

Since 2.14.0

You can create detached signatures where the signature is a sibling of the signed element. The following example contains two detached signatures. The first signature is for the element C and the second signature is for element A. The signatures are nested; the second signature is for the element A which also contains the first signature.
Example Detached XML Signatures

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<root>
  <A ID="IDforA">
    <B>
      <C ID="IDforC">
        <D>dvalue</D>
      </C>
    </B>
  </A>
  <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#"
    Id="_6bf13099-0568-4d76-8649-faf5dcb313c0">
    <ds:SignedInfo>
      <ds:CanonicalizationMethod
        Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315" />
      <ds:SignatureMethod
        Algorithm="http://www.w3.org/2000/09/xmldsig#rsa-sha1" />
      <ds:Reference URI="#IDforC"/>
    </ds:SignedInfo>
    <ds:SignatureValue>aUDFmiG71</ds:SignatureValue>
  </ds:Signature>
</B>
</A>
```

```xml
<ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#"Id="_6b02fb8a-30df-42c6-ba25-76eba02c8214">
  <ds:SignedInfo>
    <ds:CanonicalizationMethod
      Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315" />
    <ds:SignatureMethod
      Algorithm="http://www.w3.org/2000/09/xmldsig#rsa-sha1" />
    <ds:Reference URI="#IDforA"/>
  </ds:SignedInfo>
  <ds:SignatureValue>q3tvRoGgc8cMUqUSzP6C21zb7t04riPnDuk=</ds:SignatureValue>
</ds:Signature>
```

The example shows that you can sign several elements and that for each element a signature is created as sibling. The elements to be signed must have an attribute of type ID. The ID type of the attribute must be defined in the XML schema (see option `schemaResourceUri`). You specify a list of XPATH expressions pointing to attributes of type ID (see option `xpathsToIdAttributes`). These attributes determine the elements to be signed. The elements are signed by the same key given by the `keyAccessor` bean. Elements with higher (i.e. deeper) hierarchy level are signed first. In the example, the element `C` is signed before the element `A`.

Java DSL Example

```java
from("direct:detached")
  .to("xmlsecurity:sign://detached?
keyAccessor=#keyAccessorBean&xpathsToIdAttributes=#xpathsToIdAttributesBean&schemaResourceUri=Test.xsd")
  .to("xmlsecurity:verify://detached?
```

```java
```
Spring Example

```xml
<bean id="xpathsToIdAttributesBean" class="java.util.ArrayList">
  <constructor-arg type="java.util.Collection">
    <list>
      <bean class="org.apache.camel.component.xmlsecurity.api.XmlSignatureHelper" factory-method="getXpathFilter">
        <constructor-arg type="java.lang.String" value="/ns:root/a/@ID" />
      </constructor-arg>
    </list>
  </constructor-arg>
</bean>
...
<from uri="direct:detached" />
<to uri="xmlsecurity:sign://detached?keyAccessor=#keyAccessorBean&xpathsToIdAttributes=#xpathsToIdAttributesBean&schemaResourceUri=Test.xsd" />
<to uri="xmlsecurity:verify://detached?keySelector=#keySelectorBean&schemaResourceUri=Test.xsd" />
<to uri="mock:result" />
```

344.7. XADES-BES/EPES FOR THE SIGNER ENDPOINT

Available as of Camel 2.15.0

XML Advanced Electronic Signatures (XAdES) defines extensions to XML Signature. This standard was defined by the European Telecommunication Standards Institute and allows you to create signatures which are compliant to the European Union Directive (1999/93/EC) on a Community framework for electronic signatures. XAdES defines different sets of signature properties which are called signature forms. We support the signature forms Basic Electronic Signature (XAdES-BES) and Explicit Policy Based Electronic Signature (XAdES-EPES) for the Signer Endpoint. The forms Electronic Signature with Validation Data XAdES-T and XAdES-C are not supported.

We support the following properties of the XAdES-EPES form ("?" denotes zero or one occurrence):

Supported XAdES-EPES Properties

```xml
<QualifyingProperties Target>
  <SignedProperties>
    <SignedSignatureProperties>
      (SigningTime)?
```
(SigningCertificate)?
(SignaturePolicyIdentifier)
(SignatureProductionPlace)?
(SignerRole)?
</SignedSignatureProperties>
</SignedProperties>
</QualifyingProperties>

The properties of the XAdES-BES form are the same except that the SignaturePolicyIdentifier property is not part of XAdES-BES.

You can configure the XAdES-BES/EPES properties via the bean org.apache.camel.component.xmlsecurity.api.XAdESSignatureProperties or org.apache.camel.component.xmlsecurity.api.DefaultXAdESSignatureProperties. XAdESSignatureProperties does support all properties mentioned above except the SigningCertificate property. To get the SigningCertificate property, you must overwrite either the method XAdESSignatureProperties.getSigningCertificate() or XAdESSignatureProperties.getSigningCertificateChain(). The class DefaultXAdESSignatureProperties overwrites the method getSigningCertificate() and allows you to specify the signing certificate via a keystore and alias. The following example shows all parameters you can specify. If you do not need certain parameters you can just omit them.

XAdES-BES/EPES Example in Java DSL

```java
Keystore keystore = ... // load a keystore
DefaultKeyAccessor accessor = new DefaultKeyAccessor();
accessor.setKeyStore(keystore);
accessor.setPassword("password");
accessor.setAlias("cert_alias"); // signer key alias

DefaultXAdESSignatureProperties props = new DefaultXAdESSignatureProperties();
props.setNamespace("http://uri.etsi.org/01903/v1.3.2#"); // sets the namespace for the XAdES elements; the namespace is related to the XAdES version, default value is "http://uri.etsi.org/01903/v1.3.2#", other possible values are "http://uri.etsi.org/01903/v1.1.1#" and "http://uri.etsi.org/01903/v1.2.2#"
props.setPrefix("etsi"); // sets the prefix for the XAdES elements, default value is "etsi"

// signing certificate
props.setKeystore(keystore);
props.setAlias("cert_alias"); // specify the alias of the signing certificate in the keystore = signer key alias
props.setDigestAlgorithmForSigningCertificate(DigestMethod.SHA256); // possible values for the algorithm are "http://www.w3.org/2000/09/xmldsig#sha1", "http://www.w3.org/2001/04/xmlenc#sha256", "http://www.w3.org/2001/04/xmlsig-more#sha384", "http://www.w3.org/2001/04/xmlenc#sha512", default value is "http://www.w3.org/2001/04/xmlenc#sha256"
props.setSigningCertificateURIs(Collections.singletonList("http://certuri"));

// signing time
props.setAddSigningTime(true);

// policy
```
props.setSignaturePolicy(XAdESSignatureProperties.SIG_POLICY_EXPLICIT_ID);
   // also the values XAdESSignatureProperties.SIG_POLICY_NONE ("None"), and
   XAdESSignatureProperties.SIG_POLICY_IMPLIED ("Implied") are possible, default value is
   XAdESSignatureProperties.SIG_POLICY_EXPLICIT_ID ("ExplicitId")
   // For "None" and "Implied" you must not specify any further policy parameters
   props.setSigPolicyId("urn:oid:1.2.840.113549.1.9.16.6.1");
   props.setSigPolicyIdQualifier("OIDAsURN"); //allowed values are empty string, "OIDAsURI",
   "OIDAsURN"; default value is empty string
   props.setSigPolicyIdDescription("invoice version 3.1");
   props.setSignaturePolicyDigestAlgorithm(DigestMethod.SHA256);// possible values for the algorithm
   are "http://www.w3.org/2000/09/xmldsig#sha1", http://www.w3.org/2001/04/xmlenc#sha256",,
   "http://www.w3.org/2001/04/xmlmdsig-more#sha384", "http://www.w3.org/2001/04/xmlenc#sha512",
   default value is http://www.w3.org/2001/04/xmlmdsig-sha256"
   props.setSignaturePolicyDigestValue("0hixl6upD6av8N7pEvDABhEL6hM=");
   // you can add qualifiers for the signature policy either by specifying text or an XML fragment with the
   root element "SigPolicyQualifier"
   props.setSigPolicyQualifiers(Arrays.asList(new String[]{
      "<SigPolicyQualifier xmlns="http://uri.etsi.org/01903/v1.3.2#">
         <SPURI>http://test.com/sig.policy.pdf</SPURI><SPUserNotice><ExplicitText>display
      text</ExplicitText>" + 
      "</SPUserNotice></SigPolicyQualifier>", "category B" )));
   props.setSigPolicyIdDocumentationReferences(Arrays.asList(new String[]{
      "http://test.com/policy.doc.ref1.txt",
      "http://test.com/policy.doc.ref2.txt" }));

   // production place
   props.setSignatureProductionPlaceCity("Munich");
   props.setSignatureProductionPlaceCountryName("Germany");
   props.setSignatureProductionPlacePostalCode("80331");
   props.setSignatureProductionPlaceStateOrProvince("Bavaria");

   //role
   // you can add claimed roles either by specifying text or an XML fragment with the root element
   "ClaimedRole"
   props.setSignerClaimedRoles(Arrays.asList(new String[]{"test",
      "<a:ClaimedRole xmlns:a="http://uri.etsi.org/01903/v1.3.2#"><TestRole>TestRole</TestRole>
   </a:ClaimedRole>"}));
   props.setSignerCertifiedRoles(Collections.singletonList(new
   XAdESEncapsulatedPKIData("Ahixl6upD6av8N7pEvDABhEL6hM=",
      "http://uri.etsi.org/01903/v1.2.2#DER", "IdCertifiedRole");

   // data object format
   props.setDataObjectFormatDescription("invoice");
   props.setDataObjectFormatMimeType("text/xml");
   props.setDataObjectFormatIdentifier("urn:oid:1.2.840.113549.1.9.16.6.2");
   props.setDataObjectFormatIdentifierQualifier("OIDAsURN"); //allowed values are empty string,
   "OIDAsURI", "OIDAsURN"; default value is empty string
   props.setDataObjectFormatIdentifierDescription("identifier desc");
   props.setDataObjectFormatIdentifierDocumentationReferences(Arrays.asList(new String[]{

   //commitment
   props.setCommitmentTypeId("urn:oid:1.2.840.113549.1.9.16.6.4");
   props.setCommitmentTypeIdQualifier("OIDAsURN"); //allowed values are empty string, "OIDAsURI",
   "OIDAsURN"; default value is empty string
props.setCommitmentTypeIdDescription("description for commitment type ID");
props.setCommitmentTypeIdDocumentationReferences(Arrays.asList(new String[]{
    "http://test.com/commitment.ref1.txt",
    "http://test.com/commitment.ref2.txt" }));
// you can specify a commitment type qualifier either by simple text or an XML fragment with root
element "CommitmentTypeQualifier"
props.setCommitmentTypeQualifiers(Arrays.asList(new String[]{
    "commitment qualifier",
    "<c:CommitmentTypeQualifier xmlns:c="http://uri.etsi.org/01903/v1.3.2#" xmlns:test="http://test.com/">test</c:CommitmentTypeQualifier>" }));

beanRegistry.bind("xmlSignatureProperties",props);
beanRegistry.bind("keyAccessorDefault",keyAccessor);

// you must reference the properties bean in the "xmlsecurity" URI
from("direct:xades").to("xmlsecurity:sign://xades?keyAccessor=#keyAccessorDefault&properties=#xmlSignatureProperties")
.to("mock:result");

XAdES-BES/EPES Example in Spring XML

...<from uri="direct:xades" />
  <to>
    url="xmlsecurity:sign://xades?keyAccessor=#accessorRsa&properties=#xadesProperties"
  />
  <to uri="mock:result" />

<td>String</td>
<td>overwrites the XAdES prefix parameter value</td>
</tr>
</tbody>
</table>

### 344.7.2. Limitations with regard to XAdES version 1.4.2

- No support for signature form XAdES-T and XAdES-C
- Only signer part implemented. Verifier part currently not available.
- No support for the QualifyingPropertiesReference element (see section 6.3.2 of spec).
- No support for the Transforms element contained in the SignaturePolicyId element contained in the SignaturePolicyIdentifier element
- No support of the CounterSignature element → no support for the UnsignedProperties element
- At most one DataObjectFormat element. More than one DataObjectFormat element makes no sense because we have only one data object which is signed (this is the incoming message body to the XML signer endpoint).
• At most one `CommitmentTypeIndication` element. More than one `CommitmentTypeIndication` element makes no sense because we have only one data object which is signed (this is the incoming message body to the XML signer endpoint).

• A `CommitmentTypeIndication` element contains always the `AllSignedDataObjects` element. The `ObjectReference` element within `CommitmentTypeIndication` element is not supported.

• The `AllDataObjectsTimeStamp` element is not supported

• The `IndividualDataObjectsTimeStamp` element is not supported

344.8. SEE ALSO

• Best Practices
CHAPTER 345. XMPP COMPONENT

Available as of Camel version 1.0

The `xmpp:` component implements an XMPP (Jabber) transport.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xmpp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

345.1. URI FORMAT

`xmpp://[login@]hostname[:port]/[participant][?Options]`

The component supports both room based and private person-person conversations. The component supports both producer and consumer (you can get messages from XMPP or send messages to XMPP). Consumer mode supports rooms starting.

You can append query options to the URI in the following format, `?option=value&option=value&...`

345.2. OPTIONS

The XMPP component has no options.

The XMPP endpoint is configured using URI syntax:

`xmpp:host:port/participant`

with the following path and query parameters:

345.2.1. Path Parameters (3 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Required Hostname for the chat server</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>port</td>
<td>Required Port number for the chat server</td>
<td></td>
<td>int</td>
</tr>
<tr>
<td>participant</td>
<td>JID (Jabber ID) of person to receive messages. room parameter has precedence over participant.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

345.2.2. Query Parameters (18 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>login (common)</td>
<td>Whether to login the user.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>nickname (common)</td>
<td>Use nickname when joining room. If room is specified and nickname is not, user will be used for the nickname.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>pubsub (common)</td>
<td>Accept pubsub packets on input, default is false</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>room (common)</td>
<td>If this option is specified, the component will connect to MUC (Multi User Chat). Usually, the domain name for MUC is different from the login domain. For example, if you are supermanjabber.org and want to join the krypton room, then the room URL is kryptonconference.jabber.org. Note the conference part. It is not a requirement to provide the full room JID. If the room parameter does not contain the symbol, the domain part will be discovered and added by Camel</td>
<td>false</td>
<td>String</td>
</tr>
<tr>
<td>serviceName (common)</td>
<td>The name of the service you are connecting to. For Google Talk, this would be gmail.com.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>testConnectionOnStartup (common)</td>
<td>Specifies whether to test the connection on startup. This is used to ensure that the XMPP client has a valid connection to the XMPP server when the route starts. Camel throws an exception on startup if a connection cannot be established. When this option is set to false, Camel will attempt to establish a lazy connection when needed by a producer, and will poll for a consumer connection until the connection is established. Default is true.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>createAccount (common)</td>
<td>If true, an attempt to create an account will be made. Default is false.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>resource (common)</td>
<td>XMPP resource. The default is Camel.</td>
<td>Camel</td>
<td>String</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>connectionPollDelay (consumer)</td>
<td>The amount of time in seconds between polls (in seconds) to verify the health of the XMPP connection, or between attempts to establish an initial consumer connection. Camel will try to re-establish a connection if it has become inactive. Default is 10 seconds.</td>
<td>10</td>
<td>int</td>
</tr>
<tr>
<td>doc (consumer)</td>
<td>Set a doc header on the IN message containing a Document form of the incoming packet; default is true if presence or pubsub are true, otherwise false</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>connectionConfig (advanced)</td>
<td>To use an existing connection configuration. Currently org.jivesoftware.smack.tcp.XMPPConnectionConfiguration is only supported (XMPP over TCP).</td>
<td>ConnectionConfiguration</td>
<td></td>
</tr>
<tr>
<td>synchronous (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>headerFilterStrategy (filter)</td>
<td>To use a custom HeaderFilterStrategy to filter header to and from Camel message.</td>
<td>HeaderFilterStrategy</td>
<td></td>
</tr>
<tr>
<td>password (security)</td>
<td>Password for login</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>user (security)</td>
<td>User name (without server name). If not specified, anonymous login will be attempted.</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

### 345.3. HEADERS AND SETTING SUBJECT OR LANGUAGE

Camel sets the message IN headers as properties on the XMPP message. You can configure a HeaderFilterStrategy if you need custom filtering of headers. The Subject and Language of the XMPP message are also set if they are provided as IN headers.

### 345.4. EXAMPLES

User superman to join room krypton at jabber server with password, secret.
User **superman** to send messages to **joker**:

```java
from("timer://kickoff?period=10000").
setBody(constant("I will win! You're Superman.")));.
to("xmp://superman@jabber.org/joker@jabber.org?password=secret");
```

Consumer configuration, which writes all messages from **joker** into the queue, **evil.talk**.

```java
from("xmp://superman@jabber.org/joker@jabber.org?password=secret").
to("activemq:evil.talk");
```

Consumer configuration, which listens to room messages:

```java
from("xmp://superman@jabber.org/?password=secret&room=krypton@conference.jabber.org").
to("activemq:krypton.talk");
```

Room in short notation (no domain part):

```java
from("xmp://superman@jabber.org/?password=secret&room=krypton").
to("activemq:krypton.talk");
```

When connecting to the Google Chat service, you'll need to specify the **serviceName** as well as your credentials:

```java
from("direct:start").
to("xmp://talk.google.com:5222/touser@gmail.com?
serviceName=gmail.com&user=fromuser&password=secret").
to("mock:result");
```

- Getting Started
CHAPTER 346. XPATH LANGUAGE

Available as of Camel version 1.1

Camel supports XPath to allow an Expression or Predicate to be used in the DSL or Xml Configuration. For example you could use XPath to create a Predicate in a Message Filter or as an Expression for a Recipient List.

Streams

If the message body is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream once. So often when you use XPath as Message Filter or Content Based Router then you need to access the data multiple times, and you should use Stream Caching or convert the message body to a String prior which is safe to be re-read multiple times.

```java
from("queue:foo").
  filter().xpath("//foo").
  to("queue:bar")
```

```java
from("queue:foo").
  choice().xpath("//foo").to("queue:bar").
  otherwise().to("queue:others");
```

346.1. XPATH LANGUAGE OPTIONS

The XPath language supports 9 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>documentType</td>
<td>String</td>
<td>String</td>
<td>Name of class for document type, the default value is org.w3c.dom.Document</td>
</tr>
<tr>
<td>resultType</td>
<td>NODE SET</td>
<td>String</td>
<td>Sets the class name of the result type, (type from output), the default result type is NodeSet</td>
</tr>
<tr>
<td>saxon</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to use Saxon.</td>
</tr>
<tr>
<td>factoryRef</td>
<td>String</td>
<td>String</td>
<td>References to a custom XPathFactory to lookup in the registry</td>
</tr>
<tr>
<td>objectModel</td>
<td>String</td>
<td>String</td>
<td>The XPath object model to use</td>
</tr>
<tr>
<td>logNamespaces</td>
<td>false</td>
<td>Boolean</td>
<td>Whether to log namespaces which can assist during troubleshooting</td>
</tr>
<tr>
<td>headerName</td>
<td>String</td>
<td>String</td>
<td>Name of header to use as input, instead of the message body</td>
</tr>
</tbody>
</table>
### 346.2. NAMESPACES

You can easily use namespaces with XPath expressions using the Namespaces helper class.

### 346.3. VARIABLES

Variables in XPath is defined in different namespaces. The default namespace is `http://camel.apache.org/schema/spring`.

<table>
<thead>
<tr>
<th>Namespac e URI</th>
<th>Local part</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>http://camel.apache.org/xml/in/</code></td>
<td>in</td>
<td>Message</td>
<td>the exchange.in message</td>
</tr>
<tr>
<td><code>http://camel.apache.org/xml/out/</code></td>
<td>out</td>
<td>Message</td>
<td>the exchange.out message</td>
</tr>
<tr>
<td><code>http://camel.apache.org/xml/function/</code></td>
<td>functions</td>
<td>Object</td>
<td>Camel 2.5: Additional functions</td>
</tr>
<tr>
<td>Namespace URI</td>
<td>Local part</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------------------------------------</td>
<td>------------</td>
<td>-------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td><a href="http://camel.apache.org/variables/environment-variables">http://camel.apache.org/variables/environment-variables</a></td>
<td>env</td>
<td>Object</td>
<td>OS environment variables</td>
</tr>
<tr>
<td><a href="http://camel.apache.org/variables/system-properties">http://camel.apache.org/variables/system-properties</a></td>
<td>system</td>
<td>Object</td>
<td>Java System properties</td>
</tr>
<tr>
<td><a href="http://camel.apache.org/variables/exchange-property">http://camel.apache.org/variables/exchange-property</a></td>
<td>Object</td>
<td></td>
<td>the exchange property</td>
</tr>
</tbody>
</table>

Camel will resolve variables according to either:

- namespace given
- no namespace given

### 346.3.1. Namespace given

If the namespace is given then Camel is instructed exactly what to return. However when resolving either **in** or **out** Camel will try to resolve a header with the given local part first, and return it. If the local part has the value `body` then the body is returned instead.

### 346.3.2. No namespace given

If there is no namespace given then Camel resolves only based on the local part. Camel will try to resolve a variable in the following steps:

- from `variables` that has been set using the `variable(name, value)` fluent builder
from message.in.header if there is a header with the given key
from exchange.properties if there is a property with the given key

### 346.4. FUNCTIONS

Camel adds the following XPath functions that can be used to access the exchange:

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>in:body</td>
<td>none</td>
<td>Object</td>
<td>Will return the in message body.</td>
</tr>
<tr>
<td>in:header</td>
<td>the header name</td>
<td>Object</td>
<td>Will return the in message header.</td>
</tr>
<tr>
<td>out:body</td>
<td>none</td>
<td>Object</td>
<td>Will return the out message body.</td>
</tr>
<tr>
<td>out:header</td>
<td>the header name</td>
<td>Object</td>
<td>Will return the out message header.</td>
</tr>
<tr>
<td>function:properties</td>
<td>key for property</td>
<td>String</td>
<td><strong>Camel 2.5:</strong> To lookup a property using the Properties component (property placeholders).</td>
</tr>
<tr>
<td>function:simple</td>
<td>simple expression</td>
<td>Object</td>
<td><strong>Camel 2.5:</strong> To evaluate a Simple expression.</td>
</tr>
</tbody>
</table>

**CAUTION**

*function:properties* and *function:simple* is not supported when the return type is a **NodeSet**, such as when using with a Splitter EIP.

Here’s an example showing some of these functions in use.

And the new functions introduced in Camel 2.5:

### 346.5. USING XML CONFIGURATION

If you prefer to configure your routes in your Spring XML file then you can use XPath expressions as follows

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd"
```
346.6. SETTING RESULT TYPE

The XPath expression will return a result type using native XML objects such as `org.w3c.dom.NodeList`. But many times you want a result type to be a String. To do this you have to instruct the XPath which result type to use.

In Java DSL:

```java
xpath("/foo:person/@id", String.class)
```

In Spring DSL you use the `resultType` attribute to provide a fully qualified classname:

```xml
<xpath resultType="java.lang.String"/>foo:person/@id</xpath>
```

In @XPath:

```java
@XPath(value = "concat('foo-',//order/name/)", resultType = String.class) String name)
```

Where we use the xpath function concat to prefix the order name with `foo-`. In this case we have to specify that we want a String as result type so the concat function works.

346.7. USING XPATH ON HEADERS

Available as of Camel 2.11

Some users may have XML stored in a header. To apply an XPath to a header’s value you can do this by defining the ‘headerName’ attribute.

And in Java DSL you specify the headerName as the 2nd parameter as shown:

```java
xpath("/invoice/@orderType = 'premium'", "invoiceDetails")
```
346.8. EXAMPLES

Here is a simple example using an XPath expression as a predicate in a Message Filter

If you have a standard set of namespaces you wish to work with and wish to share them across many different XPath expressions you can use the NamespaceBuilder as shown in this example

In this sample we have a choice construct. The first choice evaluates if the message has a header key type that has the value Camel. The 2nd choice evaluates if the message body has a name tag <name> which value is Kong. If neither is true the message is routed in the otherwise block:

And the spring XML equivalent of the route:

346.9. XPATH INJECTION

You can use Bean Integration to invoke a method on a bean and use various languages such as XPath to extract a value from the message and bind it to a method parameter.

The default XPath annotation has SOAP and XML namespaces available. If you want to use your own namespace URIs in an XPath expression you can use your own copy of the XPath annotation to create whatever namespace prefixes you want to use.

i.e. cut and paste upper code to your own project in a different package and/or annotation name then add whatever namespace prefix/uris you want in scope when you use your annotation on a method parameter. Then when you use your annotation on a method parameter all the namespaces you want will be available for use in your XPath expression.

For example

```java
public class Foo {
    @MessageDriven(uri = "activemq:my.queue")
    public void doSomething(@MyXPath("/ns1:foo/ns2:bar/text()") String correlationID, @Body String body) {
        // process the inbound message here
    }
}
```

346.10. USING XPATHBUILDER WITHOUT AN EXCHANGE

Available as of Camel 2.3

You can now use the org.apache.camel.builder.XPathBuilder without the need for an Exchange. This comes handy if you want to use it as a helper to do custom xpath evaluations.

It requires that you pass in a CamelContext since a lot of the moving parts inside the XPathBuilder requires access to the Camel Type Converter and hence why CamelContext is needed.

For example you can do something like this:

```java
boolean matches = XPathBuilder.xpath("/foo/bar/@xyz").matches(context, "<foo><bar xyz='cheese'/>
</foo>")
```
This will match the given predicate.

You can also evaluate for example as shown in the following three examples:

```java
String name = XPathBuilder.xpath("foo/bar").evaluate(context, 
"<foo><bar>cheese</bar></foo>",
String.class);
Integer number = XPathBuilder.xpath("foo/bar").evaluate(context, 
"<foo><bar>123</bar></foo>",
Integer.class);
Boolean bool = XPathBuilder.xpath("foo/bar").evaluate(context, 
"<foo><bar>true</bar></foo>",
Boolean.class);
```

Evaluating with a String result is a common requirement and thus you can do it a bit simpler:

```java
String name = XPathBuilder.xpath("foo/bar").evaluate(context, 
"<foo><bar>cheese</bar></foo>");
```

### 346.11. USING SAXON WITH XPATHBUILDER

**Available as of Camel 2.3**

You need to add `camel-saxon` as dependency to your project.

It's now easier to use Saxon with the XPathBuilder which can be done in several ways as shown below. Where as the latter ones are the easiest ones.

- Using a factory
- Using ObjectModel

The easy one

### 346.12. SETTING A CUSTOM XPATHFACTORY USING SYSTEM PROPERTY

**Available as of Camel 2.3**

Camel now supports reading the JVM system property `javax.xml.xpath.XPathFactory` that can be used to set a custom XPathFactory to use.

This unit test shows how this can be done to use Saxon instead:

Camel will log at **INFO** level if it uses a non default XPathFactory such as:

```java
XPathBuilder INFO Using system property
javax.xml.xpath.XPathFactory:http://saxon.sf.net/jaxp(xpath/om with value:
   net.sf.saxon.xpath.XPathFactoryImpl when creating XPathFactory
```

To use Apache Xerces you can configure the system property

```java
-Djavax.xml.xpath.XPathFactory=org.apache.xpath.jaxp.XPathFactoryImpl
```

### 346.13. ENABLING SAXON FROM SPRING DSL

**Available as of Camel 2.10**
Similarly to Java DSL, to enable Saxon from Spring DSL you have three options:

Specifying the factory

```xml
<xpath factoryRef="saxonFactory" resultType="java.lang.String">current-dateTime()</xpath>
```

Specifying the object model

```xml
<xpath objectModel="http://saxon.sf.net/jaxp/xpath/om" resultType="java.lang.String">current-dateTime()</xpath>
```

Shortcut

```xml
<xpath saxon="true" resultType="java.lang.String">current-dateTime()</xpath>
```

### 346.14. NAMESPACE AUDITING TO AID DEBUGGING

Available as of Camel 2.10

A large number of XPath-related issues that users frequently face are linked to the usage of namespaces. You may have some misalignment between the namespaces present in your message and those that your XPath expression is aware of or referencing. XPath predicates or expressions that are unable to locate the XML elements and attributes due to namespaces issues may simply look like "they are not working", when in reality all there is to it is a lack of namespace definition.

Namespaces in XML are completely necessary, and while we would love to simplify their usage by implementing some magic or voodoo to wire namespaces automatically, truth is that any action down this path would disagree with the standards and would greatly hinder interoperability.

Therefore, the utmost we can do is assist you in debugging such issues by adding two new features to the XPath Expression Language and are thus accesible from both predicates and expressions.

#### === Logging the Namespace Context of your XPath expression/predicate

Every time a new XPath expression is created in the internal pool, Camel will log the namespace context of the expression under the `org.apache.camel.builder.xml.XPathBuilder` logger. Since Camel represents Namespace Contexts in a hierarchical fashion (parent-child relationships), the entire tree is output in a recursive manner with the following format:

```
[me: {prefix -> namespace}, {prefix -> namespace}], [parent: [me: {prefix -> namespace}, {prefix -> namespace}]], [parent: [me: {prefix -> namespace}]]
```

Any of these options can be used to activate this logging:

1. Enable TRACE logging on the `org.apache.camel.builder.xml.XPathBuilder` logger, or some parent logger such as `org.apache.camel` or the root logger

2. Enable the `logNamespaces` option as indicated in Auditing Namespaces, in which case the logging will occur on the INFO level

### 346.15. AUDITING NAMESPACEs
Camel is able to discover and dump all namespaces present on every incoming message before evaluating an XPath expression, providing all the richness of information you need to help you analyse and pinpoint possible namespace issues.

To achieve this, it in turn internally uses another specially tailored XPath expression to extract all namespace mappings that appear in the message, displaying the prefix and the full namespace URI(s) for each individual mapping.

Some points to take into account:

- The implicit XML namespace (xmlns:xml="http://www.w3.org/XML/1998/namespace") is suppressed from the output because it adds no value
- Default namespaces are listed under the DEFAULT keyword in the output
- Keep in mind that namespaces can be remapped under different scopes. Think of a top-level 'a' prefix which in inner elements can be assigned a different namespace, or the default namespace changing in inner scopes. For each discovered prefix, all associated URIs are listed.

You can enable this option in Java DSL and Spring DSL.

Java DSL:

```java
XPathBuilder.xpath("/foo:person/@id", String.class).logNamespaces()
```

Spring DSL:

```xml
<xpath logNamespaces="true" resultType="String">/foo:person/@id</xpath>
```

The result of the auditing will be appear at the INFO level under the org.apache.camel.builder.xml.XPathBuilder logger and will look like the following:

```
2012-01-16 13:23:45,878 [stSaxonWithFlag] INFO XPathBuilder - Namespaces discovered in message:
{xmlns:a=[http://apache.org/camel], DEFAULT=[http://apache.org/default],
```

### 346.16. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as "classpath:“, "file:“, or "http:“. This is done using the following syntax: "resource:scheme:location“, eg to refer to a file on the classpath you can do:

```java
.setHeader("myHeader").xpath("resource:classpath:myxpath.txt", String.class)
```

### 346.17. DEPENDENCIES

The XPath language is part of camel-core.
CHAPTER 347. XQUERY COMPONENT

Available as of Camel version 1.0

Camel supports XQuery to allow an Expression or Predicate to be used in the DSL or Xml Configuration. For example you could use XQuery to create an Predicate in a Message Filter or as an Expression for a Recipient List.

347.1. OPTIONS

The XQuery component supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>moduleURIResolver (advanced)</td>
<td>To use the custom ModuleURIResolver</td>
<td></td>
<td>ModuleURIResolver</td>
</tr>
<tr>
<td>configuration (advanced)</td>
<td>To use a custom Saxon configuration</td>
<td></td>
<td>Configuration</td>
</tr>
<tr>
<td>configurationProperties (advanced)</td>
<td>To set custom Saxon configuration properties</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>resolveProperty Placeholders (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The XQuery endpoint is configured using URI syntax:

```
xquery:resourceUri
```

with the following path and query parameters:

347.1.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td>Required The name of the template to load from classpath or file system</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

347.1.2. Query Parameters (31 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowStAX (common)</td>
<td>Whether to allow using StAX mode</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>headerName (common)</td>
<td>To use a Camel Message header as the input source instead of Message body.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>namespacePrefixes (common)</td>
<td>Allows to control which namespace prefixes to use for a set of namespace mappings</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>resultsFormat (common)</td>
<td>What output result to use</td>
<td>DOM</td>
<td>ResultFormat</td>
</tr>
<tr>
<td>resultType (common)</td>
<td>What output result to use defined as a class</td>
<td>Class&lt;?&gt;</td>
<td></td>
</tr>
<tr>
<td>stripsAllWhiteSpace (common)</td>
<td>Whether to strip all whitespaces</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle (consumer)</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>exceptionHandler (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td>exchangePattern (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>

</tr>
<tr>
<td>useFixedDelay</td>
<td>Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 347.2. EXAMPLES

```xml
from("queue:foo").filter().
  xquery("//foo").
  to("queue:bar")
```

You can also use functions inside your query, in which case you need an explicit type conversion (or you will get a org.w3c.dom.DOMException: HIERARCHY_REQUEST_ERR) by passing the Class as a second argument to the `xquery()` method.

```xml
from("direct:start").recipientList().xquery("concat('mock:foo.', /person/@city)", String.class);
```

### 347.3. VARIABLES

The IN message body will be set as the `contextItem`. Besides this these Variables is also added as parameters:
### Variable Type Description

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exchange</td>
<td>Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>in.body</td>
<td>Object</td>
<td>The In message’s body</td>
</tr>
<tr>
<td>out.body</td>
<td>Object</td>
<td>The OUT message’s body (if any)</td>
</tr>
<tr>
<td>in.headers.*</td>
<td>Object</td>
<td>You can access the value of exchange.in.headers with key foo by using the variable which name is in.headers.foo</td>
</tr>
<tr>
<td>out.headers.*</td>
<td>Object</td>
<td>You can access the value of exchange.out.headers with key foo by using the variable which name is out.headers.foo variable</td>
</tr>
<tr>
<td>key name</td>
<td>Object</td>
<td>Any exchange.properties and exchange.in.headers and any additional parameters set using setParameters(Map). These parameters is added with they own key name, for instance if there is an IN header with the key name foo then its added as foo.</td>
</tr>
</tbody>
</table>

### 347.4. USING XML CONFIGURATION

If you prefer to configure your routes in your Spring XML file then you can use XPath expressions as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:foo="http://example.com/person"
       xsi:schemaLocation="http://www.springframework.org/schema/beans
                           http://www.springframework.org/schema/beans/spring-beans.xsd
                           http://camel.apache.org/schema/spring
                           http://camel.apache.org/schema/spring/camel-spring.xsd">
  <camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring">
    <route>
      <from uri="activemq:MyQueue"/>
      <filter>
        <xquery>/foo:person[@name='James']/</xquery>
      </filter>
      <to uri="mqseries:SomeOtherQueue"/>
    </route>
  </camelContext>
</beans>
```

Notice how we can reuse the namespace prefixes, foo in this case, in the XPath expression for easier namespace based XQuery expressions!

When you use functions in your XQuery expression you need an explicit type conversion which is done in the xml configuration via the @type attribute:
347.5. USING XQUERY AS TRANSFORMATION

We can do a message translation using transform or setBody in the route, as shown below:

```xml
<from("direct:start").
  transform().xquery("/people/person");
```

Notice that xquery will use DOMResult by default, so if we want to grab the value of the person node, using text() we need to tell xquery to use String as result type, as shown:

```xml
<from("direct:start").
  transform().xquery("/people/person/text()", String.class);
```

347.6. USING XQUERY AS AN ENDPOINT

Sometimes an XQuery expression can be quite large; it can essentially be used for Templating. So you may want to use an XQuery Endpoint so you can route using XQuery templates.

The following example shows how to take a message of an ActiveMQ queue (MyQueue) and transform it using XQuery and send it to MQSeries.

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="activemq:MyQueue"/>
    <to uri="xquery:com/acme/someTransform.xquery"/>
    <to uri="mqseries:SomeOtherQueue"/>
  </route>
</camelContext>
```

Currently custom functions in XQuery might result in a NullPointerException (Camel 2.18, 2.19 and 2.20). This is expected to be fixed in Camel 2.21

347.7. EXAMPLES

Here is a simple example using an XQuery expression as a predicate in a Message Filter

This example uses XQuery with namespaces as a predicate in a Message Filter

347.8. LEARNING XQUERY

XQuery is a very powerful language for querying, searching, sorting and returning XML. For help learning XQuery try these tutorials

- Mike Kay’s XQuery Primer
- the W3Schools XQuery Tutorial

You might also find the XQuery function reference useful
347.9. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as "classpath:\", "file:\", or "http:". This is done using the following syntax: "resource:scheme:location", eg to refer to a file on the classpath you can do:

```java
.setHeader("myHeader").xquery("resource:classpath:myxquery.txt", String.class)
```

347.10. DEPENDENCIES

To use XQuery in your camel routes you need to add the a dependency on camel-saxon which implements the XQuery language.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-saxon</artifactId>
  <version>x.x.x</version>
</dependency>
```
CHAPTER 348. XSLT COMPONENT

Available as of Camel version 1.3

The `xslt:` component allows you to process a message using an XSLT template. This can be ideal when using Templating to generate responses for requests.

348.1. URI FORMAT

```
xslt:templateName[?options]
```

The URI format contains `templateName`, which can be one of the following:

- the classpath-local URI of the template to invoke
- the complete URL of the remote template.

You can append query options to the URI in the following format:

```
?option=value&option=value&...
```

Refer to the Spring Documentation for more detail of the URI syntax.

Table 348.1. Example URIs

<table>
<thead>
<tr>
<th>URI</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xslt:com/acme/mytransform.xsl</td>
<td>Refers to the file com/acme/mytransform.xsl on the classpath</td>
</tr>
<tr>
<td>xslt:file:///foo/bar.xsl</td>
<td>Refers to the file /foo/bar.xsl</td>
</tr>
<tr>
<td>xslt:<a href="http://acme.com/cheese/foo.xsl">http://acme.com/cheese/foo.xsl</a></td>
<td>Refers to the remote http resource</td>
</tr>
</tbody>
</table>

For Camel 2.8 or older, Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

From Camel 2.9 onwards the XSLT component is provided directly in the camel-core.

348.2. OPTIONS

The XSLT component supports 9 options which are listed below.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlConverter</td>
<td>To use a custom implementation of org.apache.camel.converter.jaxp.XmlConverter</td>
<td></td>
<td>XmlConverter</td>
</tr>
<tr>
<td>uriResolverFactory</td>
<td>To use a custom UriResolver which depends on a dynamic endpoint resource URI. Should not be used together with the option 'uriResolver'.</td>
<td></td>
<td>XsltUriResolverFactory</td>
</tr>
<tr>
<td>uriResolver</td>
<td>To use a custom UriResolver. Should not be used together with the option 'uriResolverFactory'.</td>
<td></td>
<td>URIResolver</td>
</tr>
<tr>
<td>contentCache</td>
<td>Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>saxon</td>
<td>Whether to use Saxon as the transformerFactoryClass. If enabled then the class net.sf.saxon.TransformerFactoryImpl. You would need to add Saxon to the classpath.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>saxonExtensionFuncions</td>
<td>Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can comma to separate multiple values to lookup.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>saxonConfiguration</td>
<td>To use a custom Saxon configuration</td>
<td></td>
<td>Object</td>
</tr>
<tr>
<td>saxonConfigurationProperties</td>
<td>To set custom Saxon configuration properties</td>
<td></td>
<td>Map</td>
</tr>
<tr>
<td>resolvePropertyPlaceholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The XSLT endpoint is configured using URI syntax:

```
xslt:resourceUri
```

with the following path and query parameters:

### 348.2.1. Path Parameters (1 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceUri</td>
<td><strong>Required</strong> Path to the template. The following is supported by the default URIResolver. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 348.2.2. Query Parameters (17 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowStAX</td>
<td>Whether to allow using StAX as the javax.xml.transform.Source.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>contentCache</td>
<td>Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>deleteOutputFile</td>
<td>If you have output=file then this option dictates whether or not the output file should be deleted when the Exchange is done processing. For example suppose the output file is a temporary file, then it can be a good idea to delete it after use.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>failOnNullBody</td>
<td>Whether or not to throw an exception if the input body is null.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>output</td>
<td>Option to specify which output type to use. Possible values are: string, bytes, DOM, file. The first three options are all in memory based, where as file is streamed directly to a java.io.File. For file you must specify the filename in the IN header with the key Exchange.XSLT_FILE_NAME which is also CamelXsltFileName. Also any paths leading to the filename must be created beforehand, otherwise an exception is thrown at runtime.</td>
<td>string</td>
<td>XsltOutput</td>
</tr>
<tr>
<td>saxon</td>
<td>Whether to use Saxon as the transformerFactoryClass. If enabled then the class net.sf.saxon.TransformerFactoryImpl. You would need to add Saxon to the classpath.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
### Name | Description | Default | Type
--- | --- | --- | ---
**transformerCacheSize** *(producer)*  | The number of javax.xml.transform.Transformer object that are cached for reuse to avoid calls to Template.newTransformer(). | 0 | int

**converter** *(advanced)*  | To use a custom implementation of org.apache.camel.converter.jaxp.XmlConverter |  | XmlConverter

**entityResolver** *(advanced)*  | To use a custom org.xml.sax.EntityResolver with javax.xml.transform.sax.SAXSource. |  | EntityResolver

**errorListener** *(advanced)*  | Allows to configure to use a custom javax.xml.transform.ErrorListener. Beware when doing this then the default error listener which captures any errors or fatal errors and store information on the Exchange as properties is not in use. So only use this option for special use-cases. |  | ErrorListener

**resultHandlerFactory** *(advanced)*  | Allows you to use a custom org.apache.camel.builder.xml.ResultHandlerFactory which is capable of using custom org.apache.camel.builder.xml.ResultHandler types. |  | ResultHandlerFactory

**saxonConfiguration** *(advanced)*  | To use a custom Saxon configuration |  | Object

**saxonExtensionFunctions** *(advanced)*  | Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can comma to separate multiple values to lookup. |  | String

**synchronous** *(advanced)*  | Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported). | false | boolean

**transformerFactory** *(advanced)*  | To use a custom XSLT transformer factory |  | TransformerFactory

**transformerFactoryClass** *(advanced)*  | To use a custom XSLT transformer factory, specified as a FQN class name |  | String

**uriResolver** *(advanced)*  | To use a custom javax.xml.transform.URIResolver |  | URIResolver

### 348.3. USING XSLT ENDPOINTS
The following format is an example of using an XSLT template to formulate a response for a message for InOut message exchanges (where there is a JMSReplyTo header)

```xml
from("activemq:My.Queue").
to("xslt:com/acme/mytransform.xsl");
```

If you want to use InOnly and consume the message and send it to another destination you could use the following route:

```xml
from("activemq:My.Queue").
to("xslt:com/acme/mytransform.xsl").
to("activemq:Another.Queue");
```

### 348.4. GETTING USEABLE PARAMETERS INTO THE XSLT

By default, all headers are added as parameters which are then available in the XSLT. To make the parameters useable, you will need to declare them.

```xml
<setHeader headerName="myParam"><constant>42</constant></setHeader>
<to uri="/xslt:MyTransform.xsl"/>
```

The parameter also needs to be declared in the top level of the XSLT for it to be available:

```xml
<xsl:......>
  <xsl:param name="myParam"/>
  <xsl:template ...>
```

### 348.5. SPRING XML VERSIONS

To use the above examples in Spring XML you would use something like the following code:

```xml
<camelContext xmlns="http://activemq.apache.org/camel/schema/spring">
  <route>
    <from uri="/activemq:My.Queue"/>
    <to uri="/xslt:org/apache/camel/spring/processor/example.xsl"/>
    <to uri="/activemq:Another.Queue"/>
  </route>
</camelContext>
```

To see an example, look at the test case along with its Spring XML.

### 348.6. USING XSL:INCLUDE

**Camel 2.2 or older**

If you use `xsl:include` in your XSL files in Camel 2.2 or older, the default `javax.xml.transform.URIResolver` is used. Files will be resolved relative to the JVM starting folder.

For example the following include statement will look up the `staff_template.xsl` file starting from the folder where the application was started.
Camel 2.3 or newer
For Camel 2.3 or newer, Camel provides its own implementation of URIResolver. This allows Camel to load included files from the classpath.

For example the include file in the following code will be located relative to the starting endpoint.

```xml
<xsl:include href="staff_template.xsl"/>
```

This means that Camel will locate the file in the classpath as org/apache/camel/component/xslt/staff_template.xsl

You can use classpath: or file: to instruct Camel to look either in the classpath or file system. If you omit the prefix then Camel uses the prefix from the endpoint configuration. If no prefix is specified in the endpoint configuration, the default is classpath:

You can also refer backwards in the include paths. In the following example, the xsl file will be resolved under org/apache/camel/component.

```xml
<xsl:include href="../staff_other_template.xsl"/>
```

### 348.7. USING XSL:INCLUDE AND DEFAULT PREFIX

In Camel 2.10.3 and older, classpath: is used as the default prefix.

If you configure the starting resource to load using file: then all subsequent incudes will have to be prefixed with file:

From Camel 2.10.4, Camel will use the prefix from the endpoint configuration as the default prefix.

You can explicitly specify file: or classpath: loading. The two loading types can be mixed in a XSLT script, if necessary.

### 348.8. USING SAXON EXTENSION FUNCTIONS

Since Saxon 9.2, writing extension functions has been supplemented by a new mechanism, referred to as integrated extension functions you can now easily use camel as shown in the below example:

```java
SimpleRegistry registry = new SimpleRegistry();
registry.put("function1", new MyExtensionFunction1());
registry.put("function2", new MyExtensionFunction2());

CamelContext context = new DefaultCamelContext(registry);
context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("direct:start")
        .to("xslt:org/apache/camel/component/xslt/extensions/extensions.xslt?saxonExtensionFunctions=#function1,#function2");
    }
});
```

With Spring XML:
348.9. DYNAMIC STYLESHEETS

To provide a dynamic stylesheet at runtime you can define a dynamic URI. See How to use a dynamic URI in to() for more information.

Available as of Camel 2.9 (removed in 2.11.4, 2.12.3 and 2.13.0)
Camel provides the CamelXsltResourceUri header which you can use to define an alternative stylesheet to that configured on the endpoint URI. This allows you to provide a dynamic stylesheet at runtime.

348.10. ACCESSING WARNINGS, ERRORS AND FATALERRORS FROM XSLT ERRORLISTENER

Available as of Camel 2.14

From Camel 2.14, any warning/error or fatalError is stored on the current Exchange as a property with the keys Exchange.XSLT_ERROR, Exchange.XSLT_FATAL_ERROR, or Exchange.XSLT_WARNING which allows end users to get hold of any errors happening during transformation.

For example in the stylesheet below, we want to terminate if a staff has an empty dob field. And to include a custom error message using xsl:message.

```
<xsl:template match="/">
  <html>
    <body>
      <xsl:for-each select="staff/programmer">
        <p>Name: <xsl:value-of select="name"/><br/>
          <xsl:if test="dob=''">
            <xsl:message terminate="yes">Error: DOB is an empty string!</xsl:message>
          </xsl:if>
        </p>
      </xsl:for-each>
    </body>
  </html>
</xsl:template>
```

The exception is stored on the Exchange as a warning with the key Exchange.XSLT_WARNING.

348.11. NOTES ON USING XSLT AND JAVA VERSIONS

Here are some observations from Sameer, a Camel user, which he kindly shared with us:
In case anybody faces issues with the XSLT endpoint please review these points.

I was trying to use an xslt endpoint for a simple transformation from one xml to another using a simple xsl. The output xml kept appearing (after the xslt processor in the route) with outermost xml tag with no content within.

No explanations show up in the DEBUG logs. On the TRACE logs however I did find some error/warning indicating that the XMLConverter bean could no be initialized.

After a few hours of cranking my mind, I had to do the following to get it to work (thanks to some posts on the users forum that gave some clue):

1. Use the transformerFactory option in the route ("xslt:my-transformer.xsl? transformerFactory=tFactory") with the tFactory bean having bean defined in the spring context for class="org.apache.xalan.xslt.trax.TransformerFactoryImpl".

2. Added the Xalan jar into my maven pom.

My guess is that the default xml parsing mechanism supplied within the JDK (I am using 1.6.0_03) does not work right in this context and does not throw up any error either. When I switched to Xalan this way it works. This is not a Camel issue, but might need a mention on the xslt component page.

Another note, jdk 1.6.0_03 ships with JAXB 2.0 while Camel needs 2.1. One workaround is to add the 2.1 jar to the jre/lib/endorsed directory for the jvm or as specified by the container.

Hope this post saves newbie Camel riders some time.

- Endpoint
- Getting Started
CHAPTER 349. XSTREAM DATAFORMAT

Available as of Camel version 1.3

XStream is a Data Format which uses the XStream library to marshal and unmarshal Java objects to and from XML.

To use XStream in your camel routes you need to add the a dependency on camel-xstream which implements this data format.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xstream</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

349.1. OPTIONS

The XStream dataformat supports 10 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>permissions</td>
<td>String</td>
<td>String</td>
<td>Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo,-com.foo.bar.MySecretBean. The following default permission is always included: - java.lang,.java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.</td>
</tr>
<tr>
<td>encoding</td>
<td>String</td>
<td>String</td>
<td>Sets the encoding to use</td>
</tr>
<tr>
<td>driver</td>
<td>String</td>
<td>String</td>
<td>To use a custom XStream driver. The instance must be of type com.thoughtworks.xstream.io.HierarchicalStreamDriver</td>
</tr>
<tr>
<td>driverRef</td>
<td>String</td>
<td>String</td>
<td>To refer to a custom XStream driver to lookup in the registry. The instance must be of type com.thoughtworks.xstream.io.HierarchicalStreamDriver</td>
</tr>
</tbody>
</table>
### Name | Default | Java Type | Description
--- | --- | --- | ---
**mode** | String |  | Mode for dealing with duplicate references. The possible values are: NO_REFERENCES, ID_REFERENCES, XPATH_RELATIVE_REFERENCES, XPATH_ABSOLUTE_REFERENCES, SINGLE_NODE_XPATH_RELATIVE_REFERENCES, SINGLE_NODE_XPATH_ABSOLUTE_REFERENCES

**converters** | List |  | List of class names for using custom XStream converters. The classes must be of type com.thoughtworks.xstream.converters.Converter

**aliases** | Map |  | Alias a Class to a shorter name to be used in XML elements.

**omitFields** | Map |  | Prevents a field from being serialized. To omit a field you must always provide the declaring type and not necessarily the type that is converted.

**implicitCollections** | Map |  | Adds a default implicit collection which is used for any unmapped XML tag.

**contentTypeHeader** | false | Boolean | Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

#### 349.2. USING THE JAVA DSL

```java
// lets turn Object messages into XML then send to MQSeries
from("activemq:My.Queue").marshal().xstream().
to("mqseries:Another.Queue");
```

If you would like to configure the XStream instance used by the Camel for the message transformation, you can simply pass a reference to that instance on the DSL level.

```java
XStream xStream = new XStream();
xStream.aliasField("money", PurchaseOrder.class, "cash");
```

// new Added setModel option since Camel 2.14
xStream.setModel("NO_REFERENCES");
...  

```java
from("direct:marshal").marshal(new XStreamDataFormat(xStream)).to("mock:marshaled");
```
349.3. XMLINPUTFACTORY AND XMLOUTPUTFACTORY

The XStream library uses the `javax.xml.stream.XMLInputFactory` and `javax.xml.stream.XMLOutputFactory`, you can control which implementation of this factory should be used.

The Factory is discovered using this algorithm: 1. Use the `javax.xml.stream.XMLInputFactory`, `javax.xml.stream.XMLOutputFactory` system property. 2. Use the `lib/xml.stream.properties` file in the `JRE_HOME` directory. 3. Use the Services API, if available, to determine the classname by looking in the `META-INF/services/javax.xml.stream.XMLInputFactory`, `META-INF/services/javax.xml.stream.XMLOutputFactory` files in jars available to the JRE. 4. Use the platform default XMLInputFactory,XMLOutputFactory instance.

349.4. HOW TO SET THE XML ENCODING IN XSTREAM DATAFORMAT?

From Camel 2.2.0, you can set the encoding of XML in Xstream DataFormat by setting the Exchange’s property with the key `Exchange.CHARSET_NAME`, or setting the encoding property on Xstream from DSL or Spring config.

```java
from("activemq:My.Queue").marshal("UTF-8").to("mqseries:Another.Queue");
```

349.5. SETTING THE TYPE PERMISSIONS OF XSTREAM DATAFORMAT

In Camel, one can always use its own processing step in the route to filter and block certain XML documents to be routed to the XStream’s unmarshall step. From Camel 2.16.1, 2.15.5, you can set XStream’s type permissions to automatically allow or deny the instantiation of certain types.

The default type permissions setting used by Camel denies all types except for those from java.lang and java.util packages. This setting can be changed by setting System property `org.apache.camel.xstream.permissions`. Its value is a string of comma-separated permission terms, each representing a type being allowed or denied, depending on whether the term is prefixed with "" (note "" may be omitted) or with '‐', respectively.

Each term may contain a wildcard character ". For example, value "‐java.lang,java.util." indicates denying all types except for java.lang.* and java.util.* classes. Setting this value to an empty string "" reverts to the default XStream’s type permissions handling which denies certain blacklisted classes and allow others.

The type permissions setting can be extended at an individual XStream DataFormat instance by setting its type permissions property.

```xml
<dataFormats>
  <xstream id="xstream-default"
    permissions="org.apache.camel.samples.xstream.*"/>
...
```
CHAPTER 350. YAML SNAKEYAML DATAFORMAT

Available as of Camel version 2.17

YAML is a Data Format to marshal and unmarshal Java objects to and from YAML.

For YAML to object marshalling, Camel provides integration with three popular YAML libraries:

- The SnakeYAML library

Every library requires adding the special camel component (see “Dependency...” paragraphs further down). By default Camel uses the SnakeYAML library.

350.1. YAML OPTIONS

The YAML SnakeYAML dataformat supports 11 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>library</td>
<td>SnakeYAML</td>
<td>YAML Library</td>
<td>Which yaml library to use. By default it is SnakeYAML</td>
</tr>
<tr>
<td>unmarshalTypeNa me</td>
<td>String</td>
<td>Class name of the java type to use when unarmshalling</td>
<td></td>
</tr>
<tr>
<td>constructor</td>
<td>String</td>
<td>BaseConstructor to construct incoming documents.</td>
<td></td>
</tr>
<tr>
<td>representer</td>
<td>String</td>
<td>Representer to emit outgoing objects.</td>
<td></td>
</tr>
<tr>
<td>dumperOptions</td>
<td>String</td>
<td>DumperOptions to configure outgoing objects.</td>
<td></td>
</tr>
<tr>
<td>resolver</td>
<td>String</td>
<td>Resolver to detect implicit type</td>
<td></td>
</tr>
<tr>
<td>useApplicationContextClassLoader</td>
<td>true</td>
<td>Boolean</td>
<td>Use ApplicationContextClassLoader as custom ClassLoader</td>
</tr>
<tr>
<td>prettyFlow</td>
<td>false</td>
<td>Boolean</td>
<td>Force the emitter to produce a pretty YAML document when using the flow style.</td>
</tr>
<tr>
<td>allowAnyType</td>
<td>false</td>
<td>Boolean</td>
<td>Allow any class to be un-marshaled</td>
</tr>
<tr>
<td>typeFilter</td>
<td>List</td>
<td>Set the types SnakeYAML is allowed to un-marshal</td>
<td></td>
</tr>
</tbody>
</table>
### 350.2. USING YAML DATA FORMAT WITH THE SNAKEYAML LIBRARY

- Turn Object messages into yaml then send to MQSeries

```java
from("activemq:My.Queue")
.marshall().yaml()
.to("mqseries:Another.Queue");
```

```java
from("activemq:My.Queue")
.marshall().yaml(YAMLLibrary.SnakeYAML)
.to("mqseries:Another.Queue");
```

- Restrict classes to be loaded from YAML

```java
// Creat a SnakeYAMLDataFormat instance
SnakeYAMLDataFormat yaml = new SnakeYAMLDataFormat();

// Restrict classes to be loaded from YAML
yaml.addTypeFilters(TypeFilters.types(MyPojo.class, MyOtherPojo.class));

from("activemq:My.Queue")
.unmarshall(yaml)
.to("mqseries:Another.Queue");
```

### 350.3. USING YAML IN SPRING DSL

When using Data Format in Spring DSL you need to declare the data formats first. This is done in the `DataFormats` XML tag.
And then you can refer to those ids in the route:

```xml
<route>
  <from uri="direct:unmarshal"/>
  <unmarshal>
    <custom ref="snake"/>
  </unmarshal>
  <to uri="mock:unmarshal"/>
</route>

<route>
  <from uri="direct:unmarshal-safe"/>
  <unmarshal>
    <custom ref="snake-safe"/>
  </unmarshal>
  <to uri="mock:unmarshal-safe"/>
</route>
```

### 350.4. DEPENDENCIES FOR SNAKEYAML

To use YAML in your camel routes you need to add the a dependency on `camel-snakeyaml` which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-snakeyaml</artifactId>
  <version>${camel-version}</version>
</dependency>
```
 CHAPTER 351. YAMMER COMPONENT

Available as of Camel version 2.12

The Yammer component allows you to interact with the Yammer enterprise social network. Consuming messages, users, and user relationships is supported as well as creating new messages.

Yammer uses OAuth 2 for all client application authentication. In order to use camel-yammer with your account, you'll need to create a new application within Yammer and grant the application access to your account. Finally, generate your access token. More details are at https://developer.yammer.com/authentication/.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-yammer</artifactId>
  <version>${camel-version}</version>
</dependency>
```

### 351.1. URI FORMAT

```text
yammer:[function]?[options]
```

### 351.2. COMPONENT OPTIONS

The Yammer component can be configured with the Yammer account settings which are mandatory to configure before using.

The Yammer component supports 5 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>consumerKey</td>
<td>The consumer key</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td></td>
<td>(security)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>consumerSecret</td>
<td>The consumer secret</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td></td>
<td>(security)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>accessToken</td>
<td>The access token</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td></td>
<td>(security)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>config</td>
<td>To use a shared yammer configuration</td>
<td></td>
<td>YammerConfiguration</td>
</tr>
<tr>
<td></td>
<td>(advanced)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>resolveProperty</td>
<td>Whether the component should resolve property</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Placeholder</td>
<td>placeholders on itself when starting. Only properties</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>which are of String type can use property</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>placeholders.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(advanced)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You can also configure these options directly in the endpoint.

## 351.3. ENDPOINT OPTIONS

The Yammer endpoint is configured using URI syntax:

```
yammer:function
```

with the following path and query parameters:

### 351.3.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>function</td>
<td>Required The function to use</td>
<td></td>
<td>YammerFunctionType</td>
</tr>
</tbody>
</table>

### 351.3.2. Query Parameters (28 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>useJson (common)</td>
<td>Set to true if you want to use raw JSON rather than converting to POJOs.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>delay (consumer)</td>
<td>Delay between polling in millis</td>
<td>5000</td>
<td>long</td>
</tr>
<tr>
<td>limit (consumer)</td>
<td>Return only the specified number of messages. Works for threaded=true and threaded=extended.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>newerThan (consumer)</td>
<td>Returns messages newer than the message ID specified as a numeric string. This should be used when polling for new messages. If you’re looking at messages, and the most recent message returned is 3516, you can make a request with the parameter newerThan=3516 to ensure that you do not get duplicate copies of messages already on your page.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>olderThan</td>
<td>Returns messages older than the message ID specified as a numeric string. This is useful for paginating messages. For example, if you’re currently viewing 20 messages and the oldest is number 2912, you could append olderThan=2912 to your request to get the 20 messages prior to those you’re seeing.</td>
<td>-1</td>
<td>int</td>
</tr>
<tr>
<td>sendEmptyMessageWhenIdle</td>
<td>If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>threaded</td>
<td>threaded=true will only return the first message in each thread. This parameter is intended for apps which display message threads collapsed. threaded=extended will return the thread starter messages in order of most recently active as well as the two most recent messages, as they are viewed in the default view on the Yammer web interface.</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>userId</td>
<td>The user id</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>ExceptionHandler</td>
<td></td>
</tr>
<tr>
<td>exchangePattern</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td>ExchangePattern</td>
<td></td>
</tr>
<tr>
<td>pollStrategy</td>
<td>A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.</td>
<td>PollingConsumerPollingStrategy</td>
<td></td>
</tr>
<tr>
<td>synchronous</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>backoffErrorThreshold</td>
<td>The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>backoffIdleThreshold</td>
<td>The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td><strong>backoffMultiplier</strong></td>
<td>To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.</td>
<td>int</td>
<td></td>
</tr>
<tr>
<td><strong>greedy</strong></td>
<td>If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>initialDelay</strong></td>
<td>Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).</td>
<td>1000</td>
<td>long</td>
</tr>
<tr>
<td><strong>runLoggingLevel</strong></td>
<td>The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.</td>
<td>TRACE</td>
<td>LoggingLevel</td>
</tr>
<tr>
<td><strong>scheduledExecutorService</strong></td>
<td>Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.</td>
<td>ScheduledExecutorService</td>
<td></td>
</tr>
<tr>
<td><strong>scheduler</strong></td>
<td>To use a cron scheduler from either camel-spring or camel-quartz2 component</td>
<td>none</td>
<td>ScheduledPollConsumer</td>
</tr>
<tr>
<td><strong>schedulerProperties</strong></td>
<td>To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.</td>
<td>Map</td>
<td></td>
</tr>
<tr>
<td><strong>startScheduler</strong></td>
<td>Whether the scheduler should be auto started.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>timeUnit</strong></td>
<td>Time unit for initialDelay and delay options.</td>
<td>MILLISECONDS</td>
<td>TimeUnit</td>
</tr>
<tr>
<td><strong>useFixedDelay</strong></td>
<td>Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>accessToken</strong></td>
<td><strong>Required</strong> The access token</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td><strong>consumerKey</strong></td>
<td><strong>Required</strong> The consumer key</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>
351.4. CONSUMING MESSAGES

The Yammer component provides several endpoints for consuming messages:

<table>
<thead>
<tr>
<th>URI</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>yammer:messages?[options]</td>
<td>All public messages in the user’s (whose access token is being used to make the API call) Yammer network. Corresponds to “All” conversations in the Yammer web interface.</td>
</tr>
<tr>
<td>yammer:my_feed?[options]</td>
<td>The user’s feed, based on the selection they have made between “Following” and “Top” conversations.</td>
</tr>
<tr>
<td>yammer:algo?[options]</td>
<td>The algorithmic feed for the user that corresponds to “Top” conversations, which is what the vast majority of users will see in the Yammer web interface.</td>
</tr>
<tr>
<td>yammer:following?[options]</td>
<td>The “Following” feed which is conversations involving people, groups and topics that the user is following.</td>
</tr>
<tr>
<td>yammer:sent?[options]</td>
<td>All messages sent by the user.</td>
</tr>
<tr>
<td>yammer:private?[options]</td>
<td>Private messages received by the user.</td>
</tr>
<tr>
<td>yammer:received?[options]</td>
<td>Camel 2.12.1: All messages received by the user</td>
</tr>
</tbody>
</table>

351.4.1. Message format

All messages by default are converted to a POJO model provided in the org.apache.camel.component.yammer.model package. The original message coming from yammer is in JSON. For all message consuming and producing endpoints, a Messages object is returned. Take for example a route like:

```java
from("yammer:messages?consumerKey=aConsumerKey&consumerSecret=aConsumerSecretKey&accessToken=aAccessToken")
.to("mock:result");
```
and lets say the yammer server returns:

```json
{
  "messages": [
    {
      "replied_to_id": null,
      "network_id": 7654,
      "url": "https://www.yammer.com/api/v1/messages/305298242",
      "thread_id": 305298242,
      "id": 305298242,
      "message_type": "update",
      "chat_client_sequence": null,
      "body": {
        "parsed": "Testing yammer API...",
        "plain": "Testing yammer API...",
        "rich": "Testing yammer API..."
      },
      "client_url": "https://www.yammer.com/",
      "content_excerpt": "Testing yammer API...",
      "created_at": "2013/06/25 18:14:45 +0000",
      "client_type": "Web",
      "privacy": "public",
      "sender_type": "user",
      "liked_by": {
        "count": 1,
        "names": [
          {
            "permalink": "janstey",
            "full_name": "Jonathan Anstey",
            "user_id": 1499642294
          }
        ]
      }
    },
    {
      "replied_to_id": null,
      "network_id": 7654,
      "url": "https://www.yammer.com/api/v1/messages/294326302",
      "thread_id": 294326302,
      "id": 294326302,
      "message_type": "system",
      "chat_client_sequence": null,
      "body": {
        "parsed": "(Principal Software Engineer) has [[tag:14658]] the redhat.com network. Take a moment to welcome Jonathan.",
        "plain": "(Principal Software Engineer) has #joined the redhat.com network. Take a moment
```
Camel will marshal that into a `Messages` object containing 2 `Message` objects. As shown below there is a rich object model that makes it easy to get any information you need:

```
{  
"rich": "(Principal Software Engineer) has #joined the redhat.com network. Take a moment to welcome Jonathan.",  
"client_url": "https://www.yammer.com/",  
"content_excerpt": "(Principal Software Engineer) has #joined the redhat.com network. Take a moment to welcome Jonathan.",  
"created_at": "2013/05/10 19:08:29 +0000",  
"client_type": "Web",  
"sender_type": "user",  
"privacy": "public",  
"liked_by": {  
  "count": 0,  
  "names": [  
  ]  
}  
}  
```

That said, marshaling this data into POJOs is not free so if you need you can switch back to using pure JSON by adding the `useJson=false` option to your URI.

### 351.5. CREATING MESSAGES

To create a new message in the account of the current user, you can use the following URI:

```
yammer:messages? [options]  
```

The current Camel message body is what will be used to set the text of the Yammer message. The response body will include the new message formatted the same way as when you consume messages (i.e. as a `Messages` object by default).

Take this route for instance:

```
from("direct:start")  
.to("yammer:messages? consumerKey=aConsumerKey&consumerSecret=aConsumerSecretKey&accessToken=aAccessToken")  
.to("mock:result");  
```
By sending to the `direct:start` endpoint a "Hi from Camel!" message body:

```
template.sendBody("direct:start", "Hi from Camel!");
```

a new message will be created in the current user’s account on the server and also this new message will be returned to Camel and converted into a `Messages` object. Like when consuming messages you can interrogate the `Messages` object:

```
Exchange exchange = mock.getExchanges().get(0);
Messages messages = exchange.getIn().getBody(Messages.class);

assertEquals(1, messages.getMessages().size());
assertEquals("Hi from Camel!", messages.getMessages().get(0).getBody().getPlain());
```

### 351.6. RETRIEVING USER RELATIONSHIPS

The Yammer component can retrieve user relationships:

```
yammer:relationships?[options]
```

### 351.7. RETRIEVING USERS

The Yammer component provides several endpoints for retrieving users:

<table>
<thead>
<tr>
<th>URI</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>yammer:users?[options]</td>
<td>Retrieve users in the current user’s Yammer network.</td>
</tr>
<tr>
<td>yammer:current?[options]</td>
<td>View data about the current user.</td>
</tr>
</tbody>
</table>

### 351.8. USING AN ENRICHER

It is helpful sometimes (or maybe always in the case of users or relationship consumers) to use an enricher pattern rather than a route initiated with one of the polling consumers in camel-yammer. This is because the consumers will fire repeatedly, however often you set the delay for. If you just want to look up a user’s data, or grab a message at a point in time, it is better to call that consumer once and then get one with your route.

Let’s say you have a route that at some point needs to go out and fetch user data for the current user. Rather than polling for this user over and over again, use the `pollEnrich` DSL method:

```
from("direct:start")
  .pollEnrich("yammer:current?consumerKey=aConsumerKey&consumerSecret=aConsumerSecretKey&accessToken=aAccessToken")
  .to("mock:result");
```
This will go out and fetch the current user’s User object and set it as the Camel message body.

351.9. SEE ALSO

- Configuring Camel
- Component
- Endpoint
- Getting Started
CHAPTER 352. YAHOO QUERY LANGUAGE COMPONENT

Available as of Camel version 2.21

The yql component is used for accessing the Yahoo Query Language platform.

The YQL (Yahoo! Query Language) platform enables you to query, filter, and combine data across the web through a single interface. It exposes a SQL-like syntax that is both familiar to developers and expressive enough for getting the right data.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-yql</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

352.1. URI FORMAT

yql://query[?options]

Where query represents the YQL query.

352.2. OPTIONS

The Yahoo Query Language component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectionManager (producer)</td>
<td>To use a custom configured HttpClientConnectionManager.</td>
<td></td>
<td>HttpClientConnectionManager</td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Yahoo Query Language endpoint is configured using URI syntax:

yql://query

with the following path and query parameters:

352.2.1. Path Parameters (1 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>Required The YQL statement to execute.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 352.2.2. Query Parameters (10 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>The name of the JavaScript callback function for JSONP format. If callback is set and if format=json, then the response format is JSON. For more information on using XML instead of JSON, see JSONP-X. <a href="https://developer.yahoo.com/yql/guide/response.html">https://developer.yahoo.com/yql/guide/response.html</a></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>crossProduct</td>
<td>When given the value optimized, the projected fields in SELECT statements that may be returned in separate item elements in the response are optimized to be in a single item element instead. The only allowed value is optimized. More information <a href="https://developer.yahoo.com/yql/guide/response.htmlresponse-optimizing=">https://developer.yahoo.com/yql/guide/response.htmlresponse-optimizing=</a></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>debug</td>
<td>If true, and if diagnostic is set to true, debug data is returned with the response. More information: <a href="https://developer.yahoo.com/yql/guide/dev-external_tables.html#idt-enable-logging=">https://developer.yahoo.com/yql/guide/dev-external_tables.html#idt-enable-logging=</a></td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>diagnostics</td>
<td>If true, diagnostic information is returned with the response.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>format</td>
<td>The expected format. Allowed values: xml or json.</td>
<td>json</td>
<td>String</td>
</tr>
<tr>
<td>jsonCompat</td>
<td>Enables lossless JSON processing. The only allowed value is new. More information <a href="https://developer.yahoo.com/yql/guide/response.htmljson-to-json">https://developer.yahoo.com/yql/guide/response.htmljson-to-json</a></td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>throwExceptionOnFailure</td>
<td>Option to disable throwing the YqlHttpException in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>
352.3. EXCHANGE DATA FORMAT

Camel will deliver the body as a JSON or XML formatted java.lang.String (see the `format` option above).

352.4. MESSAGE HEADERS

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camel YqlHttpRequest</td>
<td>Original HTTP request sent to YQL.</td>
</tr>
<tr>
<td>Camel YqlHttpStatus</td>
<td>Status code from the response.</td>
</tr>
</tbody>
</table>

352.5. SAMPLES

352.5.1. Sample 1

In this example we query YQL to obtain the current wind and atmosphere data in Chicago:

```java
from("direct:start")
  .to("yql://select wind, atmosphere from weather.forecast where woeid in (select woeid from geo.places(1) where text='chicago, il' )");
```

Which will setup the body as:

```json
{
  "query":{
    "count":1,
    "created":"2017-11-01T19:37:26Z",
    "lang":"en-US",
    "results":{
      "channel":{
        "wind":{
          "chill":"32",
          "direction":"165",
```
and the headers:

<table>
<thead>
<tr>
<th>Header</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelYqlHttpRequest</td>
<td><a href="https://query.yahooapis.com/v1/public/yql?q=select+wind%2C+atmosphere+from+weather.forecast+where+woeid+in+%28select+woeid+from+geo.places%281%29+where+text%3D%22chicago%2C+il%22%29+and+location%3D%22chicago%2C+il%22%29&amp;format=json&amp;callback=&amp;diagnostics=false&amp;debug=false">https://query.yahooapis.com/v1/public/yql?q=select+wind%2C+atmosphere+from+weather.forecast+where+woeid+in+%28select+woeid+from+geo.places%281%29+where+text%3D%22chicago%2C+il%22%29+and+location%3D%22chicago%2C+il%22%29&amp;format=json&amp;callback=&amp;diagnostics=false&amp;debug=false</a></td>
</tr>
<tr>
<td>CamelYqlHttpStatus</td>
<td>200</td>
</tr>
</tbody>
</table>

352.5.2. Sample 2

In this example we query YQL to obtain the Google quote.

```yql
from("direct:start")
.to("yql://select symbol, Ask, Bid, AverageDailyVolume from yahoo.finance.quotes where symbol in ('GOOG')?env=store://datatables.org/alltableswithkeys&https=false&callback=yqlCallback");
```

Which will setup the body as:

```json
/**/yqlCallback({
  "query":{
    "count":1,
    "created":"2017-11-01T19:48:17Z",
    "lang":"en-US",
    "results":{
      "quote":{
        "symbol":"GOOG",
        "Bid":"1025.57",
        "Ask":"1025.92",
        "AverageDailyVolume":"1350640"AverageDailyVolume
      }
    }
  }
});
```

and the headers:
352.5.3. Sample 3

In this example we query YQL to obtain one book written by Barack Obama

```xml
<?xml version="1.0" encoding="UTF-8"?>
  <results>
    <json>
      <kind>books#volumes</kind>
      <totalItems>1993</totalItems>
      <items>
        <kind>books#volume</kind>
        <id>HRCHJp-V0QUC</id>
        <etag>SeTJeSgFDzo</etag>
        <selfLink>https://www.googleapis.com/books/v1/volumes/HRCHJp-V0QUC</selfLink>
        <volumeInfo>
          <title>Dreams from My Father</title>
          <subtitle>A Story of Race and Inheritance</subtitle>
          <authors>Barack Obama</authors>
          <publisher>Broadway Books</publisher>
          <publishedDate>2007-01-09</publishedDate>
        </volumeInfo>
      </items>
    </json>
  </results>
</query>
```

and the headers:

#### 352.6. See Also

- YQL Official Guide
CHAPTER 353. ZENDESK COMPONENT

Available as of Camel version 2.19

The Zendesk component provides access to all of the zendesk.com APIs accessible using `zendesk-java-client`. It allows producing messages to manage Zendesk ticket, user, organization, etc.

Maven users will need to add the following dependency to their pom.xml for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-zendesk</artifactId>
  <version>${camel-version}</version>
</dependency>
```

353.1. ZENDESK OPTIONS

The Zendesk component supports 3 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>configuration</code> (common)</td>
<td>To use the shared configuration</td>
<td></td>
<td>ZendeskConfiguration</td>
</tr>
<tr>
<td><code>zendesk</code> (advanced)</td>
<td>To use a shared Zendesk instance.</td>
<td></td>
<td>Zendesk</td>
</tr>
<tr>
<td><code>resolvePropertyPlaceholders</code> (advanced)</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
</tbody>
</table>

The Zendesk endpoint is configured using URI syntax:

```
zendesk:methodName
```

with the following path and query parameters:

353.1.1. Path Parameters (1 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>methodName</code></td>
<td>Required What operation to use</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

353.1.2. Query Parameters (10 parameters):
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>inBody</strong> (common)</td>
<td>Sets the name of a parameter to be passed in the exchange In Body</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>serverUrl</strong> (common)</td>
<td>The server URL to connect.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>bridgeErrorHandler</strong> (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>exceptionHandler</strong> (consumer)</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td></td>
<td>ExceptionHandler</td>
</tr>
<tr>
<td><strong>exchangePattern</strong> (consumer)</td>
<td>Sets the exchange pattern when the consumer creates an exchange.</td>
<td></td>
<td>ExchangePattern</td>
</tr>
<tr>
<td><strong>synchronous</strong> (advanced)</td>
<td>Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td><strong>oauthToken</strong> (security)</td>
<td>The OAuth token.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>password</strong> (security)</td>
<td>The password.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>token</strong> (security)</td>
<td>The security token.</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td><strong>username</strong> (security)</td>
<td>The user name.</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 353.2. URI FORMAT

```
zendesk://endpoint?[options]
```

### 353.3. PRODUCER ENDPOINTS:
Producer endpoints can use endpoint names and associated options described next.

353.4. CONSUMER ENDPOINTS:

Any of the producer endpoints can be used as a consumer endpoint. Consumer endpoints can use Scheduled Poll Consumer Options with a `consumer` prefix to schedule endpoint invocation. Consumer endpoints that return an array or collection will generate one exchange per element, and their routes will be executed once for each exchange.

353.5. MESSAGE HEADER

Any of the options can be provided in a message header for producer endpoints with `CamelZendesk` prefix. In principal, parameter names are same as the argument name of each API methods on the original `org.zendesk.client.v2.Zendesk` class. However some of them are renamed to the other name to avoid confliction in the camel API component framework. To see actual parameter name, please check `org.apache.camel.component.zendesk.internal.ZendeskApiMethod`.

353.6. MESSAGE BODY

All result message bodies utilize objects provided by the Zendesk Java Client. Producer endpoints can specify the option name for incoming message body in the `inBody` endpoint parameter.
The Zip Data Format is a message compression and de-compression format. Messages marshalled using Zip compression can be unmarshalled using Zip decompression just prior to being consumed at the endpoint. The compression capability is quite useful when you deal with large XML and Text based payloads. It facilitates more optimal use of network bandwidth while incurring a small cost in order to compress and decompress payloads at the endpoint.

INFO:*About using with Files* The Zip data format, does not (yet) have special support for files. Which means that when using big files, the entire file content is loaded into memory. This is subject to change in the future, to allow a streaming based solution to have a low memory footprint.

### 354.1. OPTIONS

The Zip Deflate Compression dataformat supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>compressionLevel</td>
<td>-1</td>
<td>Integer</td>
<td>To specify a specific compression between 0–9. -1 is default compression, 0 is no compression, and 9 is best compression.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

### 354.2. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload employing zip compression `Deflater.BEST_COMPRESSION` and send it an ActiveMQ queue called MY_QUEUE.

```java
from("direct:start").marshal().zip(Deflater.BEST_COMPRESSION).to("activemq:queue:MY_QUEUE")
```

Alternatively if you would like to use the default setting you could send it as

```java
from("direct:start").marshal().zip().to("activemq:queue:MY_QUEUE");
```

### 354.3. UNMARSHAL

In this example we unmarshal a zipped payload from an ActiveMQ queue called MY_QUEUE to its original format, and forward it for processing to the UnZippedMessageProcessor. Note that the compression Level employed during the marshalling should be identical to the one employed during unmarshalling to avoid errors.

```java
from("activemq:queue:MY_QUEUE").unmarshal().zip().process(new UnZippedMessageProcessor());
```
354.4. DEPENDENCIES

This data format is provided in camel-core so no additional dependencies are needed.
CHAPTER 355. ZIP FILE DATAFORMAT

Available as of Camel version 2.11

The Zip File Data Format is a message compression and de-compression format. Messages can be marshalled (compressed) to Zip files containing a single entry, and Zip files containing a single entry can be unmarshalled (decompressed) to the original file contents. This data format supports ZIP64, as long as Java 7 or later is being used.

355.1. ZIPFILE OPTIONS

The Zip File dataformat supports 4 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Java Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usingIterator</td>
<td>false</td>
<td>Boolean</td>
<td>If the zip file has more than one entry, the setting this option to true, allows to work with the splitter EIP, to split the data using an iterator in a streaming mode.</td>
</tr>
<tr>
<td>allowEmptyDirectory</td>
<td>false</td>
<td>Boolean</td>
<td>If the zip file has more than one entry, setting this option to true, allows to get the iterator even if the directory is empty.</td>
</tr>
<tr>
<td>preservePathElements</td>
<td>false</td>
<td>Boolean</td>
<td>If the file name contains path elements, setting this option to true, allows the path to be maintained in the zip file.</td>
</tr>
<tr>
<td>contentTypeHeader</td>
<td>false</td>
<td>Boolean</td>
<td>Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.</td>
</tr>
</tbody>
</table>

355.2. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload using Zip file compression, and send it to an ActiveMQ queue called MY_QUEUE.

```camel
from("direct:start")
    .marshal().zipFile()
    .to("activemq:queue:MY_QUEUE");
```

The name of the Zip entry inside the created Zip file is based on the incoming CamelFileName message header, which is the standard message header used by the file component. Additionally, the outgoing CamelFileName message header is automatically set to the value of the incoming CamelFileName message header, with the ".zip" suffix. So for example, if the following route finds a file named "test.txt" in the input directory, the output will be a Zip file named "test.txt.zip" containing a single Zip entry named "test.txt":

```camel
from("file:input/directory?antInclude=*/.txt")
    .marshal().zipFile()
    .to("file:output/directory");
```
If there is no incoming **CamelFileName** message header (for example, if the file component is not the consumer), then the message ID is used by default, and since the message ID is normally a unique generated ID, you will end up with filenames like `ID-MACHINENAME-2443-1211718892437-1-0.zip`. If you want to override this behavior, then you can set the value of the **CamelFileName** header explicitly in your route:

```java
from("direct:start")
  .setHeader(Exchange.FILE_NAME, constant("report.txt"))
  .marshal().zipFile()
  .to("file:output/directory");
```

This route would result in a Zip file named "report.txt.zip" in the output directory, containing a single Zip entry named "report.txt".

### 355.3. UNMARSHAL

In this example we unmarshal a Zip file payload from an ActiveMQ queue called MY_QUEUE to its original format, and forward it for processing to the `UnZippedMessageProcessor`.

```java
from("activemq:queue:MY_QUEUE")
  .unmarshal().zipFile()
  .process(new UnZippedMessageProcessor());
```

If the zip file has more than one entry, the usingIterator option of ZipFileDataFormat to be true, and you can use splitter to do the further work.

```java
ZipFileDataFormat zipFile = new ZipFileDataFormat();
zipFile.setUsingIterator(true);

from("file:src/test/resources/org/apache/camel/dataformat/zipfile/?consumer.delay=1000&noop=true")
  .unmarshal(zipFile)
  .split(body(Iterator.class)).streaming()
  .process(new UnZippedMessageProcessor())
  .end();
```

Or you can use the ZipSplitter as an expression for splitter directly like this

```java
from("file:src/test/resources/org/apache/camel/dataformat/zipfile?consumer.delay=1000&noop=true")
  .split(new ZipSplitter()).streaming()
  .process(new UnZippedMessageProcessor())
  .end();
```

### 355.4. AGGREGATE

**NOTE**

Please note that this aggregation strategy requires eager completion check to work properly.

In this example we aggregate all text files found in the input directory into a single Zip file that is stored in the output directory.
The outgoing CamelFileName message header is created using java.io.File.createTempFile, with the ".zip" suffix. If you want to override this behavior, then you can set the value of the CamelFileName header explicitly in your route:

```java
from("file:input/directory?antInclude=/*.txt")
  .aggregate(constant(true), new ZipAggregationStrategy())
  .completionFromBatchConsumer().eagerCheckCompletion()
  .to("file:output/directory");
```

355.5. DEPENDENCIES

To use Zip files in your camel routes you need to add a dependency on camel-zipfile which implements this data format.

If you use Maven you can just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-zipfile</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```
CHAPTER 356. ZIPKIN COMPONENT

Available as of Camel 2.18

The camel-zipkin component is used for tracing and timing incoming and outgoing Camel messages using zipkin.

Events (span) are captured for incoming and outgoing messages being sent to/from Camel.

NOTE

camel-zipkin is planned to be refactored in Camel 2.22.0 to not use zipkin-scribe but use the default http transport. This work may cause backwards incompatibility.

This means you need to configure which Camel endpoints map to zipkin service names.

The mapping can be configured using:

- route id - A Camel route id
- endpoint url - A Camel endpoint url

For both kinds you can match using wildcards and regular expressions, using the rules from Intercept.

To match all Camel messages you can use * in the pattern and configure that to the same service name.

If no mapping has been configured, Camel will fallback and use endpoint uri’s as service names. However, it’s recommended to configure service mappings so you can use human-readable names instead of Camel endpoint uris in the names.

Camel will auto-configure a span reporter one hasn’t been explicitly configured, and if the hostname and port to a zipkin collector has been configured as environment variables

- ZIPKIN_COLLECTOR_HTTP_SERVICE_HOST - The http hostname
- ZIPKIN_COLLECTOR_HTTP_SERVICE_PORT - The port number

or

- ZIPKIN_COLLECTOR_THRIFT_SERVICE_HOST - The Scribe (Thrift RPC) hostname
- ZIPKIN_COLLECTOR_THRIFT_SERVICE_PORT - The port number

This makes it easy to use camel-zipkin in container platforms where the platform can run your application in a linux container where service configurations are provided as environment variables.

356.1. OPTIONS

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rate</td>
<td>1.0f</td>
<td>Configures a rate that decides how many events should be traced by zipkin. The rate is expressed as a percentage (1.0f = 100%, 0.5f is 50%, 0.1f is 10%).</td>
</tr>
</tbody>
</table>
### Option | Default | Description
--- | --- | ---
spanReporter | Mandatory: The reporter to use for sending zipkin span events to the zipkin server. | 
service Name | To use a global service name that matches all Camel events | 
clientService Mappings | Sets the client service mappings that matches Camel events to the given zipkin service name. The content is a Map<String, String> where the key is a pattern and the value is the service name. The pattern uses the rules from Intercept. | 
serverService Mappings | Sets the server service mappings that matches Camel events to the given zipkin service name. The content is a Map<String, String> where the key is a pattern and the value is the service name. The pattern uses the rules from Intercept. | 
excludePatterns | Sets exclude pattern(s) that will disable tracing with zipkin for Camel messages that matches the pattern. The content is a Set<String> where the key is a pattern. The pattern uses the rules from Intercept. | 
includeMessageBody | false | Whether to include the Camel message body in the zipkin traces. This is not recommended for production usage, or when having big payloads. You can limit the size by configuring the max debug log size. |
includeMessageBodyStreams | false | Whether to include message bodies that are stream based in the zipkin traces. This requires enabling streamcaching on the routes or globally on the CamelContext. This is not recommended for production usage, or when having big payloads. You can limit the size by configuring the max debug log size. |

### 356.2. EXAMPLE

To enable camel-zipkin you need to configure first

```java
ZipkinTracer zipkin = new ZipkinTracer();
// Configure a reporter, which controls how often spans are sent
// (the dependency is io.zipkin.reporter2:zipkin-sender-okhttp3)
sender = OkHttpSender.create("http://127.0.0.1:9411/api/v2/spans");
zipkin.setSpanReporter(AsyncReporter.create(sender));
// and then add zipkin to the CamelContext
zipkin.init(camelContext);
```

The configuration above will trace all incoming and outgoing messages in Camel routes.

To use ZipkinTracer in XML, all you need to do is to define scribe and zipkin tracer beans. Camel will automatically discover and use them.

```xml
<!-- configure how to reporter spans to a Zipkin collector (the dependency is io.zipkin.reporter2:zipkin-reporter-spring-beans) -->
```
### 356.2.1. ServiceName

However, if you want to map Camel endpoints to human friendly logical names, you can add mappings

- `ServiceName *`

You can configure a global service name that all events will fallback and use, such as:

```java
zipkin.setServiceName("invoices");
```

This will use the same service name for all incoming and outgoing zipkin traces. If your application uses different services, you should map them to more finely grained client / server service mappings.

### 356.2.2. Client and Server Service Mappings

- `ClientServiceMappings`
- `ServerServiceMappings`

If your application hosts a service that others can call, you can map the Camel route endpoint to a server service mapping. For example, suppose your Camel application has the following route:

```camel
from("activemq:queue:inbox")
.to("http:someserver/somepath");
```

And you want to make that as a server service, you can add the following mapping:

```java
zipkin.addServerServiceMapping("activemq:queue:inbox", "orders");
```

Then when a message is consumed from that inbox queue, it becomes a zipkin server event with the service name 'orders'.

Now suppose that the call to http:someserver/somepath is also a service, which you want to map to a client service name, which can be done as:

```java
zipkin.addClientServiceMapping("http:someserver/somepath", "audit");
```
Then in the same Camel application you have mapped incoming and outgoing endpoints to different zipkin service names.

You can use wildcards in the service mapping. To match all outgoing calls to the same HTTP server you can do:

```java
zipkin.addClientServiceMapping("http:someserver*", "audit");
```

### 356.3. MAPPING RULES

The service name mapping for server occurs using the following rules:

1. Is there an exclude pattern that matches the endpoint uri of the from endpoint? If yes then skip.
2. Is there a match in the serviceServiceMapping that matches the endpoint uri of the from endpoint? If yes, then use the found service name
3. Is there a match in the serviceServiceMapping that matches the route id of the current route? If yes, then use the found service name
4. Is there a match in the serviceServiceMapping that matches the original route id where the exchange started? If yes, then use the found service name
5. No service name was found, the exchange is not traced by zipkin

The service name mapping for client occurs using the following rules:

1. Is there an exclude pattern that matches the endpoint uri of the from endpoint? If yes then skip.
2. Is there a match in the clientServiceMapping that matches the endpoint uri of endpoint where the message is being sent to? If yes, then use the found service name
3. Is there a match in the clientServiceMapping that matches the route id of the current route? If yes, then use the found service name
4. Is there a match in the clientServiceMapping that matches the original route id where the exchange started? If yes, then use the found service name
5. No service name was found, the exchange is not traced by zipkin

#### 356.3.1. No client or server mappings

If there has been no configuration of client or server service mappings, CamelZipkin runs in a fallback mode, and uses endpoint uris as the service name.

In the example above, this would mean the service names would be defined as if you add the following code yourself:

```java
```

This is not a recommended approach, but gets you up and running quickly without doing any service name mappings. However, when you have multiple systems across your infrastructure, then you should consider using human-readable service names, that you map to instead of using the camel endpoint uris.
356.4. CAMEL-ZIPIN-STARTER

If you are using Spring Boot then you can add the camel-zipkin-starter dependency, and turn on zipkin by annotating the main class with @CamelZipkin. You can then configure camel-zipkin in the application.properties file where you can configure the hostname and port number for the Zipkin Server, and all the other options as listed in the options table above.

You can find an example of this in the camel-example-zipkin
CHAPTER 357. ZOOKEEPER COMPONENT

Available as of Camel version 2.9

The ZooKeeper component allows interaction with a ZooKeeper cluster and exposes the following features to Camel:

1. Creation of nodes in any of the ZooKeeper create modes.
2. Get and Set the data contents of arbitrary cluster nodes (data being set must be convertible to `byte[]`).
3. Create and retrieve the list the child nodes attached to a particular node.
4. A Distributed RoutePolicy that leverages a Leader election coordinated by ZooKeeper to determine if exchanges should get processed.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-zookeeper</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

357.1. URI FORMAT

```
zookeeper://zookeeper-server[:port]/[path][?options]
```

The path from the URI specifies the node in the ZooKeeper server (a.k.a. `znode`) that will be the target of the endpoint:

357.2. OPTIONS

The ZooKeeper component supports 2 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>To use a shared ZooKeeperConfiguration</td>
<td></td>
<td>ZooKeeperConfig</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>resolveProperty Placeholders</td>
<td>Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>(advanced)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The ZooKeeper endpoint is configured using URI syntax:

```
zookeeper:serverUrls/path
```
with the following path and query parameters:

### 357.2.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>serverUrls</td>
<td>Required The zookeeper server hosts (multiple servers can be separated by comma)</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>path</td>
<td>Required The node in the ZooKeeper server (aka znode)</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

### 357.2.2. Query Parameters (12 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>awaitExistence</td>
<td>Deprecated Not in use</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>listChildren</td>
<td>Whether the children of the node should be listed</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>timeout</td>
<td>The time interval to wait on connection before timing out.</td>
<td>5000</td>
<td>int</td>
</tr>
<tr>
<td>backoff</td>
<td>The time interval to backoff for after an error before retrying.</td>
<td>5000</td>
<td>long</td>
</tr>
<tr>
<td>bridgeErrorHandler</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>repeat</td>
<td>Should changes to the znode be 'watched' and repeatedly processed.</td>
<td>false</td>
<td>boolean</td>
</tr>
<tr>
<td>sendEmptyMessageOnDelete</td>
<td>Upon the delete of a znode, should an empty message be send to the consumer</td>
<td>true</td>
<td>boolean</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Default</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>exceptionHandler</td>
<td>To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>

<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>

### 357.3. USE CASES

#### 357.3.1. Reading from a znode

The following snippet will read the data from the znode/somepath/somenode/ provided that it already exists. The data retrieved will be placed into an exchange and passed onto the rest of the route:

```java
from("zookeeper://localhost:39913/somepath/somenode").to("mock:result");
```

If the node does not yet exist then a flag can be supplied to have the endpoint await its creation:

```java
from("zookeeper://localhost:39913/somepath/somenode?awaitCreation=true").to("mock:result");
```

#### 357.3.2. Reading from a znode (additional Camel 2.10 onwards)

When data is read due to a `WatchedEvent` received from the ZooKeeper ensemble, the `CamelZookeeperEventType` header holds ZooKeeper’s `EventType` value from that `WatchedEvent`. If the data is read initially (not triggered by a `WatchedEvent`) the `CamelZookeeperEventType` header will not be set.

#### 357.3.3. Writing to a znode

The following snippet will write the payload of the exchange into the znode at /somepath/somenode/ provided that it already exists:
from("direct:write-to-znode")
    .to("zookeeper://localhost:39913/somepath/somenode");

For flexibility, the endpoint allows the target znode to be specified dynamically as a message header. If a header keyed by the string `CamelZooKeeperNode` is present then the value of the header will be used as the path to the znode on the server. For instance using the same route definition above, the following code snippet will write the data not to `/somepath/somenode` but to the path from the header `/somepath/someothernode`.

```
from("direct:create-and-write-to-znode")
    .to("zookeeper://localhost:39913/somepath/somenode?create=true");
```

To also create the node if it does not exist the `create` option should be used.

```
from("direct:delete-znode")
    .setHeader(ZooKeeperMessage.ZOOKEEPER_OPERATION, constant("DELETE"))
    .to("zookeeper://localhost:39913/somepath/somenode");
```

Starting version 2.11 it is also possible to delete a node using the header `CamelZookeeperOperation` by setting it to `DELETE`:

```
from("direct:delete-znode")
    .setHeader(ZooKeeperMessage.ZOOKEEPER_OPERATION, constant("DELETE"))
    .to("zookeeper://localhost:39913/somepath/somenode");
```

or equivalently:

```
<route>
    <from uri="direct:delete-znode" />
    <setHeader headerName="CamelZookeeperOperation">
        <constant>DELETE</constant>
    </setHeader>
    <to uri="zookeeper://localhost:39913/somepath/somenode" />
</route>
```

ZooKeeper nodes can have different types; they can be ‘Ephemeral’ or ‘Persistent’ and ‘Sequenced’ or ‘Unsequenced’. For further information of each type you can check [here](https://redis.io). By default endpoints will create unsequenced, ephemeral nodes, but the type can be easily manipulated via a uri config parameter or via a special message header. The values expected for the create mode are simply the names from the `CreateMode` enumeration:

- **PERSISTENT**
- **PERSISTENT_SEQUENTIAL**
357.4. ZOOKEEPER ENABLED ROUTE POLICIES

ZooKeeper allows for very simple and effective leader election out of the box. This component exploits this election capability in a RoutePolicy to control when and how routes are enabled. This policy would typically be used in fail-over scenarios, to control identical instances of a route across a cluster of Camel based servers. A very common scenario is a simple ‘Master-Slave’ setup where there are multiple instances of a route distributed across a cluster but only one of them, that of the master, should be running at a time. If the master fails, a new master should be elected from the available slaves and the route in this new master should be started.

The policy uses a common znode path across all instances of the RoutePolicy that will be involved in the election. Each policy writes its id into this node and Zookeeper will order the writes in the order it received them. The policy then reads the listing of the node to see what position of its id; this position is used to determine if the route should be started or not. The policy is configured at startup with the number of route instances that should be started across the cluster and if its position in the list is less than this value then its route will be started. For a Master-slave scenario, the route is configured with 1 route instance and only the first entry in the listing will start its route. All policies watch for updates to the listing and if the listing changes they recalculate if their route should be started. For more info on Zookeeper’s leader election capability see this page.

The following example uses the node /someapplication/somepolicy for the election and is set up to start only the top ‘1’ entries in the node listing i.e. elect a master:
There are currently 3 policies defined in the component, with different SLAs:

- **ZooKeeperRoutePolicy**
- **CuratorLeaderRoutePolicy** (since 2.19)
- **MultiMasterCuratorLeaderRoutePolicy** (since 2.19)

**ZooKeeperRoutePolicy** supports multiple active nodes, but it’s activation kicks in only after a Camel component and its correspondent Consumer have already been started, this introduces, depending on your routes definition, the risk that you component can already start consuming events and producing `Exchange`'s, before the policy could establish that the node should not be activated.

**CuratorLeaderRoutePolicy** supports only a single active node, but it’s bound to a different CamelContext lifecycle method; this Policy kicks in before any route or consumer is started thus you can be sure that no even is processed before the Policy takes its decision.

**MultiMasterCuratorLeaderRoutePolicy** support multiple active nodes, and it’s bound to the same lifecycle method as **CuratorLeaderRoutePolicy**; this Policy kicks in before any route or consumer is started thus you can be sure that no even is processed before the Policy takes its decision.

CHAPTER 358. ZOOKEEPER MASTER COMPONENT

Available as of Camel version 2.19

The zookeeper-master: endpoint provides a way to ensure only a single consumer in a cluster consumes from a given endpoint; with automatic failover if that JVM dies.

This can be very useful if you need to consume from some legacy back end which either doesn’t support concurrent consumption or due to commercial or stability reasons you can only have a single connection at any point in time.

358.1. USING THE MASTER ENDPOINT

Just prefix any camel endpoint with zookeeper-master:someName: where someName is a logical name and is used to acquire the master lock. e.g.

```plaintext
from("zookeeper-master:cheese:jms:foo").to("activemq:wine");
```

The above simulates the [Exclusive Consumers](http://activemq.apache.org/exclusive-consumer.html) type feature in ActiveMQ; but on any third party JMS provider which maybe doesn’t support exclusive consumers.

358.2. URI FORMAT

zookeeper-master:name:endpoint[?options]

Where endpoint is any Camel endpoint you want to run in master/slave mode.

358.3. OPTIONS

The ZooKeeper Master component supports 7 options which are listed below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>containerIdFactory</td>
<td>To use a custom ContainerIdFactory for creating container ids.</td>
<td></td>
<td>ContainerIdFactory</td>
</tr>
<tr>
<td>zkRoot</td>
<td>The root path to use in zookeeper where information is stored which nodes are master/slave etc. Will by default use: /camel/zookeepermaster/clusters/master</td>
<td>/camel/zookeepermaster/clusters/master</td>
<td>String</td>
</tr>
<tr>
<td>curator</td>
<td>To use a custom configured CuratorFramework as connection to zookeeper ensemble.</td>
<td></td>
<td>CuratorFramework</td>
</tr>
</tbody>
</table>
maximumConnect ion Timeout (consumer)
  Timeout in millis to use when connecting to the zookeeper ensemble
  Default 10000 int

zooKeeperUrl (consumer)
  The url for the zookeeper ensemble
  Default localhost:2181 String

zooKeeperPassword (security)
  The password to use when connecting to the zookeeper ensemble
  Default String

resolveProperty Placeholders (advanced)
  Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.
  Default true boolean

The ZooKeeper Master endpoint is configured using URI syntax:

zookeeper-master:groupName:consumerEndpointUri

with the following path and query parameters:

358.3.1. Path Parameters (2 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupName</td>
<td>Required The name of the cluster group to use</td>
<td></td>
<td>String</td>
</tr>
<tr>
<td>consumerEndpointUri</td>
<td>Required The consumer endpoint to use in master/slave mode</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

358.3.2. Query Parameters (4 parameters):

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridgeErrorHandler (consumer)</td>
<td>Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.</td>
<td>false</td>
<td>boolean</td>
</tr>
</tbody>
</table>
exceptionHandler (consumer)
To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.

ExceptionHandler

exchangePattern (consumer)
Sets the exchange pattern when the consumer creates an exchange.
ExchangePattern

synchronous (advanced)
Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).
false boolean

### 358.4. EXAMPLE

You can protect a clustered Camel application to only consume files from one active node.

```java
// the file endpoint we want to consume from
String url = "file:target/inbox?delete=true";

// use the zookeeper master component in the clustered group named myGroup
// to run a master/slave mode in the following Camel url
from("zookeeper-master:myGroup:" + url)
  .log(name + " - Received file: ${file:name}")
  .delay(delay)
  .log(name + " - Done file:     ${file:name}")
  .to("file:target/outbox");
```

ZooKeeper will by default connect to `localhost:2181`, but you can configure this on the component level.

```java
MasterComponent master = new MasterComponent();
master.setZooKeeperUrl("myzookeeper:2181");
```

However you can also configure the url of the ZooKeeper ensemble using environment variables.

```java
export ZOOKEEPER_URL = "myzookeeper:2181"
```
CHAPTER 359. MASTER ROUTEPOLICY

You can also use a RoutePolicy to control routes in master/slave mode.

When doing so you must configure the route policy with

- url to zookeeper ensemble
- name of cluster group
- **important** and set the route to not auto startup

A little example

```java
MasterRoutePolicy master = new MasterRoutePolicy();
master.setZooKeeperUrl("localhost:2181");
master.setGroupName("myGroup");

// its important to set the route to not auto startup
// as we let the route policy start/stop the routes when it becomes a master/slave etc
from("file:target/inbox?delete=true").noAutoStartup()
    // use the zookeeper master route policy in the clustered group
    // to run this route in master/slave mode
    .routePolicy(master)
    .log(name + " - Received file: ${file:name}")
    .delay(delay)
    .log(name + " - Done file: ${file:name}")
    .to("file:target/outbox");
```
